In the present work, we discuss how the functional form of thermodynamic observables can be deduced from the geometric properties of subsets of phase space. The geometric quantities taken into account are mainly extrinsic curvatures of the energy level sets of the Hamiltonian of a system under investigation. In particular, it turns out that peculiar behaviours of thermodynamic observables at a phase transition point are rooted in more fundamental changes of the geometry of the energy level sets in phase space. More specifically, we discuss how microcanonical and geometrical descriptions of phase-transitions are shaped in the special case of ϕ^4 models with either nearest-neighbours and mean-field interactions.

Keywords: microcanonical ensemble, phase transitions

I. INTRODUCTION

The microcanonical ensemble provides the statistical description of an isolated system at equilibrium. Within the microcanonical ensemble, thermodynamic quantities, like temperature and specific heat, are derived from the entropy through suitable thermodynamic relations. The Boltzmann entropy is defined [1] as

$$S(E, \alpha) = k_B \ln(\omega(E, \alpha)\Delta), \quad (1)$$

where k_B is the Boltzmann constant, $\omega(E, \alpha)$ is the density of microstates per unit energy interval, E is the total energy, $\alpha = (\alpha_1, \dots, \alpha_m)$ summarizes external parameters as, for instance, the volume, and Δ is a constant with the dimension of an energy. In the following we assume units such that $k_B = 1$. We have to recall that, in point of fact, recently [2] it has been argued that only the Gibbs entropy yields a consistent thermodynamics, whereas the microcanonical statistical mechanics founded on the Boltzmann entropy, would unveil some issues. We do not share the point of view of these authors as we have clarified in Refs. [3–5] where we have shown that the Boltzmann entropy provides a consistent description of the microcanonical ensemble.

We have already mentioned that the entropy S constitutes the fundamental thermodynamic potential in the

microcanonical ensemble. Indeed, from the entropy S of a given system, secondary thermodynamic observables, such as the absolute temperature T or the pressure p , are derived by differentiation of S with respect to the parameters $\{E, \alpha\}$. Let us denote the partial derivatives with respect to E by a prime, in this case the temperature T is

$$T = \left(\frac{\partial S}{\partial E} \right)^{-1} = \frac{\omega}{\omega'}. \quad (2)$$

Similarly, for the specific heat we have

$$C_v = - \frac{\left(\frac{\partial S}{\partial E} \right)^2}{\left(\frac{\partial^2 S}{\partial E^2} \right)} = \frac{(\omega'/\omega)^2}{(\omega'/\omega)^2 - \omega''/\omega}. \quad (3)$$

In the following, we will derive the explicit formulas for several thermodynamic quantities in the case of a generic Hamiltonian system. Indeed, in this case, the geometric structure related to the dynamics allows one to derive explicit formulas that can be used in numerical simulations of a Hamiltonian flow to work out thermodynamic observables through time averages. Furthermore, we consider two lattice models for which we specify such formulas and for which we perform numerical simulations in order to exemplify the method. In addition, we consider several geometric quantities that seem to clearly detect the phase transition point.

II. GEOMETRIC MICROCANONICAL THERMODYNAMICS

The geometric microcanonical formalism in the general case of an Hamiltonian system is derived as follows. Consider a generic classical many-particle system described by an autonomous Hamiltonian $H(x_1, \dots, x_N)$ depending on N canonical coordinates, $\mathbf{x} = (\mathbf{p}, \mathbf{q})$ in which the energy is the only first integral of motion. In this case the Boltzmann entropy reads

$$S(E) = \ln \int d^N \mathbf{x} \delta(E - H(\mathbf{x})), \quad (4)$$

where δ is the Dirac function.

In accordance with the conservation of energy, during its evolution in time the representative point of the system moves on a given energy-level set. The Liouville theorem shows that the measure of the Euclidean volume is preserved by the dynamics. Consistently, the invariant measure μ induced on each energy level set Σ_E , of energy E , is given by [6]

$$d\mu = \frac{d\Sigma}{\|\nabla H\|}, \quad (5)$$

where $d\Sigma$ is the Euclidean measure induced on Σ_E , and $\|\cdot\|$ is the Euclidean norm. Remarkably, the density of microstates corresponding to E just depends on such invariant measure as

$$\omega(E) = \int_{\Sigma_E} d\mu. \quad (6)$$

Since temperature, specific heat and other thermodynamic quantities depend on the derivatives of the microcanonical entropy with respect to the energy, they can be measured by averages of the form

$$\langle \Phi \rangle = \frac{\int_{\Sigma_E} d\mu \Phi}{\int_{\Sigma_E} d\mu}, \quad (7)$$

where Φ stands for any function of interest. The latter fact has been proven by Rugh [7] in the case of Hamiltonian systems for which the energy is the only conserved quantity and, in Ref. [8] and Ref. [9] for the case of two and $k \in \mathbb{N}$, $k > 2$ conserved quantities, respectively. The formalism derived in [8] has been successfully adopted for the study of the microcanonical thermodynamics of systems describing Bose-Einstein condensates in optical lattices [3, 4, 10, 11] for which there exist two conserved quantities.

The two ϕ^4 models considered in the following have just one conserved quantity, that is the total energy, therefore from now on we will limit our discussion to the simpler case studied in Ref. [7]. The geometric key tool in this case is the Federer-Laurence derivation formula [12, 13]

$$\partial^k \left(\int_{\Sigma_E} \psi d\Sigma \right) / \partial E^k = \int_{\Sigma_E} A^k(\psi) d\Sigma, \quad (8)$$

where

$$A(\bullet) = \frac{1}{\|\nabla H\|} \nabla \left(\frac{\nabla H}{\|\nabla H\|} \bullet \right). \quad (9)$$

By using this formula in the inverse temperature definition

$$\frac{1}{T} = \frac{\partial S}{\partial E} \quad (10)$$

one obtains

$$\beta = \frac{\omega'}{\omega} = \langle \Phi_1 \rangle, \quad (11)$$

where $\beta = 1/T$, $\omega' = \frac{\partial \omega}{\partial E}$ and

$$\Phi_1 = \nabla \cdot \left(\nabla H / \|\nabla H\|^2 \Phi_0 \right), \quad (12)$$

with $\Phi_0 = 1$.

It is worth mentioning here that in a recent paper [5], one of the present authors has suggested using the surface entropy, that is the logarithm of the area of the constant energy hypersurfaces in the phase space, as the definition for the thermodynamic microcanonical entropy, in place of the standard definition (4). Besides the fact that the surface entropy has properties which make it an attractive definition for small systems [14], from a geometric point of view, the inverse temperature β_s derived from the surface entropy is linked to the mean curvature of the hypersurface $H(\mathbf{x}) = E$, that is with a geometric quantity. In fact, in [14] it is shown that in the case of the surface entropy the inverse temperature results

$$\beta_s = \frac{\int_{\Sigma_E} M(x) m^{N-1}(\Sigma_E)}{\int_{\Sigma_E} m^{N-1}(\Sigma_E)}, \quad (13)$$

where

$$M(x) = \frac{1}{\|\nabla H\|} \nabla \cdot \left(\frac{\nabla H}{\|\nabla H\|} \right) \quad (14)$$

is the local mean curvature divided by $\|\nabla H\|$.

Coming back to the standard entropy definition (4), after the Federer-Laurence derivation formula (8) we get

$$\frac{\omega''}{\omega} = \langle \Phi_2 \rangle, \quad (15)$$

where

$$\Phi_2 = \nabla \cdot \left(\nabla H / \|\nabla H\|^2 \Phi_1 \right), \quad (16)$$

thus the specific heat (3) results

$$C_v = \frac{\langle \Phi_1 \rangle^2}{\langle \Phi_1 \rangle^2 - \langle \Phi_2 \rangle}. \quad (17)$$

More generally, the derivative of order k is obtained by a recursion according to the relation

$$\frac{1}{\omega} \frac{\partial^k \omega}{\partial E^k} = \langle \Phi_k \rangle \quad (18)$$

where

$$\Phi_k = \nabla \cdot (\nabla H / \|\nabla H\|^2 \Phi_{k-1}). \quad (19)$$

We will discuss in the following the relevance of the behaviour of the second derivative of the entropy with respect to the energy density E/N . The latter quantity is expressed in terms of the averages of Φ_1 and Φ_2 according to the following equation

$$\left(\frac{\partial^2 S}{\partial E^2} \right) = \langle \Phi_2 \rangle - \langle \Phi_1 \rangle^2 \quad (20)$$

In the following we will report the microcanonical inverse temperature $\beta(E)$ and the specific heat $C_v(E)$ by time averages of the relevant functions Φ_1 and Φ_2 . In fact, under the hypothesis of ergodicity, the microcanonical averages of each observable Φ can be equivalently measured along the dynamics according to

$$\langle \Phi \rangle = \lim_{\tau \rightarrow \infty} \frac{1}{\tau} \int_0^\tau dt \Phi(t), \quad (21)$$

equivalent to an average on Σ_E as in Eq. (7).

The explicit form for the function Φ_1 is

$$\Phi_1 = \frac{\Delta H}{\|\nabla H\|^2} - 2 \frac{\nabla H \cdot \mathcal{H} \cdot \nabla H}{\|\nabla H\|^4}, \quad (22)$$

where \mathcal{H} is the Hessian matrix of the Hamiltonian function, whereas Φ_2 is a little bit more complicated

$$\Phi_2 = \Phi_1^2 + \frac{\nabla H \cdot \nabla(\Phi_1)}{\|\nabla H\|^2}. \quad (23)$$

A. Phase transitions in the microcanonical ensemble

The inequivalence of statistical ensembles in presence of long-range interactions, and Molecular Dynamics studies of energy conserving systems have motivated several investigations of the microcanonical description of phase transitions [15–20]. In particular, we emphasize a recent and very interesting proposal in Ref. [20] which proves very effective to interpret the outcomes of numerical simulations, as it will be seen in the following. A complementary viewpoint *à la Ehrenfest* has been heuristically put forward in [21]. This proceeds from the fact that the natural counterpart of microscopic Hamiltonian dynamics is the microcanonical ensemble where, as we have already recalled above, the relevant thermodynamic potential is entropy. From the latter, one derives the specific heat (3), where we see that C_v can diverge only as a consequence of the vanishing of $(\partial^2 S / \partial E^2)$ which a-priori has nothing to do with a loss of analyticity of $S(E)$. This disagrees with Ehrenfest's classification of phase transitions in the canonical ensemble, associated with a loss of analyticity of Helmholtz free energy, and thus also of the entropy. As is well known, the identification of a phase

transition with an analyticity loss of a thermodynamic potential (in the gran-canonical ensemble) is rigorously stated by the Yang-Lee theorem.

Coming to the microcanonical ensemble, for standard Hamiltonian systems (i.e. quadratic in the momenta) the relevant information is carried by the configurational microcanonical entropy

$$S_n(\bar{v}) = \frac{1}{n} \log \int dq_1 \cdots dq_n \delta[V_n(q_1, \dots, q_n) - \bar{v}],$$

where $\bar{v} = v/n$ is the potential energy per degree of freedom, $\delta[\cdot]$ is the Dirac function, $S_n(\bar{v})$ is related to the configurational canonical free energy

$$f_n(\beta) = \frac{1}{n} \log \int dq_1 \cdots dq_n e^{-\beta V_n(q_1, \dots, q_n)}$$

for any $n \in \mathbb{N}$, $\bar{v} \in \mathbb{R}$, and $\beta \in \mathbb{R}$, through the Legendre transform

$$-f_n(\beta) = \beta \cdot \bar{v}_n - S_n(\bar{v}_n), \quad (24)$$

where the inverse of the configurational temperature $T(v)$ is given by $\beta_N(\bar{v}) = \partial S_N(\bar{v}) / \partial \bar{v}$.

Then consider the function $\phi(\bar{v}) = f_n[\beta(\bar{v})]$, from $\phi'(\bar{v}) = -\bar{v} [d\beta_n(\bar{v})/d\bar{v}]$ we see that if $\beta_n(\bar{v}) \in \mathcal{C}^k(\mathbb{R})$ then also $\phi(\bar{v}) \in \mathcal{C}^k(\mathbb{R})$ which in turn means $S_n(\bar{v}) \in \mathcal{C}^{k+1}(\mathbb{R})$ while $f_n(\beta) \in \mathcal{C}^k(\mathbb{R})$. Hence, if the functions $\{S_n(\bar{v})\}_{n \in \mathbb{N}}$ are convex, thus ensuring the existence of the above Legendre transform, and if in the $n \rightarrow \infty$ limit it is $f_\infty(\beta) \in \mathcal{C}^0(\mathbb{R})$ then $S_\infty(\bar{v}) \in \mathcal{C}^1(\mathbb{R})$, and if $f_\infty(\beta) \in \mathcal{C}^1(\mathbb{R})$ then $S_\infty(\bar{v}) \in \mathcal{C}^2(\mathbb{R})$. So far we have seen that, generically (that is apart from any possible counterexample), if $f_n(\beta) \in \mathcal{C}^k(\mathbb{R})$ then $S_n(\bar{v}) \in \mathcal{C}^{k+1}(\mathbb{R})$. This all what is needed to *heuristically* proceed to a classification of phase transitions *à la Ehrenfest* in the present microcanonical configurational context. Indeed, in the original definition, Ehrenfest associates a first or second-order phase transition with a discontinuity in the first or second derivatives of $f_\infty(\beta)$, respectively. By analogy, we associate a first (second) order phase transition with a discontinuity of the second (third) derivative of the entropy $S_\infty(\bar{v})$. It is worth emphasizing that this definition of the order of a phase transition is given regardless of the existence of the Legendre transform. Indeed, the latter is very often unachievable in the presence of first-order phase transitions which bring about a kink-shaped entropy as a function of the energy [15]. Therefore, rigorously, the definition that we are putting forward does not stem either mathematically and logically from the original Ehrenfest classification.

This entropy-based classification of phase-transitions *à la Ehrenfest*, although to some extent arbitrary, has a *heuristic* motivation. Besides, it does not suffer any longer the difficulty arising in the framework of canonical ensemble where a divergent specific heat can exist also in presence of a second-order phase transition, as is the case of the Ising model in dimension two. This classification is useful also in case of ensemble non-equivalence when only the microcanonical description is the correct one.

The usefulness of this classification has to be confirmed against practical examples beyond Ref. [21].

III. THE MODELS

The ϕ^4 models are defined by the Hamiltonian

$$H = \sum_{\mathbf{j}} \frac{1}{2} \pi_{\mathbf{j}}^2 + V(\phi) \quad (25)$$

where

$$V(\phi) = \sum_{\mathbf{j}} \left[\frac{\lambda}{4!} \phi_{\mathbf{j}}^4 - \frac{\mu^2}{2} \phi_{\mathbf{j}}^2 + \frac{J}{D} \sum_{\mathbf{k} \in I(\mathbf{j})} (\phi_{\mathbf{j}} - \phi_{\mathbf{k}})^2 \right], \quad (26)$$

$\pi_{\mathbf{j}}$ is the conjugate momentum of the variable $\phi_{\mathbf{j}}$ that defines the position of the \mathbf{j}^{th} particle. In the case of the two dimensional model, $\mathbf{j} = (j_1, j_2)$ denotes a site of a two dimensional lattice, the number of nearest neighbours is $D = 4$ and $I(\mathbf{j})$ are the nearest neighbour lattice sites of the \mathbf{j}^{th} site. The coordinates of the sites are integer numbers $j_k = 1, \dots, N_k$, $k = 1, 2$, so that the total number of sites in the lattice is $N = N_1 N_2$. Furthermore periodic boundary conditions are assumed. In the case of the mean-field model $\mathbf{j} = 1, \dots, N$ denotes the indices of the $2N$ canonical coordinates of the system, $D = N - 1$ and $I(\mathbf{j}) = 1, \dots, N$. The Hamiltonian equations of motion read

$$\begin{aligned} \dot{\phi}_{\mathbf{j}} &= \pi_{\mathbf{j}}, \\ \dot{\pi}_{\mathbf{j}} &= -\frac{\partial V}{\partial \phi_{\mathbf{j}}}. \end{aligned} \quad (27)$$

The local potential displays a double-well shape whose minima are located at $\pm \sqrt{3! \mu^2 / \lambda}$ and to which it corresponds the ground-state energy per particle $e_0 = -3! \mu^4 / (2\lambda)$. At low-energies the system is dominated by an ordered phase where the time averages of the local fields are not vanishing. By increasing the system energy the local \mathbb{Z}_2 symmetry is restored and the averages of the local fields are zero.

Naturally, the explicit form for the geometric quantities entering in

$$\Phi_1 = \frac{\Delta H}{\|\nabla H\|^2} - 2 \frac{\nabla H \cdot \mathcal{H} \cdot \nabla H}{\|\nabla H\|^4}, \quad (28)$$

and

$$\Phi_2 = \Phi_1^2 + \frac{\nabla H}{\|\nabla H\|^2} \cdot \nabla(\Phi_1), \quad (29)$$

where

$$\begin{aligned} \frac{\nabla H}{\|\nabla H\|^2} \cdot \nabla(\Phi_1) &= \\ \sum_{\mathbf{j}\mathbf{k}} \frac{\partial_{\mathbf{j}} H \partial_{\mathbf{j}\mathbf{k}}^3 H}{\|\nabla H\|^4} - 2 \sum_{\mathbf{j}\mathbf{k}\mathbf{r}} \frac{\partial_{\mathbf{j}} H \partial_{\mathbf{k}} H \partial_{\mathbf{r}} H \partial_{\mathbf{j}\mathbf{k}\mathbf{r}}^3 H}{\|\nabla H\|^6} + & \\ - 4 \frac{\nabla H \cdot \mathcal{H} \cdot \nabla H}{\|\nabla H\|^6} - 2 \frac{\nabla H \cdot \mathcal{H} \cdot \nabla H}{\|\nabla H\|^4} \times & \\ \left(\Phi_1 - 2 \frac{\nabla H \cdot \mathcal{H} \cdot \nabla H}{\|\nabla H\|^4} \right), & \end{aligned} \quad (30)$$

depend on the details of the Hamiltonian of each model. Therefore, in the following we will consider these two cases separately and we will set

$$\nabla \equiv \begin{pmatrix} \vdots \\ \partial_{\pi_{\mathbf{j}}} \\ \vdots \\ \partial_{\phi_{\mathbf{j}}} \\ \vdots \end{pmatrix}.$$

A. 2-d ϕ^4 model.

In the case of the two dimensional model we have

$$\Delta H = N(1 + 4J - \mu^2) + \frac{\lambda}{2!} \|\phi\|^2, \quad (31)$$

where $\|\phi\| = \sqrt{\sum_{\mathbf{j}} \phi_{\mathbf{j}}^2}$. In addition it results

$$\|\nabla H\| = \sqrt{2K + \|\nabla V\|^2}, \quad (32)$$

where K stands for the total kinetic energy $K = \sum_{\mathbf{j}} \pi_{\mathbf{j}}^2 / 2$ and

$$\nabla_{\mathbf{k}} V = \frac{\lambda}{3!} \phi_{\mathbf{k}}^3 + (4J - \mu^2) \phi_{\mathbf{k}} - J \sum_{\mathbf{j} \in I(\mathbf{k})} \phi_{\mathbf{j}}. \quad (33)$$

The Hessian matrix of the Hamiltonian function is

$$\mathcal{H} = \begin{pmatrix} \mathbb{I} & 0 \\ 0 & \mathcal{H}_V \end{pmatrix}, \quad (34)$$

where the entries of the Hessian matrix \mathcal{H}_V of the potential function V result

$$(\mathcal{H}_V)_{\mathbf{i}\mathbf{j}} = \partial_{\mathbf{i}\mathbf{j}}^2 V = \left(\frac{\lambda}{2!} \phi_{\mathbf{j}}^2 + 4J - \mu^2 \right) \delta_{\mathbf{i},\mathbf{j}} - J \delta_{\mathbf{j},I(\mathbf{i})}.$$

Finally, it is

$$\partial_{\mathbf{i}\mathbf{j}\mathbf{k}}^3 V = \lambda \delta_{\mathbf{i},\mathbf{j}} \delta_{\mathbf{j},\mathbf{k}} \phi_{\mathbf{j}}.$$

B. Mean-field ϕ^4 model.

The analogous quantities for the case of the mean-field model are the following. ΔH has the same form of (31), whereas

$$\nabla_{\mathbf{k}} V = \frac{\lambda}{3!} \phi_{\mathbf{k}}^3 + \left[4J \frac{N}{N-1} - \mu^2 \right] \phi_{\mathbf{k}} - \frac{4J}{N-1} \mathcal{M}, \quad (35)$$

where we have introduced the total magnetization

$$\mathcal{M} = \left| \sum_{\mathbf{j}} \phi_{\mathbf{j}} \right|. \quad (36)$$

In this case the Hessian matrix \mathcal{H}_V of the potential function V is

$$(\mathcal{H}_V)_{ij} = \partial_{ij}^2 V = \left[\frac{\lambda}{2!} \phi_j^2 + 4J \frac{N}{N-1} - \mu^2 \right] \delta_{i,j} - \frac{4J}{N-1},$$

and $\partial_{ijk}^3 V$ has the same form of the 2-d case.

IV. NUMERICAL RESULTS

We have investigated the microcanonical thermodynamics of these two systems by measuring some geometric quantities as illustrated above which are relevant to catch the thermodynamical properties of these models at their respective phase transition points. Thus, we have numerically integrated the equations of motion (27) of both models, by using a third order symplectic algorithm [22] and starting from random initial conditions corresponding to different values of the total energy E . In such a way, we have measured - along the dynamics - the time averages of the quantities Φ_1 and Φ_2 for several values of the total energy E , according to Eq. (21). From the time averages $\langle \Phi_1 \rangle(E)$ and $\langle \Phi_2 \rangle(E)$ by means of Eqs. (11) and (17), we have derived the caloric curve $T(E)$ and the specific heat $C_v(E)$ of the two models. In addition to the thermodynamic quantities, we have measured geometric quantities as the average of the Ricci curvature $K_R(q, \dot{q})$ (see App. A for details). The main outcome of our analysis is the better effectiveness of the geometric indicators as phase-transitions detectors with respect to the traditional thermodynamic indicators, with the exception of the order parameter. In a recent paper [21], by resorting to geometric indicators, it has been possible to unambiguously characterize and explain the phenomenology of a system that undergoes a thermodynamic phase transition in the absence of a global symmetry-breaking and thus in the absence of an order parameter.

A. 2-d ϕ^4 model

In this section, we analyse the results of the simulations performed in the case of the 2d ϕ^4 model. In two dimension the ϕ^4 model undergoes a second-order phase transition which is detected by a bifurcation of the order parameter. This is clearly seen in Fig. 1 which reports the

typical behaviour of the order parameter $M = \langle \mathcal{M} \rangle / N$, the average of the total magnetization \mathcal{M} defined in (36), as a function of the energy density E/N , behavior typical of a second-order phase transition. Figure 1 allows one

FIG. 1. The figure shows the plot of the quantity order parameter M vs the energy density E/N for 128×128 particles (blue circles) and 48×48 particles (red circles).

to determine the critical energy density ϵ_c of the phase-transition, which is found to be $\epsilon_c \approx 11.1$. Another typ-

FIG. 2. The figure reports the temperature derived by means of time averages of Φ_1 whence $T = 1/\Phi_1$ according to Eqs. (11) and (21), as a function of the energy density E/N for the 2-d ϕ^4 model for 128×128 particles.

ical signature of a phase transition is provided by the shape of the caloric curve $T(E)$, i.e. the temperature as a function of the energy. In the case of the 2d ϕ^4 model, we have derived such a curve by time-averaging Φ_1 , along with the dynamics, for different initial conditions corresponding to several energy densities. The caloric curve derived by $1/\langle \Phi_1 \rangle$, according to Eq. (11), is reported in Fig. 2. In the case of the 2d ϕ^4 model, the caloric curve $T(E/N)$ displays an inflection point just at the critical energy density value identified by the bifurcation point of the order parameter - highlighted with the vertical dashed line in Fig. 2 - and this is in perfect agreement

with the proposition put forward by Bachmann in Refs. [20, 23]. Through time averages of Φ_1 computed along with the numeric integration of the equations of motion for different initial conditions, we have derived the curve of the inverse temperature β as a function of E/N . Fig. 3 shows this curve for the 2d ϕ^4 model. Also in the case of $\beta(E/N)$, the transition point $E_c/N = \epsilon_c$ (located by the dashed vertical line in the same figure) corresponds to an inflection point of this curve. The expected growth

FIG. 3. β vs E/N obtained from the time average of Φ_1 for several energies E in the case of the 2d- ϕ^4 model with 128×128 particles.

with the system-size, of the peak of the specific-heat in correspondence of the phase-transition is shown in Fig. 4. The curve of the specific heat C_V vs the energy-density E/N has been obtained via Eq. (17) where the averages have been again computed by means of time averages of the quantities (22) and (23) according to Eq. (21), for different lattice sizes, that is, 24×24 sites (open circles), 48×48 sites (open squares) and 128×128 sites (crosses).

FIG. 4. The specific-heat per particle C_v/N is reported as a function of the energy density E/N measured according to Eq. (17) and performing time averages (21) of the relevant quantities (22) and (23). The lattice sizes are: 24×24 (open circles), 48×48 (open squares) and 128×128 (crosses).

Fig. 5 reports the second derivative of the entropy with respect to the energy E . As mentioned above, the divergence of the specific heat stems from the vanishing of this derivative. This figure displays the outcomes of a numerical derivation of the curve $\beta(E)$ obtained for systems of different sizes: 24×24 lattice sites (open circles), and 48×48 lattice sites (crosses). In addition, Fig. 5 reports the values of $N\partial^2S/\partial E^2$ vs E/N derived by means Eq. (20) through time averages of Φ_1 and Φ_2 in the case of a system with 24×24 (open squares), 48×48 (full circles) and 128×128 (stars) lattice sizes. Remark-

FIG. 5. $N\partial^2S/\partial E^2$ vs E/N derived with a numeric derivative of the curve $\beta(E/N)$. The latter has been obtained as time average of Φ_1 for several values of the total energy E in the case of a 24×24 lattice (open circles) and a 48×48 lattice (crosses). Furthermore, the figure plots the $N\partial^2S/\partial E^2$ derived by the formula $N(\langle\Phi_2\rangle - \langle\Phi_1\rangle^2)$ in which the averages are temporal. Symbols refer to 24×24 (open squares), 48×48 (full circles) and 128×128 (stars) lattice sizes, respectively. The figure shows distinctly the transition point, corresponding to a discontinuity of the fourth order of the derivative of S .

ably, these numerical outcomes confirm that the growth with the system-size of the specific-heat, in correspondence of the phase-transition, as a consequence of the approaching of $N\partial^2S/\partial E^2$ to zero as per Eq. (3). Fig. 5 shows that the larger the system size the closer the value of $N\partial^2S/\partial E^2$ to zero, in correspondence of the phase-transition point. In Figure 6 the curve $\langle\Delta H\rangle/N$ vs E/N is reported, that is the time average of the Laplacian of the Hamiltonian function per degree of freedom, and again it clearly shows an inflection point at the transition energy density. The quantity $\langle\Delta H\rangle/N$ has a geometric meaning but of a different kind with respect to those related with the extrinsic curvature of the energy level sets. In fact, as shown in the Appendix, it turns out that the Laplacian of the Hamiltonian [in Eq.(A15)] coincides, apart from a constant, with the Ricci-curvature of a Riemannian manifold, an enlarged configurational space-time endowed with a metric due to Eisenhart [24]. The geodesics of this manifold are just the natural motions of the Newton equations associated with the Hamiltonian of the system.

FIG. 6. Figure report the time average of $\Delta H/N$ as a function of E/N in the case of a system with 24×24 lattice sites.

B. Mean-field ϕ^4 model

In the present section, we analyse the results of the numerical simulations performed for the mean-field ϕ^4 model. This model undergoes a second-order phase transition which is displayed by the bifurcation of a standard order parameter, the magnetization, related with the breaking of the Z_2 symmetry of the Hamiltonian of this system. This is shown in Figure 7 where the order parameter $M = \langle \mathcal{M} \rangle / N$, the average of the total magnetization \mathcal{M} in Eq.(36), is reported as a function of the energy density E/N . From this figure one can estimate the value $\epsilon_c \approx 25$ for the critical energy density corresponding to the phase transition.

FIG. 7. The order parameter M for the mean-field ϕ^4 model is reported vs E/N for 1024 particles (green circles) and 2048 particles (blue circles).

With respect to the $2d$ model, the long-range interactions make this system harder to simulate. In fact, considerable difficulties have been encountered in computing stabilized time averages of the same quantities computed for the ϕ^4 model with short-range interactions. These

difficulties depend on the worsening of the properties of self-averaging of this model for energy values close to the transition point, clearly due the long-range interactions. Besides that, and again except for the order parameter, the mean-field model undergoes a phase transition which appears much "softer" than the one undergone by the $2d$ model. This fact is put in evidence by the basic thermodynamic functions $T(E/N)$ and $\beta(E/N)$, computed though the time averages of Φ_1 along with the numeric integration of the equations of motion for different initial conditions, and reported in Figures 8 and 9, respectively. In particular the curve $\beta(E/N)$ does not display at all any feature to identify the presence of a transition. All in all, these functions are not very helpful neither to clearly identify the presence of a phase-transition nor, possibly, its transition point. In Figure 10 we report the

FIG. 8. T vs E/N for the mean-field ϕ^4 model. $N = 4096$ red circles, $N = 2048$ blue circles, $N = 1024$ green circles.

FIG. 9. The figure show the curve β vs E/N for the mean-field ϕ^4 model. $N = 4096$ red circles, $N = 2048$ blue circles, $N = 1024$ green circles.

derivative $N\partial^2 S/\partial E^2$ as a function of E/N worked out in the same way as previously done for the short-range model. The energy density pattern of this derivative is found to be very noisy, even after many millions of in-

tegration time steps, and this goes together with a very bad outcome for the specific heat, which, on purpose, is not reported here. To the contrary, and together with the order parameter, Figure 11 shows an interesting pattern of the time average of the Ricci curvature of the mechanical manifold $(M \times \mathbb{R}^2, g_e)$ (see Appendix) as a function of the energy density. The pattern of $\langle \Delta H \rangle(E/N)/N$ displays a "cuspy" point in correspondence with the vertical red dashed line locating the phase transition point. Of course, within the obvious limits of numerical outcomes, such a "cuspy" point appears as an abrupt change of the second derivative of the Ricci curvature - with respect to the energy - because above the transition point its pattern appears convex (of positive second derivative), whereas just below the transition point the values of the Ricci curvature appear to align along a straight segment, thus with a vanishing second derivative. Loosely speaking, this is reminiscent of similar jumps of the second derivative with respect to the energy of an average curvature function which has been found for a gauge model [21].

FIG. 10. The figure shows the plot of the quantity $N\partial^2 S/\partial E^2$ vs E/N derived with a numeric derivative of the curve $\beta(E)$ for 1025 particles.

V. CONCLUDING REMARKS

We have considered the second order phase transitions stemming from the same kind of \mathbb{Z}_2 symmetry-breaking phenomenon occurring in two ϕ^4 models. Besides the standard detection of the presence of a phase transition through the bifurcation of an order parameter, we have focused on basic geometric properties of different manifolds, highlighting that the values of thermodynamic observables, like temperature and specific heat, and their functional dependence on the energy are the consequences of more fundamental changes with energy of curvature properties of the energy level sets in phase space. The conceptual interest of this fact is that a phase transition phenomenon can be seen as just depending on the interaction potential of the forces acting among the

degrees of freedom of a system, that is, the possibility for a system of undergoing a phase transition is already "encoded" in its Hamiltonian function and thus can be read in the variation of some extrinsic curvature properties of the hypersurfaces $H(p, q) = E$ foliating the phase space. When the variations with energy the geometry of these level-set manifolds are too "mild", as is the case of the mean-field ϕ^4 model, one can again recover a rather sharp geometric signature of the transition by considering the energy variation of the Ricci curvature of a manifold the geodesics of which are the motions of the system. In other words, in both cases, a phase transition phenomenon can be seen as stemming from a deeper level than the usual one which consist of attributing them to a loss of analyticity of the statistical measures in the thermodynamic limit. The statistical measures represent an "epistemic" description of the occurrence of phase transitions, in what statistical measures do not correspond to physically measurable entities, whereas the forces acting among the degrees of freedom of a system belong to an "ontic" level because forces are real physical entities, velocities of the kinetic energy and potentials can be in principle measured, so that for an energy conserving closed system the quantities entering the relation $H(p, q) = E$ are real physical ones.

Finally, since geometric indicators, like the Ricci curvature, are independent of the order parameter among the other thermodynamic quantities, the proposed geometric analysis can be applied also in the case of systems that undergo phase-transitions in absence of a global symmetry breaking and thus in the absence of an order parameter [21].

Appendix A: Eisenhart Metric on Enlarged Configuration Space-Time $M \times \mathbb{R}^2$

The natural motions of a standard Hamiltonian system, that is, having a quadratic kinetic energy term, can be identified with a geodesic flow on a Riemannian manifold. Among the other possibilities, Eisenhart proposed a geometric formulation of Hamiltonian/Newtonian dynamics by resorting to an enlarged configuration space-time $M \times \mathbb{R}^2$ having the local coordinates $(q^0, q^1, \dots, q^i, \dots, q^N, q^{N+1})$. This space can be endowed with a nondegenerate pseudo-Riemannian metric [25] whose arc length is

$$ds^2 = (g_e)_{\mu\nu} dq^\mu dq^\nu = a_{ij} dq^i dq^j - 2V(q)(dq^0)^2 + 2dq^0 dq^{N+1}, \quad (\text{A1})$$

where μ and ν run from 0 to $N+1$ and i and j run from 1 to N . The following theorem [24] holds

Theorem (Eisenhart) *The natural motions of a Hamiltonian dynamical system are obtained as the canonical projection of the geodesics of $(M \times \mathbb{R}^2, g_e)$ on the configuration space-time, $\pi : M \times \mathbb{R}^2 \mapsto M \times \mathbb{R}$. Among the totality of geodesics, only those whose arc lengths are positive definite and are given by*

$$ds^2 = c_1^2 dt^2 \quad (\text{A2})$$

correspond to natural motions; the condition (A2) can be equivalently cast in the following integral form as a condition on the extra coordinate q^{N+1} :

$$q^{N+1} = \frac{c_1^2}{2} t + c_2 - \int_0^t L d\tau, \quad (\text{A3})$$

where c_1 and c_2 are given real constants. Conversely, given a point $P \in M \times \mathbb{R}$ belonging to a trajectory of the system, and given two constants c_1 and c_2 , the point $P' = \pi^{-1}(P) \in M \times \mathbb{R}^2$, with q^{N+1} given by (A3), describes a geodesic curve in $(M \times \mathbb{R}^2, g_e)$ such that $ds^2 = c_1^2 dt^2$.

The explicit table of the entries of the Eisenhart metric is

$$g_e = \begin{pmatrix} -2V(q) & 0 & \cdots & 0 & 1 \\ 0 & a_{11} & \cdots & a_{1N} & 0 \\ \vdots & \vdots & \ddots & \vdots & \vdots \\ 0 & a_{N1} & \cdots & a_{NN} & 0 \\ 1 & 0 & \cdots & 0 & 0 \end{pmatrix}, \quad (\text{A4})$$

where a_{ij} is the kinetic energy metric. The only nonvanishing Christoffel symbols, for $a_{ij} = \delta_{ij}$, are

$$\Gamma_{00}^i = -\Gamma_{0i}^{N+1} = \partial_i V, \quad (\text{A5})$$

whence the geodesic equations

$$\frac{d^2 q^i}{ds^2} + \Gamma_{jk}^i \frac{dq^j}{ds} \frac{dq^k}{ds} = 0,$$

reduce to

$$\frac{d^2 q^0}{ds^2} = 0, \quad (\text{A6})$$

$$\frac{d^2 q^i}{ds^2} + \Gamma_{00}^i \frac{dq^0}{ds} \frac{dq^0}{ds} = 0, \quad (\text{A7})$$

$$\frac{d^2 q^{N+1}}{ds^2} + \Gamma_{0i}^{N+1} \frac{dq^0}{ds} \frac{dq^i}{ds} = 0; \quad (\text{A8})$$

using $ds = dt$ one obtains

$$\frac{d^2 q^0}{dt^2} = 0, \quad (\text{A9})$$

$$\frac{d^2 q^i}{dt^2} = -\frac{\partial V}{\partial q_i}, \quad (\text{A10})$$

$$\frac{d^2 q^{N+1}}{dt^2} = -\frac{dL}{dt}. \quad (\text{A11})$$

Equation (A9) states only that $q^0 = t$. The N equations (A10) are Newton's equations, and (A11) is the differential version of (A3).

The Riemann curvature tensor, associated with Eisenhart metric, has the following nonvanishing components

$$R_{0i0j} = \partial_i \partial_j V; \quad (\text{A12})$$

thus the only nonzero component of the Ricci tensor is

$$R_{00} = \Delta V, \quad (\text{A13})$$

finally the Ricci curvature is

$$K_R(q, \dot{q}) = R_{00} \dot{q}^0 \dot{q}^0 \equiv \Delta V, \quad (\text{A14})$$

so that $\Delta H/N$ is just

$$\frac{\Delta H}{N} = \frac{K_R(q, \dot{q})}{N} + 1. \quad (\text{A15})$$
