The first $p$-widths of the unit disk

SIDNEY DONATO

ABSTRACT. On compact 2-manifolds with non-empty convex boundary, we prove a regularity result for integral 1-varifolds $V$ that are stationary with free boundary and $\mathbb{Z}_2$-almost minimizing in small annuli. That regularity says that $V$ is a free boundary finite geodesic network. Next, using that regularity, we compute the first $p$-widths of the unit closed ball $B^2$, for $p = 1, \ldots, 4$. As a consequence, we find an unstable geodesic with free boundary as a min-max critical varifold with multiplicity.

1 Introduction

For $n > 0$, let $(M^{n+1}, g)$ be a compact Riemannian manifold with (possibly empty) boundary. Gromov [6, 7], Guth [8], Marques and Neves [17] introduced the notion of volume spectrum $\{\omega_p(M)\}_{p=1}^{\infty}$ for the area functional in the space of relative mod 2 cycles $\mathbb{Z}_n(M, \partial M, \mathbb{Z}_2)$. The volume spectrum is a sequence of positive numbers that satisfies similar properties to the eigenvalues spectrum:

$$0 < \omega_p(M) \leq \omega_{p+1}(M) \quad \text{and} \quad \omega_p(M) \to \infty \quad \text{as} \quad p \to \infty.$$

Where $\omega_p(M)$ is called the $p^{th}$ min-max width of $M$.

It is not known a full description of that spectrum, even in the simple cases as our case for the unit disk. The most recent progress in this direction was the proof of the Weyl law for that spectrum by Liokumovich, Marques and Neves [15]. The Weyl law gives the asymptotic behavior of that spectrum, precisely:

$$\lim_{p \to \infty} \omega_p(M)p^{-\frac{1}{n+1}} = a(n)\text{vol}(M)^{\frac{n}{n+1}},$$

where $a(n) > 0$ is a constant that depends only of $n > 0$. This result was recently used to show the density and equidistribution of minimal surfaces for generic metric (Irie, Marques and Neves [9], and Marques, Neves and Song [18]).

In contrast with the Weyl law for eigenvalues, the constant above is still unknown. Obviously, if we have a description of the volume spectrum, we can deduce the constant $a(n)$. So far this full description seems to be very hard. In fact, the results on this direction got only to compute some initial widths (Aix [1], Gaspar and Guaraco [5], and Nurser [19]).

The main objective of this article is to compute the first widths of the unit closed ball (unit disk) $B^2 \subset \mathbb{R}^2$ and of planar full ellipses $E^2$ closed to $B^2$ (see Theorem [4,5]).

\footnote{The author was supported by the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior (CAPES) - Brazil.}
When $M^{n+1}$ is closed and $3 \leq n + 1 \leq 7$, the Multiplicity One Conjecture of Marques and Neves [10] states that the two-sided unstable components of a closed minimal hypersurface obtained by a min-max method should have multiplicity one. This conjecture was proved partially by Marques and Neves [14], Zhou [28, 29], and Ketover, Marques and Neves [10]. The complete proof for a bump metric $g$ was did recently by Zhou [30]. It is expected that this conjecture holds for the case with non empty convex boundary, as was partially proved by Wang [27]. In Aïex [1] is proved that the conjecture above is false for the closed case and $n + 1 = 2$. Similarly, as a consequence of the calculated widths for ellipsoids, we obtain a concrete counterexample for this conjecture in the case with non-empty convex boundary and $n + 1 = 2$ (see Remark 4.8).

The ideas to proof our results are similar to what was done by Aïex [1] for the 2-sphere $S^2$ and for Ellipsoids close to $S^2$. In that case, he uses a regularity result due to Allard and Almgren [2] which says that stationary integral 1-varifolds on closed Riemannian manifolds are (finite) geodesic networks. This means that the varifold is a finite union of geodesic segments such that the singularities are given by their possible stationary junctions. This regularity is an important tool, because it holds for the 1-varifolds obtained in the Min-Max Theorem, so for each $p \in N$ there are geodesic networks sufficiently close to achieve the $p$-width. In our case, we had to extend this regularity result for two dimensional manifolds $M^2$ with non-empty boundary and we did this supposing the boundary strictly convex. In this hypothesis we get

**Theorem** (see Theorem 3.15). *If $V$ is a stationary integral 1-varifold which is $\mathbb{Z}_2$-almost minimizing in small annuli, then $V$ is a free boundary (finite) geodesic network.*

This means that $V$ restricted to the interior, $\text{int}(M)$, of $M$ is a geodesic network, each geodesic segment has its interior in $\text{int}(M)$, and each point $p \in \partial M$ that is on the support of $V$ is given by the intersection of boundaries of geodesic segments from $\text{int}(M)$ such that: if each of these segments at $p$ are parameterized to start at $p$, then the resultant of the unit tangent vectors of the segments (and multiplicities) is perpendicular to $\partial M$ at $p$.

The extra hypothesis that $V$ is $\mathbb{Z}_2$-almost minimizing in small annuli is a classical hypothesis to get regularity for the codimension one case and for $3 \leq n + 1 \leq 7$ (see Pitts [22], Simon [26] and Li and Zhou [12]). Essentially, the regularity comes from the fact that almost minimizing varifolds are locally stable almost everywhere. The hypothesis of strictly convex boundary follows the ideas from [12], where they prove a regularity result for strictly convex boundary and $3 \leq n + 1 \leq 7$.

As in [1], the regularity is an important step to calculate the $p$-widths. In fact, by that regularity the varifolds obtained in our adapted version of the Min-Max Theorem (see Theorem 2.13) are free boundary geodesic networks. We did a classification (Theorem 3.6 and Corollary 3.7) of these varifolds which have low mass in $B^2$ and $E^2$ and then, getting a finite number of candidates for the first $p$-widths.
Finally, to compute the \( p \)-widths of \( B^2 \) we use \( p \)-sweepouts whose image are given by real algebraic varieties restricted to \( B^2 \). We estimate these \( p \)-sweepouts and we combine with the classification to deduce the first widths. For \( E^2 \) we do similarly and using continuity.

This article is organized in the following way: in Section 2 we remember some basic theory and we give some definitions, also we explain how we adapt the Min-Max Theorem for our case (Theorem 2.13 and Corollary 2.14); in Section 3 we talk about free boundary geodesic networks and its properties, also we classify the free boundary geodesic networks which are \( \mathbb{Z}_2 \)-almost minimizing in small annuli and have low mass in \( B^2 \) and \( E^2 \), and we conclude proving our regularity result (Theorem 3.15); and in the Section 4 we compute the first \( p \)-widths of \( B^2 \) and \( E^2 \) (Theorem 4.5) using the regularity, classification and the estimates obtained for the \( p \)-sweepouts.

2 Preliminaries

Throughout this section \( M \) denotes a compact Riemannian \( (n+1) \)-manifold, \( n \geq 0 \), with smooth and possibly empty boundary \( \partial M \). We can always assume that \( M \) is isometrically embedded in some Euclidean space \( \mathbb{R}^Q \) for some \( Q \in \mathbb{Z}_+ \). We denote \( B_r(p) \) the open Euclidean ball of radius \( r \) centered at \( p \), and \( A_{s,r}(p) \) the open annulus \( B_r(p) \setminus \overline{B}_s(p) \) for \( 0 < s < r \).

When \( M \) has non-empty boundary, the embedding above is obtained in the following way: we can extend \( M \) to a closed Riemannian manifold \( \widetilde{M} \) with the same dimension such that \( M \subset \widetilde{M} \) (see \cite{20}), and so, by the Nash’s Theorem, we get the isometric embedding \( \widetilde{M} \hookrightarrow \mathbb{R}^Q \). We denote by \( \tilde{B}_r(p) \) the open geodesic ball in \( \widetilde{M} \) of radius \( r \) centered at \( p \).

We consider the following spaces of vector fields:

\[
\mathfrak{X}(M) := \{ X \in \mathfrak{X}(\mathbb{R}^Q) : X(p) \in T_pM \text{ for all } p \in M \}
\]
and

\[
\mathfrak{X}_{\text{tan}}(M) := \{ X \in \mathfrak{X}(M) : X(p) \in T_p(\partial M) \text{ for all } p \in \partial M \}.
\]

**Definition 2.1.** (Relative Topology) Given any subset \( A \subset M \), where \( M \) is equipped with the subspace topology, the \emph{interior relative} of \( A \), \( \text{int}_M(A) \), is defined as the set of all \( p \in M \) such that there exists a relatively open neighborhood \( U \subset A \) of \( p \). The \emph{exterior relative} of \( A \) is denoted by \( \text{int}_M(M \setminus A) \). And the \emph{relative boundary} of \( A \), \( \partial_{\text{rel}} A \), is the subset of \( M \) such that is neither in the relative interior nor exterior of \( A \).

**Definition 2.2.** (Relative Convexity) A subset \( \Omega \subset M \) is said to be a \emph{relatively convex} (respect. \emph{relatively strictly convex}) domain in \( M \) if it is a relatively open connected subset in \( M \) whose relative boundary \( \partial_{\text{rel}} \Omega \) is smooth and convex (respect. strictly convex) in \( M \).

**Definition 2.3.** (Fermi coordinates) Given \( p \in \partial M \) and suppose that the coordinates \( (x_1, \cdots, x_n) \) are the geodesic normal coordinates of \( \partial M \) in a neighborhood of \( p \). Take \( t = \text{dist}_M(\cdot, \partial M) \), which is a smooth map well-defined
in a relatively open neighborhood of \( p \) in \( M \). The Fermi coordinates system of \((M, \partial M)\) centered at \( p \) is given by the coordinates \((x_1, \cdots, x_n, t)\). Also, the Fermi distance function from \( p \) on a relatively open neighborhood of \( p \) in \( M \) is defined by

\[
\tilde{r} := \tilde{r}_p(q) = |(x, t)| = \sqrt{x_1^2 + \cdots + x_n^2 + t^2}.
\]

**Definition 2.4.** Given \( p \in \partial M \), we define the Fermi half-ball and half-sphere of radius \( r \) centered at \( p \) respectively by

\[
\tilde{B}^+_r(p) := \{ q \in M : \tilde{r}_q(x) < r \}, \quad \tilde{S}^+_r(p) := \{ q \in M : \tilde{r}_q(p) = r \}.
\]

Also we consider the following open annular neighborhood in the Fermi coordinates:

\[
\mathcal{A}_{s,t}(p) := \tilde{B}^+_s(p) \setminus \text{Clos}(\tilde{B}^+_t(p))
\]

for \( p \in \partial M \), and \( 0 < s < t \). Where \( \text{Clos}(\tilde{B}^+_t(p)) \) denotes the closure of \( \tilde{B}^+_t(p) \) on \( M \). Also, when \( p \in \text{int}(M) \), we require that \( t < \text{dist} \_M(p, \partial M) \).

The geometric properties of the Fermi half-ball and half-sphere can be summarized in the following proposition:

**Proposition 2.5.** [12, Lemma A.5] There exists a small constant \( r_{\text{Fermi}} > 0 \), depending only on the isometric embedding \( M \subset \mathbb{R}^Q \), such that for all \( 0 < r < r_{\text{Fermi}} \)

(i) \( \tilde{S}^+_r(p) \) is a smooth hypersurface meeting \( \partial M \) orthogonally;

(ii) \( \tilde{B}^+_r(p) \) is a relatively strictly convex\(^{3}\) domain in \( M \);

(iii) \( B_{r/2}(p) \cap M \subset \tilde{B}^+_r(p) \subset B_{2r}(p) \cap M \).

### 2.1 Relative Flat Cycles

We recall some definitions that can be founded in Federer [4, Section 4]. For each \( 0 \leq k \leq n+1 \), \( \mathcal{R}_k(M; \mathbb{Z}_2) \) denotes the set of \( k \)-dimensional rectifiable mod 2 flat chains in \( \mathbb{R}^Q \) whose support lies in \( M \). Given \( T \in \mathcal{R}_k(M; \mathbb{Z}_2) \), we denote by \( \mathcal{F}(T) \) and \( \textbf{M}(T) \) the flat norm and the mass of \( T \), respectively. Also, the support of \( T \) is denoted by \( \text{spt}(T) \).

Consider the following sets:

\[
\mathcal{I}_k(M; \mathbb{Z}_2) = \{ T \in \mathcal{R}_k(M; \mathbb{Z}_2) : \partial T \in \mathcal{R}_{k-1}(M; \mathbb{Z}_2) \},
\]

\[
\mathcal{Z}_k(M; \mathbb{Z}_2) = \{ T \in \mathcal{I}_k(M; \mathbb{Z}_2) : \partial T = 0 \},
\]

\[
\mathcal{Z}_k(M, \partial M; \mathbb{Z}_2) = \{ T \in \mathcal{I}_k(M; \mathbb{Z}_2) : \text{spt}(\partial T) \subset \partial M \},
\]

and

\[
\mathcal{Z}_{k,\text{rel}}(M, \partial M; \mathbb{Z}_2) = \mathcal{Z}_k(M, \partial M; \mathbb{Z}_2)/\mathcal{I}_k(\partial M; \mathbb{Z}_2).
\]

The set \( \mathcal{Z}_k(M; \mathbb{Z}_2) \) is the space of mod 2 (integral) flat \( k \)-cycles in \( M \) and we call the quotient space \( \mathcal{Z}_{k,\text{rel}}(M, \partial M; \mathbb{Z}_2) \) as the space of relative (mod 2) flat \( k \)-cycles.

\(^{3}\)The convexity in [12] is assumed to be strictly convex.
flat cycles. When \( \partial M = \emptyset \), we have that \( \mathcal{Z}_{k,\text{rel}}(M, \partial M; \mathbb{Z}_2) \) is identical to \( \mathcal{Z}_k(M; \mathbb{Z}_2) \).

The support of a class \([T] \in \mathcal{Z}_{k,\text{rel}}(M, \partial M; \mathbb{Z}_2)\) is given by \( \text{spt}([T]) = \bigcap_{T \in [T]} \text{spt}(T) \). Also, the mass norm and flat norm in the space of relative cycles are defined, respectively, by

\[
\mathcal{M}([T]) = \inf_{T \in [T]} \mathcal{M}(T), \quad \mathcal{F}([T]) = \inf_{T \in [T]} \mathcal{F}(T),
\]

for \([T] \in \mathcal{Z}_{k,\text{rel}}(M, \partial M; \mathbb{Z}_2)\).

We consider the space of relative flat cycles \( \mathcal{Z}_{k,\text{rel}}(M, \partial M; \mathbb{Z}_2) \) endowed with the flat norm \( \mathcal{F} \). When it is endowed with the topology of the mass norm, we denote it by \( \mathcal{Z}_k(M, \partial M; \mathcal{M}) \).

Note that each \([T] \in \mathcal{Z}_{k,\text{rel}}(M, \partial M; \mathbb{Z}_2)\) has a unique canonical representative \( T^0 \in [T] \) such that \( T^0 \mathcal{L} \partial M = 0 \), in particular, \( \mathcal{M}([T]) = \mathcal{M}(T^0) \) and \( \text{spt}([T]) = \text{spt}(T^0) \), see [22, Lemma 3.3]. Also, it follows that \( \mathcal{F}([T]) \leq \mathcal{M}([T]) \). This canonical representative is obtained take \( T^0 = S \mathcal{L} (M \setminus \partial M) \) for any \( S \in [T] \). To keep the notation simple we denote \([T]\) by \( T \).

### 2.2 Varifolds in manifolds with boundary

The following definitions can be founded in [22] and [26]. We denote by \( \mathcal{R}_k(M) \) the set of \( k \)-dimensional rectifiable varifolds in \( \mathbb{R}^Q \) with support contained in \( M \) and equipped with the weak topology. Also \( \mathcal{V}_k(M) \) is the closure of \( \mathcal{R}_k(M) \) in the weak topology.

Given a varifold \( V \in \mathcal{V}_k(M) \), the weight and the support of \( V \) are denoted by \( \|V\| \) and \( \text{spt}\|V\| \), respectively. Also, for \( x \in \text{spt}\|V\| \), we denote by \( \text{VarTan}(V, x) \subset \mathcal{V}(\mathbb{R}^Q) \) as the set of the varifold tangents of \( V \) at \( x \), which is a natural generalization of tangent planes for smooth surfaces.

Given \( V, W \in \mathcal{V}_k(M) \), the Pitts’ \( \mathcal{F} \)-metric is denoted by \( \mathcal{F}(V, W) \). This metric induces precisely the usual weak topology on the set \( \{ V \in \mathcal{V}_k(M) : \|V\|(M) \leq L \} \), for each constant \( L > 0 \).

If \( R \subset M \) is a \( k \)-rectifiable set and \( \theta \) is a \( \mathcal{H}^k \)-integrable non-negative function on \( R \), we denote by \( \nu(R, \theta) \in \mathcal{V}_k(M) \) as being the rectifiable \( k \)-varifold associated to \( R \) with multiplicity function \( \theta \). If \( \theta \) assumes only positive integers values, we say that \( \nu(R, \theta) \) is an integral varifold. We denote by \( \mathcal{IV}_k(M) \) the space of \( k \)-dimensional integral varifolds in \( M \).

Given \( T \in \mathcal{R}_k(M; \mathbb{Z}_2) \), we denote by \( [T] \in \mathcal{V}_k(M) \) the varifold induced by the support of \( T \) and its coefficients. And for \( T \in \mathcal{Z}_{k,\text{rel}}(M, \partial M; \mathbb{Z}_2) \), we take \( [T] = [T^0] \).

Given \( V \in \mathcal{V}_k(M) \), let \( X \in \mathcal{X}_{\text{tan}}(M) \) be a generator of a one-parameter family of diffeomorphisms \( \phi_t \in \mathbb{R}^Q \) with \( \phi_0(M) = M \), we have that the first variation of \( V \) along the vector field \( X \) is given by

\[
\delta V(X) := \frac{d}{dt} \bigg|_{t=0} \mathcal{M}(\phi_t)_* V,
\]

where \( (\phi_t)_* V \) is the pushforward varifold of \( V \) (see [26, 39.2]).
Definition 2.6. Let $U \subset M$ be a relatively open subset. A varifold $V \in \mathcal{V}_k(M)$ is said to be stationary in $U$ with free boundary if $\delta V(x) = 0$ for any $x \in \mathcal{X}_{\text{tan}}(M)$ compactly supported in $U$.

Note that a free boundary minimal submanifold is also stationary with free boundary. However, the reverse may not be true. Indeed, any constant multiple of a connected component of $\partial M$ is a stationary varifold with free boundary, even though it can be nothing like a minimal hypersurface in $M$.

By the relative topology we consider the $k$-dimensional density, $\Theta^k(V, x)$, of a stationary varifold $V \in \mathcal{V}_k(M)$ as the density restricted to $M$, that is, given $x \in M$, we take

$$\Theta^k(V, x) := \lim_{\rho \to 0} \frac{\|V\|(B_\rho(x) \cap M)}{\rho^k|B^k|},$$

where $|B^k|$ is the volume of the $k$-dimensional unit Euclidean ball $B^k$. For a fixed $x$, define the function

$$\Theta^k_x(V, \rho) := \frac{\|V\|(B_\rho(x) \cap M)}{\rho^k|B^k|}.$$

In the case $\partial M = \emptyset$, we have $B_\rho(x) \subset M$ and it is known that the function above for stationary varifolds satisfies the monotonicity formula [26, Sections 17 and 40]: $\Theta^k_x(V, \rho)$ is non-decreasing in $\rho$. Also, it is well known that any tangent varifold of a stationary varifold is a stationary Euclidean cone and $\Theta^k_x(C, \rho) = \Theta^k_x(V, x)$ for any $C \in \text{VarTan}(V, x)$ and for all $\rho > 0$. We write this fact as $\Theta^k_x(C, \infty) = \Theta^k_x(V, x)$.

2.3 Min-Max Definitions

In the following we use the notions of homotopy as in [17, Section 2], just replacing $\mathcal{Z}_n(M; \mathbb{M}; \mathbb{Z}_2)$ by $\mathcal{Z}_{n,\text{rel}}(M, \partial M; \mathbb{M}; \mathbb{Z}_2)$ in those definitions.

The set $[X, \mathcal{Z}_{n,\text{rel}}(M, \partial M; \mathbb{M}; \mathbb{Z}_2)]^1$ denotes the set of all equivalence classes of $(X, \mathcal{M})$-homotopy classes of mappings into $\mathcal{Z}_{n,\text{rel}}(M, \partial M; \mathbb{M}; \mathbb{Z}_2)$.

Given an equivalence class $\Pi \in [X, \mathcal{Z}_{n,\text{rel}}(M, \partial M; \mathbb{M}; \mathbb{Z}_2)]^1$, each $S \in \Pi$ is given by $S = \{\phi_i\}_{i \in \mathbb{N}}$ for some $(X, \mathcal{M})$-homotopy sequence of mappings $\{\phi_i\}_{i \in \mathbb{N}}$ into $\mathcal{Z}_{n,\text{rel}}(M, \partial M; \mathbb{M}; \mathbb{Z}_2)$. We define

$$L(S) = \limsup_{i \to \infty} \max \{\mathcal{M}(\phi_i(x)); x \in \text{dmm}(\phi_i)\}.$$

Definition 2.7. The width of $\Pi$ is defined by

$$L(\Pi) = \inf \{L(S) : S \in \Pi\}.$$

We say that $S \in \Pi$ is a critical sequence for $\Pi$ if $L(S) = L(\Pi)$, and the critical set $C(S)$ of a critical sequence $S$ is given by

$$C(S) = K(S) \cap \{V \in \mathcal{V}_n(M) : \|V\|(M) = L(S)\},$$
where

\[
K(S) = \left\{ V \in \mathcal{V}_n(M) : V = \lim_{j \to \infty} |\phi_{ij}(x_j)| \text{ as varifolds, for some subsequence } \\
\{\phi_{ij}\} \subset S \text{ and } x_j \in \text{dmm}(\phi_{ij}) \right\}.
\]

From [15, Th. 15.1] (see also [22, 4.1 (4)]) we know that there exist critical sequences for each class \(\Pi\), and from [22, 4.2 (2)], \(C(S)\) is compact and non-empty.

**Definition 2.8.** [13, Section 2.5] Let \(X \subset I^n\) be a cubical subcomplex. We say that a continuous map in the flat topology \(\Phi : X \to \mathbb{Z}_{n,rel}(M, \partial M; \mathbb{Z}_2)\) is a \(p\)-sweepout if the \(p\)-th cup power of \(\Phi^*(\lambda)\) is nonzero in \(H^p(X; \mathbb{Z}_2)\), where \(\lambda\) is the generator of \(H^1(\mathbb{Z}_{n,rel}(M, \partial M; \mathbb{Z}_2); \mathbb{Z}_2)\).

**Definition 2.9.** A flat continuous map \(\Phi : X \to \mathbb{Z}_{n,rel}(M, \partial M; \mathbb{Z}_2)\) has no concentration of mass if

\[
\lim_{r \to 0} \sup \{\|\Phi(x)\| : x \in \text{dmm}(\Phi), p \in M\} = 0.
\]

The set of all \(p\)-sweepouts with no concentration of mass is denoted by \(P_p(M)\).

**Definition 2.10.** The \(p\)-width of \(M\) is given by

\[
\omega_p(M) = \inf_{\Phi \in P_p(M)} \sup \{\text{M}(\Phi(x)) : x \in \text{dmm}(\Phi)\}.
\]

### 2.4 Min-Max Theorem

**Definition 2.11.** Let \(U \subset M\) be a relatively open subset, we say that a varifold \(V \in \mathcal{V}_k\) is \(\mathbb{Z}_2\)-almost minimizing in \(U\) with free boundary if for every \(\epsilon > 0\) we can find \(\delta > 0\) and \(T \in \mathbb{Z}_{k,rel}(M, \partial M; \mathbb{Z}_2)\) with \(F(V, |T|) < \epsilon\) and such that the following property holds true: if \(T = T_0, T_1, \ldots, T_m \in \mathbb{Z}_{k,rel}(M, \partial M; \mathbb{Z}_2)\) with

- \(\text{spt}(T - T_i) \subset U\) for \(i = 1, \ldots, m\);
- \(F(T_i - T_{i-1}) \leq \delta\) for \(i = 1, \ldots, m\) and
- \(\text{M}(T_i) \leq \text{M}(T) + \delta\) for \(i = 1, \ldots, m\)

then \(\text{M}(T_m) \geq \text{M}(T) - \epsilon\).

Roughly speaking, it means that we can approximate \(V\) by a varifold induced from a current \(T\) such that for any deformation of \(T\) by a discrete family supported in \(U\), and with the mass not increasing too much (parameter \(\delta\)), then at the end of the deformation the mass cannot be deformed down too much (parameter \(\epsilon\)).

A varifold \(V \in \mathcal{V}_k(M)\) is said to be \(\mathbb{Z}_2\)-almost minimizing in annuli with free boundary if for each \(p \in \text{spt}[V]\) there exists \(r > 0\) such that \(V\) is \(\mathbb{Z}_2\)-almost minimizing in the annuli \(M \cap A_{s,r}(p) = M \cap B_r(p) \setminus \overline{B_s}(p)\) for all \(0 < s < r\).
If \( p \notin \partial M \), we require that \( r < \text{dist}(p, \partial M) \). By Proposition 2.5 (iii), this definition with respect to \( A_{s,t}(p) \) or \( A_{s,r}(p) \) is equivalent. When \( \partial M = \emptyset \), we do not need use the expression ‘with free boundary’.

If \( V \in \mathcal{V}_k(M) \) is \( \mathbb{Z}_2 \)-almost minimizing in a relatively open set \( U \subset M \) with free boundary, then \( V \) is stationary in \( U \) with free boundary (22, Th. 3.3).

In the following, we proof a tightening process to a critical sequence \( S \in \Pi \) so that every \( V \in \mathcal{C}(S) \) becomes a stationary varifold with free boundary.

**Theorem 2.12.** Let \( \Pi \in [X, \mathbb{Z}_{n,\text{rel}}(M, \partial M; M; \mathbb{Z}_2)]^\sharp \). For each critical sequence \( S^* \in \Pi \), there exists another critical sequence \( S \in \Pi \) such that \( C(S) \subset C(S^*) \) and each \( V \in \mathcal{C}(S) \) is stationary in \( M \) with free boundary.

**Proof.** The proof of this result is essentially the same as [15, Th. 8.5]. The only modifications are the use of Th. 13.1 and 14.1 of [15], as noted in [12, Th. 4.17]. In place of [15, Th. 14.1] we use [13, Th. 2.11]; and a compatible version of [15, Th. 13.1] follows from [13, Lemma A.1] in the same way that the [15, Th. 13.1] follows from [15, Lemma 13.4].

With the tightening process above we can prove the existence of a \( \mathbb{Z}_2 \)-almost minimizing varifolds with free boundary such that it reaches the width of a chosen \((X; M)\)-homotopy class \( \Pi \in [X, \mathbb{Z}_{n,\text{rel}}(M, \partial M; M; \mathbb{Z}_2)]^\sharp \). When \( \partial M = \emptyset \), it was first proved by Pitts [22, Th. 4.10] with maps in cubical domains for \( 1 \leq k \leq n \) and later by Marques and Neves [17, Th. 2.9] for cubical subcomplex domains when \( k = n \). For the case with boundary, a version for cubical domains was proved by Li and Zhou [12, Th. 4.21]. We present below a version for the case \( \partial M \neq \emptyset \) and take maps in cubical subcomplex domains when \( k = n \).

**Theorem 2.13.** For any \( \Pi \in [X, \mathbb{Z}_{n,\text{rel}}(M, \partial M; M; \mathbb{Z}_2)]^\sharp \), there exists \( V \in IV_n(M) \) such that

(i) \( \|V\|(M) = L(\Pi) \);

(ii) \( V \) is stationary in \( M \) with free boundary;

(iii) \( V \) is \( \mathbb{Z}_2 \)-almost minimizing in small annuli with free boundary.

**Proof.** Using the previous theorem, we can follow the same procedure in the proof of [22, Th. 4.10] (see also [12, Th. 4.21]). To prove that \( V \) is \( \mathbb{Z}_2 \)-almost minimizing in small annuli with free boundary on \( \partial M \), just do as in the proof of [12, Th. 4.21].

We present now an important result that we use in the last section.

**Corollary 2.14.** For \( p \in \mathbb{N} \) and each \( \epsilon > 0 \), we can find \( V \in IV_n(M) \) such that

(i) \( \omega_p(M) \leq \|V\|(M) \leq \omega_p(M) + \epsilon \).
(ii) \( V \) is stationary in \( M \) with free boundary;

(iii) \( V \) is \( \mathbb{Z}_2 \)-almost minimizing in small annuli with free boundary.

**Proof.** Note that the results in Section 3.3 of [17] can be extended for compact manifolds (with or without boundary) from the results in Section 2 of [13]. So we can use the results from Section 3.3 of [17].

By definition we can find \( \Phi : X \to Z_{n,rel}(M, \partial M; \mathbb{Z}_2) \) a \( p \)-sweepout with no concentration of mass such that \( \sup_x M(\Phi(x)) : x \in \text{dmm}(\Phi) \leq \omega_p(M) + \epsilon \). From 3.6 of [17] there exists an \((X,M)\)-homotopy sequence of mappings \( S = \{ \phi_i \} \) associated. By 3.7 and 3.9 (ii) of [17] we can extended this sequence to a sequence \( \{ \Phi_i \} \) of maps continuous in the mass norm and homotopics to \( \Phi \) in the flat topology for large \( i \). Moreover

\[
L(\Pi) \leq L(S) = \lim_{i \to \infty} \sup_x M(\Phi_i(x)) \leq \sup_x M(\Phi(x)).
\]

As \( \Phi \) is a \( p \)-sweepout and \( \Phi_i \) is flat continuous and homotopic to \( \Phi \) for large \( i \), then \( \Phi_i \) is also a \( p \)-sweepout for large \( i \) with no concentration of mass by 3.5 of [17]. Also from 3.9 (i) of [17] we have that \( \{ \Phi_i \} \subset P_p(M) \) for each \( \Phi_i \) for large \( i \). Together with the above inequality we conclude that

\[
\omega_p(M) \leq L(\Pi) \leq \sup_x M(\Phi(x)) \leq \omega_p(M) + \epsilon.
\]

The remaining items are deduced from the above theorem. \( \Box \)

### 3 One Dimensional Stationary Varifolds

In this section we proof some results related to stationary integral 1-varifolds. In particular, we proof some properties of free boundary geodesic networks. When \( M \) is the unit disk \( B^2 = B_1(0) \subset \mathbb{R}^2 \), or a planar full ellipse \( E^2 \subset \mathbb{R}^2 \) sufficiently close to \( B^2 \), we classify the free boundary geodesic networks, provided they are \( \mathbb{Z}_2 \)-almost minimizing in annuli and have mass bounded by \( 6 \). Also we prove our main theorem about regularity (Theorem 3.15).

#### 3.1 Free Boundary Geodesic Networks

Here we define certain stationary integral 1-varifolds whose support is given by geodesic segments. We follow the notations of Aix [1].

**Definition 3.1.** Let \( U \subset M \) be a relatively open set. A varifold \( V \in IV(M) \) is called a free boundary geodesic network in \( U \) if there exist geodesic segments \( \{ \alpha_1, \ldots, \alpha_l \} \subset \text{int}(M) \) and \( \{ \theta_1, \ldots, \theta_l \} \subset \mathbb{Z}_+ \) such that

(i) \( V \lfloor U = \sum_{i=1}^l v(\alpha_i \cap U, \theta_i) \);
(ii) The set of junctions is the set \( \Sigma_V = \bigcup_{i=1}^{l} (\partial \alpha_i) \cap U \). Each \( p \in \Sigma_V \) belongs to a set \( \{ \alpha_1, \ldots, \alpha_m \} \) for some \( m = m(p) \in \mathbb{Z}_+ \), with \( m \geq 3 \) if \( p \in \text{int}(M) \). If each of those geodesic segments is parameterized by arc-length with initial point \( p \), then

\[
\sum_{k=1}^{m} \theta_{i_k} \dot{\alpha}_{i_k}(0) = 0, \quad \text{if } p \in \Sigma_V \cap \text{int}(M), \quad \text{and} \quad (1)
\]

\[
\sum_{k=1}^{m} \theta_{i_k} \dot{\alpha}_{i_k}(0) \perp \partial M, \quad \text{if } p \in \Sigma_V \cap \partial M. \tag{2}
\]

A junction \( p \in \Sigma_V \cap \text{int}(M) \) is said to be singular in \( \text{int}(M) \) if there exist at least two geodesic segments with \( \theta_{i_k} \dot{\alpha}_{i_k}(0) \neq -\theta_{i_k} \dot{\alpha}_{i_k}(0) \), and regular in \( \text{int}(M) \) otherwise. In other words, an interior regular junction belong to the intersection of longer geodesic segments. When \( p \in \Sigma_V \cap \partial M \), we said that it is regular if \( \alpha_{i_k}(0) \perp \partial M \) for every \( \alpha_i \) such that \( p \in \partial \alpha_{i_k} \). A triple junction is a point \( p \in \Sigma_V \) such that it belongs to exactly three geodesic segments with multiplicity 1 each. Obviously a triple junction is not regular in \( \text{int}(M) \).

We can deduce the following properties as did in [I]:

**Proposition 3.2.** (Prop. 3.2 and Cor. 3.3 and 3.4 of [I]). Let \( V \) be as above.

(i) \( V \) is stationary in \( U \);

(ii) \( \Theta^1(V, x) = \sum_{k=1}^{s} \frac{\theta_{i_k}}{2} \) for \( x \in \bigcap_{k=1}^{s} v(\alpha_{i_k} \cap U, \theta_{i_k}) \);

(iii) If \( \Theta^1(V, x) < 2 \) for all \( x \in \text{spt}(\|V\| \cap \text{int}(M)) \), then every \( p \in \Sigma_V \cap \text{int}(M) \) is a triple junction;

(iv) If \( \Theta^1(V, x) \leq 2 \) for all \( x \in \text{spt}(\|V\| \cap \text{int}(M)) \), then either \( \Sigma_V \cap \text{int}(M) \) contains a triple junction or all junctions are regular in \( \text{int}(M) \) and the geodesic segments of each junction have multiplicity one;

(v) If \( \Theta^1(V, x) \leq 1 \) for \( x \in \text{spt}(\|V\| \cap \partial M) \), then a junction on \( x \) is given by a geodesic segment with multiplicity one or two and orthogonal to \( \partial M \), or by two geodesic segments with multiplicity one each and with the same angles with respect to \( \partial M \).

### 3.2 Upper Bound for the Density

Now we prove important properties of free boundary geodesic networks. We do similar results to Prop. 3.6 and Th. 3.7 from [I], but in a different approach.

**Lemma 3.3.** Let \( M^2 \) be a compact region in \( \mathbb{R}^2 \) with non-empty boundary and \( V \in \mathcal{N}_1(M) \) be a free boundary geodesic network. For each \( p_i \in \Sigma_V \cap \partial M \), let

\[
F_i = \sum_{k=1}^{m} \theta_{i_k} \dot{\alpha}_{i_k}(0),
\]
as in the Definition 3.1 (ii).

(i) For $M^2 = B^2$ we have that $\sum_i |F_i| = \|V\|(M)$.

(ii) If $M^2 \rightarrow B^2$ in the manifold sense, then $\sum_i |F_i| \rightarrow \|V\|(M)$. More precisely: given $\varepsilon > 0$, then for $M^2$ sufficiently close to $B^2$, depending only on a parameter $C > 0$, we have that

$$\left| \left\|V\|(M) - \sum_i |F_i| \right\| < \varepsilon$$

for every free boundary geodesic network $V \in IV_1(M)$ with $\|V\|(M) < C$.

Proof. Denote by $J_i$ the $i$-th junction of $V$. Each segment of $V$ is determined by two junctions $J_i$ and $J_j$. Denote that segment by $\alpha_{i,j}$. Also we have two angles $\phi_{i,j}$ and $\phi_{j,i}$ associated, which are the intern angles of the respective junctions in the triangle given by the origin $O$ and the junctions $J_i$ and $J_j$ (see Fig. 1). Note that, in these notations, we have $\alpha_{i,j} = \alpha_{j,i}$.

Let $\theta_{i,j} \in \mathbb{Z}_+$ be the multiplicity of $\alpha_{i,j}$. Note that

$$\sum_{i,j} \theta_{i,j} \cos(\phi_{i,j}) = 0,$$

for all $i$ or $j$ fixed such that $J_i \in \text{int}(M)$, or $J_j \in \text{int}(M)$, respectively. Indeed, $\cos(\phi_{i,j})$ is the projection of $\hat{\alpha}_{i,j}(0)$ (recall that $|\hat{\alpha}_{i,j}(0)| = 1$) on the straight line that passes through $O$ and $J_i$. So, the condition (1) concludes.
Let \( r_i \) be the distance from the origin \( O \) to the the junction \( J_i \). The length \(|\alpha_{i,j}|\) of each \( \alpha_{i,j} \) is given by
\[
|\alpha_{i,j}| = (r_i \cos(\phi_{i,j}) + r_j \cos(\phi_{j,i})).
\]

Using this and (4),
\[
\|V\|(M) = \sum_{i,j} \theta_{i,j}|\alpha_{i,j}| = \sum_{i,j} \theta_{i,j} r_i \cos(\phi_{i,j}) = \sum_{k,l} \theta_{l,k} r_l \cos(\phi_{l,k})
\]
for \( l \in \mathbb{N} \) such that \( J_l \in \partial M \).

For \( J_l \in \partial M \), let \( \psi_{l,k} \) be the angle between the segment \( \alpha_{l,k} \) and the normal to \( \partial M \) at \( J_l \) (see Fig. 1). Thus,
\[
|F_l| = \sum_k \theta_{l,k} \cos(\psi_{l,k}).
\]

If \( M = B^2 \), then \( r_l = 1 \) and \( \phi_{l,k} = \psi_{l,k} \) for all \( l, k \) such that \( J_l \in \partial M \). So,
\[
\|V\|(B^2) = \sum_l |F_l|.
\]

For \( M \) close to \( B^2 \), we have \( r_l \approx 1 \) and \( \phi_{l,k} \approx \psi_{l,k} \) for all \( l, k \) such that \( J_l \in \partial M \). Then,
\[
\|V\|(M) = (1 \pm \varepsilon_1) \sum_l |F_l|
\]
for some \( \varepsilon_1 > 0 \), which depends only on the approximation \( M \approx B^2 \). Note that, as \( \|V\|(M) < C \), we see by the above expression that \( \sum_l |F_l| < C_1 = C_1(C) \) for some constant \( C_1 > 0 \). Therefore, for \( \varepsilon_1 < \varepsilon/C_1 \), we obtain
\[
\left|\|V\|(M) - \sum_l |F_l|\right| \leq \varepsilon_1 \sum_l |F_l| < \varepsilon_1 C_1 < \varepsilon.
\]

From the above theorem we have the following upper bound for the density.

**Theorem 3.4.** Let \( V \in IV_1(B^2) \) be a free boundary geodesic network. Suppose that \( \|V\|(B^2) < m + 1 \) for some integer positive \( m \), then

(i) \( \Theta^1(V, x) \leq \frac{m}{2} \) for all \( x \in \text{int}(B^2) \).

(ii) \( \Theta^1(V, x) \leq \frac{m}{4} \) for all \( x \in \partial B^2 \).

Furthermore, let \( V \in IV_1(M^2) \) be a free boundary geodesic network and \( 0 < \varepsilon < m + 1 \) such that \( \|V\|(M^2) < m + 1 - \varepsilon \), where \( M^2 \) is a compact region of \( \mathbb{R}^2 \) with convex boundary, sufficiently close to \( B^2 \) and satisfying (5) for \( C = m + 1 - \varepsilon \). Then, the conclusions (i) and (ii) above are still true for \( M^2 \) in place of \( B^2 \).
Proof. We can extend the geodesic network \( V \in \mathcal{V}_1(M^2) \) for a varifold \( \tilde{V} \in \mathcal{V}_1(\mathbb{R}^2) \) (not necessary a geodesic network) in the following way: for each \( J_i \in \Sigma_V \cap \partial M \) we take the semi-straight line \( r_i \) starting in \( J_i \) with direction \( -F_i = -\sum_{k=1}^m \theta_{i_k} \hat{\alpha}_{i_k}(0) \) and multiplicity \( |F_i| \). Then \( \tilde{V} \) is a stationary varifold on \( \mathbb{R}^2 \).

Fix \( x \in \text{spt}[V] \) and let \( d_i = \text{dist}(J_i, x) \), \( \phi_i \) be the angle between \( \overline{xJ_i} \) and \( r_i \) at \( J_i \), and \( d_0 \) be the minimal value of \( s \) such that \( B_s(x) \) contains \( M \) (see Fig. 2).

![Figure 2: When the domain \( M^2 \subset \mathbb{R}^2 \) is convex, it is easy to extend a free boundary geodesic network to a stationary varifold in \( \mathbb{R}^2 \). See notations in the proof of Theorem 3.4](image-url)

As \( M \) has convex boundary, we have that each \( r_i \) does not intersect \( M \) in \( \mathbb{R}^2 \setminus M \). So, for \( s \geq d_0 \), the monotonicity formula at \( x \) is given by

\[
\Theta^1_x(s) = \frac{\|V\|(B_s(x))}{2s} = \frac{\|V\|(M) + \sum_i |F_i| \left( d_i \cos(\phi_i) + \sqrt{d_i^2 \cos^2(\phi_i) - (d_i^2 - s^2)} \right)}{2s}.
\]

First, consider the case \( M^2 \) close to \( B^2 \) and \( \|V\|(M) < m + 1 - \varepsilon \). By the expression above \( \Theta^1_x(s) \to \frac{1}{2} \sum_i |F_i| \) for \( s \to \infty \). And by the above theorem we know that \( \sum_i |F_i| \) is close to \( \|V\|(M) \), so for \( s \) large

\[
\Theta^1(\tilde{V}, x) \leq \Theta^1_x(s) < \frac{m + 1 - \varepsilon}{2} < \frac{m}{2} + \frac{1}{2}.
\]

Where we used the fact that the function \( \Theta^1_x(s) \) is non-decreasing for each \( x \) fixed, so \( \Theta^1_x(x, \tilde{V}) \leq \Theta^1_x(s) \) for all \( s > 0 \).

(i) If \( x \in \text{spt}[V] \cap \text{int}(M) \), then \( \Theta^1(x, V) = \Theta^1(x, \tilde{V}) < m/2 + 1/2 \). By the property (ii) of Proposition 3.2, we actually have that \( \Theta^1(x, V) \leq m/2 \).

(ii) If \( x \in \text{spt}[V] \cap \partial M \), then \( \Theta^1(x, V) = \Theta^1(x, \tilde{V})/2 < m/4 + 1/4 \). Again, by the property (ii) of Proposition 3.2, we actually have that \( \Theta^1(x, V) \leq m/4 \).

For the case \( M^2 = B^2 \), just take \( \varepsilon = 0 \) in the above expressions. 

\[\square\]
3.3 Free Boundary Geodesic Networks with Low Mass

In the following, we describe the free boundary geodesic networks with low mass and \( \mathbb{Z}_2 \)-almost minimizing in annuli on the unit ball \( B^2 \), and on full ellipses \( E^2 \) sufficiently close to \( B^2 \). We need the following theorem:

**Theorem 3.5.** ([1], Th. 4.13) Given \( V \in IV_1(M) \) a geodesic network with free boundary and \( p \in \Sigma_V \cap \text{int}(M) \). If \( V \) is \( \mathbb{Z}_2 \)-almost minimizing in annuli with free boundary at \( p \), then

\[
\Theta^1(V, p) \in \mathbb{N}.
\]

For \( k \geq 3 \), let \( P_k \) be a regular \( k \)-sided polygon inscribed in the unit circle. We consider \( P_2 \) as a diameter of the unit ball \( B^2 \). Note that \( P_k \) and \( r \cdot P_k \) are distinguished by a rotation. More generally, we use the term closed \( k \)-polygon, \( k \geq 3 \), to denote a periodic billiard trajectory inside of a domain \( \Omega \) with boundary \( \partial \Omega \), which is a closed trajectory obtained by \( k \) reflexions on \( \partial \Omega \).

**Theorem 3.6.** Let \( V \in IV(B^2) \) be a free boundary geodesic network and \( \mathbb{Z}_2 \)-almost minimizing in annuli with free boundary in \( B^2 \). If \( 0 < |V| \langle B^2 \rangle < 6 \), then \( V = P_k \) for some \( k = 2, \ldots, 5 \), or \( V = P_2 + \tilde{P}_2 \).

**Proof.** From Theorem 3.4 we know that \( \Theta^1(V, x) \leq 5/2 \) for \( x \in \text{int}(B^2) \), and \( \Theta^1(V, x) \leq 5/4 \) for \( x \in \partial B^2 \). Now using Proposition 3.2 (ii) and Theorem 3.5, we deduce that \( \Theta^1(V, x) = 1 \) or 2 for \( x \in \text{int}(B^2) \), and \( \Theta^1(V, x) = 0.5 \), or 1 for \( x \in \partial B^2 \). Therefore, Proposition 3.2 (iv) says that all junctions of \( V \) in \( \text{int}(B^2) \) are regular and the geodesic segments of each junction have multiplicity one. Also, Proposition 3.2 (iv) and (v) say that each segment of \( V \) has multiplicity one or two and touches \( \partial B^2 \) orthogonally, or has multiplicity one and touches \( \partial B^2 \) making a reflexion generating another segment with multiplicity one also. As \( |V| \langle B^2 \rangle < 6 \), we note that: if \( V \) touches \( \partial B^2 \) orthogonally in some point, we have that \( V \) is a diameter \( (V = P_2) \) or two diameters \( (V = P_2 + \tilde{P}_2) \) of \( B^2 \) (see Fig. 3 (a)); and if \( V \) does a reflexion in a point of \( \partial B^2 \), then \( V \) is a regular polygon \( P_k \) for some \( k = 3, 4 \) or 5 (see Fig. 3 (b), (c) and (d)).

![Figure 3](image-url)

Figure 3: Illustrated a possible combination of two diameters and the first three regular polygons inscribed in the unit disk

In fact, for \( k > 6 \) we have \( |P_k| > |P_6| = 6 \). From five reflexions, we can have non-convex closed polygons as in the Fig. 4 (a) and (b). A closed \( k \)-polygon in \( B^2 \) has all the sides with the same length and tangent to some circle \( C_k \) concentric with \( \partial B^2 \) (see Fig. 4 (c)), then the perimeter is at least \( |C_k| \).
Each polygon $P_k$ gives a unique turn around $C_k$, and a non-convex (closed) $k$-polygon in $B^2$ gives at least two turns around $C'_k$. So, if the radius of $C'_k$ is bigger than 0.5, then the perimeter of a non-convex $k$-polygon is bigger than $2 \cdot 2 \cdot 0.5 \pi > 6$. Otherwise, if the radius of $C'_k$ is less or equal to 0.5 (see Fig. 4 (d)), then each side of a non-convex $k$-polygon is bigger than 1.7, and so the perimeter is bigger than $5 \cdot 1.7 > 6$, since for non-convex $k$-polygons we have $k \geq 5$. Therefore, there is not candidates for $V$ in the set of non-convex $k$-polygons.

(a) (b) (c) (d)

Figure 4: As the regular convex polygons inscribed in the unity disk, the non-convex inscribed polygons (as in (a) and (b)) have the sides tangent to some circle $C'_k$ concentric with $B^2$ (see (c) above), where $C'_k$ depends on the number of sides $k$.

A similar result holds replacing $B^2$ by a planar full ellipse $E^2$ sufficiently close to $B^2$. We denote by $P^E_k$, for $k \geq 3$, the closed convex polygon (not necessary regular) inscribed in $E^2$ defined by $k$ reflexions on $k$ different points of $\partial E^2$. Here, $P^E_k$ is the smallest or the largest diameter of $E^2$. Clearly, as $E^2$ is close to $B^2$, we have that $P^E_k$ is close to $P_k$. These polygons $P^E_k$ are examples of closed billiard trajectories in ellipses (Poncelet polygons). We see more properties of these polygons in the proof below.

Corollary 3.7. Let $E^2$ be a planar full ellipse and $0 < R < 6$ be a real number. For $E^2$ sufficiently close to $B^2$, depending only in the parameter $R$, the following is true: if $V \in IV_1(E^2)$ is a free boundary geodesic network such that it is $\mathbb{Z}_2$-almost minimizing in annuli with free boundary in $E^2$ and $0 < \|V\|(E^2) < R$, then $V = P^E_k$ for some $k = 2, \ldots, 5$, or $V = P^E_3 + P^E_2$.

Remark 3.8. In the proof below we note that, for a fixed $k \geq 3$, all the polygons $P^E_k$ have the same perimeter. So, in the hypothesis of the corollary above, there are only six possible values for $\|V\|(E^2) = d, d + D, 2D, |P^E_3|, |P^E_4|$ or $|P^E_5|$.

Proof. Consider $E^2$ a planar full ellipse which boundary is given by an ellipse $x^2/a^2 + y^2/b^2 = 1$ for $a > b$ with focus $F_1, F_2 \in Ox$ (see Fig. 5 (a)). Let $d$ and $D$ the values of the smallest and largest diameters of $E^2$, respectively. So, $d = 2b$ and $D = 2a$. Also, here we are always considering $E^2$ sufficiently close to $B^2$, so $d \approx D \approx 2$, for example.

Take $E^2 \approx B^2$ such that it satisfies (8) from Lemma 3.3 for $C = 6 - R$. So we can use the Theorem 3.4 for $C = 6 - R = 5 + 1 - \varepsilon$ for some $\varepsilon > 0$ and,
as in the proof of the theorem above, applying Proposition 3.2 and Theorem 3.5 we get: all junctions of $V$ in $\text{int}(E^2)$ are regular and the geodesic segments of each junction have multiplicity one; each segment of $V$ has multiplicity one or two and touches $\partial E^2$ orthogonally, or has multiplicity one and touches $\partial E^2$ making a reflexion generating another segment with multiplicity one also. Therefore, $V$ could be the smallest or the largest diameters of $E^2$, since they touch $\partial E^2$ orthogonally (see Fig. 5 (a)). Also, $V$ could be $P_2^E + \tilde{P}_2^E$, and then $\|V\|(E^2) = 2d, d + D$ or $2D$, since $d \approx D \approx 2$ and $\|V\| < R < 6$. We could have $V$ as in the Fig. 5 (b): a segment touching $\partial E^2$ orthogonally at $A_1$, making a reflexion at $(0, b) \in \partial E^2$ with respect to $\partial E^2$, generating another segment which touches orthogonally $\partial E^2$ at $A_2 = (-x(A_1), y(A_1))$. This can happen for $a >> b$. However, for $E^2$ close to $B^2$ we have $a, b \approx 1$, and the cases $V = P_2^E$ or $V = P_2^E + \tilde{P}_2^E$ are the only possibility such that $V$ touches $\partial M$ orthogonally in some point with $\|V\|(E^2) < R$. Indeed, considering $(a \sin(t), b \sin(t))$ the polar coordinates on $\partial E^2$ for $t \in [0, 2\pi)$, and taking without loss of generality (by symmetry) $A \in \partial E^2$ such that $A = (a \sin(t_A), b \sin(t_A))$ for $t_A \in (3/4\pi, 2\pi)$, we claim that if a segment $\overline{AB} \subset E^2$ touches $\partial E^2$ orthogonally at $A$, then $\overline{AB}$ is not orthogonal to $\partial E^2$ at $B \in \partial E^2$, and the segment $\overline{BC}$, reflexion of $\overline{AB}$ at $B$, is also not orthogonal to $\partial E^2$ at $C$ (see Fig. 5 (c)).

In fact, the equation of the straight line which is perpendicular to $\partial E^2$ at $A$ is given by

$$y = \frac{a \tan(t_A)}{b} x + \sin(t_A) \left( b - \frac{a^2}{b} \right).$$

Note that $a^2 \leq 2b^2$, since $E^2 \approx B^2$ and then $a, b \approx 1$. So, for $x = 0$ above we see that $y(I) < b$, where $I$ is the intersection of $\overline{AB}$ with $Oy$ (Fig. 5 (c)).

In an ellipse we have the following fact: if $\overline{AB}$ is orthogonal to $\partial E^2$ at $A$, then $\overline{AB}$ bisects the angle $\angle F_1 AF_2$. In particular, $\overline{AB}$ passes through $F_1 F_2$ and, since $y(I) < b$, we have $t_B \in (\pi/2, \pi)$, where $B = (a \sin(t_B), b \cos(t_B))$. Also, if $\overline{AB}$ was orthogonal to $\partial E^2$ at $B$, the equation of the straight line through $B$ would be similar to above, which would imply that $\tan(t_A) = \tan(t_B)$ and $\sin(t_A) = \sin(t_B)$, contradicting the fact that $t_A \in (3/4\pi, 2\pi)$ and $t_B \in (\pi/2, \pi)$. So, $\overline{AB}$ is not orthogonal to $\partial E^2$ at $B$ and there exists
$BC$, reflexion of $AB$ at $B$. Remember from billiard theory in ellipses that, if
a segment in $E^2$ passes through $F_1F_2$, then all the segments in that billiard
trajectory (segments reflected at $\partial E^2$) pass through $F_1F_2$ (see for example [11
Th. 4]). So $BC$ passes through $F_1F_2$.

Supposing that $BC$ is orthogonal to $\partial E^2$ at $C$, the same argument applied
for $AB$ could be apply to $BC$ to get that $t_C \in (3/4\pi, 2\pi)$ and $t_C \neq t_A$, where
$C = (a\sin(t_C), b\cos(t_C))$. Taking the equations of the straight lines that are
perpendicular to $A$ and $C$, respectively, we would have that they intersect at $B = (a\cos(t_B), b\sin(t_B))$, then

$$
\frac{a^2}{b} \cos(t_B)(\tan(t_A) - \tan(t_C)) + \left(\frac{b^2 - a^2}{b}\right)(\sin(t_A) - \sin(t_C)) = 0.
$$

As $t_A, t_C \in (3/4\pi, 2\pi)$, $t_A \neq t_C$ and $\cos(t_B), (b^2 - a^2) < 0$, the left side of
the last expression above is not equal to zero. Then, $BC$ is not perpendicular
to $\partial E^2$ at $C$ and there is another reflexion $CD$ at $C$ (see Fig. 5(c)).

Consider $E^2 \approx B^2$ such that each segment in $E^2$ through $F_1F_2$ has length
at least $R/3$, since the length of each of these segments tending to 2 as $E^2$ tends
to $B^2$ and $R < 6$. By the above arguments, if $V \neq P_k^E$ and $V \neq P_k^E + \hat{P}_k^E$,
then $V$ has at least three segments, none of them is orthogonal to $\partial E^2$ and
neither passes through $F_1F_2$. So, $V$ is a closed $k$-polygon $P$, and moreover
each segment is tangent to the same ellipse $\partial(E_k)$, where $E_k$ is a planar full ellipse
inside of $P$ and with the same focus of $E^2$ (see [11, Th. 4]). For simplicity, we
just say that $P$ is tangent to $\partial(E_k)$ (see Fig. 4).

The Poncelet theorem (see for instance [21 Th. 4]) says that if a closed
$k$-polygon $P$ is tangent to $\partial(E_k)$, then any other polygon $Q$ that is tangent to
$\partial(E_k)$ is also a closed $k$-polygon with the same perimeter of $P$. Moreover, for
each $k \geq 3$ there exists a unique $E_k$ such that all the convex closed $k$-polygons
$P_k^E$ have its trajectory tangent to $\partial(E_k)$ (see for example [21 Section 4]). In
particular for a fixed $k \geq 3$, all the polygons $P_k^E$ have the same perimeter.

\begin{figure}[h]
\centering
\includegraphics[width=0.7\textwidth]{figure6}
\caption{Examples of the first three convex polygons $P_k^E$ inscribed in an ellipse and its
respectively $\partial E_k$}
\end{figure}

Note that, given $A \in \partial E^2$ there is a unique $P_k^E$ through $A$ for each $k \geq 3$.
Indeed, just take the billiard trajectory starting at $A$ and tangent to $\partial E_k$. Also,
note that $|\partial(E_k)| < |\partial(E_{k+1})|$ since the tangency property of the polygons and
the convexity of the ellipses $\partial(E_k)$ and $\partial(E_{k+1})$ (see Fig. 4(a)).

\footnote{Actually we can proof that $|P_k^E| < |P_{k+1}^E|$ for all $k \geq 3$.}
By the above facts, we require $E^2 \approx B^2$ such that $2D < |P^E_3|, |P^E_4|, |P^E_5| < 6$, $|P^E_k| > R$ for $k = 6, \cdots, 11$, and $|\partial E(12)| > 6$ since $|P_k| > |P_6| = 6 > |P_3|$ for $k > 6$, and $|C_{12}| > 6$. As $|P^E_k| > |\partial(E_k)| > |\partial(E_{k-1})|$, we have that $|P^E_k| > R$ for all $k \geq 6$. So the only candidates for $V$ in the set of closed convex $k$-polygons are $P^E_3, P^E_4$ and $P^E_5$ (Fig. 6).

Finally, with the same argument as in the proof of the theorem above, we see that all closed non-convex polygons in $E^2$ have perimeter bigger than 6, so there is not candidates for $V$ in that set. Indeed, the estimates in the accounts of the theorem above are strict, so for $E^2 \approx B^2$ and replace $C^i_k$ by $E^i_k$ with average radius approximately 0.5, we conclude that the perimeters are bigger than 6. Compare the Fig. 4(d) and 7(c). In the Fig. 7(b) below, we have an example of a closed non-convex 5-polygon.

![Figure 7: In an ellipse $\partial E^2$, a billiard trajectory that does not pass through $F_1 F_2$ is tangent to a concentric ellipse](image)

The following theorem is about replacements of almost minimizing varifolds, which is one of the most important properties of this kind of varifolds.
Roughly speaking, we can replace an almost minimizing varifold $V$ by another almost minimizing varifold $V^*$, which has better regularity properties.

**Theorem 3.11.** Let $U \subset M$ be a relatively open set, $K \subset U$ compact and $V \in \mathcal{V}_k(M)$ be an $\mathbb{Z}_2$-almost minimizing varifold in $U$ with free boundary. There exists $V^* \in \mathcal{V}_k(M)$ such that

1. $V^* \llcorner (M \setminus K) = V \llcorner (M \setminus K)$;
2. $\|V^*\|(M) = \|V\|(M)$;
3. $V^*$ is $\mathbb{Z}_2$-almost minimizing in $U$ with free boundary;
4. $V^* \in IV(U \cap int(M))$;
5. $V^* \llcorner U = \lim_{i \to \infty} |T_i|$ as varifolds for some $\{T_i\} \in \mathcal{Z}_{k,\text{rel}}(M, (M \setminus U) \cup \partial M; \mathbb{Z}_2)$ such that each $T_i^0$ is locally mass minimizing in $int_M(K)$.

**Proof.** The proof follows as in Prop. 5.3 from [12], replacing Lemmas 3.10 and 3.7 by Th. 2.3 and Prop. 2.4 from [13], respectively. See also Th. 3.11 and 3.13 from [22] to get (iv) from (iii).

The varifold $V^*$ in the above theorem is called a replacement of $V$ in $K$.

In the next lemma we prove a weak regularity of $V^* \in \mathcal{V}_1(M)$ for manifolds with strictly convex boundary.

**Lemma 3.12.** (Weak Regularity of Replacements) Under the same hypotheses of Theorem 3.11, assume that $\partial M$ is strictly convex and take $V$ an one-dimensional varifold. Then $\text{spt}(V^*) \cap int_M(K)$ is a free boundary geodesic network (possibly infinite) without junctions in $(K \cap int(M)) \setminus \partial_{\text{rel}}K$, such that each geodesic segment has to touch $\partial_{\text{rel}}K \cup \partial M$, and they can only touch $\partial M \cap int_M(K)$ orthogonally.

**Proof.** From [11 Prop. 4.6] we know that if $T$ is an one-cycle that is locally mass minimizing in an open set $W \subset int(M)$ and $Z \subset W$ is compact, then $T \llcorner Z$ is a geodesic network (finite) such that each geodesic segment has endpoints in $\partial Z$ and those segments do not intersect each other, since the coefficients are in $\mathbb{Z}_2$. So, for a relatively compact $K \subset M$ and $T_i^0$ locally mass minimizing in $int_M(K)$ (as in Theorem 3.11 (v)), we have that $T_i^0 \llcorner int_M(K)$ is given by geodesic segments without intersecting each other, all segments has to touch $\partial_{\text{rel}}K \cup \partial M$, and each segment that touches $\partial M \cap int_M(K)$ is orthogonal to $\partial M$, in particular $T_i^0 \llcorner int_M(K)$ is a free boundary geodesic network (possibly infinite). Indeed, as $T_i^0$ is locally mass minimizing, each segment of $T_i^0$ that touches $\partial M$ is locally the shortest path, so it is orthogonal to $\partial M$.

Since $V^*$ is given by the limit as in the Theorem 3.11 (v), we use the properties from geodesics and the fact that $\partial M$ is strictly convex to see that $V^*$ is given by geodesic segments that can only touch $\partial M \cap int_M(K)$ orthogonally. In fact, the strict convexity implies that any geodesic segment can only touch $\partial M$ only in its endpoints. So, given a limit segment $\alpha$ that touches $\partial M$ at
$p \in \partial M$, we have that there exists a sequence of geodesic segments converging to $\alpha$ such that each segment of that sequence touches $\partial M$ orthogonally in a neighborhood of $p$. Therefore, $\alpha$ is orthogonal to $\partial M$ at $p$. Moreover, as the segments of $T^p_i$ do not intersect each other, we get that in the limit the geodesic segments of $V^*$ can have multiplicity, but $V$ cannot have junctions.

We called the result above as weak regularity, because we do not know if the number of geodesic segments could be infinite. However, the above lemma is true for any codimension.

Let $p \in \mathbb{R}^2$ and let $C \in \mathcal{V}_1(\mathbb{R}^2)$ be a varifold such that $C = \sum_{i=1}^{l} v(r_i, m_i)$ for some $l, m_1, \ldots, m_l \in \mathbb{N}$, and each $r_i$ is some semi-straight line from $p$. We call $C$ of a cone with vertex at $p$.

The next proposition is very important to prove our main result about regularity. Essentially, we use it to glue replacements on overlapping annuli (see Step 2 in the proof of Theorem 3.15).

**Proposition 3.13.** Let $C \in \mathcal{V}_1(\mathbb{R}^2)$ be a stationary cone with vertex at the origin $0 \in \mathbb{R}^2$, and such that it is $\mathbb{Z}_2$-almost minimizing in $B_2(0) \subset \mathbb{R}^2$. Then $C = v(r, m)$, for some $r$ a straight line passing through the origin $0$, and for some $m \in \mathbb{N}$.

**Proof.** We use the following fact: if $C$ is $\mathbb{Z}_2$-almost minimizing in $B_2(0)$, then each varifold tangent is also a stationary integral varifold on $T^p_i \mathbb{R}^2 = \mathbb{R}^2$ such that it is $\mathbb{Z}_2$-almost minimizing in any bounded open subset of $\mathbb{R}^2$ (22, Th. 3.11 and 3.12(1)).

By Theorem 3.4 we have that $\Theta^1(C, 0) = k$ for some $k \in \mathbb{N}$.

We prove the result by induction on $\Theta^1(C, \infty)$. Indeed, the result is obvious for $\Theta^1_0(C, \infty) \leq 1$. Suppose that $\Theta^1_0(C, \infty) = k + 1$, and that the result is true for $\Theta^1_0(C, \infty) \leq k$, $k \geq 1$. Let $C^*$ be a replacement of $C$ on $\overline{B}_1(0)$, we know that $C^*$ is integral, stationary and $\mathbb{Z}_2$-almost minimizing in $B_2(0)$. Also, $\|C^*\|_2(B_2(0)) = \|C\|_2(B_2(0))$, so

$$
\Theta^1_1(\text{VarTan}(C^*, y), \infty) = \Theta^1(C^*, y) \leq \Theta^1_0(C^*, \infty) = \Theta^1_0(C, \infty),
$$

where $y \in \partial B_1(0) \setminus \text{spt}\|C^*\|$.

We have two cases: $\Theta^1(C^*, y) = \Theta^1_0(C^*, \infty)$ for some $y \in \partial B_1(0) \setminus \text{spt}\|C^*\|$, or $\Theta^1(C^*, y) < \Theta^1_0(C^*, \infty)$ for any $y \in \partial B_1(0) \setminus \text{spt}\|C^*\|$. In the first case, $C^*$ is a cone with vertex at $y$. This implies that $C = mr_y$, for some $m \in \mathbb{N}$ and $r_y$ is the straight line that passes through $y$ and the origin, since by the previous lemma $C^*$ does not have junctions on $B_1(0)$ and $C^* \bigcap (B_2(0) \setminus \overline{B}_1(0)) = C^* \bigcap (B_2(0) \setminus \overline{B}_1(0))$.

In the second case, $\Theta^1_1(\text{VarTan}(C^*, y), \infty) \leq k$ for any $y \in \partial B_2(0)$, since $\Theta^1_0(C, \infty) = k + 1$. So, as $\text{VarTan}(C^*, y)$ is $\mathbb{Z}_2$-almost minimizing in $B_2(0)$, we can use the induction hypothesis for each $y$ to get that $\text{VarTan}(C^*, y) = nm_y r_y$ for some $m_y \in \mathbb{N}$ and $r_y$ is the straight line that passes through $y$ and the origin. By the previous lemma and $C^* \bigcap (B_2(0) \setminus \overline{B}_1(0)) = C \bigcap (B_2(0) \setminus \overline{B}_1(0))$,
we conclude that $C^*$ is a cone with vertex at $0 \in \mathbb{R}^2$. As before, we obtain that $C = mr$ for some $m \in \mathbb{N}$, and for some straight line $r$ through the origin.

The next result is a boundary maximum principle for stationary varifolds with free boundary in codimension one case.

**Theorem 3.14.** (Boundary maximum principle [12 Th. 2.5]). Let $U \subset M^{n+1}$ be a relatively open subset and $V \in \mathcal{V}_n(M)$ be stationary with free boundary in $U$. Suppose $N \subset U$ is a relatively open connected subset in $M$ such that

(i) $\partial_{rel} N$ meets $\partial M$ orthogonally, if $\partial_{rel} N \cap \partial M \neq \emptyset$;

(ii) $N$ is relatively strict convex in $M$;

(iii) $\text{spt}\|V\| \subset \overline{N}$.

Then we have $\text{spt}\|V\| \cap \partial_{rel} N = \emptyset$.

Now we prove our main theorem about regularity of stationary $\mathbb{Z}_2$-almost minimizing varifolds with free boundary.

**Theorem 3.15.** Let $M^2$ be a compact Riemannian manifold with non-empty strictly convex boundary. If $V \in \mathcal{V}_1(M)$ is a stationary varifold with free boundary such that it is integral in $M$ and $\mathbb{Z}_2$-almost minimizing in small anulli with free boundary, then $V$ is a free boundary geodesic network.

**Proof.** Here we follow similarly to the proof of [12, Th. 5.2] and [3, Prop. 6.3], with the necessary modifications.

Given $p \in \text{spt}\|V\| \cap \text{int}(M)$, we know by the Theorem 3.9 that in a small compact neighborhood around $p$ we have that $V$ is a geodesic network. So, assume that $p \in \text{spt}\|V\| \cap \partial M$ and fix $r > 0$ such that

$$r < \frac{1}{4} \min\{r_{\text{Fermi}}, r_{\text{am}}(p), r_{\text{ort}}(p)\},$$

where $r_{\text{am}}(p) > 0$ is such that $V$ is $\mathbb{Z}_2$-almost minimizing in $A_{s,t}(p)$ with free boundary for all $0 < s < t < r_{\text{am}}$, and $r_{\text{ort}}(p) > 0$ is such that two distinct geodesics that are orthogonal to $\partial M \cap \tilde{B}_\delta^+(p)$ do not intersect each other in $\tilde{B}_\delta^+(p)$ for all $0 < \delta < r_{\text{ort}}(p)$.

Note that, as a consequence of the maximum principle (Theorem 3.14), we have the following: if $W \in \mathcal{V}_1(M)$ is stationary in $\tilde{B}_t^+(p)$ with free boundary for $p \in \text{spt}\|W\|$ and $r$ as above, then

$$\text{spt}\|W\| \cap \tilde{S}_t^+(p) \neq \emptyset$$

for all $0 < t \leq r$.

In fact, suppose that there exists $\tilde{t}_1 \in (0, r]$ such that $\text{spt}\|W\| \cap \tilde{S}_{\tilde{t}_1}^+(p) = \emptyset$, then \text{spt}\$W \cup \tilde{B}_{\tilde{t}_1}^+(p) \cap \tilde{B}_{\tilde{t}_2}^+(p)$ for some $0 < \tilde{t}_2 < \tilde{t}_1$. By the maximum principle we conclude that $\text{spt}\|W \cup \tilde{B}_{\tilde{t}_2}^+(p) \cap \tilde{S}_{\tilde{t}_2}^+(p) = \emptyset$ and we could repeat this argument indefinitely, which contradicts the fact that $p \in \text{spt}\|W\|$. Using the
same argument and suppose only that \( W \neq 0 \) in \( \tilde{B}_r^+(p) \) for some \( p \in \partial M \), we conclude that there exists \( 0 < \tilde{t} < r \) such that

\[
\text{spt}\|W\| \cap \tilde{S}_t^+(p) \neq \emptyset \quad \text{for all} \quad 0 < \tilde{t} < t \leq r.
\]  

(7)

**Step 1:** Constructing successive replacements on two overlapping annuli.

Fix any \( 0 < s < t < r \). As \( r < (1/4)r_{am} \) and \( V \) is \( \mathbb{Z}_2 \)-almost minimizing in \( A_{\tilde{s}, r_{am}/2}(p) \) with free boundary for all \( 0 < \tilde{s} < t < r_{am}/2 \), we can use the Theorem 3.11 to get a first replacement \( V^* \) of \( V \) on \( K = A_{s,t}(p) \). The Lemma 3.12 says that

\[
\Sigma_1 := \text{spt}\|V^*\| \cap A_{s,t}(p)
\]

is a free boundary geodesic network (possibly infinite). By Theorem 3.11 (iv) we have that \( V^* \) is still \( \mathbb{Z}_2 \)-almost minimizing in \( A_{\tilde{s},r_{am}/2}(p) \) with free boundary for all \( 0 < \tilde{s} < t < r_{am}/2 \), so we can apply again the Theorem 3.11 to get a second replacement \( V^{**} \) of \( V^* \) on \( K = A_{s_1, s_2}(p) \) for \( 0 < s_1 < s < s_2 < t \). Again,

\[
\Sigma_2 := \text{spt}\|V^{**}\| \cap A_{s_1, s_2}(p)
\]

is a free boundary geodesic network (possibly infinite). Let us consider the following choices: we fix any \( s_1 \in (0, s) \), and we choose \( s_2 \in (s, t) \) such that \( \text{VarTan}(\Sigma_1, x) \) is a straight line transversal to \( \tilde{S}_s^+(p) \) for all \( x \in (\tilde{S}_s^+(p) \setminus \partial M) \), and \( (\alpha \cap \tilde{S}_s^+(p)) \setminus \partial M \neq \emptyset \) for every geodesic segment \( \alpha \in \Sigma_1 \). Indeed, fixing \( s_2 \in (s, t) \), we know by the regularity of replacements (Lemma 3.12) that \( \text{VarTan}(\Sigma_1, x) \) is a straight line for any \( x \in A_{s,t}(p) \). Also, we have only a finite number of geodesic segments \( \{\alpha_i\} \subset \Sigma_1 \) in \( A_{s,t}(p) \) for any \( 0 < s < \tilde{t} < t \). To see the last one, note that any geodesic segment (with possible multiplicity) \( \alpha_i \in \Sigma_1 \cap A_{s,t}(p) \) has to touch \( \tilde{S}_s^+(p) \). Indeed, by the Lemma 3.12 each \( \alpha_i \) has to touch \( \tilde{S}_s^+(p) \cup \tilde{S}_t^+(p) \cup (\partial M \cap A_{s,t}(p)) \) and it can only touch \( \partial M \cap A_{s,t}(p) \) orthogonally. Using that any two orthogonal geodesic segments to \( \partial M \) do not intersect each other in \( \tilde{B}_r^+(p) \), together with the fact that \( \tilde{S}_s^+(p) \) is strictly convex and orthogonal to \( \partial M \), we conclude that if \( \alpha_i \in \Sigma_1 \) touches \( \partial M \cap A_{s,t}(p) \), then \( \alpha_i \cap \tilde{S}_s^+(p) \neq \emptyset \) only if \( \alpha_i \) touches \( \tilde{S}_s^+(p) \cap \partial M \) (see Fig. 3). Also, if \( \alpha_i \) does not touch \( \tilde{S}_s^+(p) \), then its endpoints can not be on \( \partial M \cap A_{s,t}(p) \), because \( \alpha_i \) would be a stationary varifold with free boundary, contradicting (7). Then, any \( \alpha_i \) that touches \( \tilde{S}_s^+(p) \) or \( \partial M \cap A_{s,t}(p) \), should touch \( \tilde{S}_t^+(p) \). Therefore, if there is an infinite number of geodesic segments \( \{\alpha_i\} \subset \Sigma_1 \) in \( A_{s,t}(p) \), then there are an infinite number of geodesic segments from \( \tilde{S}_t^+(p) \) to \( \tilde{S}_t^+(p) \), contradicting the fact that \( \Sigma_1 \) has finite mass. Thus the set \( \{\alpha_i\} \) is finite. Finally, using again the strict convexity of \( \tilde{S}_s^+(p) \), each geodesic segment that is tangent to \( \tilde{S}_s^+(p) \) can not touch \( \tilde{S}_{\tilde{s}_2}^+(p) \) for all \( 0 < \tilde{s}_2 < s_2 \). So, by the finitude of the geodesic segments and by (8), we can choose \( s_2 \in (0, t) \) as requested (see Fig. 8).

Note that each \( \alpha_i \subset \Sigma_1 \) has to touch \( \tilde{S}_t^+(p) \) at points in \( \text{int}(M) \), since \( \tilde{S}_t^+(p) \) is orthogonal to \( \partial M \).
Figure 8: We can choose $s_2 \in (0, t)$ such that $\Sigma_1$ is transversal to $\tilde{S}^+_{s_2}(p)$ and it only touches $\tilde{S}^+_{s_2}(p)$ on $\text{int}(M)$.

**Step 2: Gluing $\Sigma_1$ and $\Sigma_2$ across $\tilde{S}^+_{s_2}(p)$.**

As before, any geodesic segment (with possible multiplicity) $\beta_i \in \Sigma_2 \cap A_{s,s_2}(p)$ has to touch $\tilde{S}^+_{s_2}(p)$ in points belonging to $\text{int}(M)$. Since $V^{**}$ is stationary and integral in $A_{s_1,t}(p)$, we have by the interior regularity (Theorem 3.9) that each $x \in \text{spt}|V^{**}| \cap \text{int}(M) \cap A_{s,t}(p)$ belongs to a finite number of geodesic segments (including multiplicity). In particular, if $x \in \text{spt}|V^{**}| \cap \text{int}(M) \cap \tilde{S}^+_{s_2}(p)$ then $x$ belongs to $\Sigma_1 \cap \Sigma_2$, since each geodesic segment of $\Sigma_1$ touches $\tilde{S}^+_{s_2}(p)$ transversally. So, $\Sigma_1$ and $\Sigma_2$ glue continuously across $\tilde{S}^+_{s_2}(p)$. Note that $\text{spt}|V^{**}| \cap \tilde{S}^+_{s_2}(p) = \Sigma_1 \cap \tilde{S}^+_{s_2}(p) = \Sigma_2 \cap \tilde{S}^+_{s_2}(p) \subset \text{int}(M)$. Moreover, as VarTan($V^{**}, x$) is a cone satisfying Proposition 3.13 we see that the gluing is actually $C^1$, since VarTan($V^{**}, x$) is a straight line (with possible multiplicity).

**Step 3: Unique continuation up to the point $p$.**

By Step 2 and property (i) of Theorem 3.11 we can extend $\Sigma_2$ to $\tilde{\Sigma}_2$ in $A_{s_1,t}(p)$ such that $\tilde{\Sigma}_2 = \Sigma_1$ on $A_{s,t}(p)$, $\tilde{\Sigma}_2$ is given by geodesic segments possibly with multiplicity and without interior junctions that can only touch $A_{s_1,t}(p) \cap \partial M$ orthogonally, $\tilde{\Sigma}_2 \pitchfork A_{s,s_2}(p)$ has a finite number of geodesic segments, and each geodesic segment of $\tilde{\Sigma}_2$ has to touch $\tilde{S}^+_{t}(p)$. Using (6), we can continue to take replacements in this way for all $0 < s_1 < s$. For each $0 < s_1 < s$ as before, denote $\tilde{\Sigma}_2$ by $\Sigma_{s_1}$. If $0 < s'_1 < s_1 < 0$, then we have that $\Sigma_{s'_1} = \Sigma_{s_1}$ on $A_{s_1,t}(p)$. Thus

$$\Sigma := \bigcup_{0 < s_1 < s} \Sigma_{s_1}$$

in $\tilde{\Sigma}^+_t(p)$ is given by geodesic segments possibly with multiplicity and without interior junctions that can touch $\partial M \cap (\tilde{\Sigma}^+_t(p) \setminus \{p\})$ orthogonally only, and each geodesic segment of $\Sigma$ has to touch $\tilde{S}^+_{s_2}(p)$. Moreover, $\Sigma \pitchfork \tilde{\Sigma}^+_t(p)$ has a
finite number of segments for all $0 < \tilde{t} < t$ (see Fig. 9).

![Figure 9: $\Sigma$ as defined above is a geodesic network finite in $B^+_t(p)$ for $0 < \tilde{t} < t$](image)

Claim: $\text{spt}\|V\| = \Sigma$ in the punctured ball $B^+_s(p)\setminus\{p\}$.

Proof of Claim: Consider the set

$$T^V_p = \{ y \in \text{spt}\|V\| : \text{VarTan}(V, y) \text{ is a straight line or a semi-straight line transversal to } \hat{S}^+_p(p) \}.$$  

We know by [3, Lemma B.2] (see also [12], Claim 3, p. 42) that the set $T^V_p$ is a dense subset of $\text{spt}\|V\| \cap \hat{B}^+_p(p)$.

Given $y \in T^V_p \cap (\hat{B}^+_s(p) \setminus \{p\})$, let $\rho = \hat{r}_p(y)$. Take $V^*$ the replacement of $V$ in $A_{s,t}(p)$ and $V^{**}$ the replacement of $V^*$ in $A_{s_2}(p)$ for $s_2 \in (s,t)$ chosen as in Step 1. By the property (i) from Th. 3.11, we have $V^{**} = V^* = V$ in $\hat{B}^+_p(p)$, then

$$y \in \text{spt}\|V\| \cap \hat{B}^+_p(p) \cap \hat{S}^+_p(p) = \text{spt}\|V^{**}\| \cap \hat{B}^+_p(p) \cap \hat{S}^+_p(p).$$

Since $\text{spt}\|V^{**}\| = \Sigma$ in $A_{s,t}(p)$ and $\text{VarTan}(V^{**}, y)$ is transversal to $\hat{S}^+_p(p)$, we have by (6) and above that $y \in \Sigma$. Thus, $T^V_p \cap (\hat{B}^+_s(p) \setminus \{p\}) \subset \Sigma$, and hence $\text{spt}\|V\| \cap (\hat{B}^+_s(p) \setminus \{p\}) \subset \Sigma$. The last one is deduced using that $T^V_p$ is a dense subset of $\text{spt}\|V\| \cap \hat{B}^+_p(p)$, and the fact that $\Sigma$ is compact in $\hat{B}^+_p(p)$.

To see the converse inclusion $\Sigma \subset \text{spt}\|V\| \text{ in } B^+_s(p)$, note that by the Constancy Theorem [20] Th. 41.1, we have $\text{spt}\|V\| \cap (\hat{B}^+_s(p) \setminus \{p\}) = \Sigma$ in $M \setminus \partial M$. For $y \in \Sigma \setminus \partial M \cap (\hat{B}^+_s(p) \setminus \{p\})$, we know that $\text{VarTan}(\Sigma, y)$ is a straight line perpendicular to $T_p(\partial M)$, which implies that $y$ is a limit point of $\Sigma \cap \text{int}(M)$ and thus $y \in \text{spt}\|V\|$. Therefore, $\text{spt}\|V\| \cap (\hat{B}^+_s(p) \setminus \{p\}) = \Sigma$.

Step 4: $V$ is a free boundary geodesic network

From the interior regularity (Theorem 3.9) and the Step 3, $V$ is a geodesic network (finite) in $\hat{B}^+_s(p)$ and a free boundary geodesic network (finite) in $(\hat{B}^+_s(p) \setminus \{p\})$. In particular, $\Theta^1(V \cdot \partial M, p) = 0$. So, if there exist geodesic segments at $p$, as in the Fig. 9 then those segments must satisfy (2), and then $V$ is a free boundary geodesic network (finite) in $\hat{B}^+_s(p)$. 

Varying \( p \in \partial M \), we see that \( V \) is a free boundary geodesic network (not necessarily finite) on \( M \). Given any compact \( K \subset \text{int}(M) \), the interior regularity says that \( V, K \) has a finite number of geodesic segments. So, we only need to show that there exists a compact \( K \subset \text{int}(M) \) such that \( V \cup (M \setminus K) \) has also a finite number of geodesic segments. Indeed, take a cover of \( \partial M \) by open balls \( B^+(p_j) \) as in the previous steps, extract a finite cover \( \{B^+(p_j)\}'_{j=1}^l \), and define \( K := M \setminus ( \bigcup_{j=1}^l B^+(p_j) ) \). This finishes the proof.

4 The Width of a Full Ellipse

In this section we prove our main theorem about \( p \)-widths: we calculate the first \( p \)-widths of \( B^2 \) and \( E^2 \), where \( E^2 \) is a planar full ellipse \( C\mathbb{R}^2 \)-close to \( B^2 \). As in [1], we take the \( p \)-sweepouts from Guth [8, Section 6]. We consider some adaptations to get a convenient upper bound for the mass of the cycles. Also, we need to take a better estimate than that given by the Cauchy-Crofton Formula. Indeed, to calculate the widths of the unit sphere in [1], the Cauchy-Crofton Formula gives a sharp estimate, which does not happen in our case. Fortunately, by our regularity results, we do not need a sharp estimate a priori.

4.1 A Sweepout for \( B^2 \)

The sweepout that we use to calculate the \( p \)-widths is obtained by a map whose image is given by real algebraic varieties. The properties of this map can be found in Guth [8, Section 6].

Let \( Q_i : \mathbb{R}^2 \to \mathbb{R} \) denote the following polynomials for \( i = 1, \ldots, 4 : \)

\[
Q_1(x, y) = x, \quad Q_2(x, y) = y, \quad Q_3(x, y) = x^2 \quad \text{and} \quad Q_4(x, y) = xy.
\]

Also, put \( A_p = \text{span}(1 \cup_{i=1}^4 Q_i) \setminus \{0\} \) and define the relation \( Q \sim \lambda Q \), for \( \lambda \neq 0 \) and \( Q \in A_p \). The quotient \( (A_p, \sim) \) can be identified with \( \mathbb{R}^{p} \) and by this identification we can define the map \( F_P : \mathbb{R}^{p} \to Z_{1, \text{rel}}(B^2, \partial B^2; \mathbb{Z}_2) \), which send a class \([Q]\) to the real algebraic variety defined by \( Q(x, y) = 0 \) restricted to \( B^2 \), considered as a mod 2 relative Lipschitz cycle. As proved in [8, Section 6], \( F_p \) is a flat continuous map and it defines a \( p \)-sweepout.

In the next lemma we use the Cauchy-Crofton formula to prove that \( F_p \) has no concentration of mass, thus \( F_p \in P_p(B^2) \).

**Lemma 4.1.** The map \( F_p : \mathbb{R}^{p} \to Z_{1, \text{rel}}(B^2, \partial B^2; \mathbb{Z}_2) \) has no concentration of mass for \( p = 1, \ldots, 4 \).

**Proof.** Without loss of generality, consider \( P_0 = (p_0, 0) \in B^2 \) for \( p_0 \geq 0 \), and the ball \( B_s(P_0) \) for \( s > 0 \) sufficiently small.

Fixing \([Q] \in \mathbb{R}^{p}\) and recall that every straight line \( r \) in the plane can be parameterized by the equation \( x \cos(\theta) + y \sin(\theta) = \rho \), where \( \rho \) is the distance from \( r \) to the origin and \( \theta \in [0, 2\pi) \) is the angle between the axis Ox and the straight line that is perpendicular to \( r \) and passes through the origin. Denote
a such straight line by \( r_{\rho, \theta} \) and let \( n(\rho, \theta) \) be the number of intersection points (with multiplicity) of the straight line \( r_{\rho, \theta} \) with \( F_p([Q]) \) in \( B_s(P_0) \).

If \( p_0 > 0 \), note that for \( \theta \in [0, \pi/2] \) the straight line \( r_{\rho, \theta} \) intersects \( B_s(P_0) \) if and only if \( \rho \in [p_0 \cos(\theta) - s, p_0 \cos(\theta) + s] \) (see Fig. 10 (a)). On the other hand, if \( \theta \in (\pi/2 + \sin^{-1}(s/p_0), \pi] \), then \( r_{\rho, \theta} \) does not intersect \( B_s(P_0) \cap B^2 \) for all \( \rho \) (see Fig. 10 (b)).

For \( p = 1, \ldots, 4 \), we have that \( F_p([Q]) \) is an algebraic variety of degree at most 2, so \( F_p([Q]) \) intersects \( r_{\rho, \theta} \) at most two times. By the Cauchy-Crofton Formula we obtain

\[
\|F_p([Q])\|(B_s(P_0) \setminus \partial B^2) \leq \|F_p([Q])\|(B_s(P_0)) \leq \frac{1}{2} \int_0^{2\pi} \int_{\mathbb{R}^+} n(\rho, \theta) d\rho d\theta 
\leq \frac{2}{2} \int_0^{\pi/2 + \sin^{-1}(s/p_0)} \int_{p_0 \cos(\theta) - s}^{p_0 \cos(\theta) + s} 2d\rho d\theta 
= 4s \left( \frac{\pi}{2} + \sin^{-1}\left( \frac{s}{p_0} \right) \right).
\]

Similarly we have \( \|F_p([Q])\|(B_s(P_0) \setminus \partial B^2) \leq 4s\pi \), when \( p_0 = 0 \). Then, in all the cases we conclude that \( \|F_p([Q])\|(B_s(P_0) \setminus \partial B^2) \to 0 \) as \( s \to 0 \).

In the following, we estimate an upper bound for \( \|F_p([Q])\|, \ p = 1, \ldots, 4 \). In other words, we estimate the maximum length of the algebraic variety \( F_p([Q]) \). By the definitions above, \( F_p([Q]) \) is degenerate or is the restriction to \( B^2 \) of a straight line, or of two straight lines, or of a parabola, or of a hyperbola. In other words, \( F_p([Q]) \) is a quadratic curve which is not an ellipse, since we excluded the monomial \( Q_5(x, y) = y^2 \).

Lemma 4.2. For any \([Q] \in \mathbb{RP}^p\) we have that \( \|F_p([Q])\| \leq 2, \ p = 1, 2, \) and \( \|F_p([Q])\| < 4.52, \ p = 3, 4. \)
Proof. Clearly, for $p = 1, 2$ the algebraic variety $F_p([Q])$ is degenerate or the restriction to $B^2$ of a straight line, thus $\|F_p([Q])\| \leq 2$ for $p = 1, 2$ and for all $[Q] \in \mathbb{RP}^k$.

For $p = 1, \ldots, 4$ note that if $F_p([Q])$ is degenerate or the intersection to $B^2$ of a straight line, or two straight lines, then $\|F_p([Q])\| \leq 4$. Also, this estimate holds when $F_p([Q])$ is the restriction to $B^2$ of a hyperbola $H$ such that each branch of the hyperbola intersects $B^2$. Indeed, if we take $B_r(0)$ for $r$ large, each arm of the branches tends to their respective asymptotes, so the length of the two asymptotes restricted to $B_r(0)$ is bigger than the length $L(H)$ of this hyperbola restricted to $B_r(0)$, then $L(H) \leq 4r$ in $B_r(0)$ (see Fig. 11 (a)). Decreasing $r$, we note that the reduction of length is at least the reduction of $4r$, since there exist four points in $H \cap \partial B^2$ during the reduction $r \to 1^+$. We conclude that $L(H) \leq 4$ in $B^2$.

![Figure 11](image-url)

Figure 11: By the Cauchy-Crofton Formula, holds $L(F_p([Q])) \leq 2\pi$ for $p = 1, \ldots, 4$. Basically, using symmetry and convexity of the curves $F_p([Q])$, we can improve this upper bound.

In the other cases (hyperbolas with a unique branch intersecting $B^2$, or parabolas intersecting $B^2$), we choose an orientation such that the axis of symmetry of the curve is orthogonal to $x$-axis. Hence, $F_p([Q])$ is a convex downward curve intersected with $B^2$ and we have two cases: there exist two points $A, C$ in the intersection of the curve with $\partial B^2$ such that $y(A), y(C) > 0$; or there exists at most one such point. In the first case, as in the examples of the Fig. 11 (b), take $B = (x(A), -y(A)), D = (x(C), -y(C)) \in \partial B^2$ (AB and CD are perpendicular to x-axis), and the circular arc BD. The length of this convex curve in $B^2$ is at most the length of $AB + BD + CD$. Let $\alpha$ (resp. $\beta$) be the angle between $OA$ (resp. OC) and $x$-axis for $\alpha, \beta \in (0, \pi/2]$, then

$$L(F_p([Q])) \leq AB + CD + BD = 2\sin(\alpha) + 2\sin(\beta) + \pi - (\alpha + \beta) \leq 4.52.$$ 

In the second case, as in the example of the Fig. 11 (c), where does not exist $A$ or $C$ as in the first case, we take $\alpha = 0$ or $\beta = 0$ in the above estimate, respectively. Without loss of generality suppose $\beta = 0$, then

$$L(F_p([Q])) \leq 2\sin(\alpha) + \pi - (\alpha) < 3.83 \text{ for } \alpha \in [0, \pi/2].$$
Remark 4.3. Let $L_0$ the maximum length of a parabola inside of a unity disk. In [23] was proved that $L_0 \approx 4.00267$. Actually, we can proof that $\|F_p([Q])\| \leq L_0$ for $p = 1, \ldots, 4$ and this estimate is sharp.

4.2 The First Widths of $B^2$ and $E^2$

Now, we prove our main result about $p$-widths: we calculate the low $p$-widths of the unit ball $B^2$, and of full ellipses $C^\infty$-close to $B^2$.

The next theorem is similar to Prop. A.1 from [1] and a weaker version of the results of Marques and Neves [17].

Theorem 4.4. Let $M^2$ be a Riemannian manifold with non-empty strictly convex boundary. If $\omega_p(M) = \omega_{p+1}(M)$ for some $p$, then there exist infinitely many free boundary geodesic networks whose masses tend to $\omega_p(M)$.

Proof. Similarly to [1], the proof follows from [17] Th. 6.1 for the case without boundary. For our case, take the following modifications: note that the results of [17] Section 3.3 can be extended to the case with boundary from the results of [13] Section 2; the conclusion of [17] Prop. 4.8 holds for free boundary geodesic networks in consequence of Theorems 2.13 and 3.15; take Theorem 2.12 in place of [17, Prop. 2.4]; for the sets $S$ and $T$ we take the supports on free boundary geodesic networks.

As $\text{spt}\{V\}$ is a geodesic network with free boundary, we can use the Constancy Theorem in [17] Claim 6.2 as in [1] Prop. A.1. Finally, [17, Th. 2.8] follows from Theorem 2.13 as in the proof of Th. 4.21 from [12], and the conclusion about the masses follow from the fact that the infinitely many free boundary geodesic networks are taken from the proof of [17, Prop. 4.8].

Finally, we compute the first widths of $B^2$ and $E^2$.

Theorem 4.5. For $B^2$ we have

(i) $\omega_1(B^2) = \omega_2(B^2) = 2$;

(ii) $\omega_3(B^2) = \omega_4(B^2) = 4$.

Also, if $E^2$ is a full ellipse $C^\infty$-close to $B^2$ with small diameter $d$ and large diameter $D$, then

(iii) $\omega_1(E^2) = d$ and $\omega_2(E^2) = D$;

(iv) $\omega_3(E^2), \omega_4(E^2) \in \{2d, d + D, 2D\}$ such that $\omega_3(E^2) \neq \omega_4(E^2)$.

Proof. (i) Let $p = 1, 2$ and take the $p$-sweepout $F_p \in \mathcal{P}_p(B^2)$. By Lemma 1.2 we know that $\|F_p([Q])\| \leq 2$ for all $[Q] \in \mathbb{RP}^p$, thus $\omega_1(B^2), \omega_2(B^2) \leq 2$. Now, given $\epsilon > 0$ we can find by the Corollary 2.14 a special varifold $V$ such that $0 < \omega_p(B^2) \leq \|V\|(B^2) \leq \omega_p(B^2) + \epsilon \leq 2 + \epsilon$. By Theorems 3.17 and 3.6, we actually have that $V$ is a diameter of $B^2$ and $\|V\|(B^2) = 2$. Therefore, $\omega_1(B^2) = \omega_2(B^2) = 2$. 
(iii) Still consider \( p = 1, 2 \). As \( E^2 \) is close to \( B^2 \), we deduce by continuity (as did in [1] Prop. 5.4 (iv)]) that \( \omega_p(E^2) \) is close to \( \omega_p(B^2) \). Then, \( \omega_p(E^2) < 2 + \delta \) for some small \( \delta > 0 \). By the same argument above using Corollary 2.14 and Theorem 3.6, we conclude that the only possible values for \( \omega_1(E^2) \) and \( \omega_2(E^2) \) are \( d \) or \( D \). Finally, by Theorem 4.4 and Corollary 3.7 we know that \( \omega_1(E^2) \neq \omega_2(E^2) \) and \( \omega_1(E^2) = d, \omega_2(E^2) = D \).

(ii) As \( \omega_2(E^2) = D \), by the same argument above we have that \( \omega_2(E^2) \neq \omega_3(E^2) \). It follows from Corollary 3.7 that \( \omega_3(E^2) > 2d > 2 \). Therefore, by continuity \( \omega_3(B^2) > 2 \), which implies by Theorem 3.6 that \( \omega_3(B^2) \geq 4 \) (two diameters). Now, by Lemma 1.2 we obtain \( 4 \leq \omega_3(B^2), \omega_4(B^2) < 4.52 < (\text{length of } P_3) \), and so by Theorem 3.6 we actually have that \( 4 \leq \omega_3(B^2), \omega_4(B^2) \leq 4 \), which concludes this case.

(iv) We use again the continuity and Corollary 3.7 to conclude that the only possible values to \( \omega_3(E^2) \) and \( \omega_4(E^2) \) are \( 2d, d + D \) or \( 2D \). Finally, by Theorem 4.4 and Corollary 3.7 we know that \( \omega_3(E^2) \neq \omega_4(E^2) \).

\[ \square \]

Remark 4.6. An alternative way to see that \( \omega_3(B^2) > 2 \), without using Theorem 4.4, is to use the Lusternik-Schnirelmann theory as in Guth [8], p. 1923-24. Indeed, we can take three disjoint closed balls \( B_i \) in \( B^2 \setminus \partial B^2 \) with radius 0.4 each ball. Each 3-sweepout \( \Phi \) of \( B^2 \) is also an 1-sweepout of \( B^2 \), in particular it is an 1-sweepout of each \( B_i \). The Lusternik-Schnirelmann theory says that \( \Phi \) contains a cycle such that its mass is at least the sum of the first width of each \( B_i \). By the item (i) above we know that the first width of a ball is equal to the diameter of that ball, so \( \omega_3(B^2) \geq 3 \times 0.8 > 2 \). Similarly for \( E^2 \), suppose that \( \omega_1(E^2) = D \) for some \( E^2 \). As \( a^2 \leq 2b^2 \) (notation in the proof of Corollary 3.7), we can take two small ellipses defined by scaling \( E^2 \) by half, taking a \( \pi/2 \) rotation and translating the variable \( x \) by \( +b/2 \) and \( -b/2 \), respectively. These two ellipses are inside of \( \text{int}(E^2) \) and, as \( \omega_1(E^2) = D \), we have that the 1-width of each small ellipse is equal to \( D/2 \). Using the Lusternik-Schnirelmann theory as before and the fact that we can slightly increase the scale, we conclude that \( \omega_2(E^2) > D/2 + D/2 = D \), which contradicts the fact that \( \omega_2(E^2), \omega_2(E^2) \in \{d, D\} \). So \( \omega_1(E^2) = d \) and \( \omega_2(E^2) = D \). Therefore, we could calculate the widths of \( B^2 \) and \( E^2 \) without use Theorem 4.4 except we can not deduce that \( \omega_3(E^2) \neq \omega_4(E^2) \) as in (iv) above.

Remark 4.7. For \( p = 1, 2 \), note that \( F_p \) is an optimal \( p \)-sweepout in the sense that

\[ \omega_p(B^2) = \sup\{M(F_p([Q])) : [Q] \in \text{dmm}(F_p)\}. \]

However, for \( p = 3, 4 \), \( F_p \) is almost an optimal \( p \)-sweepout, since Remark 4.3 says that

\[ 4 < \sup\{M(F_p([Q])) : [Q] \in \text{dmm}(F_p)\} \approx 4.00276. \]

Remark 4.8. Notice how similar is our result comparing with the results in Aiex [11] Th. 5.2 and 5.6] about the \( p \)-widths for the unit sphere and the ellipsoid in \( \mathbb{R}^3 \). In fact, as in that article, we obtained in (iv) above an example

...
of a min-max critical varifold with multiplicity. So, as in the closed case [1], we see that in the case with boundary the Multiplicity One Conjecture [16] is also false for min-max critical curves.

**Acknowledgements:** I would like to deeply thank to Professor Fernando Marques for suggesting me to work on this problem, your guidance to develop and your support while visiting him at Princeton University in 2017-2018, under the support of the Coordenação de Aperfeiçoamento de Pessoal de Nível Superior - Brazil (CAPES) - Finance Code 001. I am very thankful to Professor Feliciano Vitório (PhD adviser) by your support and valuable discussions. I thank to Professor Rafael Montezuma by comments and suggestions at the end of this work, and I am grateful to Department of Mathematic of Princeton University by its hospitality and where part of this work was done.
