Abstract

We describe a supersymmetric generalization of the construction of Kontsevich and Arbarello, De Concini, Kac, and Procesi, which utilizes a relation between the moduli space of curves with the infinite-dimensional Sato Grassmannian. Our main result is the existence of a flat holomorphic connection on the line bundle $\lambda_{3/2} \otimes \lambda_{1/2}^{-5}$ on the moduli space of triples: a super Riemann surface, a Neveu-Schwarz puncture, and a formal coordinate system.

1 Introduction

The constant $c_j = 6j^2 - 6j + 1$, proportional to the 2nd Bernoulli polynomial, arises independently in studying representations of the Virasoro algebra and by studying the geometry of the moduli space of algebraic curves. Manin [15] conjectured based on this numerical coincidence that there exists a direct connection between these seemingly independent mathematical areas. This conjecture was shown to be true in the simultaneous publications [1, 2, 11, 13], which was important to the quantum theory of (bosonic) strings, as it unified path integral quantization and operator quantization.

The numerical coincidence goes as follows. The Witt algebra has natural representations $g_j$ defined by Lie derivative action on $\mathbb{C}((z))dz^{\otimes j}$. The Japanese cocycle $\eta$ on $\mathfrak{gl}(\mathbb{C}((z)))$ by restriction to the Witt algebra induces the unique central extension of the Witt algebra, known as the Virasoro algebra. Then we find

$$g_j^*(\eta) = c_j g_1^*(\eta), \quad c_j = 6j^2 - 6j + 1.$$  

When the Virasoro algebra is realized as operators on the state space of a string, the string must propagate in $2c_j$ (real) spacetime dimensions for both unitarity and Lorentz invariance of the string theory to hold. On the other hand, for any smooth proper family of curves $\pi: X \to S$, the Mumford isomorphism is the isomorphism of line bundles

$$\lambda_j \cong \lambda_1^{c_j},$$

where $\lambda_j := \text{det} R\pi_* (\omega_X^{\otimes j})$ and $\omega_X := \Omega_X^1$. If $S$ is the moduli space of algebraic curves and $\pi: X \to S$ is the universal curve, then we find the dualizing sheaf $\omega_S := \text{det} \Omega_S^1 \cong \lambda_2$, and therefore $\omega_S \cong \lambda_1^{c_j} \cong (\pi_* \omega_X)^{c_j}$. This is important to Polyakov path integration on the moduli space.

An alternative description of the Polyakov measure comes through the connection between representations of the Virasoro algebra and the moduli space; this connection is roughly the following. The Virasoro algebra acts on the moduli space $\mathcal{M}_{g,1}$ of triples $(C, p, z)$, a Riemann surface, an point, and a parameter. This action can be used to show that there exists a flat holomorphic connection on the line bundle $\lambda_1 \otimes \lambda_1^{-c_j}$, which can be used to write differential equations for the Polyakov measure. For another summary, see the introduction of [16].

In fact, Manin in [15] hypothesized this relationship existed in the superized case as well. The numerical coincidence is analogous: The super Witt algebra has representations $g_j$ defined by Lie derivative action on $\mathbb{C}((z))[\zeta][dz][d\zeta]^{\otimes j}$ such that pulling back the super Japanese cocycle $\eta$ (defining the unique central extension, the Neveu-Schwarz algebra) gives

$$g_j^*(\eta) = c_j g_1^*(\eta), \quad c_j = (-1)^j(2j - 1).$$

And for any smooth proper family of supercurves $\pi: X \to S$, the super Mumford isomorphism is the isomorphism of line bundles

$$\lambda_{j/2} \cong \lambda_{1/2}^{c_j},$$

where $\lambda_{j/2} := \text{Ber} R\pi_* (\omega_X^{\otimes j})$ and $\omega_X = \text{Ber} \Omega_X^1$.

The goal of the paper is to describe a supersymmetric generalization of the construction of Kontsevich [13] and Arbarello, De Concini, Kac, and Procesi [1], which utilizes a relation between the moduli space of curves with the infinite-dimensional Grassmannian. The consequences of their construction shows that the Chern classes of the line bundles of the Mumford isomorphism are equal. Manin proved a supersymmetric generalization of this result in Theorem 3.3 of [16] by generalizing the methods of Beilinson and Schechtman in [2], which prove a version of the Riemann-Roch theorem for the Atiyah algebras of vector bundles. Instead, our paper extends the results of Ueno and Yamada [24] of the representations of the Neveu-Schwarz algebra and the results of Mulase and Rabin [18] of the super Sato Grassmannian and the super Krichever map.
Our use of the super Grassmannian $\text{Gr}(\mathbb{C}((z))[\zeta])$ appears to provide an alternative approach for integrating over the moduli space of SRSs $\mathfrak{M}_g$. The Torelli map sending a super Riemann surface to its Jacobian $J: \mathfrak{M}_g \to \mathfrak{A}_g$, where $\mathfrak{A}_g$ is the moduli space of principally polarized abelian supervarieties, plays a prominent role in the papers [5, 6, 7, 8] of D’Hoker and Phong and [9] of Grushevsky, who compute explicitly or propose an ansatz for chiral superstring measure in low genus. In higher genus, these methods face the problem that the locus of moduli space inside $\mathfrak{A}_g$, known as the super Jacobian locus, is very hard to describe. The known characterizations of the super Jacobian locus, i.e. solutions to the super Schottky problem, are very implicit. Since the known solution of the super Schottky problem, as in [17] of Mulase, goes through the super Krichever map $\mathfrak{M}_g \to \text{Gr}(\mathbb{C}((z))[\zeta])$, and since a more explicit description of the moduli space locus is an orbit of the super Witt algebra under the super Krichever map, it appears that the computation of physically meaningful integrals, such as scattering amplitudes, can be carried out in the super Grassmannian, rather than on the moduli space $\mathfrak{A}_g$. This idea does not seem to have been utilized in the classical (i.e. non-super) case.

1.1 Summary of the Results of Kontsevich

1.1.1 The Moduli Space $\mathcal{M}_{g,1^\infty}$

Let a Riemann surface refer to a compact complex manifold of dimension 1, equivalently a complete nonsingular curve over $\mathbb{C}$. A family of Riemann surfaces of genus $g$ is a smooth proper morphism $\pi: X \to S$ of relative dimension 1, where each fiber is a genus $g$ Riemann surface. A section $\sigma: S \to X$ of the morphism $\pi$ is a coherent way to choose a puncture in each fiber, which we sometimes denote by a divisor $P = \text{div}(\sigma)$ of $X$.

Define the moduli stack $\mathcal{M}_{g,1^\infty}$ to be the moduli space of triples $(C, p, z)$, where $C$ is a genus $g$ Riemann surface, $p \in C$, and $z$ is a $k$-jet equivalence class of a formal parameter vanishing at $p$. Specifically, we have the parameter $z \in \mathcal{O}_p$, the formal neighborhood at $p$, and $z$ has a zero of order one at $p$. By taking the projective limit we construct the pro-Deligne-Mumford stack

$$\mathcal{M}_{g,1^\infty} = \lim_{\longleftarrow} \mathcal{M}_{g,1^k}.$$ 

Simply by forgetting the parameter $z$ and puncture $p$, we have the projection

$$\mathcal{M}_{g,1^\infty} \to \mathcal{M}_g$$

$$(C, p, z) \mapsto C$$

where $\mathcal{M}_g$ is the moduli space of genus $g$ Riemann surfaces.

The Witt algebra $\text{witt}$ is the Lie algebra of vector fields on a punctured formal neighborhood in $\mathbb{C}^1$. Explicitly, $\text{witt} = \mathbb{C}((z)) \frac{\partial}{\partial z}$. In terms of a basis, we have $L_n = z^{-n+1} \frac{\partial}{\partial z}$ for $n \in \mathbb{Z}$ with $[L_m, L_n] = (m-n)L_{m+n}$.

For $\pi: X \to \mathcal{M}_{g,1^k}$ the universal family of Riemann surfaces with punctures represented by the divisor $P$ and a $k$-jet of a coordinate near the punctures, we have the short exact sequence

$$0 \to T_{X/\mathcal{M}_{g,1^k}}(-(k+1)P) \to T_X(-(k+1)P) \to \pi^*(T_{\mathcal{M}_{g,1^k}}) \to 0.$$ 

The resulting Kodaira-Spencer map preserving this structure is

$$\delta: T_{\mathcal{M}_{g,1^k}} \xrightarrow{\sim} R^1\pi_*T_{X/\mathcal{M}_{g,1^k}}(-(k+1)P),$$

which locally for $(C, p, z)$ is

$$\delta_{(C, p, z)}: T_{(C, p, z)}\mathcal{M}_{g,1^k} \xrightarrow{\sim} H^1(C, T_C(-(k+1)P)).$$
where $P \mid C = p$ is the puncture on $C$. From this we find the dimension of $\mathcal{M}_{g,1^k}$ is $3g - 2 + k$ for $g \geq 2$.

Let $U$ be a formal neighborhood of a puncture $p \in C$. Choosing the formal parameter $z$ on $U$ such that the divisor $p$ is given by $z = 0$ gives a trivialization of $\mathcal{T}_C$ on $U$. Using Čech cohomology, then

\[
T_{(C,p,z)}(\mathcal{M}_{g,1^k}) \cong \Gamma(U \setminus p, \mathcal{T}_C)/\left(\Gamma(U, \mathcal{T}_C;(-(k+1)p)) + \Gamma(C \setminus p, \mathcal{T}_C)\right)
\]

\[
\cong \text{witt}/\left((z^{k+1}\mathbb{C}[\llbracket z \rrbracket])^2 + D_{C,p,z}\right),
\]

where we denote by $D_{C,p,z}$ the image of $\Gamma(C \setminus p, \mathcal{T}_C)$ in witt using the local coordinate $z$. Further, taking the projective limit gives a description of the tangent space of $\mathcal{M}_{g,1^\infty}$:

\[
T_{(C,p,z)}(\mathcal{M}_{g,1^\infty}) \cong \text{witt}/D_{C,p,z}.
\]

This identification of the tangent space with a quotient of the Witt algebra then clearly gives the next theorem.

**Proposition 1.1** (Kontsevich [13]). The Witt algebra acts on the moduli space $\mathcal{M}_{g,1^\infty}$ by vector fields.

**Definition 1.1** (Deligne [3]). Let $\pi : X \rightarrow S$ be a smooth proper family of schemes of dimension 1. Let $\mathcal{F}$ be a locally free sheaf on $X$. Then the determinant of cohomology of $\mathcal{F}$ is an invertible sheaf on $S$ given by

\[
D(\mathcal{F}) := \otimes_i (\det R^i \pi_* \mathcal{F})^{(-1)^i}
\]

We define the determinant line bundles $\lambda_j$ for the universal family $\pi : X \rightarrow \mathcal{M}_{g,1^\infty}$ as

\[
\lambda_j := D(\omega_X^{\otimes j})
\]

where $\omega_X := \Omega_X^1$.

**Theorem 1.1** (Mumford [19]). The Mumford isomorphism is the collection of canonical isomorphisms

\[
\lambda_j \cong \lambda_1^{(6j^2 - 6j + 1)}, \quad \text{in particular} \quad \lambda_2 \cong \lambda_1^{13}.
\]

### 1.1.2 The Semi-Infinite Grassmannian of $\mathbb{C}(\llbracket z \rrbracket)$

The semi-infinite Grassmannian, defined originally by Sato and Sato in [21], originated via the study of soliton equations and KP equations. Following the spirit of Kontsevich, we define the discrete subspaces which form the infinite-dimensional Grassmannian. We state here the important findings highlighting any differences with the superized case.

Consider $\mathbb{C}(\llbracket z \rrbracket)$, the infinite-dimensional topological space of formal Laurent series with the $z$-adic topology. Define the vector spaces $H = \mathbb{C}(\llbracket z \rrbracket)$, $H^+ = \mathbb{C}[\llbracket z \rrbracket]$, and $H^- = z^{-1}\mathbb{C}[\llbracket z^{-1} \rrbracket]$.

**Definition 1.2.** Define a subspace of $H$ to be compact if it is commensurable with $H^+$. Explicitly, subspaces $K$ and $H^+$ are commensurable when $K/(K \cap H^+)$ and $H^+/(K \cap H^+)$ are both finite-dimensional. Define a subspace $D$ of $H$ to be discrete if there exists a compact subspace $K$ such that the natural map $D \oplus K \rightarrow H$ is an isomorphism.

**Lemma 1.1.** Let $K$ be any compact subspace. Then $D$ is discrete if and only if the natural map $D \oplus K \rightarrow H$ is Fredholm.
Definition 1.3. The Grassmannian $\text{Gr}(H)$ is the set of all discrete subspaces $D \subset H$.

Proposition 1.2. $\text{Gr}(H)$ is locally modeled on vector spaces $\text{Hom}_C(H^-, H^+)$. And thus $\text{Gr}(H)$ is an infinite-dimensional manifold.

Proof. This proof is essentially follows the check of Def. 3.2. See also Proposition 7.1.2 of [20]. □

Define $\mathfrak{gl}(H) = \text{Hom}(H, H)$ to be the space of continuous linear maps on $H$. For any endomorphism of $H$ we may write it as

$$F = \begin{pmatrix} F^{--} & F^{-+} \\ F^{+-} & F^{++} \end{pmatrix}$$

where $F^{+-} : H^- \to H^+$ etc.

Define the group $\text{GL}_F(H) \subset \text{Hom}(H, H)$ to be the subspace of invertible maps with $F^{--}$ and $F^{++}$ Fredholm.

Define an endomorphism of a discrete subspace to be trace class if it factors through some compact subspace.

Proposition 1.3 (cf. Pressley and Segal Proposition 7.1.3 [20]). The group $\text{GL}_F(H)$ acts transitively on $\text{Gr}(H)$, and the stabilizer of $D$ is $\left( \begin{smallmatrix} \ast & \ast \\ 0 & \ast \end{smallmatrix} \right)$ expressed in a decomposition $D \oplus K$.

Proof. The proof reads the same as the proof of Proposition 3.1 with the condition $\nu(z^i \theta) = z^{i-m} \theta$ for some $m$ omitted. □

Therefore we may describe $\text{Gr}(H)$ as the homogeneous space

$$\text{Gr}(H) \cong \text{GL}_F(H)/P$$

where $P = \left( \begin{smallmatrix} \ast & \ast \\ 0 & \ast \end{smallmatrix} \right)$ in the $H^- \oplus H^+$ decomposition.

Proposition 1.4 (Kontsevich [13]). The Lie algebra $\mathfrak{gl}(H)$ acts by vector fields on $\text{Gr}(H)$. Explicitly, $F \mapsto L_F$ is a Lie algebra homomorphism $\mathfrak{gl}(H) \to T_{\text{Gr}(H)}$. In the chart $U_{D,K}$, this action is given by the formula

$$L_F(A) = F^{KD} + F^{KK} A - A F^{DD} - A F^{DK} A$$

where $L_F \in \text{Hom}_C(S^*(\text{Hom}_C(D, K)), \text{Hom}_C(D, K))$.

Proof. The proof is the same as the proof of Proposition 3.2. □

We can take as definition

$$\text{det}_K(D) := \frac{\text{det}(D \cap K)}{\text{det}(H/(D + K))},$$

which is well-defined for discrete $D$ and compact $K$.

Definition 1.4. As in [1], we define the determinant line bundle on $\text{Gr}(H)$ as $\text{det}_{\text{Gr}(H)} := \text{det}_{H^+}$, in other words, $\text{det}_K$ with $K = H^+$, the distinguished compact subspace.

It is known that $H^2(\mathfrak{gl}(H))$ is one-dimensional. For any choice of discrete $D$ and compact $K$ such that the natural map $D \oplus K \to H$ is an isomorphism, we define a 2-cocycle on $\mathfrak{gl}(H)$ as

$$\eta_{D,K}(F,G) := \text{tr}(F^{DK} G^{KD} - F^{DK} G^{KD}).$$

We choose a distinguished 2-cocycle:

$$\eta(F,G) := \text{str}(F^{-+}G^{+-} - F^{-+}G^{+-}),$$
which is known as the Japanese cocycle [12]. The unique Lie superalgebra central extension defined by the super Japanese cocycle will be denoted \( \widetilde{\mathfrak{gl}}(H) \).\(^1\) We denote the bracket on \( \widetilde{\mathfrak{gl}}(H) \) as \( [F,G] = [F,G] + \eta(F,G) \).

See the Appendix 5.1 for the definition of Lie algebroids and Atiyah algebras. The Atiyah algebra \( A_L \) may be regarded as the Lie algebroid of infinitesimal symmetries of the pair \((X,L)\).

**Theorem 1.2** (Kontsevich [13]). The Lie algebra \( \widetilde{\mathfrak{gl}}(H) \) acts by first order differential operators on \( \det_{Gr(H)} \). Explicitly, \( F + c \mapsto \widetilde{L}_F + c \) is a Lie algebra homomorphism \( \widetilde{\mathfrak{gl}}(H) \to A_{\text{det}}(Gr(H)) \) sending \( [F,G] \) to \( [\widetilde{L}_F, \widetilde{L}_G] \). In the chart \( U_{D,K} \), this action is given by the formula

\[
\widetilde{L}_F(A) = L_F(A) + \text{tr}(F^{DK} A) + \alpha(F)
\]

where \( \alpha \in C^1(\mathfrak{gl}(H)) \) is the unique 1-cochain such that

\[
d\alpha(F,G) = \alpha([F,G]) = \eta_{D,K}(F,G) - \eta(F,G).
\]

**Proof.** The proof is analogous to the proof of Proposition 3.3. \( \Box \)

We now summarize the above Lie algebra action using the concept of an action Lie algebroid, defined in the Appendix 5.1. The global map \( \widetilde{\mathfrak{gl}}(H) \to A_{\text{det}}(Gr(H)) \) may be used to define a morphism of Lie algebroids \( \widetilde{G} \to A_{\text{det}} \), where \( \widetilde{G} \) is the action Lie algebroid over \( Gr(H) \) of the Lie algebra \( \widetilde{\mathfrak{gl}}(H) \). By restriction to the action Lie algebroid \( G \) corresponding to \( \mathfrak{gl}(H) \), we have the Lie algebroid morphism \( G \to T_{Gr(H)} \) corresponding to the global map in Proposition 1.4. In summary, we have the commutative diagram of Lie algebroids below.

\[
\begin{array}{cccc}
0 & \longrightarrow & \mathcal{O}_{Gr(H)} & \longrightarrow & \widetilde{G} & \longrightarrow & G & \longrightarrow & 0 \\
\downarrow{\text{Id}} & & \downarrow{\widetilde{L}} & & \downarrow{L} & & \downarrow{L} & & \downarrow{0} \\
0 & \longrightarrow & \mathcal{O}_{Gr(H)} & \longrightarrow & A_{\text{det}} & \longrightarrow & T_{Gr(H)} & \longrightarrow & 0
\end{array}
\]

**1.1.3 The Krichever Map and a Flat Connection**

Consider the vector subspace of sections \( \Gamma(C \setminus p, \omega_C^{\otimes j}) \subset \mathbb{C}((z)) d^\otimes \). Using the isomorphism as vector spaces \( H \cong \mathbb{C}((z)) d^\otimes \), we may regard \( \Gamma(C \setminus p, \omega_C^{\otimes j}) \subset H \).

**Proposition 1.5** (Segal and Wilson [23]). The Krichever map \( \mathcal{M}_{p,1^\infty} \to Gr \) defined by

\[
\kappa_j(C,p,z) = \Gamma(C \setminus p, \omega_C^{\otimes j}) \subset \mathbb{C}((z)) d^\otimes.
\]

where \( \omega_C := \Omega_C^1 \), is an injective map.

**Proof.** We check that this definition is well-defined. Notice \( \Gamma(C \setminus p, \omega_C^{\otimes j}) \in \text{Gr}(H) \) since the map \( p_\text{-} \) restricted to \( \Gamma(C \setminus p, \omega_C^{\otimes j}) \) is Fredholm.

\[
0 \to \Gamma(C, \omega_C^{\otimes j}) \to \Gamma(C \setminus p, \omega_C^{\otimes j}) \to H^\perp \to H^1(C, \omega_C^{\otimes j}) \to 0.
\]

See Proposition 6.2 in [23] for a proof of injectivity. \( \Box \)

The Witt algebra \( \text{witt} \) acts on \( \omega_C^{\otimes j} \) by Lie derivative

\[
\mathcal{L}_{f(z)}(g(z) d^\otimes) = \left( f(z) g'(z) + jf'(z)g(z) \right) d^\otimes.
\]

\(^1\)The group central extension \( \mathcal{G}_{L_F}^0(H) \) corresponding to the Japanese cocycle is described in [23, 20].
Since \( \omega^\otimes_j \cong H \) as vector spaces, we define the map \( \varrho_j : \text{witt} \to \mathfrak{gl}(H) \) as

\[
\varrho_j \left( f(z) \frac{\partial}{\partial z} \right) (g(z)) = f(z)g'(z) + jf'(z)g(z).
\]

**Proposition 1.6.** The pullbacks of the Japanese cocycle along the representations \( \varrho_j \) satisfies:

\[
\varrho_j^*(\eta) = (6j^2 - 6j + 1)\varrho_0^*(\eta) \quad \varrho_j^*(\eta) = \varrho_{j-1}^*(\eta).
\]

It is known that \( H^2(\text{witt}) \) is one dimensional. Let \( c_j = (6j^2 - 6j + 1) \) and define \( \text{vir}_j \) to be the central extension of \( \text{witt} \) by \( \varrho_j^*(\eta) = c_j \varrho_0^*(\eta) \). When \( j = 0 \) or \( j = 1 \), we recover the standard definition of the Virasoro algebra, denoted \( \text{vir} \). On the basis of \( \text{witt} \) the standard cocycle is given by

\[
\varrho_0^*(\eta)(L_m, L_n) = \frac{m^3 - m}{4} \delta_{m+n,0}
\]

This is summarized in the following commutative diagram of Lie algebras.

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & \mathbb{C} & \longrightarrow & \text{vir} & \longrightarrow & \text{witt} & \longrightarrow & 0 \\
\downarrow c_j & & \downarrow j & & \downarrow \text{id} & & \downarrow \varrho_j & & \\
0 & \longrightarrow & \mathbb{C} & \longrightarrow & \text{vir}_j & \longrightarrow & \text{witt} & \longrightarrow & 0 \\
\downarrow \text{id} & & \downarrow r & & \downarrow \varrho_j & & \\
0 & \longrightarrow & \mathbb{C} & \longrightarrow & \mathfrak{gl}(H) & \longrightarrow & \mathfrak{gl}(H) & \longrightarrow & 0
\end{array}
\]

**Proposition 1.7** (cf. Arabrello et al. Proposition 3.2.4 [1]). For \( m = (C, p, z) \in \mathcal{M}_{g,1} \), we have the following commutative diagram of Lie algebras with exact horizontal sequences.

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & \mathfrak{gl}(H)^{\kappa_j(m)} & \longrightarrow & \mathfrak{gl}(H)^{L\kappa_j(m)} & \longrightarrow & T_{\kappa_j(m)} \text{Gr}(H) & \longrightarrow & 0 \\
\downarrow \varrho_j^\epsilon & & \downarrow \varrho_j^\epsilon & & \downarrow \text{d}\kappa_j & & \\
0 & \longrightarrow & \Gamma(C \setminus p, T_C) & \longrightarrow & \text{witt} & \longrightarrow & T_m \mathcal{M}_{g,1} & \longrightarrow & 0
\end{array}
\]  \hspace{1cm} (2)

**Proof.** The top exact sequence is the action of \( \mathfrak{gl}(H) \) along a fiber. This gives \( T_D \text{Gr}(H) \cong \text{Hom}_C(D, H/D) \), where in the above diagram we have \( D = \kappa_j(m) \). The bottom exact sequence is given by the action of \( \text{witt} \) along a fiber. The left map is well-defined since the Lie derivative of an element of \( \kappa_j(m) = \kappa_j(C, p, z) = \Gamma(C \setminus p, \omega^\otimes_j) \) by an element of \( \Gamma(C \setminus p, T_C) \) is again an element of \( \kappa_j(C, p, z) \). Then we must check that the right map induced by \( \varrho_j \) is isomorphic to the map \( \text{d}\kappa_j \). Let \( f(z) \frac{\partial}{\partial z} \in \text{witt} \) and \( v_f \in T_m \mathcal{M}_{g,1} \) be its image. Then for \( g(z) dz^\otimes_j \in \kappa_j(m) \)

\[
d\kappa_j(v_f) \left( g(z) dz^\otimes_j \right) = \lim_{\epsilon \to 0} \frac{1}{\epsilon} g(z + \epsilon f(z)) \left( d(z + \epsilon f(z))^\otimes_j \right) \mod \kappa_j(m)
\]

\[
= L_{f(z) \frac{\partial}{\partial z}} g(z) dz^\otimes_j \mod \kappa_j(m)
\]

which matches the definition of the Lie derivative. \( \square \)

We easily upgrade the diagram (2) into a diagram of Lie algebroids on \( \mathcal{M}_{g,1} \).

\[
\begin{array}{ccccccccc}
0 & \longrightarrow & \kappa_j^* \mathcal{J} & \longrightarrow & \kappa_j^* G & \longrightarrow & \kappa_j^* \mathcal{T}_{\text{Gr}(H)} & \longrightarrow & 0 \\
\downarrow \varrho_j & & \downarrow \varrho_j & & \downarrow d\kappa_j & & \\
0 & \longrightarrow & \mathcal{K} & \longrightarrow & \mathcal{W} & \longrightarrow & T_{\mathcal{M}} & \longrightarrow & 0
\end{array}
\]  \hspace{1cm} (3)
Lemma 1.2. In an abelian category, if the following commutative diagram has exact short exact rows and the left map is an isomorphism, then the right square is a pullback square, i.e. \( B = B' \times_{C'} C \).

\[
\begin{array}{ccc}
0 & \longrightarrow & A \\
\downarrow^{l} & & \downarrow^{b} \\
0 & \longrightarrow & A'
\end{array}
\quad
\begin{array}{ccc}
\quad & & \quad \\
\downarrow^{a} & & \downarrow^{c} \\
B & \longrightarrow & C
\end{array}
\quad
\begin{array}{ccc}
\quad & & \quad \\
\quad & & \quad \\
\downarrow^{\pi} & & \downarrow^{\pi'} \\
B' & \longrightarrow & C'
\end{array}
\quad
\begin{array}{ccc}
0 & \longrightarrow & 0
\end{array}
\]

Proof. See the Appendix 5.2. \(\square\)

Let \( \phi : X \to Y \) be a smooth map, and let \( L \) be a line bundle on \( Y \). The natural map \( \phi_* : \mathcal{A}_\phi^* L \to \phi^* \mathcal{A}_L \) is given by \( \phi_* \delta = \delta (s \circ \phi) \) where \( \delta \in \mathcal{A}_\phi^* L \) and \( s \) is a section of \( L \).

Corollary 1.1. The Atiyah algebra of the pullback of the determinant line bundle is the pullback in the following diagram.

\[
\begin{array}{ccc}
0 & \longrightarrow & \mathcal{O}_{\mathcal{M}} \\
\downarrow^{Id} & & \downarrow^{\kappa_j^*} \\
0 & \longrightarrow & \kappa_j^* \mathcal{O}_{Gr(H)}
\end{array}
\quad
\begin{array}{ccc}
\quad & & \quad \\
\downarrow^{\kappa_j^*} & & \downarrow^{d\kappa_j} \\
\kappa_j^* \mathcal{A}_\det & \longrightarrow & \kappa_j^* \mathcal{T}_{Gr(H)} \\
\quad & & \quad \\
\downarrow^{\kappa_j^* \text{sym}_1} & & \downarrow^{\kappa_j^* \text{sym}_1} \\
\kappa_j^* \mathcal{A}_\det & \longrightarrow & \kappa_j^* \mathcal{T}_{Gr(H)}
\end{array}
\]

Proof. By Lemma 1.2, it suffices to notice that \( \kappa_j^* \) restricts to an isomorphism \( \mathcal{O}_{\mathcal{M}} \to \kappa_j^* \mathcal{O}_{Gr(H)} \), and that the right square (with the similarly defined map \( d\kappa_j \) on the tangent sheaves) commutes. \(\square\)

We now combine several commuting squares to pullback the diagram (1) from the Grassmannian to the moduli space \( \mathcal{M}_{g,1} \). The transfer of this diagram from the Grassmannian to the moduli space originates from compatibility of the representation of the Witt algebra with the derivative of the Krichever map, as given in (3). The process is analogous to the super case, so we summarize with these commuting diagrams. We denote the action Lie algebroid of \( \text{vir}_j \) by \( \mathcal{V}_j \).

\[
\begin{array}{ccc}
\mathcal{O}_{\mathcal{M}} & \longrightarrow & \mathcal{V}_j \\
\downarrow^{Id} & & \downarrow^{e_j^* \kappa_j^* \mathcal{L}} \\
\mathcal{O}_{\mathcal{M}} & \longrightarrow & \mathcal{V}_j \\
\downarrow^{Id} & & \downarrow^{\gamma_j^* \mathcal{G}} \\
\mathcal{O}_{\mathcal{M}} & \longrightarrow & \mathcal{A}_\det \\
\downarrow^{Id} & & \downarrow^{\gamma_j^* \mathcal{T}_{Gr(H)}} \\
\mathcal{O}_{\mathcal{M}} & \longrightarrow & \mathcal{A}_\det \\
\downarrow^{c_j \text{Id}} & & \downarrow^{\hat{\gamma}_j} \\
\mathcal{O}_{\mathcal{M}} & \longrightarrow & \mathcal{A}_\det \\
\downarrow^{\gamma_j^* \mathcal{T}_{Gr(H)}} & & \downarrow^{P} \\
0 & \longrightarrow & \mathcal{W} \\
0 & \longrightarrow & \mathcal{W}
\end{array}
\]

Proposition 1.8 (Kontsevich [13]). The pullback of the determinant line bundle from the Grassmannian along the \( j \)th Krichever map is canonically isomorphic to \( \lambda_j \).

\[
\kappa_j^* \det_{Gr(H)} \cong \lambda_j
\]

Proof. We see \( \kappa_j (C, p, z) = \Gamma(C \setminus p, \omega^j_C) \). Using the definition of the determinant line bundle on the Grassmannian, we have

\[
\det_{Gr(H)} \left( \Gamma(C \setminus p, \omega^j_C) \right) = \frac{\det(H^0(C, \omega^j_C))}{\det(H^1(C, \omega^j_C))}
\]

which can be seen using Čech cohomology. This is exactly the definition of \( \lambda_j \). \(\square\)
In the Appendix 5.1, we review standard operations of Atiyah algebras. Using these standard properties of Atiyah algebras, we describe the action of the Virasoro Lie algebroid on the Mumford isomorphism. Denote $A_j := A_{\lambda_j \otimes \lambda_j} - c_j 1$. Firstly, $V$ acts on $-c_j A_{\lambda_j} \otimes 1$ with central charge $-c_j$. Then the action of $V$ on $A_j$ is defined via the action on $A_{\lambda_j} \times \mathcal{T}_X - c_j A_{\lambda_j}$. Importantly, we see that $V$ acts with central charge $c_j - c_j = 0$, as in the diagram of Lie algebroids below.

\[
\begin{array}{cccccc}
\mathcal{K} & \downarrow & \mathcal{O}_M & \longrightarrow & V & \longrightarrow & W & \longrightarrow & 0 \\
 0 & \downarrow & 0 & \downarrow & \kappa & \longrightarrow & A_j & \longrightarrow & \mathcal{T}_M & \longrightarrow & 0
\end{array}
\]

A straightforward diagram chase gives the unique morphism of Lie algebroids $\alpha_j: W \rightarrow A_j$.

**Proposition 1.9** (Arabrello et al. [1]). Let $C$ be an affine Riemann surface. Denote the Lie algebra of global vector fields as $\mathfrak{k} := \Gamma(C, \mathcal{T}_C)$. Then the Lie algebra $\mathfrak{k}$ is perfect, that is to say, $H_1(\mathfrak{k}; \mathcal{O}_C) = \mathfrak{k}/[\mathfrak{k}, \mathfrak{k}] = 0$.

**Proof.** When $C$ is an open subset of $\mathbb{A}^1$, we have the global nonvanishing vector field $\partial := \frac{\partial}{\partial z}$. Then since $\mathfrak{k}$ is generated by $\partial$ as an $\mathcal{O}_C$ module, it suffices to notice:

$$h \partial = \frac{1}{2} [h \partial, z \partial] + \frac{1}{2} [\partial, h z \partial].$$

For a more general curve $C$, the rest of the proof may continue similarly to the proof of Proposition 4.4, or alternatively as in [1].

In the standard sense, a holomorphic connection on a line bundle $L$ is a splitting of the Atiyah sequence (20) as a sequence of $\mathcal{O}_X$-modules, i.e. an $\mathcal{O}_X$-linear map $\nabla: \mathcal{T}_X \rightarrow \mathcal{A}$ such that $\text{sym}_1 \circ \nabla = \text{Id}_{\mathcal{T}_X}$. The curvature $c_\nabla \in \Omega^2$ is defined by

$$c_\nabla(v \wedge w) = \left[ \nabla(v), \nabla(w) \right] - \nabla \left( [v, w] \right).$$

When $c_\nabla = 0$, we say the connection $\nabla$ is flat or integrable. A connection is flat exactly when it is a morphism of Lie algebroids.

**Theorem 1.3** (Kontsevich [13]). There exists a flat holomorphic connection on the line bundle $\lambda_1^{-c_j} \otimes \lambda_j$.

**Proof.** The proof is identical to the proof of Theorem 4.6.

## 2 The Supermoduli Space $\mathcal{M}_{g, 1|\mathbb{NS}}$

### 2.1 Definition and Projection

**Definition 2.1.** A super Riemann surface (SRS or SUSY curve) is a complex supermanifold of dimension $1|1$ with a maximally nonintegrable distribution $\mathcal{D}_\Sigma$ of rank $0|1$. Precisely, a super Riemann surface is the data $(\Sigma, \mathcal{O}_\Sigma, \mathcal{D}_\Sigma)$ such that

- $\Sigma$ is a complex manifold of dimension 1
- $\mathcal{O}_\Sigma$ is a sheaf on $\Sigma$ of supercommutative $\mathbb{C}$ algebras
• $O_\Sigma$ is locally isomorphic to $O_C[\xi]$
• $D_\Sigma$ is an odd subbundle of the tangent bundle $T_\Sigma$
• the induced map by Lie bracket $[\ ,\ ] : D_\Sigma^2 \to T_\Sigma/D_\Sigma$ is an isomorphism.

Locally, we can always find coordinates (called superconformal coordinates) $z|\zeta$ such that

$$D_\xi = \frac{\partial}{\partial \xi} + \xi \frac{\partial}{\partial x}$$

generates the distribution $D_\Sigma$.

Define a family of SUSY curves in the algebro-geometric sense: a smooth proper morphism $\pi : X \to S$ of super Riemann surfaces (i.e. relative dimension 1|1) parameterized by the superscheme $S$ with a relative distribution $D_{X/S} \subset T_{X/S}$ of rank 0|1 such that the map $[\ ,\ ] : D_{X/S}^2 \to T_{X/S}/D_{X/S}$ is an isomorphism. A section $\sigma : S \to X$ of the morphism $\pi$ is a coherent way to choose a Neuev-Schwarz (NS) puncture in each fiber. Since the section $\sigma$ is locally $\text{Spec} A \to \text{Spec} A[z,\zeta]$, these NS punctures may be described by $z = z_0$ and $\zeta = \zeta_0$ for some even function $z_0$ and some odd function $\zeta_0$ in $O_S$. Note that the image of $\sigma$ is a codimension 1|0 subsuperscheme of $X$. However, the orbit generated by the $D_{X/S}$ canonically associates a divisor of $X$ to the section $\sigma$.

Expressed with an odd parameter $\alpha$, the divisor, denoted $P = \text{div}(s)$, is the codimension 1|0 subsuperscheme $z = z_0 + \alpha \zeta$,

$$\zeta = \zeta_0 + \alpha.$$

Define the moduli stack $\mathcal{M}_{g,1|^k_{NS}}$ to be the moduli space of triples $(\Sigma, p, z|\zeta)$, where $\Sigma$ is a genus $g$ SUSY curve, $p$ is the divisor associated to a NS puncture on $\Sigma$, both $z$ and $\zeta$ are a $k$-jet equivalence class of an even (resp. odd) formal parameter vanishing at $p$. Specifically, we have the parameters $z, \zeta \in \hat{O}_p$, the formal neighborhood at $p$, and $z$ and $\zeta$ each have a zero of order one at $p$. And since $z|\zeta$ is a $k$-jet, the coordinate system is equivalent to any $y|\gamma$ such that $y|\gamma$ equals $z|\zeta$ modulo $m_p^{k+1}|m_p^{k+1}$. Note that $\mathcal{M}_{g,1|^k_{NS}}$ has dimension $3g - 3 + 1 + k|2g - 2 + 1 + k$.

By taking the projective limit of $\mathcal{M}_{g,1|^k_{NS}}$ as $k \to \infty$, we construct the pro-Deligne-Mumford stack

$$\mathcal{M}_{g,1|\infty_{NS}} = \lim \leftarrow \mathcal{M}_{g,1|^k_{NS}}.$$

Simply by forgetting the coordinate system $z|\zeta$ and the NS puncture $p$, we have the projection

$$\mathcal{M}_{g,1|^k_{NS}} \to \mathcal{M}_g$$

$$(\Sigma, p, z|\zeta) \mapsto \Sigma$$

where $\mathcal{M}_g$ is the supermoduli space of SUSY curves of genus $g$.

### 2.2 Action of the Super Witt Algebra

The sheaf of superconformal vector fields $T^*_\Sigma$ on a super Riemann surface is the largest subsheaf of $T_\Sigma$ such that $[T^*_\Sigma, D_\Sigma] = D_\Sigma$. In this sense, the superconformal vector fields are those which preserve the supersymmetry structure of the SRS. In local superconformal coordinates $z|\zeta$, a vector field may be expressed as

$$\partial = f(z, \zeta) \frac{\partial}{\partial z} + g(z, \zeta) D_\zeta.$$

And further, we can calculate

$$[\partial, D_\zeta] = -(-1)^{|f|}(D_\zeta f) \frac{\partial}{\partial z} + 2g \frac{\partial}{\partial z} + (-1)^{|g|}(D_\zeta g) D_\zeta.$$
Therefore if \( \partial \in \mathcal{T}_X^r \), then

\[
\partial = \partial f(z, \zeta) := f(z, \zeta) \frac{\partial}{\partial z} + \frac{(-1)^{|f|} D_\zeta f(z, \zeta)}{2} D_\zeta.
\]  

(4)

This expression in local coordinates shows two facts. Firstly, \( \mathcal{T}_X^r \) is not a \( \mathcal{O}_S \) module, it is only a sheaf of super \( \mathbb{C} \) vector spaces. Secondly, the projection \( \mathcal{T}_X^r \to \mathcal{T}_X^r / \mathcal{D} \) given locally by \( \partial f \to f \) is a canonical isomorphism (of sheaves of \( \mathbb{C} \) vector spaces). Therefore we have \( \mathcal{T}_X = \mathcal{T}_X^r \oplus \mathcal{D} \).

Analogously, the sheaf of superconformal vector fields \( \mathcal{T}_X^r \) on a family of super Riemann surfaces is the largest subsheaf of \( \mathcal{T}_X \) such that \([\mathcal{T}_X^r, \mathcal{D}] = \mathcal{D} \).

The following exact sequence provides much information about the structure of SUSY curves.

\[
0 \to \mathcal{D}_{X/S} \to \mathcal{T}_{X/S} \to \mathcal{T}_{X/S}/\mathcal{D}_{X/S} \to 0
\]

Further, we note that \( \mathcal{T}_{X/S}^r \cong \mathcal{T}_{X/S}/\mathcal{D}_{X/S} \cong \mathcal{D}^{\otimes r}_{X/S} \) by the induced isomorphism of the Lie bracket. Dualizing the exact sequence gives:

\[
0 \to \mathcal{D}^{\otimes r}_{X/S} \to \Omega_{X/S} \to \mathcal{D}^{-1}_{X/S} \to 0
\]

Since \( \mathcal{D}^{\otimes r}_{X/S} \) is the dual of the quotient \( \mathcal{T}_{X/S}/\mathcal{D}_{X/S} \), then we find \( \mathcal{D}^{\otimes r}_{X/S} \) is generated in local superconformal coordinates by \( dx - \xi \xi \).

We recall the definition of the Berezinian, the supergeneralization of the determinant. Let \( A \) be a superalgebra. Then \( \text{GL}(m|n, A) \) is the supergroup of automorphisms of the free \( A \)-module \( A^{m|n} \). For \( X \in \text{GL}(m|n, A) \) expressed in as an \((m+n) \times (m+n)\) matrix the Berezinian is defined as

\[
X = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \quad \text{Ber } X := \det(A - BD^{-1}C) \det^{-1} D.
\]

(6)

We note that \( \text{Ber}(\exp X) = \exp(\text{str } X) \), where \( \text{str} \) is the supertrace. Written in terms of the matrix in (6), \( \text{str}(X) := \text{tr}(A) - \text{tr}(D) \). Let \( \mathcal{F} \) be a vector bundle of rank \( m|n \) with associated transition functions \( \{f_{ij}\} \). Then we define \( \text{Ber } \mathcal{F} \) to be the bundle with transition functions \( \{\text{Ber } f_{ij}\} \). We enforce that \( \text{Ber } \mathcal{F} \) is rank \( 1|0 \) if \( n \) is even and rank \( 0|1 \) if \( n \) is odd. We denote a trivializing section of \( \text{Ber } \mathcal{F} \) as \( \{e_1, \ldots, e_m | f_1, \ldots, f_n\} \), where \( e_1, \ldots, e_m | f_1, \ldots, f_n \) are trivializing local coordinates for \( \mathcal{F} \).

The Berezinian of the exact sequence (5) induces an isomorphism

\[
\text{Ber } \Omega_{X/S}^1 \cong \text{Ber } \mathcal{D}^{\otimes r}_{X/S} \otimes \text{Ber } \mathcal{D}^{-1}_{X/S} \cong \mathcal{D}^{\otimes r}_{X/S} \otimes \mathcal{D}_{X/S} \cong \mathcal{D}^{-1}_{X/S}.
\]

We define \( \omega_{X/S} := \text{Ber } \Omega_{X/S}^1 \), which we call the relative Berezinian of \( X \) over \( S \). Therefore in local superconformal coordinates, we may describe the relative Berezinian as relative one-forms modulo \( dx - \xi \xi \).

The super Witt algebra \( \text{switt} \) is the Lie superalgebra of superconformal vector fields on a punctured formal neighborhood in \( \mathbb{C}^{1|1} \). Explicitly, the elements of \( \text{switt} \) are of the form (4) with \( f \) a formal super Laurent series:

\[
\text{switt} = \left\{ f(z, \zeta) \frac{\partial}{\partial z} + \frac{(-1)^{|f|} D_\zeta f(z, \zeta)}{2} D_\zeta : f(z, \zeta) \in \mathbb{C}((z))[\zeta] \right\}
\]

Expressed as a basis of even and odd vector fields:

\[
f = z^{-n+1} \quad L_n = z^{-n+1} \frac{\partial}{\partial z} + \frac{-n + 1}{2} z^{-n} \zeta \frac{\partial}{\partial \zeta} \quad n \in \mathbb{Z}
\]

\[
f = 2i \zeta z^{-r+\frac{1}{2}} \quad G_r = i z^{-r+\frac{1}{2}} \left( \zeta \frac{\partial}{\partial z} - \frac{\partial}{\partial \zeta} \right) \quad r \in \mathbb{Z} + \frac{1}{2}
\]
\[ [L_m, L_n] = (m - n)L_{m+n} \quad [L_n, G_r] = \left(\frac{n}{2} - r\right)G_{n+r} \quad [G_r, G_s] = 2L_{r+s} \]

Now, we use the sheaf of superconformal vector fields to analyze the tangent spaces of the moduli spaces. For \( \pi : X \to \mathcal{M}_g \) the universal family of super Riemann surfaces, we have the short exact sequence

\[ 0 \to T_{X/\mathcal{M}_g} \to T_X \to \pi^*(\mathcal{T}_{\mathcal{M}_g}) \to 0. \]

In the long exact sequence of higher direct images, we find the Kodaira-Spencer map \([10]\) is

\[ \delta : T_{\mathcal{M}_g} \xrightarrow{\sim} R^1\pi_*T_{X/\mathcal{M}_g}, \]

where the source \( T_{\mathcal{M}_g} \) follows from the projection formula \( \pi_* (\pi^*(\mathcal{T}_{\mathcal{M}_g})) = \mathcal{T}_{\mathcal{M}_g} \otimes \pi_*(\mathcal{O}_X) = \mathcal{T}_{\mathcal{M}_g} \).

The restriction to a SRS \( \Sigma \) is

\[ \delta_{\Sigma} : T_{\Sigma}\mathcal{M}_g \xrightarrow{\sim} H^1(\Sigma, \mathcal{T}_X^e). \]

This map is a natural bijection between the isomorphism classes of infinitesimal deformations \( v \in T_{(\Sigma, p, z|\zeta)}\mathcal{M}_g \) and elements of \( H^1(\Sigma, \mathcal{T}_X^e) \). From this we find the dimension of \( \mathcal{M}_g \) is \( 3g - 3 | 2g - 2 \) for \( g \geq 2 \).

Further, for \( \pi : X \to \mathcal{M}_{g,1}^{NS} \) the family of super Riemann surfaces with NS punctures represented by the divisor \( P \) and a \( k \)-jet coordinate system near the punctures, the Kodaira-Spencer map preserving this extra structure is

\[ \delta : T_{\mathcal{M}_{g,1}^{NS}} \xrightarrow{\sim} R^1\pi_*T_{X/\mathcal{M}_{g,1}^{NS}} (-k + 1)P, \]

which locally for \((\Sigma, p, z|\zeta)\) is

\[ \delta_{(\Sigma, p, z|\zeta)} : T_{(\Sigma, p, z|\zeta)}\mathcal{M}_{g,1}^{NS} \xrightarrow{\sim} H^1(\Sigma, \mathcal{T}_X^e (-k + 1)p) \]

where \( P|_{\Sigma} = p \) is the NS puncture on \( \Sigma \). From this we find the dimension of \( \mathcal{M}_{g,1}^{NS} \) is \( 3g - 2 + k | 2g - 1 + k \) for \( g \geq 2 \).

Let \( U \) be a formal neighborhood of a NS puncture \( p \) in \( \Sigma \). Choosing the superconformal formal parameters \( z, \zeta \) on \( U \) such that the divisor \( p \) is given by \( z = 0 \) gives a trivialization of \( \mathcal{T}_X^e \) on \( U \).

Using Čech cohomology, then

\[ T_{(\Sigma, p, z|\zeta)}(\mathcal{M}_{g,1}^{NS}) \cong \Gamma(U \setminus p, \mathcal{T}_X^e)/\left(\Gamma(U, \mathcal{T}_X^e (-k + 1)p) + \Gamma(\Sigma \setminus p, \mathcal{T}_X^e)\right) \]

\[ \cong \text{switt}/\left((\text{switt}/z^kC[z^{-1}]\text{switt}) + D_{\Sigma, p, z|\zeta}\right), \]

where we denote by \( D_{\Sigma, p, z|\zeta} \) the image of \( \Gamma(\Sigma \setminus p, \mathcal{T}_X^e) \) in \( \text{switt} \) using the local coordinate system \( z|\zeta \).

Further, taking the projective limit gives a description of the tangent space of \( \mathcal{M}_{g,1}^{NS} \):

\[ T_{(\Sigma, p, z|\zeta)}(\mathcal{M}_{g,1}^{NS}) \cong \text{switt}/D_{\Sigma, p, z|\zeta}. \] \( (7) \)

**Proposition 2.1.** The super Witt algebra acts on the moduli space \( \mathcal{M}_{g,1}^{NS} \) by vector fields.

**Proof.** The isomorphism given in (7) can be used to define the global map

\[ P : \text{switt} \to \text{Vect}(\mathcal{M}_{g,1}^{NS}). \]

This map \( P \) is a Lie superalgebra homomorphism by the naturality of the Kodaira-Spencer map.

\( \square \)
2.3 The Super Mumford Isomorphism

**Definition 2.2.** Let \( \pi : X \to S \) be a smooth proper family of complex supermanifolds of dimension 1|1. Let \( \mathcal{F} \) be a locally free sheaf on \( X \). Then the Berezinian of cohomology of \( \mathcal{F} \) is a sheaf on \( S \) of dimension 1|0 or 0|1 given by

\[
B(\mathcal{F}) := \otimes_i \left( \text{Ber} R^i \pi_\ast \mathcal{F} \right)^{(-1)^i}
\]

We define the Berezin line bundles \( \lambda_{j/2} \) for the universal family \( \pi : X \to \mathcal{M}_{a,1\mathbb{Z}} \) as

\[
\lambda_{j/2} := B(\omega_X^{\otimes j})
\]

where \( \omega_X := \text{Ber} \Omega_X^1 \) is the Berezinian of \( X \).

**Theorem 2.1** (Deligne, and Voronov [25]). The super Mumford isomorphism is the collection of canonical isomorphisms

\[
\lambda_{j/2} \cong \lambda_{1/2}^{(-1)^i(2j-1)}, \text{ in particular } \lambda_{3/2} \cong \lambda_{1/2}^5.
\]

3 The Semi-Infinite Super Grassmannian of \( \mathbb{C}((z))[\zeta] \)

3.1 Definition

Consider \( \mathbb{C}((z)) \), the infinite-dimensional topological space of formal Laurent series with the \( z \)-adic topology. Define \( H = \mathbb{C}((z))[\zeta] = \mathbb{C}((z))\zeta + \mathbb{C}((z)) \) where \( \zeta \) is a Grassmann variable, i.e. \( \zeta^2 = 0 \). We define two classes of subspaces: compact and discrete.

**Definition 3.1.** Define a super subspace of \( H \) to be compact if it is commensurable with \( \mathbb{C}[[z]][[\zeta]] = H^+ \). Explicitly, super subspaces \( K \) and \( H^+ \) are commensurable when the \( K/(K \cap H^+) \) and \( H^+/(K \cap H^+) \) both have finite even dimension and finite odd dimension. Define a (not necessarily super) subspace \( D \) of \( H \) to be discrete if there exists a compact subspace \( K \) such that the natural map \( D \oplus K \to H \) is an isomorphism of vector spaces.\(^2\)

**Lemma 3.1.** Let \( K \) be any compact subspace. Then \( D \) is discrete if and only if the natural map \( D \oplus K \to H \) is Fredholm, that is when the kernel and cokernel are finite-dimensional in the exact sequence below.

\[
0 \to D \cap K \to D \oplus K \to H \to H/(D+K) \to 0 \tag{8}
\]

**Proof.** The proof is a purely linear algebraic argument, see the Appendix 5.3. \( \square \)

Just as \( H^+ \) is a natural choice for a compact subspace, the discrete subspace \( H^- = z^{-1} \mathbb{C}[z^{-1}][\zeta] \) is a natural choice for a discrete subspace since \( H = H^+ \oplus H^- \). We call \( H^+ \) the distinguished compact subspace, and \( H^- \) the distinguished discrete subspace. Equivalently to (8), we may check \( p_-|D \) is Fredholm, where \( p_- \) is the projection \( H \to H^- \).

\[
0 \to D \cap H^+ \to D \xrightarrow{p} H^- \to H^-/(H^- \cap D) \cong H/(D+H^+) \to 0 \tag{9}
\]

**Definition 3.2.** We define the super Grassmannian \( \text{Gr}(H) \) as a infinite-dimensional supermanifold based on the infinite-dimensional manifold \( \text{Gr}_{\text{rd}}(H) \) of the discrete super subspaces \( D \subset H \) and locally modeled on the vector superspaces \( \text{Hom}_{\text{rd}}(D,K) \), glued out of charts as follows.

\( ^2 \)We have defined discrete and compact subspaces purely algebraically. The topological names are motivated by the \( z \)-adic topology on \( H \).
Remark 3.1. One may view $\text{Gr}(H)$ as a superstack representing the corresponding functor of points. What follows is a construction of this superstack by gluing affine superstacks representing the functors of points in $\text{Hom}_C(D, K)$.

We follow [20]. Consider discrete $D$ and compact $K$ such that the natural map $D \oplus K \to H$ is an isomorphism. Consider $A \in \text{Hom}_C(D, K)$.

We define $I$ as the identity map expressed as $I$. Consider two such charts: $U \subseteq \text{Hom}_C(D, K)$ and $I' \subseteq \text{Hom}_C(D', K')$ each correspond to $U_{D, K} \cap U_{D', K'}$. We wish to show $I$ and $I'$ are open and that the change of coordinates $I \to I'$ is smooth.

Let

$$
\begin{pmatrix}
T^{D'D} & T^{D'K} \\
T^{K'D} & T^{K'K}
\end{pmatrix}
$$

be the identity map expressed as $D \oplus K \to D' \oplus K'$. Since $K'$ and $K$ are commensurable, then $T^{K'K}$ is Fredholm. Suppose $W = \text{graph}(A: D \to K) = \text{graph}(B: D' \to K')$, i.e. $W$ corresponds to a point in $U_{D, K} \cap U_{D', K'}$. Then we must have

$$
\begin{pmatrix}
T^{D'D} & T^{D'K} \\
T^{K'D} & T^{K'K}
\end{pmatrix}
\begin{pmatrix}
I \\
A
\end{pmatrix} = \begin{pmatrix}
I \\
B
\end{pmatrix} Q
$$

where $Q: D \to D'$ is some isomorphism. We find

$$
B = (T^{K'D} + T^{K'K}A)(T^{D'D} + T^{D'K}A)^{-1}.
$$

So $B$ is a smooth function of $A$ and $I = \{ A \in \text{Hom}_C(D, K): T^{D'D} + T^{D'K}A \text{ is invertible} \}$ and so $I$ is indeed open; and similarly for $I'$.

3.2 Action of $GL\left(\mathbb{C}(z)[\zeta]\right)$ and $gl\left(\mathbb{C}(z)[\zeta]\right)$

Define $gl(H) = \text{Hom}_C(H, H)$ to be the superspace of continuous linear maps on $H$. For any endomorphism of $H$ we may write it as

$$
F = \begin{pmatrix}
F^{--} & F^{-+} \\
F^{++} & F^{++}
\end{pmatrix}
$$

where $F^{+-}: H^- \to H^+$ etc. Define the restricted linear supergroup $GL_F(H)$ to be the supergroup of continuous linear isomorphisms $G: H \to H$, where $G = \left(\begin{smallmatrix} G^{--} & G^{-+} \\ G^{+-} & G^{++} \end{smallmatrix}\right)$, with $G^{--}$ and $G^{++}$ Fredholm.

It is defined by the functor of points assigning a supercommutative algebra $R$ the group $GL_F(R \otimes H)$ of $R$-linear automorphisms $G: R \otimes H \to R \otimes H$ with $G^{--}$ and $G^{++}$ having finitely generated locally free kernels and cokernels.

Define an endomorphism of a discrete subspace to be supertrace class if it factors through some compact subspace.

Proposition 3.1. The group $GL_F(H)$ acts transitively on $\text{Gr}(H)$, and the stabilizer of $D$ is $(0:z)$ expressed in a decomposition $D \oplus K$.  

3In the $z$-adic topology, any linear map from $D$ to $K$ is continuous.
Proof. Consider \( G \in \text{GL}_F(H) \) and discrete \( D \). Every \( D \) is the image of an operator \( w = \left( \begin{array}{c} w_- \\ w_+ \end{array} \right) : H^- \to H \) such that \( p_- \circ w = w_- \) is Fredholm. The action of \( G \) on \( D \) can be easily computed by matrix multiplication resulting in the new subspace given by the operator

\[
Gw = \left( \begin{array}{c} G^- w_- + G^- w_+ \\ G^+ w_- + G^+ w_+ \end{array} \right)
\]

where the top map is clearly Fredholm.

To show the transitivity of the action, consider the map \( w \) as above and a map \( v = \left( \begin{array}{c} v_- \\ v_+ \end{array} \right) : H^+ \to H \) where the columns of \( v \) are a basis for \( K \) such that the natural map \( D \oplus K \to H \) is an isomorphism, and where eventually \( v(z^i) = z^{i-n} \) for some \( n \) and \( v(z^i\theta) = z^{i-m\theta} \) for some \( m \). We claim that

\[
G = \left( \begin{array}{c} w_- \\ w_+ \\ v_- \\ v_+ \end{array} \right)
\]

is in \( \text{GL}_F(H) \) and \( G(H^-) = D \). We need only to check that \( v \) is continuous and \( v_+ \) is Fredholm, both of which are satisfied by the condition that eventually \( v(z^i) = z^{i-n} \) for some \( n \) and \( v(z^i\theta) = z^{i-m\theta} \) for some \( m \).

The stabilizer is obvious. \( \square \)

Therefore we may describe \( \text{Gr}(H) \) as the homogeneous superspace

\[
\text{Gr}(H) \cong \text{GL}_F(H)/P
\]

where \( P = (v \, v) \) in the \( H^- \oplus H^+ \) decomposition.

**Proposition 3.2.** The Lie superalgebra \( \mathfrak{gl}(H) \) acts by vector fields on \( \text{Gr}(H) \). Explicitly, \( F \mapsto L_F \) is a Lie superalgebra homomorphism \( \mathfrak{gl}(H) \to T_{\text{Gr}(H)} \). In the chart \( U_{D,K} \), this action is given by the formula

\[
L_F(A) = F^{KD} + F^{KK}A - AF^{DD} - AF^{DK}A
\]

where \( L_F \in \mathop{\text{Hom}}_C(S^*(\mathop{\text{Hom}}_C(D,K)), \mathop{\text{Hom}}_C(D,K)) \).

Proof. Consider the action of \( G \in \text{GL}_F \) on the point in \( U_{D,K} \) represented by coordinates \( A: D \to K \).

\[
\left[ \begin{array}{cc} G^{DD} & G^{DK} \\ G^{KD} & G^{KK} \end{array} \right] \left[ \begin{array}{cc} I & 0 \\ A & I \end{array} \right] = \left[ \begin{array}{cc} G^{DD} + G^{DK}A & G^{DK} \\ G^{KD} + G^{KK}A & G^{KK} \end{array} \right] \sim \left[ \begin{array}{cc} I & 0 \\ (G^{DD} + G^{DK}A)(G^{DD} + G^{DK}A)^{-1} & I \end{array} \right]
\]

The equivalence relation is given by multiplication on the right by the stabilizer of \( D \), which in the \( D \oplus K \) decomposition is \((v \, v)\). We calculate \( L_F(A) \) as the derivative at \( t = 0 \) of the lower left block with \( G = I + tF \). \( \square \)

### 3.3 Berezinian Line Bundle

We can take as definition

\[
\text{Ber}_K(D) := \frac{\text{Ber}(D \cap K)}{\text{Ber}(H/(D + K))}.
\]

which is well-defined for discrete \( D \) and compact \( K \). The Berezinian of the exact sequence (8), gives \( \text{Ber}_K(D) \cong \frac{\text{Ber}(D)\text{Ber}(K)}{\text{Ber}(H)} \) if \( D, K, H \) were finite-dimensional. Since this finite-dimensional expression is \( \text{Ber}(D) \) multiplied by other constant\(^4\), though actually infinite, factors, it is an appropriate choice

\(^4\)If we fix any compact \( K \), for example \( K = H^+ \).
of the fiber of a Berezinian line bundle over the point corresponding to $D$. As in [13], we denote the line bundle $\text{Ber}_K$. The price we paid is that now our line bundle depends on a choice of compact subspace $K$. However, any two Berezinian line bundles are isomorphic by

$$\text{Ber}_K \cong \frac{\text{Ber}(K/(K \cap K'))}{\text{Ber}(K'/(K \cap K'))} \otimes \text{Ber}_K'. \quad (10)$$

**Definition 3.3.** As in [1], we define the Berezinian line bundle on $\text{Gr}(H)$ as

$$\text{Ber}_{\text{Gr}(H)} := \text{Ber}_{H^+},$$

in other words, $\text{Ber}_K$ with $K = H^+$, the distinguished compact subspace.

In an affine coordinate chart $U_{D,K}$, the fiber $\text{Ber}_K(D)$ is canonically trivialized: $\text{Ber}_K(D) \cong \mathbb{C}$. So there is a canonical trivialization $\text{Ber}_K|_{U_{D,K}} \cong U_{D,K} \times \mathbb{C}$. Since the charts $U_{D,K}$ cover $\text{Gr}(H)$ and $\text{Ber}_{H^+}$ is isomorphic to each $\text{Ber}_K$ by (10), this gives $\text{Ber}_{H^+}$ the structure of a line bundle.

Recall the definitions of a Lie algebroid and Atiyah algebra, which are stated in Appendix 5.1. To generalize these definitions to Lie superalgebroids and Atiyah superalgebras, we simply require that any vector bundle map is a super vector bundle map (parity preserving) and that any commutator is the super commutator [10]. The Atiyah superalgebra $A_L$ of a line bundle $L$ on a supermanifold $X$ may be regarded as the Lie superalgebra of infinitesimal symmetries of the pair $(X, L)$.

### 3.4 Action of Central Extension

It is known that $H^2(\mathfrak{gl}(H))$ is one-dimensional. For any choice of discrete $D$ and compact $K$ such that the natural map $D \oplus K \xrightarrow{\sim} H$ is an isomorphism, we define a 2-cocycle on $\mathfrak{gl}(H)$ as

$$\eta_{D,K}(F,G) := \text{str}(F^{DK}G^{KD} - (-1)^{|F||G|} F^{DK}G^{KD}).$$

We choose a distinguished 2-cocycle to correspond our distinguished decomposition $H^- \oplus H^+ \cong H$.\footnote{The cocycle defined by Ueno and Yamada in [24] is $\eta_{D,K}$ with choice $D = \mathbb{C}[z^{-1}, \zeta]$ and $K = z\mathbb{C}[z][\zeta]$.}

$$\eta(F,G) := \text{str}(F^+G^- - (-1)^{|F||G|} F^-G^+),$$

which we call the super Japanese cocycle. The unique Lie superalgebra central extension defined by the super Japanese cocycle will be denoted $\tilde{\mathfrak{gl}}(H)$. We denote the bracket on $\tilde{\mathfrak{gl}}(H)$ as $[F,G]^\sim = [F,G] + \eta(F,G)$.

**Proposition 3.3.** The Lie superalgebra $\tilde{\mathfrak{gl}}(H)$ acts by first order differential operators on $\text{Ber}_{\text{Gr}(H)}$. Explicitly, $F + c \mapsto \tilde{L}_F + c$ is a Lie superalgebra homomorphism $\tilde{\mathfrak{gl}}(H) \rightarrow A_{\text{Ber}(\text{Gr}(H))}$ sending $[F,G]^\sim$ to $[\tilde{L}_F, \tilde{L}_G]$. In the chart $U_{D,K}$, this action is given by the formula

$$\tilde{L}_F(A) = L_F(A) + \text{str}(F^{DK}A) + \alpha(F)$$

where $\alpha \in C^1(\mathfrak{gl})$ is the unique 1-cochain such that

$$d\alpha(F,G) = \alpha([F,G]) = \eta_{D,K}(F,G) - \eta(F,G).$$

Before providing the proof, we remark about the case that $D, K, H$ were finite-dimensional as motivation for the definition of the Lie superalgebra action. Consider the natural action of $G \in \text{GL}_F$ on $\text{Ber}_K(D_A)$ where $D_A \in U_{D,K}$ is represented by coordinates $A$: $D \rightarrow K$.

$$\begin{array}{ccc}
\text{Ber}(D) \text{ Ber}(K) & \xrightarrow{\text{Ber}(G^{DK} + c^{DK}A)} & \text{Ber}(G^{DKK}) \\
\downarrow \text{graph}(A) & & \downarrow \pi_{D, K} \\
\text{Ber}(D_A) \text{ Ber}(K) & \rightarrow & \text{Ber}(D_A) \text{ Ber}(K)
\end{array}$$

$$\begin{array}{ccc}
\text{Ber}(H) & \xrightarrow{\text{Ber}(G^{DKK})} & \text{Ber}(H) \\
\downarrow \pi_{D, K} & & \downarrow \pi_{D, K} \\
\text{Ber}(H) & \rightarrow & \text{Ber}(H)
\end{array}$$

$$\begin{array}{ccc}
\text{Ber}(H) & \xrightarrow{\text{Ber}(G^{DKK})} & \text{Ber}(H) \\
\downarrow \pi_{D, K} & & \downarrow \pi_{D, K} \\
\text{Ber}(H) & \rightarrow & \text{Ber}(H)
\end{array}$$

Using the canonical isomorphism of the fiber \( \text{Ber}_K(D_A) \) with \( \text{Ber}_K(D) \), we find the multiplicative factor \( \frac{\text{Ber}(G^{DK}+G^{DK}A)}{\text{Ber}(G^{DK})} \). Then for \( G = I + tF \), we derive the Lie superalgebra action of \( \text{str}(F^{DK}A) \).

**Proof.** Direct computation shows that \( \text{str}([F_1,F_2]^{DK}A) = \eta_{D,K}(F_1,F_2) \). Similarly, if \( D_A \in U_{D,K} \) and \( D_A \in U_{D,K'} \), then the change of coordinates is given by the unique 1-cochain whose exterior derivative is \( \eta_{D,K}(F_1,F_2) - \eta_{D,K'}(F_1,F_2) \). Thus, this Lie superalgebra action is glue between charts.

The Lie superalgebra homomorphism follows from:

\[
[L_{F_1}, L_{F_2}]A = [L_{F_1}, L_{F_2}] + \text{str}(F_1^{DK} L_{F_2} A) - \text{str}(F_2^{DK} L_{F_1} A) \\
= L_{[F_1,F_2]}A + \eta_{D,K}(F_1,F_2) - \eta_{D,K}(F_2,F_1) + \eta(F_1,F_2) + \eta(F_2,F_1) + \text{str}([F_1,F_2]^{DK}A) \\
= L_{[F_1,F_2]}A + \eta_{D,K}(F_1,F_2) + \eta(F_1,F_2) + \text{str}([F_1,F_2]^{DK}A) \\
= L_{[F_1,F_2]}A + \alpha([F_1,F_2]) + \eta(F_1,F_2) + \text{str}([F_1,F_2]^{DK}A) \\
= L_{[F_1,F_2]}A
\]

We now summarize the above Lie superalgebra action using the concept of an action Lie superalgebroid as defined in Appendix 5.1. The global map \( \mathfrak{g}(H) \to A_{\text{Ber}}(\text{Gr}(H)) \) in Proposition 3.3 may be used to define a morphism of Lie algebroids \( \mathcal{G} \to A_{\text{Ber}} \), where \( \mathcal{G} \) denotes the action Lie superalgebroid over \( \text{Gr}(H) \) of the Lie superalgebra \( \mathfrak{g}(H) \). By restriction to the action Lie superalgebroid \( \mathcal{G} \) corresponding to \( \mathfrak{g}(H) \), we have the Lie superalgebroid morphism \( \mathcal{G} \to T_{\text{Gr}(H)} \) corresponding to the global map in Proposition 3.2. In summary, we have the commutative diagram of Lie superalgebroids below.

\[
\begin{array}{cccccc}
0 & \longrightarrow & \mathcal{O}_{\text{Gr}(H)} & \longrightarrow & \mathcal{G} & \longrightarrow & 0 \\
\downarrow \text{id} & & \downarrow L & & \downarrow L & & \\
0 & \longrightarrow & \mathcal{O}_{\text{Gr}(H)} & \longrightarrow & A_{\text{Ber}} & \longrightarrow & T_{\text{Gr}(H)} & \longrightarrow & 0
\end{array}
\] (11)

**4 The Super Krichever Map and a Flat Connection**

**4.1 Definition of \( \kappa_j \)**

Consider the super vector subspace of sections \( \Gamma(\Sigma \setminus p, \omega_{\Sigma}^{\otimes j}) \subset \mathbb{C}((z))[\zeta][dz|d\zeta|^{\otimes j}] \). Using the super vector space isomorphism \( H \cong \mathbb{C}((z))[\zeta][dz|d\zeta|^{\otimes j}] \), we may regard \( \Gamma(\Sigma \setminus p, \omega_{\Sigma}^{\otimes j}) \subset H \).

**Definition 4.1** (Mulase [18]). The super Krichever map \( \mathfrak{M}_{g,1,\Sigma} \to \text{Gr}(H) \) is an injective analytic map given by

\[
\kappa_j(\Sigma, p, z|\zeta) = \Gamma(\Sigma \setminus p, \omega_{\Sigma}^{\otimes j}) \subset \mathbb{C}((z))[\zeta][dz|d\zeta|^{\otimes j}]
\]

where \( \omega_{\Sigma} := \text{Ber}(\Omega_{\Sigma}^1) \) is a rank 0\,1 invertible sheaf, the Berezinian of \( \Sigma \).

**Proof.** We check this definition is well-defined. Notice \( \Gamma(\Sigma \setminus p, \omega_{\Sigma}^{\otimes j}) \in \text{Gr}(H) \) since the map \( p \_ \) restricted to \( \Gamma(\Sigma \setminus p, \omega_{\Sigma}^{\otimes j}) \) is Fredholm, see (9).

\[
0 \to \Gamma(\Sigma, \omega_{\Sigma}^{\otimes j}) \to \Gamma(\Sigma \setminus p, \omega_{\Sigma}^{\otimes j}) \xrightarrow{p} H^- \to H^1(\Sigma, \omega_{\Sigma}^{\otimes j}) \to 0.
\]

See Theorem 4.2 of [18] for a proof of that the map is injective analytic. 

\[ \Box \]
4.2 Representations of \( \text{switt} \) and \( \text{ns} \) on \( C((z))[\zeta] \)

As described by Ueno and Yamada in [24], the super Witt algebra \( \text{switt} \) acts on \( \omega^{\otimes j}_{\zeta} \) by Lie derivative\(^6\)

\[
\mathcal{L}_{\partial f(z,\zeta)} \left( g(z,\zeta) [dz|d\zeta]^{\otimes j} \right) = \left( \partial_f g(z,\zeta) + \frac{j}{2} \frac{\partial f}{\partial z}(z,\zeta)g(z,\zeta) \right) [dz|d\zeta]^{\otimes j}
\]

where \( \partial_{f(z,\zeta)} \) is as in (4). Since \( \omega^{\otimes j}_{\zeta} \cong \Pi^j H \) as super vector spaces, where \( \Pi \) is the parity reversing operator, we define the map \( \rho_j : \text{switt} \to \text{gl}(H) \) as

\[
\rho_j(\partial_f(z,\zeta))(g(z,\zeta)) = \partial_f(g(z,\zeta)) + \frac{j}{2} \frac{\partial f}{\partial z}(z,\zeta)g(z,\zeta).
\]

The map \( \rho_j \) does not take into account the parity of the section \( \omega^{\otimes j}_{\zeta} \) upon which the map was based. Essentially, the map \( \rho_j \) treats \( \text{Ber}(\omega^{\otimes j}_{\zeta}) \) as rank 1 independent of \( j \). In order to keep with the convention that \( \text{Ber}(\omega^{\otimes j}_{\zeta}) \) is of rank 1 odd when \( j \) is even and 0 even if \( j \) is odd, we define the Lie superalgebra homomorphism \( \varrho_j \) : \( \text{switt} \to \text{gl}(H) \) as

\[
\varrho_j = \Pi^j \circ \rho_j \circ \Pi^j.
\]

**Proposition 4.1.** The pullbacks of the super Japanese cocycle along the representations \( \varrho_j \) satisfies:

\[
\varrho_j^*(\eta) = -(-1)^j(2j-1)\varrho_1^*(\eta) \quad \varrho_j(\eta) = \varrho_{1-j}(\eta).
\]

**Proof.** The proof is a direct computation. We note that \( \rho_j^*(\eta) = (2j-1)\rho_1^*(\eta) \) as in Proposition 4 of [24]. Since the supertrace is defined as the trace of the even-even matrix minus the trace of the odd-odd matrix, the effect of the parity operators in the definition of \( \varrho_j \) is to negate the pullback of the cocycle \( \eta \) exactly when \( j \) is odd.

It is known that \( H^2(\text{switt}) \) is one dimensional. Let \( c_j = -(-1)^j(2j-1) \) and define \( \text{ns}_j \) to be the central extension of \( \text{switt} \) by \( \varrho_j^*(\eta) = c_j \varrho_0^*(\eta) \). When \( j = 0 \) or \( j = 1 \), we recover the standard definition of the Neveu-Schwarz algebra, denoted \( \text{ns} \). On the basis of \( \text{switt} \) the standard cocycle is given by

\[
\varrho_0^*(\eta)(L_m,L_n) = \frac{m^3 - m}{4} \delta_{m+n,0} \quad \varrho_0^*(\eta)(L_n,G_r) = 0 \quad \varrho_0^*(\eta)(G_r,G_s) = \frac{4r^2 - 1}{4} \delta_{r+s,0}
\]

This is summarized in the following commutative diagram of Lie superalgebras.

\[
\begin{array}{cccccc}
0 & \longrightarrow & \mathbb{C} & \longrightarrow & \text{ns} & \longrightarrow & \text{switt} & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \mathbb{C} & \longrightarrow & \text{ns}_j & \longrightarrow & \text{switt} & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow & & \downarrow & & \\
0 & \longrightarrow & \mathbb{C} & \longrightarrow & \text{gl}(H) & \longrightarrow & \text{gl}(H) & \longrightarrow & 0 \\
\end{array}
\]  

\( (12) \)

4.3 Compatibility of \( \text{switt} \) Representation and the Krichever Map

**Proposition 4.2.** For \( m = (\Sigma,p,z|\zeta) \in \mathfrak{m}_{g,1}^{\text{NS}} \), we have the following commutative diagram of Lie superalgebras with exact horizontal sequences.

\[
\begin{array}{cccccc}
0 & \longrightarrow & \text{gl}(H)_{\kappa_j(m)} & \longrightarrow & \text{gl}(H) & \longrightarrow & T_{\kappa_j(m)} \text{Gr}(H) & \longrightarrow & 0 \\
\uparrow & & \uparrow & & \uparrow & & \uparrow & & \\
0 & \longrightarrow & \Gamma(\Sigma \setminus p, T_{\Sigma}^j) & \longrightarrow & \text{switt} & \longrightarrow & T_m \mathfrak{m}_{g,1}^{\text{NS}} & \longrightarrow & 0 \\
\end{array}
\]  

\( \uparrow \) \text{Lie derivative of sections of the Berezinian is described in §3.11 of [4].}
Proof. The top exact sequence is the action of $\mathfrak{gl}(H)$ along a fiber. This gives $T_D \text{Gr}(H) \cong \text{Hom}_{\mathbb{C}}(D, H/D)$, where in the diagram above we have $D = \kappa_j(m)$. The bottom exact sequence is given by the action of $\text{smitt}$ along a fiber. The left map is well-defined since the Lie derivative of an element of $\kappa_j(m) = \kappa_j(\Sigma, p, z|\zeta) = \Gamma(\Sigma \setminus p, \omega_{\Sigma}^{\otimes j})$ is again an element of $\kappa_j(\Sigma, p, z|\zeta)$. Then we must check that the right map induced by $\sigma_j$ is isomorphic to the map $d\kappa_j$.

Let $\partial f(z, \zeta) \in \text{smitt}$ be as in (4), and $v_f \in T_{m \mathcal{M}_{g, 1, \mathbb{N}_S}}$ be its image. Then for $g(z, \zeta)[dz|d\zeta]^{\otimes j} \in \kappa_j(m)$ and $\epsilon$ such that $|\epsilon| = |f|$

\[
d\kappa_j(v_f)\left(g(z, \zeta)[dz|d\zeta]^{\otimes j}\right) = \lim_{\epsilon \to 0} \frac{1}{\epsilon} g\left(z + \epsilon f(z) + \epsilon \zeta \frac{(-1)^j f(z, \zeta)}{2} \right) \zeta + \epsilon \frac{(-1)^j f(z, \zeta)}{2}\right) \right) s^{\otimes j} \mod \kappa_j(m) = L_{\partial f} g(z, \zeta)[dz|d\zeta]^{\otimes j} \mod \kappa_j(m)
\]

which matches the definition of the Lie derivative.

We easily upgrade the diagram (13) into a diagram of Lie superalgebroids on $\mathcal{M}_{g, 1, \mathbb{N}_S}$.

\[
0 \longrightarrow \mathcal{O}_{\mathbb{N}} \longrightarrow \mathcal{A}_{\kappa_j \text{Ber}} \longrightarrow \mathcal{T}_{\text{Gr}(H)} \longrightarrow 0
\]

4.4 Atiyah Algebra pullback

Recall Lemma 1.2 which provides a sufficient condition to be a pullback.

Corollary 4.1. The Atiyah algebra of the pullback of the Berezinian line bundle is the pullback in the following diagram.

\[
0 \longrightarrow \mathcal{O}_{\mathbb{N}} \longrightarrow \mathcal{A}_{\kappa_j \text{Ber}} \longrightarrow \mathcal{T}_{\text{Gr}(H)} \longrightarrow 0
\]

4.5 Action of Neuev-Schwarz Algebra

We now combine several commuting squares to pullback the diagram (11) from the Grassmannian to the moduli space $\mathcal{M}_{g, 1, \mathbb{N}_S}$. The transfer of this diagram from the Grassmannian to the moduli space originates from compatibility of the representation of the super Witt algebra with the derivative of the Krichever map, as given in (14).

Beginning with diagram (11) as the front face and the square of (14) as the right face, we build
the following commuting cube of Lie superalgebroids on $\mathcal{M}_{g,1\overline{\Sigma}_{\mathbb{P}}}$.

\[
\begin{array}{cccccc}
\mathcal{O}_{\mathcal{M}} & \xrightarrow{\text{Id}} & \mathcal{O}_{\mathcal{M}} & \xrightarrow{\kappa_j^*} & \mathcal{N}_j & \xrightarrow{p} & \mathcal{W} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\mathcal{O}_{\mathcal{M}} & \xrightarrow{\text{Id}} & \mathcal{O}_{\mathcal{M}} & \xrightarrow{\kappa_j^*} & \mathcal{A}_{\kappa_j^* \text{Ber}} & \xrightarrow{\tau_{\mathcal{N}}} & \mathcal{T}_{\mathcal{M}} \\
\downarrow & & \downarrow & & \downarrow & & \downarrow \\
\mathcal{O}_{\mathcal{M}} & \xrightarrow{\text{Id}} & \mathcal{O}_{\mathcal{M}} & \xrightarrow{\kappa_j^*} & \mathcal{A}_{\text{Ber}} & \xrightarrow{\kappa_j^* \text{sym}} & \mathcal{T}_{\mathcal{N}} \\
\end{array}
\]

The top face and bottom face are pullback diagrams. The top face is the Lie superalgebroid version of (12), and the bottom face is given by (15). Since $\mathcal{N}_j$ and $\mathcal{A}_{\kappa_j^* \text{Ber}}$ are both pullbacks in the top and bottom squares respectively, there is a unique action map $\varrho_j^* \kappa_j^* L : \mathcal{N}_j \rightarrow \mathcal{A}_{\kappa_j^* \text{Ber}}$.

Further, using the relationship given in (12) between the standard ns and the nonstandard ns$_j$, we arrive at the diagram below. The crucial property of the action of the Neveu-Schwarz Lie superalgebroid $\mathcal{N}$ is that the central charge acts by $c_j$.

\[
\begin{array}{cccccc}
0 & \longrightarrow & \mathcal{O}_{\mathcal{M}} & \xrightarrow{c_j \text{Id}} & \mathcal{N} & \longrightarrow & \mathcal{W} & \longrightarrow & 0 \\
0 & \longrightarrow & \mathcal{O}_{\mathcal{M}} & \xrightarrow{\text{Id}} & \mathcal{A}_{\kappa_j^* \text{Ber}} & \longrightarrow & \mathcal{T}_{\mathcal{N}} & \longrightarrow & 0 \\
\end{array}
\]

\[\text{(16)}\]

### 4.6 A Flat Holomorphic Connection

**Proposition 4.3.** The pullback of the Berezinian line bundle from the super Grassmannian along the $j$th super Krichever map is canonically isomorphic to $\lambda_{j/2}$.

\[\kappa_j^* \text{Ber}_{\mathcal{H}} \cong \lambda_{j/2}\]

**Proof.** We see $\kappa_j(\Sigma, p, z|\zeta) = \Gamma(\Sigma \setminus p, \omega^\otimes_j)$. Using the definition in Def. 3.3 of the Berezinian line bundle on the super Grassmannian, we have

\[
\text{Ber}_{\mathcal{H}}(\Gamma(\Sigma \setminus p, \omega^\otimes_j)) = \frac{\text{Ber}(H^0(\Sigma, \omega^\otimes_j))}{\text{Ber}(H^1(\Sigma, \omega^\otimes_j))}
\]

which can be seen using Čech cohomology. This is exactly Def. ?? of $\lambda_{j/2}$. \(\square\)

The standard operations of Atiyah algebras have straightforward generalizations to super Atiyah algebras, which are described in the Appendix 5.1. Using these standard properties of Atiyah algebras, we describe the action of the Neveu-Schwarz Lie superalgebroid on the line bundles of the super Mumford isomorphism. Denote $\mathcal{A}_j := \mathcal{A}_{\lambda_{j/2} \otimes \lambda_{-c_j}}$. Firstly, as in (16), $\mathcal{N}$ acts on $-c_j \mathcal{A}_{\lambda_{1/2}}$ with central charge $-c_j$. Then the action of $\mathcal{N}$ on $\mathcal{A}_j$ is defined via the action on $\mathcal{A}_{\lambda_{j/2}} \times _{\mathcal{T}_X} -c_j \mathcal{A}_{\lambda_{1/2}}$. Importantly, we see that $\mathcal{N}$ acts with central charge $c_j - c_j = 0$, as in the diagram of Lie superalgebroids below.

\[
\begin{array}{cccccc}
\mathcal{K} & \xrightarrow{\mathcal{N}} & \mathcal{W} & \longrightarrow & 0 \\
\downarrow & & \downarrow & & \downarrow \\
\mathcal{O}_{\mathcal{M}} & \xrightarrow{\text{Id}} & \mathcal{A}_j & \longrightarrow & \mathcal{T}_{\mathcal{N}} & \longrightarrow & 0 \\
\end{array}
\]

\[\text{(17)}\]

A straightforward diagram chase gives the unique morphism of Lie superalgebroids $\alpha_j : \mathcal{W} \rightarrow \mathcal{A}_j$. 
Proposition 4.4. Let $\Sigma$ be an affine super Riemann surface. Denote the Lie superalgebra of global superconformal vector fields as $\mathfrak{t} := \Gamma(\Sigma, \mathcal{T}^\mathbb{C}_z)$. Then the Lie superalgebra $\mathfrak{t}$ is perfect, that is to say, $H_1(\mathfrak{t}; \mathbb{C}) = \mathfrak{t}/[\mathfrak{t}, \mathfrak{t}] = 0$.

Proof. If $\Sigma$ is open in $\mathbb{C}^{1|1}$, then we can find superconformal global coordinates $z|\zeta$ such that $\mathcal{D}_\Sigma$ is generated by $D_\zeta = \frac{\partial}{\partial \zeta} + \zeta \frac{\partial}{\partial z}$ and elements of $\mathfrak{t}$ are of the form $\partial_f := f \frac{\partial}{\partial z} + \frac{(-1)^{|f|}}{2} D_\zeta f \cdot D_\zeta$ where $f = f(z, \zeta) \in \mathcal{O}_\Sigma$. The supercommutator of superconformal vector fields gives

$$[\partial_f, \partial_g] = \partial_{f g} - (-1)^{|f|} \frac{1}{2} D_\zeta (f g)$$

where $f, g \in \mathcal{O}_\Sigma$. For an arbitrary $h \in \mathcal{O}_\Sigma$, we find $\partial_h \in [\mathfrak{t}, \mathfrak{t}]$ since

$$\partial_h = \frac{2}{3} [\partial_h, \partial_z] + \frac{2}{3} [\partial_1, \partial_h z] + \frac{2}{3} [\partial_h \zeta, \partial_\zeta].$$

For more general SRSs $\Sigma$, we show the Chevalley-Eilenberg cohomology $H^1_{CE}(\mathfrak{t}, \mathbb{C}) = (H^1(\mathfrak{t}, \mathbb{C}))^*$ is zero by considering the spectral sequence of the double complex $\overline{\mathcal{C}}^*(\mathcal{U}, \bigwedge \mathcal{T}^*)$, where $\mathcal{U} = \{U_i\}_{i \in I}$ is an open cover of $\Sigma$ where each $U_i$ is an open ball and where pairwise intersections are contractible or empty. The double complex $E_0^{p,q} = \overline{\mathcal{C}}^q(\mathcal{U}, \bigwedge \mathcal{T}^p)$ is shown below with horizontal differential $d_{CE}$ and vertical Čech differential $\partial$. For $v_i \in T^*(U_{i_{0},...,i_{n+1}})$ where $U_{i_0,...,i_{n+1}} = \bigcap_{j=0}^{n+1} U_{i_j}$ and $f \in E_0^{m,n}$, the differentials act as

$$d_{CE}^m(f)(U_{i_0,...,i_n})(v_1,\ldots,v_{m+1}) = \sum_{i<j} (-1)^{i+j+n+|v_i|} f(U_{i_0,...,i_n},v_1,\ldots,v_{i-1},|v_i|+\cdots+|v_{j-1}|)$$

$$\uparrow$$

$$0 \rightarrow \bigoplus_{i<j<k} \mathbb{C} \rightarrow \bigoplus_{i<j<k} T^*(U_{i,j,k})^* \rightarrow \bigoplus_{i<j<k} \bigwedge^2 T^*(U_{i,j,k})^* \rightarrow \cdots$$

$$\uparrow$$

$$0 \rightarrow \bigoplus_{i<j} \mathbb{C} \rightarrow \bigoplus_{i<j} T^*(U_{i,j})^* \rightarrow \bigoplus_{i<j} \bigwedge^2 T^*(U_{i,j})^* \rightarrow \cdots$$

$$\uparrow$$

$$0 \rightarrow \bigoplus_{i} \mathbb{C} \rightarrow \bigoplus_{i} T^*(U_i)^* \rightarrow \bigoplus_{i} \bigwedge^2 T^*(U_i)^* \rightarrow \cdots$$

$$\uparrow$$

$$0 \rightarrow \bigoplus_{i} \mathbb{C} \rightarrow \bigoplus_{i} T^*(U_i)^* \rightarrow \bigoplus_{i} \bigwedge^2 T^*(U_i)^* \rightarrow \cdots$$

$$\uparrow$$

$$0 \rightarrow \bigoplus_{i} \mathbb{C} \rightarrow \bigoplus_{i} T^*(U_i)^* \rightarrow \bigoplus_{i} \bigwedge^2 T^*(U_i)^* \rightarrow \cdots$$

This definition follows (2.21) in [22].
Since the double complex is a first quadrant double complex, the spectral sequences $\rightarrow E^{p,q}_2$ and $\rightarrow E^{p,q}_2$ both converge to $H^{p+q}(E^\bullet)$. As usual, $\rightarrow E^{0,0}_2$, $\rightarrow E^{0,1}_2$, $\rightarrow E^{1,0}_2$, and $\rightarrow E^{1,1}_2$ stabilize on the second page. Further, notice that $d^0_{CE} = 0$. From this fact, we also find that $\rightarrow E^{1,0}_2$ and $\rightarrow E^{0,1}_2$ stabilize on the second page. We therefore have the following short exact sequences:

\[
0 \to \rightarrow E^{0,1}_2 \to H^1(E^\bullet) \to \rightarrow E^{1,0}_2 \to 0, \quad (18)
\]

\[
0 \to \rightarrow E^{1,0}_2 \to H^1(E^\bullet) \to \rightarrow E^{0,1}_2 \to 0. \quad (19)
\]

We wish to show $\rightarrow E^{1,0}_2 = H^1_{CE}(\mathfrak{t}) = 0$. We have that $\rightarrow E^{0,0}_2 \cong \rightarrow E^{0,1}_2 \cong H^0(X, \mathfrak{C})$ and $\rightarrow E^{2,0}_2 \cong \rightarrow E^{2,1}_2 \cong H^1(X, \mathfrak{C})$, where $\mathfrak{C}$ is the constant sheaf with values in $C$. Further, since $H^1_{CE}(U_0, T^*) = 0$ by the first half of this proof since $U_0$ is an open ball in $\mathbb{C}^{1,1}$, then $\rightarrow E^{1,0}_2 = \ker(d^0_{CE}) = 0$. And then $\rightarrow E^{1,0}_2 = H^0(X, 0) = 0$. Thus by (18), $H^1(E^\bullet) \cong \rightarrow E^{0,1}_2$. We already know $\rightarrow E^{0,1}_2 \cong \rightarrow E^{0,1}_2$, which gives $H^1(E^\bullet) \cong \rightarrow E^{0,1}_2$, and therefore (19) gives $\rightarrow E^{1,0}_2 = 0$. \qed

The definition of a holomorphic connection on a line bundle is recalled in section 1.1.3, and this definition generalizes straightforwardly to super Atiyah algebras.

**Theorem 4.1.** There exists a flat holomorphic connection on the line bundle $\lambda_1^{-c_1} \otimes \lambda_j$.

**Proof.** Consider the kernel Lie algebroid $\mathcal{K}$ as in (17). In fact, $\mathcal{K}$ is a bundle of Lie algebras with fiber $\mathfrak{k} = \Gamma(\Sigma \setminus p, T^\ast_p)$, meaning that the bracket on $\mathcal{K}$ is simply the pointwise bracket of its fibers. By Proposition 4.4, we know every fiber is equal to its commutant, therefore $[\mathcal{K}, \mathcal{K}] = \mathcal{K}$. So wlog, let $k = [k_1, k_2] \in \mathcal{K}$. Then notice $\alpha_j(k_1), \alpha_j(k_2) \in \ker(A_{p^\ast} \to T_X) = \mathcal{O}_{\mathfrak{M}}$. Which means $\alpha_j(k) = [\alpha_j(k_1), \alpha_j(k_2)] = 0$. Then by the universal property of the cokernel of $T^\ast \mathcal{M}$, we have a unique morphism of Lie algebroids $\nabla: T^\ast \mathcal{M} \to \mathcal{A}_j$. \qed

**5 Appendix**

Here we provide some a few proofs and some background material.

**5.1 Lie Algebroids, Atiyah Algebras, and Line Bundle Operations**

We summarize the basics of Lie (super)algebroids and specifically Atiyah (super)algebras. A Lie (super)algebroid is simply the many-object generalization of a Lie (super)algebra. A good reference is [14].

**Definition 5.1.** A Lie algebroid on a $\mathbb{C}$-manifold $M$ is a $\mathbb{C}$ vector bundle $E \to M$ with a vector bundle map $\alpha: E \to TM$, called the anchor map, where $TM$ is the tangent bundle of $M$, and with a $\mathbb{C}$-bilinear alternating bracket $[,] : \Gamma(E, M) \wedge \Gamma(E, M) \to \Gamma(E, M)$, which satisfies the Jacobi identity, $\alpha([X, Y]) = [\alpha(X), \alpha(Y)]$, and $[X, fY] = f[X, Y] + \alpha(X)(f)Y$ for all $X, Y \in \Gamma(E, M)$ and $f \in \mathcal{O}_M(M)$.

Given Lie algebroids $E$ and $F$ on the same base $M$, a Lie algebroid morphism is a $\mathbb{C}$ vector bundle morphism $\phi: E \to F$ over $M$ such that $b \circ \phi = a$ and $\phi([X, Y]) = [\phi(X), \phi(Y)]$, for all $X, Y \in \Gamma(E, M)$.

**Definition 5.2.** Let $L$ be a line bundle on a manifold $X$. We take as definition the Atiyah algebra $A_L$ on $X$ is the Lie algebroid of order 1 operators on the line bundle $L$. It is a Lie algebra extension with a compatible left $\mathcal{O}_X$-module structure:

\[
0 \to \mathcal{O}_X \to A_L \xrightarrow{\text{sym}_1} T_X \to 0, \quad (20)
\]

where the anchor map is the symbol map defined as $\text{sym}_1(D)(f) = [D, f]$. 
Definition 5.3. The action Lie algebroid associated to a Lie algebra homomorphism \( \phi: \mathfrak{g} \to \text{Vect}(X) \) is given by the trivial vector bundle \( X \times \mathfrak{g} \) with anchor map \( a: X \times \mathfrak{g} \to TX \) such that 
\[ a(x, X) = \phi(X)(x), \text{ and bracket } [V, W] = \phi(V)(W) - \phi(W)(V) + [V, W]^* \text{, where } V, W \in \Gamma(X \times \mathfrak{g}, X) \text{ and } \phi(V)(x) = \phi(V(x))(x). \]

To generalize the above definitions to Lie superalgebras and Atiyah superalgebras, we simply require that any vector bundle map is a super vector bundle map (parity preserving) and that any commutator is the super commutator [16].

The Atiyah (super)algebra \( A_L \) of a line bundle \( L \) on a (super)manifold \( X \) may be regarded as the Lie (super)algebroid of infinitesimal symmetries of the pair \( (X, L) \).

We describe the pushforward of an Atiyah algebra. For \( \lambda \in \mathbb{C} \), we define \( \lambda A_L \) as the semi-direct product \( O_X \otimes A_L \) subject to the relations \( (\lambda f, 0) = (0, f) \) for \( f \in O_X \). There is a canonical map of Lie algebroids \( A_L \to \lambda A_L \) which commutes as below.

\[
\begin{array}{c}
0 \to O_X \to A_L \to T_X \to 0 \\
\downarrow \lambda \text{Id} \quad \downarrow \text{Id} \\
0 \to O_X \to \lambda A_L \to T_X \to 0
\end{array}
\]

Further we define the Atiyah algebra \( A_{L_1} \otimes A_{L_2} \) to be the semi-direct product \( O_X \times (A_{L_1} \times_{T_X} A_{L_2}) \) subject to the relations \( (f + g, 0) = (0, (f, g)) \). This definition gives the commutative diagram of the first two rows below.

\[
\begin{array}{c}
0 \to O_X \times O_X \to A_{L_1} \times_{T_X} A_{L_2} \to T_X \to 0 \\
\downarrow (f, g) \mapsto f + g \quad \downarrow \text{Id} \\
0 \to O_X \to A_{L_1} \otimes A_{L_2} \to T_X \to 0 \\
\downarrow \text{Id} \\
0 \to O_X \to A_{L_1} \otimes A_{L_2} \to T_X \to 0
\end{array}
\]

Now consider \( \phi: A_{L_1} \times_{T_X} A_{L_2} \to A_{L_1} \otimes A_{L_2} \) given by the Leibniz rule

\[
\phi(\delta_1, \delta_2)(s_1 \otimes s_2) = \delta_1(s_1) \otimes s_2 + s_1 \otimes \delta_2(s_2),
\]

where \( \delta_i \in A_{L_i} \) and \( s_i \in \Gamma(L_i) \). From this it follows that there is a morphism of Lie algebroids \( A_{L_1} \otimes A_{L_2} \to A_{L_1 \otimes L_2} \) which is a canonical isomorphism.

Comparing the definitions of the Atiyah algebras \( A_L \otimes A_L \) and \( 2A_L \), you find a canonical isomorphism \( A_L \otimes A_L \cong 2A_L : (f, (\delta_1, \delta_2)) \mapsto (f, \delta_1 \otimes \delta_2) \), and the inverse given by the natural double inclusion. Let \( L^\vee \) be the inverse line bundle of \( L \). The Leibniz rule gives a map \( \psi: A_L \to A_{L^\vee} \) given by \( \psi(\delta)(s^\vee) = -s^\vee \otimes \delta(s) \otimes s^\vee \), where \( \delta \in A_L \) and \( s \in \Gamma(L) \). By composing \( \psi^{-1} \) and the canonical map in (21), we find a canonical isomorphism of Atiyah algebras \( A_{L^\vee} \cong -A_L \). Therefore for \( n \in \mathbb{Z} \), canonically \( nA_L \cong A_{L^{\otimes n}} \).

These operations generalize straightforwardly to super Atiyah algebras with the important replacement of the Leibniz rule with the super Leibniz rule:

\[
\begin{align*}
\phi & : A_{L_1} \times_{T_X} A_{L_2} \to A_{L_1 \otimes L_2} & \phi(\delta_1, \delta_2)(s_1 \otimes s_2) &= \delta_1(s_1) \otimes s_2 + (-1)^{\vert \delta_2 \vert} s_1 \otimes \delta_2(s_2) \\
\psi & : A_L \to A_{L^\vee} & \psi(\delta)(s^\vee) &= -(-1)^{\vert \delta \vert} s^\vee \otimes \delta(s) \otimes s^\vee
\end{align*}
\]

where \( \delta_i \in A_{L_i} \) and \( s_i \in \Gamma(L_i) \), and \( \delta \in A_L \) and \( s \in \Gamma(L) \).
5.2 Proof of Lemma 1.2

Proof. Suppose we have $X$ such that the following square commutes.

\[
\begin{array}{ccc}
X & \xrightarrow{g} & C \\
\downarrow{f} & & \downarrow{c} \\
B' & \xrightarrow{\pi'} & C'
\end{array}
\]

Let $x \in X$. Choose $y \in B$ such that $\pi(y) = g(x)$. Then $b(y) - f(x) \in B'$, and further $\pi'(b(y) - f(x)) = \pi' \circ b(y) - \pi' \circ f(x) = c \circ \pi(y) - c \circ g(x) = c(\pi(y) - g(x)) = 0$. Therefore we have $b(y) - f(x) \in A'$. And using the isomorphism $a$ and inclusion into $B$, we have $a^{-1}(b(y) - f(x)) \in B$.

Define $\phi : X \to B$ as $\phi(x) = y - a^{-1}(b(y) - f(x))$. We first check this map commutes, then check it does not depend on the choice of $y$.

\[
\begin{align*}
\pi \circ \phi(x) &= \pi(y - a^{-1}(b(y) - f(x))) = \pi(y) - \pi(a^{-1}(b(y) - f(x))) = \pi(y) - g(x) \\
b \circ \phi(x) &= b(y - a^{-1}(b(y) - f(x))) = b(y) - b(a^{-1}(b(y) - f(x))) = b(y) - (b(y) - f(x)) = f(x)
\end{align*}
\]

Now consider two lifts $y, y' \in B$ such that $\pi(y) = \pi(y') = g(x)$. Consider the subtraction of the resulting maps

\[
\phi(x) - \phi'(x) = [y - a^{-1}(b(y) - f(x))] - [y' - a^{-1}(b(y') - f(x))] = (y - y') - a^{-1}(b(y - y')) = 0
\]

where the last equality results from noticing that $y - y' \in A$ and $b(y - y') \in A'$.

\[\square\]

5.3 Proof of Lemma 3.1

Lemma 3.1 provides an alternative definition of a discrete subspace.

Proof. Firstly we show that commensurability is transitive, i.e. any two compact subspaces are commensurable to each other. For $K$ and $K'$ compact, using the exact sequence

\[
0 \to \frac{(K \cap H^{+}) + (K \cap K')}{K \cap K'} \to \frac{K}{K \cap K'} \to \frac{K}{(K \cap H^{+}) + (K \cap K')} \to 0,
\]

where the first term is isomorphic to $(K \cap H^{+})/(K \cap K' \cap H^{+})$, so we see $\dim(K/(K \cap K')) \leq \dim(H^{+}/(K' \cap H^{+})) + \dim(K/(K \cap H^{+})) < \infty$. And $\dim(K/(K \cap K')) < \infty$ similarly.

Next we show that if $D \cap K$ and $H/(D + K)$ are finite-dimensional for some compact $K$, then $D \cap K'$ and $H/(D + K')$ are finite-dimensional for any other compact $K'$. Using the exact sequence

\[
0 \to D \cap K \cap K' \to D \cap K' \to D \cap K'/((D \cap K \cap K')) \to 0,
\]

we see $\dim(D \cap K') \leq \dim(D \cap K) + \dim(K'/((K \cap K')) < \infty$. Using the exact sequence

\[
0 \to \frac{K}{(D + K') \cap K} \cong \frac{D + K' + K}{D + K'} \to \frac{H}{D + K'} \to \frac{H}{D + K + K'} \to 0,
\]

we see $\dim(H/(D + K')) \leq \dim(K/(K' \cap K)) + \dim(H/(D + K)) < \infty$.

Assume $D$ is discrete. Then $D \oplus K' = H$ for some compact $K'$. Thus $D \cap K' = 0$ and $H/(D + K') = 0$. Then $D \cap K$ and $H/(D + K)$ are finite-dimensional by the previous paragraph.

Assume $D \cap K$ and $H/(D + K)$ are finite-dimensional. We show $D$ is discrete by showing $H/D$ is compact. It suffices to notice

\[
\frac{K}{K \cap (H/D)} \cong D \cap K, \quad \frac{H/D}{K \cap (H/D)} \cong \frac{H}{D + K}.
\]

\[\square\]
Acknowledgments

This paper began as a collaboration with D. Diroff and I would like to thank him for his many contributions to these results. The advice from A. Voronov was especially valuable.
