APPROXIMATION OF A CAUCHY-JENSEN ADDITIVE MAPPING IN VARIOUS NORMED SPACES

H. AZADI KENARY AND TH.M. RASSIAS

ABSTRACT. In this paper, using the fixed point and direct methods, we prove the generalized Hyers-Ulam-Rassias stability of the following Cauchy-Jensen additive functional equation:

\[ f\left(\frac{x+y+z}{2}\right) + f\left(\frac{x-y+z}{2}\right) = f(x) + f(z) \]

in various normed spaces.

1. Introduction

A classical question in the theory of functional equations is the following: When is it true that a function which approximately satisfies a functional equation must be close to an exact solution of the equation? If the problem accepts a solution, we say that the equation is stable. The first stability problem concerning group homomorphisms was raised by Ulam [59] in 1940. In the next year, Hyers [24] gave a positive answer to the above question for additive groups under the assumption that the groups are Banach spaces. In 1978, Rassias [44] proved a generalization of Hyers's theorem for additive mappings.

Keywords: Hyers-Ulam-Rassias stability, Non-Archimedean normed spaces, Random normed spaces, Fuzzy normed space.
*Corresponding author
Theorem 1.1. (Th.M. Rassias): Let $f : E \to E'$ be a mapping from a normed vector space $E$ into a Banach space $E'$ subject to the inequality

$$\|f(x + y) - f(x) - f(y)\| \leq \epsilon(\|x\|^p + \|y\|^p)$$

for all $x, y \in E$, where $\epsilon$ and $p$ are constants with $\epsilon > 0$ and $0 \leq p < 1$. Then the limit $L(x) = \lim_{n \to \infty} \frac{f(2^n x)}{2^n}$ exists for all $x \in E$ and $L : E \to E'$ is the unique additive mapping which satisfies

$$\|f(x) - L(x)\| \leq \frac{2\epsilon}{2 - 2p}\|x\|^p$$

for all $x \in E$. Also, if for each $x \in E$ the function $f(tx)$ is continuous in $t \in \mathbb{R}$, then $L$ is linear.

This new concept is known as generalized Hyers-Ulam stability or Hyers-Ulam-Rassias stability of functional equations. Furthermore, in 1994, a generalization of Rassias’s theorem was obtained by Găvruta [22] by replacing the bound $\epsilon(\|x\|^p + \|y\|^p)$ by a general control function $\varphi(x, y)$.

In 1983, a generalized Hyers-Ulam stability problem for the quadratic functional equation was proved by Skof [58] for mappings $f : X \to Y$, where $X$ is a normed space and $Y$ is a Banach space. In 1984, Cholewa [9] noticed that the theorem of Skof is still true if the relevant domain $X$ is replaced by an Abelian group and, in 2002, Czerwik [11] proved the generalized Hyers-Ulam stability of the quadratic functional equation. The reader is referred to (1-[56]) and references therein for detailed information on stability of functional equations.

In 1897, Hensel [23] has introduced a normed space which does not have the Archimedean property. It turned out that non-Archimedean spaces have many nice applications (see [14, 28, 31, 32, 37]).

Katsaras [27] defined a fuzzy norm on a vector space to construct a fuzzy vector topological structure on the space. Some mathematicians have defined fuzzy norms on a vector space from various points of view (see [21], [30], [38]).

In particular, Bag and Samanta [5], following Cheng and Mordeson [8], gave an idea of fuzzy norm in such a manner that the corresponding fuzzy metric is of Karmosil and Michalek type [29]. They established a decomposition theorem of a fuzzy norm into a family of crisp norms and investigated some properties of fuzzy normed spaces [6].
Definition 1.2. By a non-Archimedean field we mean a field $K$ equipped with a function (valuation) $| \cdot | : K \to [0, \infty)$ such that, for all $r, s \in K$, the following conditions hold:

(a) $|r| = 0$ if and only if $r = 0$;
(b) $|rs| = |r||s|$;
(c) $|r + s| \leq \max\{|r|, |s|\}$.

Clearly, by (b), $|1| = |-1| = 1$ and so, by induction, it follows from (c) that $|n| \leq 1$ for all $n \geq 1$.

Definition 1.3. Let $X$ be a vector space over a scalar field $K$ with a non-Archimedean non-trivial valuation $| \cdot |$.

(1) A function $\| \cdot \| : X \to \mathbb{R}$ is a non-Archimedean norm (valuation) if it satisfies the following conditions:

(a) $\|x\| = 0$ if and only if $x = 0$ for all $x \in X$;
(b) $\|rx\| = |r|\|x\|$ for all $r \in K$ and $x \in X$;
(c) the strong triangle inequality (ultra-metric) holds, that is,

$$\|x + y\| \leq \max\{\|x\|, \|y\|\}$$

for all $x, y \in X$.

(2) The space $(X, \| \cdot \|)$ is called a non-Archimedean normed space.

Note that $\|x_n - x_m\| \leq \max\{\|x_{j+1} - x_j\| : m \leq j \leq n - 1\}$ for all $m, n \in \mathbb{N}$ with $n > m$.

Definition 1.4. Let $(X, \| \cdot \|)$ be a non-Archimedean normed space.

(a) A sequence $\{x_n\}$ is a Cauchy sequence in $X$ if $\{x_{n+1} - x_n\}$ converges to zero in $X$.

(b) The non-Archimedean normed space $(X, \| \cdot \|)$ is said to be complete if every Cauchy sequence in $X$ is convergent.

The most important examples of non-Archimedean spaces are $p$-adic numbers. A key property of $p$-adic numbers is that they do not satisfy the Archimedean axiom: for all $x, y > 0$, there exists a positive integer $n$ such that $x < ny$.

Example 1.5. Fix a prime number $p$. For any nonzero rational number $x$, there exists a unique positive integer $n_x$ such that $x = \frac{a}{b}p^{n_x}$, where $a$ and $b$ are positive integers not divisible by $p$. Then $|x|_p := p^{-n_x}$ defines a non-Archimedean norm on $\mathbb{Q}$. The completion of $\mathbb{Q}$ with respect to the metric $d(x, y) = |x - y|_p$ is denoted by $\mathbb{Q}_p$, which is called the $p$-adic number field. In fact, $\mathbb{Q}_p$ is the set of all formal series $x = \sum_{k \geq n_x} a_k p^k$, where $|a_k| \leq p - 1$. The addition and multiplication between any two
elements of \( \mathbb{Q}_p \) are defined naturally. The norm \( |\sum_{k \geq n_x} a_k p^k|_p = p^{-n_x} \) is a non-Archimedean norm on \( \mathbb{Q}_p \) and \( \mathbb{Q}_p \) is a locally compact field.

In section 3, we adopt the usual terminology, notions and conventions of the theory of random normed spaces as in [57]. Throughout this paper, let \( \triangle^+ \) denote the set of all probability distribution functions \( F : \mathbb{R} \cup [-\infty, +\infty] \to [0, 1] \) such that \( F \) is left-continuous and nondecreasing on \( \mathbb{R} \) and \( F(0) = 0, F(+\infty) = 1 \). It is clear that the set \( D^+ = \{ F \in \triangle^+ : l^- F(-\infty) = 1 \} \), where \( l^- f(x) = \lim_{t \to x^-} f(t) \), is a subset of \( \triangle^+ \). The set \( \triangle^+ \) is partially ordered by the usual point-wise ordering of functions, that is, \( F \leq G \) if and only if \( F(t) \leq G(t) \) for all \( t \in \mathbb{R} \). For any \( a \geq 0 \), the element \( H_a(t) \) of \( D^+ \) is defined by

\[
H_a(t) = \begin{cases} 
0, & \text{if } t \leq a, \\
1, & \text{if } t > a.
\end{cases}
\]

We can easily show that the maximal element in \( \triangle^+ \) is the distribution function \( H_0(t) \).

**Definition 2.1.** A function \( T : [0, 1]^2 \to [0, 1] \) is a continuous triangular norm (briefly, a \( t \)-norm) if \( T \) satisfies the following conditions:

(a) \( T \) is commutative and associative;
(b) \( T \) is continuous;
(c) \( T(x, 1) = x \) for all \( x \in [0, 1] \);
(d) \( T(x, y) \leq T(z, w) \) whenever \( x \leq z \) and \( y \leq w \) for all \( x, y, z, w \in [0, 1] \).

Three typical examples of continuous \( t \)-norms are as follows: \( T(x, y) = xy, T(x, y) = \max\{a + b - 1, 0\}, T(x, y) = \min(a, b) \). Recall that, if \( T \) is a \( t \)-norm and \( \{x_i\} \) is a sequence in \([0, 1]\), then \( T_{i=1}^n x_i \) is defined recursively by \( T_{i=1}^1 x_1 = x_1 \) and \( T_{i=1}^n x_i = T(T_{i=1}^{n-1} x_i, x_n) \) for all \( n \geq 2 \).

**Definition 1.6.** A random normed space (briefly, \( RN \)-space) is a triple \((X, \mu, T)\), where \( X \) is a vector space, \( T \) is a continuous \( t \)-norm and \( \mu : X \to D^+ \) is a mapping such that the following conditions hold:

(a) \( \mu_x(t) = H_0(t) \) for all \( t > 0 \) if and only if \( x = 0 \);
(b) \( \mu_{\alpha x}(t) = \mu_x \left( \frac{t}{|\alpha|} \right) \) for all \( \alpha \in \mathbb{R} \) with \( \alpha \neq 0 \), \( x \in X \) and \( t \geq 0 \);
(c) \( \mu_{x+y}(t+s) \geq T(\mu_x(t), \mu_y(s)) \) for all \( x, y \in X \) and \( t, s \geq 0 \).

Every normed space \((X, \|\cdot\|)\) defines a random normed space \((X, \mu, T_M)\), where \( \mu_u(t) = \frac{t}{t + \|u\|} \) for all \( t > 0 \) and \( T_M \) is the minimum \( t \)-norm. This space \( X \) is called the induced random normed space.
If the $t$-norm $T$ is such that $\sup_{0<a<1} T(a,a) = 1$, then every RN-space $(X,\mu,T)$ is a metrizable linear topological space with the topology $\tau$ (called the $\mu$-topology or the $(\epsilon,\delta)$-topology, where $\epsilon > 0$ and $\lambda \in (0,1)$) induced by the base $\{U(\epsilon,\lambda)\}$ of neighborhoods of $\theta$, where

$$U(\epsilon,\lambda) = \{x \in X : \mu_x(\epsilon) > 1 - \lambda\}.$$

**Definition 1.7.** Let $(X,\mu,T)$ be an RN-space.

(a) A sequence $\{x_n\}$ in $X$ is said to be convergent to a point $x \in X$ (write $x_n \to x$ as $n \to \infty$) if

$$\lim_{n \to \infty} \mu_{x_n-x}(t) = 1$$

for all $t > 0$.

(b) A sequence $\{x_n\}$ in $X$ is called a Cauchy sequence in $X$ if

$$\lim_{n \to \infty} \mu_{x_n-x_m}(t) = 1$$

for all $t > 0$.

(c) The RN-space $(X,\mu,T)$ is said to be complete if every Cauchy sequence in $X$ is convergent.

**Theorem 1.8.** If $(X,\mu,T)$ is RN-space and $\{x_n\}$ is a sequence such that $x_n \to x$, then $\lim_{n \to \infty} \mu_{x_n}(t) = \mu_x(t)$.

**Definition 1.9.** Let $X$ be a real vector space. A function $N : X \times \mathbb{R} \to [0,1]$ is called a fuzzy norm on $X$ if for all $x, y \in X$ and all $s, t \in \mathbb{R}$,

(N1) $N(x,t) = 0$ for $t \leq 0$;
(N2) $x = 0$ if and only if $N(x,t) = 1$ for all $t > 0$;
(N3) $N(cx,t) = N\left(x, \frac{t}{|c|}\right)$ if $c \neq 0$;
(N4) $N(x+y,c+t) \geq \min\{N(x,s),N(y,t)\}$;
(N5) $N(x,.)$ is a non-decreasing function of $\mathbb{R}$ and $\lim_{t \to \infty} N(x,t) = 1$;
(N6) for $x \neq 0$, $N(x,.)$ is continuous on $\mathbb{R}$.

The pair $(X,N)$ is called a fuzzy normed vector space.

**Example 1.10.** Let $(X,\|\cdot\|)$ be a normed linear space and $\alpha, \beta > 0$. Then

$$N(x,t) = \begin{cases} \frac{\alpha t}{\alpha t + \beta \|x\|} & t > 0, x \in X \\ 0 & t \leq 0, x \in X \end{cases}$$

is a fuzzy norm on $X$.

**Definition 1.11.** Let $(X,N)$ be a fuzzy normed vector space. A sequence $\{x_n\}$ in $X$ is said to be convergent or converge if there exists an $x \in X$ such that $\lim_{t \to \infty} N(x_n - x,t) = 1$ for all $t > 0$. In this case, $x$ is called
the limit of the sequence \( \{x_n\} \) in \( X \) and we denote it by \( N \lim_{t \to \infty} x_n = x \).

**Definition 1.12.** Let \( (X, N) \) be a fuzzy normed vector space. A sequence \( \{x_n\} \) in \( X \) is called Cauchy if for each \( \epsilon > 0 \) and each \( t > 0 \) there exists an \( n_0 \in \mathbb{N} \) such that for all \( n \geq n_0 \) and all \( p > 0 \), we have \( N(x_{n+p} - x_n, t) > 1 - \epsilon \).

It is well known that every convergent sequence in a fuzzy normed vector space is Cauchy. If each Cauchy sequence is convergent, then the fuzzy norm is said to be complete and the fuzzy normed vector space is called a fuzzy Banach space.

We say that a mapping \( f : X \to Y \) between fuzzy normed vector spaces \( X \) and \( Y \) is continuous at a point \( x_0 \in X \) if for each sequence \( \{x_n\} \) converging to \( x_0 \), then the sequence \( \{f(x_n)\} \) converges to \( f(x_0) \). If \( f : X \to Y \) is continuous at each \( x \in X \), then \( f : X \to Y \) is said to be continuous on \( X \).

**Definition 1.13.** Let \( X \) be a set. A function \( d : X \times X \to [0, \infty] \) is called a generalized metric on \( X \) if \( d \) satisfies the following conditions:

\[(a) \quad d(x, y) = 0 \text{ if and only if } x = y \text{ for all } x, y \in X;\]
\[(b) \quad d(x, y) = d(y, x) \text{ for all } x, y \in X;\]
\[(c) \quad d(x, z) \leq d(x, y) + d(y, z) \text{ for all } x, y, z \in X.\]

**Theorem 1.14.** Let \((X, d)\) be a complete generalized metric space and \( J : X \to X \) be a strictly contractive mapping with Lipschitz constant \( L < 1 \). Then, for all \( x \in X \), either \( d(J^n x, J^{n+1} x) = \infty \) for all nonnegative integers \( n \) or there exists a positive integer \( n_0 \) such that

\[(a) \quad d(J^n x, J^{n+1} x) < \infty \text{ for all } n \geq n_0;\]
\[(b) \quad \text{the sequence } \{J^n x\} \text{ converges to a fixed point } y^* \text{ of } J;\]
\[(c) \quad y^* \text{ is the unique fixed point of } J \text{ in the set } Y = \{y \in X : d(J^{n_0} x, y) < \infty \};\]
\[(d) \quad d(y, y^*) \leq \frac{d(y, Jy)}{1-L} \text{ for all } y \in Y.\]

2. Non-Archimedean Stability of Functional Equation (0.1)

In this section, we deal with the stability problem for the Cauchy-Jensen additive functional equation (0.1) in non-Archimedean normed spaces.

2.1. A Fixed Point Approach.
Theorem 2.1. Let $X$ be a non-Archimedean normed space and that $Y$ be a complete non-Archimedean space. Let $\varphi : X^3 \to [0, \infty)$ be a function such that there exists an $\alpha < 1$ with

\[
\varphi \left( \frac{x}{2}, \frac{y}{2}, \frac{z}{2} \right) \leq \frac{\alpha \varphi(x, y, z)}{|2|} \tag{2.1}
\]

for all $x, y, z \in X$. Let $f : X \to Y$ be a mapping satisfying

\[
\|f \left( \frac{x + y + z}{2} \right) + f \left( \frac{x - y + z}{2} \right) - f(x) - f(z)\|_Y \leq \varphi(x, y, z) \tag{2.2}
\]

for all $x, y, z \in X$. Then there exists a unique additive mapping $L : X \to Y$ such that

\[
\|f(x) - L(x)\|_Y \leq \frac{\alpha \varphi(x, 2x, x)}{|2|} \tag{2.3}
\]

for all $x \in X$.

Proof. Putting $y = 2x$ and $z = x$ in (2.2), we get

\[
\|f(2x) - 2f(x)\|_Y \leq \varphi(x, 2x, x) \tag{2.4}
\]

for all $x \in X$. So

\[
\|f(x) - 2f \left( \frac{x}{2} \right)\|_Y \leq \varphi \left( \frac{x}{2}, x, \frac{x}{2} \right) \leq \frac{\alpha \varphi(x, 2x, x)}{|2|} \tag{2.5}
\]

for all $x \in X$. Consider the set $S := \{h : X \to Y\}$ and introduce the generalized metric on $S$:

\[
d(g, h) = \inf \left\{ \mu \in (0, +\infty) : \|g(x) - h(x)\|_Y \leq \mu \varphi(x, 2x, x), \forall x \in X \right\},
\]

where, as usual, $\inf \phi = +\infty$. It is easy to show that $(S, d)$ is complete (see [34]). Now we consider the linear mapping $J : S \to S$ such that

\[
Jg(x) := 2g \left( \frac{x}{2} \right)
\]

for all $x \in X$. Let $g, h \in S$ be given such that $d(g, h) = \varepsilon$. Then

\[
\|g(x) - h(x)\|_Y \leq \epsilon \varphi(x, 2x, x)
\]

for all $x \in X$. Hence

\[
\|Jg(x) - Jh(x)\|_Y = \left\|2g \left( \frac{x}{2} \right) - 2h \left( \frac{x}{2} \right)\right\|_Y = |2| \left\|g \left( \frac{x}{2} \right) - h \left( \frac{x}{2} \right)\right\|_Y \leq |2| \varphi \left( \frac{x}{2}, x, \frac{x}{2} \right) \leq \alpha \cdot \epsilon \varphi(x, 2x, x)
\]

for all $x \in X$. So $d(g, h) = \varepsilon$ implies that $d(Jg, Jh) \leq \alpha \varepsilon$. This means that $d(Jg, Jh) \leq \alpha d(g, h)$ for all $g, h \in S$. It follows from (2.5) that
By Theorem 1.14, there exists a mapping $L : X \to Y$ satisfying the following:

1. $L$ is a fixed point of $J$, i.e.,

$$L(x) = \frac{L(x)}{2}$$

for all $x \in X$. The mapping $L$ is a unique fixed point of $J$ in the set $M = \{ g \in S : d(h, g) < \infty \}$. This implies that $L$ is a unique mapping satisfying (2.6) such that there exists a $\mu \in (0, \infty)$ satisfying $\|f(x) - L(x)\|_Y \leq \mu \varphi(x, 2x, x)$ for all $x \in X$;

2. $d(J^n f, L) \to 0$ as $n \to \infty$. This implies the equality

$$\lim_{n \to \infty} 2^n f\left(\frac{x}{2^n}\right) = L(x)$$

for all $x \in X$;

3. $d(f, L) \leq \frac{\alpha}{1 - \alpha} d(f, Jf)$, which implies the inequality $d(f, L) \leq \frac{\alpha}{|2| - |2\alpha|}$. This implies that the inequalities (2.7) holds.

It follows from (2.1) and (2.2) that

$$\left\|L\left(\frac{x+y+z}{2}\right) + L\left(\frac{x-y+z}{2}\right) - L(x) - L(z)\right\|_Y$$

$$= \lim_{n \to \infty} |2|^n \left\| f\left(\frac{x+y+z}{2^{n+1}}\right) + f\left(\frac{x-y+z}{2^{n+1}}\right) - f\left(\frac{x}{2^n}\right) - f\left(\frac{z}{2^n}\right)\right\|_Y$$

$$\leq \lim_{n \to \infty} |2|^n \varphi\left(\frac{x}{2^n}, \frac{y}{2^n}, \frac{z}{2^n}\right) \leq \lim_{n \to \infty} |2|^n \frac{\alpha^n \varphi(x, y, z)}{|2|^n} = 0$$

for all $x, y, z \in X$. So

$$L\left(\frac{x+y+z}{2}\right) + L\left(\frac{x-y+z}{2}\right) = L(x) + L(z)$$

for all $x, y, z \in X$. Hence $L : X \to Y$ is an Cauchy-Jensen mapping. It follows from (2.5) and (2.10) that

$$\left\|2L\left(\frac{x}{2}\right) - L(x)\right\|_Y = \lim_{n \to \infty} |2|^n \left\|2f\left(\frac{x}{2^{n+1}}\right) - f\left(\frac{x}{2^n}\right)\right\|_Y \leq \lim_{n \to \infty} |2|^n \frac{\alpha^n \varphi(x, 2x, x)}{|2|^n} = 0$$

for all $x \in X$. So

$$2L\left(\frac{x}{2}\right) - L(x) = 0$$
for all \( x \in X \). Hence \( L : X \to Y \) is additive and we get desired results. □

**Corollary 2.2.** Let \( \theta \) be a positive real number and \( r \) is a real number with \( 0 < r < 1 \). Let \( f : X \to Y \) be a mapping satisfying

\[
\left\| f \left( \frac{x + y + z}{2} \right) + f \left( \frac{x - y + z}{2} \right) - f(x) - f(z) \right\|_Y \leq \theta \left( \|x\|^r + \|y\|^r + \|z\|^r \right)
\]

for all \( x, y, z \in X \). Then there exists a unique additive mapping \( L : X \to Y \) such that

\[
\|f(x) - L(x)\|_Y \leq \frac{2\theta(2 + |2|^r)\|x\|^r}{|2|^{r+1} - |2|^2}
\]

for all \( x \in X \).

**Proof.** The proof follows from Theorem 2.1 by taking

\[
\varphi(x, y, z) = (\|x\|^r + \|y\|^r + \|z\|^r)
\]

for all \( x, y, z \in X \). Then we can choose \( \alpha = |2|^{1-r} \) and we get the desired result. □

**Theorem 2.3.** Let \( X \) be a non-Archimedean normed space and \( Y \) be a complete non-Archimedean space. Let \( \varphi : X^3 \to [0, \infty) \) be a function such that there exists an \( \alpha < 1 \) with

\[
\varphi(x, y, z) \leq |2|\alpha\varphi \left( \frac{x}{2}, \frac{y}{2}, \frac{z}{2} \right)
\]

for all \( x, y, z \in X \). Let \( f : X \to Y \) be a mapping satisfying (2.2). Then there exists a unique additive mapping \( L : X \to Y \) such that

\[
(2.8) \quad \|f(x) - L(x)\|_Y \leq \frac{\varphi(x, 2x, x)}{|2| - |2|\alpha}
\]

for all \( x \in X \).

**Proof.** Let \((S, d)\) be the generalized metric space defined in the proof of Theorem 2.1. Now we consider the linear mapping \( J : S \to S \) such that

\[
Jg(x) := \frac{g(2x)}{2}
\]

for all \( x \in X \). Let \( g, h \in S \) be given such that \( d(g, h) = \varepsilon \). Then

\[
\|g(x) - h(x)\|_Y \leq \varepsilon \varphi(x, 2x, x)
\]
for all \( x \in X \). Hence
\[
\|Jg(x) - Jh(x)\|_Y = \left\| \frac{g(2x)}{2} - \frac{h(2x)}{2} \right\|_Y = \frac{\|g(2x) - h(2x)\|_Y}{|2|} \\
\leq \frac{\varphi(2x, 4x, 2x)}{|2|} \leq \frac{|2| \alpha \cdot \varepsilon \varphi(x, 2x, x)}{|2|}
\]
for all \( x \in X \). So \( d(g, h) = \varepsilon \) implies that \( d(Jg, Jh) \leq \alpha \varepsilon \). This means that \( d(Jg, Jh) \leq \alpha d(g, h) \) for all \( g, h \in S \). It follows from (2.4) that \( d(f, Jf) \leq \frac{1}{|2|} \).

By Theorem 1.14, there exists a mapping \( L : X \rightarrow Y \) satisfying the following:

1. \( L \) is a fixed point of \( J \), i.e.,
   \[ L(2x) = 2L(x) \] (2.9)
   for all \( x \in X \). The mapping \( L \) is a unique fixed point of \( J \) in the set \( M = \{ g \in S : d(h, g) < \infty \} \). This implies that \( L \) is a unique mapping satisfying (2.9) such that there exists a \( \mu \in (0, \infty) \) satisfying \( \|f(x) - L(x)\|_Y \leq \mu \varphi(x, 2x, x) \) for all \( x \in X \);
2. \( d(J^n f, L) \to 0 \) as \( n \rightarrow \infty \). This implies the equality
   \[ \lim_{n \to \infty} \frac{f(2^n x)}{2^n} = L(x) \] (2.10)
   for all \( x \in X \);
3. \( d(f, L) \leq \frac{1}{1 - \alpha} d(f, Jf) \), which implies the inequality \( d(f, L) \leq \frac{1}{|2| - |2| \alpha} \).

This implies that the inequalities (2.8) holds. The rest of the proof is similar to the proof of Theorem 2.1. \( \square \)

**Corollary 2.4.** Let \( \theta \) be a positive real number and \( r \) is a real number with \( r > 1 \). Let \( f : X \rightarrow Y \) be a mapping satisfying
\[
\left\| f \left( \frac{x + y + z}{2} \right) + f \left( \frac{x - y + z}{2} \right) - f(x) - f(z) \right\|_Y \leq \theta \left( \|x\|^r + \|y\|^r + \|z\|^r \right)
\]
for all \( x, y, z \in X \). Then there exists a unique additive mapping \( L : X \rightarrow Y \) such that
\[
\|f(x) - L(x)\|_Y \leq \frac{\theta(2 + |2| r) \|x\|^r}{|2| - |2| r}
\]
for all \( x \in X \).

**Proof.** The proof follows from Theorem 2.3 by taking
\[
\varphi(x, y, z) = (\|x\|^r + \|y\|^r + \|z\|^r)
\]
for all \(x, y, z \in X\). Then we can choose \(\alpha = |2|^{-1}\) and we get the desired result.

\[\square\]

### 2.2. A Direct Method.

In this section, using direct method, we prove the generalized Hyers-Ulam-Rassias stability of the Cauchy-Jensen additive functional equation \((0.1)\) in non-Archimedean space.

**Theorem 2.5.** Let \(G\) is an additive semigroup and that \(X\) is a non-Archimedean Banach space. Assume that \(\zeta : G^3 \to [0, +\infty)\) be a function such that

\[
(2.11) \quad \lim_{n \to \infty} |2|^n \zeta \left( \frac{x}{2^n}, \frac{y}{2^n}, \frac{z}{2^n} \right) = 0
\]

for all \(x, y, z \in G\). Suppose that, for any \(x \in G\), the limit

\[
(2.12) \quad \mathcal{L}(x) = \lim_{n \to \infty} \max_{0 \leq k < n} |2|^k \zeta \left( \frac{x}{2^{k+1}}, \frac{x}{2^k}, \frac{x}{2^{k+1}} \right)
\]

exists and \(f : G \to X\) be a mapping satisfying

\[
(2.13) \quad \| f \left( \frac{x + y + z}{2} \right) + f \left( \frac{x - y + z}{2} \right) - f(x) - f(z) \|_X \leq \zeta(x, y, z)
\]

Then the limit \(A(x) := \lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right)\) exists for all \(x \in G\) and defines an additive mapping \(A : G \to X\) such that

\[
(2.14) \quad \| f(x) - A(x) \| \leq \mathcal{L}(x).
\]

Moreover, if

\[
\lim_{j \to \infty} \lim_{n \to \infty} \max_{0 \leq k < n+j} |2|^k \zeta \left( \frac{x}{2^{k+1}}, \frac{x}{2^k}, \frac{x}{2^{k+1}} \right) = 0
\]

then \(A\) is the unique additive mapping satisfying \((2.14)\).

**Proof.** Putting \(y = 2x\) and \(z = x\) in \((2.13)\), we get

\[
(2.15) \quad \| f(2x) - 2f(x) \|_Y \leq \zeta(x, 2x, x)
\]

for all \(x \in G\). Replacing \(x\) by \(\frac{x}{2^{n+1}}\) in \((2.15)\), we obtain

\[
(2.16) \quad \left\| 2^{n+1} f \left( \frac{x}{2^{n+1}} \right) - 2^n f \left( \frac{x}{2^n} \right) \right\| \leq |2|^n \zeta \left( \frac{x}{2^{n+1}}, \frac{x}{2^n}, \frac{x}{2^{n+1}} \right).
\]
Thus, it follows from (2.11) and (2.16) that the sequence \( \{ \frac{2^n f\left( \frac{x}{2^n} \right)}{n} \}_{n \geq 1} \) is a Cauchy sequence. Since \( X \) is complete, it follows that \( \{ \frac{2^n f\left( \frac{x}{2^n} \right)}{n} \}_{n \geq 1} \) is convergent. Set

\[
A(x) := \lim_{n \to \infty} 2^n f\left( \frac{x}{2^n} \right). 
\]

By induction on \( n \), one can show that

\[
\left\| 2^n f\left( \frac{x}{2^n} \right) - f(x) \right\| \leq \max \left\{ \left| 2^k \zeta \left( \frac{x}{2^{k+1}}, \frac{x}{2^k}, \frac{x}{2^{k+1}} \right) \right| ; 0 \leq k < n \right\}
\]

for all \( n \geq 1 \) and \( x \in G \). By taking \( n \to \infty \) in (2.18) and using (2.12), one obtains (2.14). By (2.11), (2.13) and (2.17), we get

\[
\left\| A \left( \frac{x + y + z}{2} \right) + A \left( \frac{x - y + z}{2} \right) - A(x) - A(z) \right\|
\]

\[
= \lim_{n \to \infty} \left\| 2^n f\left( \frac{x + y + z}{2^{n+1}} \right) + f\left( \frac{x - y + z}{2^n} \right) - f\left( \frac{x}{2^n} \right) - f\left( \frac{z}{2^n} \right) \right\|
\]

\[
\leq \lim_{n \to \infty} \left\| 2^n \zeta \left( \frac{x}{2^n}, \frac{y}{2^n}, \frac{z}{2^n} \right) \right\| = 0
\]

for all \( x, y, z \in X \). So

\[
A \left( \frac{x + y + z}{2} \right) + A \left( \frac{x - y + z}{2} \right) = A(x) + A(z)
\]

for all \( x, y, z \in G \). Letting \( y = 0 \) in (2.19), we get

\[
2L \left( \frac{x + z}{2} \right) = L(x) + L(z)
\]

for all \( x, z \in G \). Since

\[
L(0) = \lim_{n \to +\infty} 2^n f\left( \frac{0}{2^n} \right) = \lim_{n \to +\infty} 2^n f(0) = 0,
\]

by letting \( y = 2x \) and \( z = x \) in (2.19), we get

\[
A(2x) = 2A(x)
\]

for all \( x \in G \). Replacing \( x \) by \( 2x \) and \( z \) by \( 2z \) in (2.20), we get

\[
A(x + z) = A(x) + A(z)
\]
for all \(x, z \in G\). Hence \(A : G \to X\) is additive.

To prove the uniqueness property of \(A\), let \(L\) be another mapping satisfying (2.14). Then we have

\[
\left\| A(x) - L(x) \right\|_X = \lim_{n \to \infty} |2|^n \left\| A \left( \frac{x}{2^n} \right) - L \left( \frac{x}{2^n} \right) \right\|_X
\]

\[
\leq \lim_{k \to \infty} |2|^n \max \left\{ \left\| A \left( \frac{x}{2^n} \right) - f \left( \frac{x}{2^n} \right) \right\|_X, \left\| f \left( \frac{x}{2^n} \right) - L \left( \frac{x}{2^n} \right) \right\|_X \right\}
\]

\[
\leq \lim \lim_{n \to \infty} \max_{j \leq k < n + j} |2|^k \zeta \left( \frac{x}{2^{k+1}}, \frac{x}{2^k}, \frac{x}{2^{k+1}} \right) = 0
\]

for all \(x \in G\). Therefore, \(A = L\). This completes the proof. \(\square\)

**Corollary 2.6.** Let \(\xi : [0, \infty) \to [0, \infty)\) be a function satisfying

\[
\xi \left( \frac{t}{|2|} \right) \leq \xi \left( \frac{1}{|2|} \right) \xi(t), \quad \xi \left( \frac{1}{|2|} \right) < \frac{1}{|2|}
\]

for all \(t \geq 0\). Assume that \(\kappa > 0\) and \(f : G \to X\) be a mapping such that

\[
\left\| f \left( \frac{x + y + z}{2} \right) + f \left( \frac{x - y + z}{2} \right) - f(x) - f(z) \right\|_Y \leq \kappa (\xi(|x|) + \xi(|y|) + \xi(|z|))
\]

for all \(x, y, z \in G\). Then there exists a unique additive mapping \(A : G \to X\) such that

\[
\left\| f(x) - A(x) \right\| \leq \frac{(2 + |2|)\xi(|x|)}{|2|}
\]

**Proof.** If we define \(\zeta : G^3 \to [0, \infty)\) by \(\zeta(x, y, z) := \kappa (\xi(|x|) + \xi(|y|) + \xi(|z|))\),
then we have

\[
\lim_{n \to \infty} |2|^n \zeta \left( \frac{x}{2^n}, \frac{y}{2^n}, \frac{z}{2^n} \right) = 0
\]

for all \(x, y, z \in G\). On the other hand, it follows that

\[
\xi(x, \frac{x}{2}, \frac{x}{2}) = \frac{(2 + |2|)\xi(|x|)}{|2|}
\]

exists for all \(x \in G\). Also, we have

\[
\lim \lim_{j \to \infty} \max_{j \leq k < n + j} |2|^j \zeta \left( \frac{x}{2^{j+1}}, \frac{x}{2^j}, \frac{x}{2^{j+1}} \right) = \lim_{j \to \infty} |2|^j \zeta \left( \frac{x}{2^{j+1}}, \frac{x}{2^j}, \frac{x}{2^{j+1}} \right) = 0.
\]

Thus, applying Theorem 2.5, we have the conclusion. This completes the proof. \(\square\)
Theorem 2.7. Let $G$ be an additive semigroup and that $X$ is a non-Archimedean Banach space. Assume that $\zeta : G^3 \to [0, +\infty)$ be a function such that
\begin{equation}
\lim_{n \to \infty} \frac{\zeta(2^nx, 2^ny, 2^nz)}{2^n} = 0
\end{equation}
for all $x, y, z \in G$. Suppose that, for any $x \in G$, the limit
\begin{equation}
\mathcal{L}(x) = \lim_{n \to \infty} \max_{0 \leq k < n} \frac{\zeta(2^kx, 2^{k+1}x, 2^kx)}{2^k}
\end{equation}
exists and $f : G \to X$ be a mapping with $f(0) = 0$ and satisfying (2.13). Then the limit $A(x) := \lim_{n \to \infty} \frac{f(2^nx)}{2^n}$ exists for all $x \in G$ and
\begin{equation}
\|f(x) - A(x)\| \leq \frac{\mathcal{L}(x)}{2},
\end{equation}
for all $x \in G$. Moreover, if
\begin{equation}
\lim_{j \to \infty} \lim_{n \to \infty} \max_{j \leq k < n+j} \frac{\zeta(2^kx, 2^{k+1}x, 2^kx)}{2^k} = 0,
\end{equation}
then $A$ is the unique mapping satisfying (2.23).

Proof. It follows from (2.15), we get
\begin{equation}
\left\|f(x) - \frac{f(2^nx)}{2}\right\|_X \leq \frac{\zeta(x, 2x, x)}{2}
\end{equation}
for all $x \in G$. Replacing $x$ by $2^nx$ in (2.24), we obtain
\begin{equation}
\left\|f\left(\frac{2^nx}{2^n}\right) - \frac{f\left(\frac{2^{n+1}x}{2^{n+1}}\right)}{2}\right\|_X \leq \frac{\zeta\left(\frac{2^n, 2^{n+1}, 2^n}{2}\right)}{2^{n+1}}.
\end{equation}
Thus it follows from (2.21) and (2.25) that the sequence $\left\{\frac{f(2^nx)}{2^n}\right\}_{n \geq 1}$ is convergent. Set
\[ A(x) := \lim_{n \to \infty} \frac{f(2^nx)}{2^n}. \]
On the other hand, it follows from (2.25) that
\begin{align*}
\left\|f\left(\frac{2^px}{2^p}\right) - \frac{f(2^qx)}{2^q}\right\| &= \left\|\sum_{k=p}^{q-1} \frac{f(2^{k+1}x)}{2^{k+1}} - \frac{f(2^kx)}{2^k}\right\| \\
&\leq \max_{p \leq k < q} \left\{\left\|\frac{f(2^{k+1}x)}{2^{k+1}} - \frac{f(2^kx)}{2^k}\right\|\right\} \\
&\leq \frac{1}{2} \max_{p \leq k < q} \frac{\zeta\left(2^kx, 2^{k+1}x, 2^kx\right)}{2^k}
\end{align*}
for all \( x \in G \) and \( p, q \geq 0 \) with \( q > p \geq 0 \). Letting \( p = 0 \), taking \( q \to \infty \) in the last inequality and using (2.22), we obtain (2.23).

The rest of the proof is similar to the proof of Theorem 2.5. This completes the proof. \( \square \)

**Corollary 2.8.** Let \( \xi : [0, \infty) \to [0, \infty) \) be a function satisfying
\[
|\xi(\frac{|2|t|}{2})| \leq \xi(\frac{|2|}{2}) \xi(t), \quad \xi(|2|) < 2
\]
for all \( t \geq 0 \). Let \( \kappa > 0 \) and \( f : G \to X \) be a mapping satisfying
\[
\left\| f\left( \frac{x+y+z}{2} \right) + f\left( \frac{x-y+z}{2} \right) - f(x) - f(z) \right\| \leq \kappa \left( \xi(|x|) \cdot \xi(|y|) \cdot \xi(|z|) \right)
\]
for all \( x, y, z \in G \). Then there exists a unique additive mapping \( A : G \to X \) such that
\[
\| f(x) - A(x) \| \leq \kappa \xi(|x|)^3.
\]

**Proof.** If we define \( \zeta : G^3 \to [0, \infty) \) by
\[
\zeta(x, y, z) := \kappa \left( \xi(|x|) \cdot \xi(|y|) \cdot \xi(|z|) \right)
\]
and apply Theorem 2.7, then we get the conclusion. \( \square \)

### 3. Random Stability of the Functional Equation (0.1)

In this section, using the fixed point and direct methods, we prove the generalized Hyers-Ulam-Rassias stability of the functional equation (0.1) in random normed spaces.

#### 3.1. Direct Method.

**Theorem 3.1.** Let \( X \) be a real linear space, \( (Z, \mu, \min) \) be an RN-space and \( \varphi : X^3 \to Z \) be a function such that there exists \( 0 < \alpha < \frac{1}{2} \) such that
\[
\mu'_{\varphi(\frac{x+y+z}{2}, \frac{x-y+z}{2}, \frac{y-z}{2})}(t) \geq \mu'_{\varphi(x,y,z)}\left( \frac{t}{\alpha} \right)
\]
for all \( x, y, z \in X \) and \( t > 0 \) and \( \lim_{n \to \infty} \mu'_{\varphi(\frac{x+y+z}{2^n}, \frac{x-y+z}{2^n}, \frac{y-z}{2^n})}(\frac{t}{2^n}) = 1 \) for all \( x, y, z \in X \) and \( t > 0 \). Let \( (Y, \mu, \min) \) be a complete RN-space. If \( f : X \to Y \) be a mapping such that
\[
\mu_{f(\frac{x+y+z}{2}) + f(\frac{x-y+z}{2}) - f(x) - f(z)}(t) \geq \mu'_{\varphi(x,y,z)}(t)
\]
for all \( x, y, z \in X \) and \( t > 0 \). Then the limit \( A(x) = \lim_{n \to \infty} 2^n f(\frac{x}{2^n}) \)
exists for all \( x \in X \) and defines a unique additive mapping \( A : X \to Y \) such that and

\[
(3.3) \quad \mu_{f(x) - A(x)}(t) \geq \mu'_{\phi(x, 2x, x)} \left( \frac{(1 - 2\alpha)t}{\alpha} \right).
\]

for all \( x \in X \) and \( t > 0 \).

**Proof.** Putting \( y = 2x \) and \( z = x \) in (3.2), we see that

\[
(3.4) \quad \mu_{f(2x) - 2f(x)}(t) \geq \mu'_{\phi(x, 2x, x)}(t).
\]

Replacing \( x \) by \( \frac{x}{2} \) in (3.4), we obtain

\[
(3.5) \quad \mu_{2f(\frac{x}{2}) - f(x)}(t) \geq \mu'_{\phi(\frac{x}{2}, x, \frac{x}{2})}(t) \geq \mu'_{\phi(x, 2x, x)}(t)
\]

for all \( x \in X \). Replacing \( x \) by \( \frac{x}{2^m} \) in (3.5) and using (3.1), we obtain

\[
\mu_{2^{n+1}f(\frac{x}{2^{n+1}}) - 2^n f(\frac{x}{2^n})}(t) \geq \mu'_{\phi(\frac{x}{2^{n+1}}, \frac{x}{2^{n+1}}, \frac{x}{2^{n+1}})} \left( \frac{t}{2^n} \right) \geq \mu'_{\phi(x, 2x, x)} \left( \frac{t}{2^n \alpha^{n+1}} \right)
\]

and so

\[
\mu_{2^n f(\frac{x}{2^n}) - f(x)} \left( \sum_{k=0}^{n-1} 2^k \alpha^{k+1} t \right) = \mu_{\sum_{k=0}^{n-1} 2^{k+1} f(\frac{x}{2^{k+1}}) - 2^k f(\frac{x}{2^k})} \left( \sum_{k=0}^{n-1} 2^k \alpha^{k+1} t \right) \geq T_{k=0}^{n-1} \left( \mu_{2^{k+1}f(\frac{x}{2^{k+1}}) - 2^k f(\frac{x}{2^k})} \right) \left( 2^k \alpha^{k+1} t \right) \geq T_{k=0}^{n-1} \left( \mu'_{\phi(x, 2x, x)}(t) \right) = \mu'_{\phi(x, 2x, x)}(t).
\]

This implies that

\[
(3.6) \quad \mu_{2^n f(\frac{x}{2^n}) - f(x)}(t) \geq \mu'_{\phi(x, 2x, x)} \left( \frac{t}{\sum_{k=0}^{n-1} 2^k \alpha^{k+1}} \right).
\]

Replacing \( x \) by \( \frac{x}{2^p} \) in (3.6), we obtain

\[
(3.7) \quad \mu_{2^{n+p} f(\frac{x}{2^{n+p}}) - 2^p f(\frac{x}{2^p})}(t) \geq \mu'_{\phi(x, 2x, x)} \left( \frac{t}{\sum_{k=p}^{n+p-1} 2^k \alpha^{k+1}} \right).
\]

Since \( \lim_{p, n \to \infty} \mu'_{\phi(x, 2x, x)} \left( \frac{t}{\sum_{k=p}^{n+p-1} 2^k \alpha^{k+1}} \right) = 1 \), it follows that \( \{2^n f(\frac{x}{2^n})\}_{n=1}^{\infty} \) is a Cauchy sequence in a complete RN-space \((Y, \mu, \min)\) and so there
exists a point $A(x) \in Y$ such that $\lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right) = A(x)$. Fix $x \in X$ and put $p = 0$ in (3.7) and so, for any $\epsilon > 0$,

$$
\mu_{A(x)} - f(x)(t + \epsilon) \geq T \left( \mu_{A(x)} - 2^n f \left( \frac{x}{2^n} \right)(\epsilon), \mu_{2^n f \left( \frac{x}{2^n} \right)} - f(x)(t) \right) 
$$

(3.8)

$$
\geq T \left( \mu_{A(x)} - 2^n f \left( \frac{x}{2^n} \right)(\epsilon), \mu'_{\varphi(\epsilon,2x,x)} \left( \frac{t}{\sum_{k=0}^{n-1} 2^k \alpha^{k+1}} \right) \right).
$$

Taking $n \to \infty$ in (3.8), we get

$$
\mu_{A(x)} - f(x)(t + \epsilon) \geq \mu'_{\varphi(\epsilon,2x,x)} \left( \frac{1 - 2\alpha t}{\alpha} \right).
$$

(3.9)

Since $\epsilon$ is arbitrary, by taking $\epsilon \to 0$ in (3.9), we get

$$
\mu_{A(x)} - f(x)(t) \geq \mu'_{\varphi(\epsilon,2x,x)} \left( \frac{1 - 2\alpha t}{\alpha} \right).
$$

Replacing $x, y$ and $z$ by $\frac{x}{2^n}, \frac{y}{2^n}$ and $\frac{z}{2^n}$ in (3.2), respectively, we get

$$
\mu_{2^n f \left( \frac{x + y + z}{2^n} \right)} - 2^n f \left( \frac{x}{2^n} \right)(t) \geq \mu'_{\varphi(\epsilon,2x,x)} \left( \frac{t}{2^n} \right)
$$

for all $x, y, z \in X$ and $t > 0$. Since $\lim_{n \to \infty} \mu'_{\varphi(\epsilon,2x,x)} \left( \frac{t}{2^n} \right) = 1$, we conclude that $A$ satisfies (0.1). On the other hand

$$
2A \left( \frac{x}{2^n} \right) - A(x) = \lim_{n \to \infty} 2^{n+1} f \left( \frac{x}{2^{n+1}} \right) - \lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right) = 0.
$$

This implies that $A : X \to Y$ is an additive mapping. To prove the uniqueness of the additive mapping $A$, assume that there exists another additive mapping $L : X \to Y$ which satisfies (3.3). Then we have

$$
\mu_{A(x)} - L(x)(t) = \lim_{n \to \infty} \mu_{2^n A \left( \frac{x}{2^n} \right)} - 2^n L \left( \frac{x}{2^n} \right)(t)
$$

$$
\geq \lim_{n \to \infty} \min \left\{ \mu_{2^n A \left( \frac{x}{2^n} \right)} - 2^n L \left( \frac{x}{2^n} \right) \left( \frac{t}{2^n} \right), \mu_{2^n f \left( \frac{x}{2^n} \right)} - 2^n L \left( \frac{x}{2^n} \right) \left( \frac{t}{2^n} \right) \right\}
$$

$$
\geq \lim_{n \to \infty} \mu'_{\varphi(\epsilon,2x,x)} \left( \frac{1 - 2\alpha t}{2^n \alpha^n} \right) \geq \lim_{n \to \infty} \mu'_{\varphi(\epsilon,2x,x)} \left( \frac{1 - 2\alpha t}{2^n \alpha^n} \right).
$$

Since $\lim_{n \to \infty} \mu'_{\varphi(\epsilon,2x,x)} \left( \frac{1 - 2\alpha t}{2^n \alpha^n} \right) = 1$. Therefore, it follows that $\mu_{A(x)} - L(x)(t) = 1$ for all $t > 0$ and so $A(x) = L(x)$. This completes the proof. \qed

**Corollary 3.2.** Let $X$ be a real normed linear space, $(Z, \mu', \min)$ be an RN-space and $(Y, \mu, \min)$ be a complete RN-space. Let $r$ be a positive
real number with \( r > 1 \), \( z_0 \in Z \) and \( f : X \to Y \) be a mapping satisfying

\[
\mu_f(\frac{t}{2} + \frac{t}{2}) - f(\frac{t}{2}) - f(\frac{t}{2}) \geq \mu'_{f(\frac{t}{2})}(t)
\]

for all \( x, y \in X \) and \( t > 0 \). Then the limit \( A(x) = \lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right) \) exists for all \( x \in X \) and defines a unique additive mapping \( A : X \to Y \) such that and

\[
\mu_f(x) - A(x)(t) \geq \mu'_f \left( \frac{t}{2} - 2 \right) \left( \frac{2^r - 2}{2^r + 2} \right)
\]

for all \( x \in X \) and \( t > 0 \).

**Proof.** Let \( \alpha = 2^{-r} \) and \( \varphi : X^3 \to Z \) be a mapping defined by \( \varphi(x, y, z) = (\|x\|^r + \|y\|^r + \|z\|^r)z_0 \). Then, from Theorem 3.1, the conclusion follows.

**Theorem 3.3.** Let \( X \) be a real linear space, \( (Z, \mu', \min) \) be an RN-space and \( \varphi : X^3 \to Z \) be a function such that there exists \( 0 < \alpha < 2 \) such that \( \mu'_{\varphi(2x, 2y, 2z)}(t) \geq \mu'_{\varphi(x, y, z)}(t) \) for all \( x \in X \) and \( t > 0 \) and

\[
\lim_{n \to \infty} \mu'_{\varphi(2^n x, 2^n y, 2^n z)}(2^n x) = 1
\]

for all \( x, y, z \in X \) and \( t > 0 \). Let \( (Y, \mu, \min) \) be a complete RN-space. If \( f : X \to Y \) be a mapping satisfying (3.2). Then the limit \( A(x) = \lim_{n \to \infty} \frac{f(2^n x)}{2^n} \) exists for all \( x \in X \) and defines a unique additive mapping \( A : X \to Y \) such that and

\[
\mu_f(x) - A(x)(t) \geq \mu'_{\varphi(x, 2x, x)}((2 - \alpha)t).
\]

for all \( x \in X \) and \( t > 0 \).

**Proof.** It follows from (3.4) that

\[
\mu'_{\varphi(2x)}(t) \geq \mu'_{\varphi(x, 2x, x)}(2t).
\]

Replacing \( x \) by \( 2^n x \) in (3.12), we obtain that

\[
\mu'_{\varphi(2^n x)}(t) \geq \mu'_{\varphi(2^n x, 2^n x, 2^n x)}(2^n t) \geq \mu'_{\varphi(x, 2x, x)} \left( \frac{2^n t}{\alpha^n} \right).
\]

The rest of the proof is similar to the proof of Theorem 3.1.

**Corollary 3.4.** Let \( X \) be a real normed linear space, \( (Z, \mu', \min) \) be an RN-space and \( (Y, \mu, \min) \) be a complete RN-space. Let \( r \) be a positive real number with \( 0 < r < 1 \), \( z_0 \in Z \) and \( f : X \to Y \) be a mapping
satisfying (3.10). Then the limit \( A(x) = \lim_{n \to \infty} f(2^n x) \) exists for all \( x \in X \) and defines a unique additive mapping \( A : X \to Y \) such that

\[
\mu_{f(x) - A(x)}(t) \geq \mu'_{\|x\|^p z_0} \left( \frac{(2 - 2^p) t}{2^p + 2} \right)
\]

for all \( x \in X \) and \( t > 0 \).

**Proof.** Let \( \alpha = 2^p \) and \( \varphi : X^3 \to Z \) be a mapping defined by \( \varphi(x, y, z) = (\|x\|^r + \|y\|^r + \|z\|^r) z_0 \). Then, from Theorem 3.3, the conclusion follows. \( \square \)

### 3.2. Fixed Point Method.

**Theorem 3.5.** Let \( X \) be a linear space, \( (Y, \mu, T_M) \) be a complete RN-space and \( \Phi \) be a mapping from \( X^3 \) to \( D^+ \) (\( \Phi(x, y, z) \) is denoted by \( \Phi_{x,y,z} \)) such that there exists \( 0 < \alpha < \frac{1}{2} \) such that

\[
(3.13) \quad \Phi_{2x, 2y, 2z}(t) \leq \Phi_{x,y,z}(\alpha t)
\]

for all \( x, y, z \in X \) and \( t > 0 \). Let \( f : X \to Y \) be a mapping satisfying

\[
(3.14) \quad \mu_{f(\frac{x+y+z}{2}) + f(\frac{x-y+z}{2}) - f(x) - f(z)}(t) \geq \Phi_{x,y,z}(t)
\]

for all \( x, y, z \in X \) and \( t > 0 \). Then, for all \( x \in X \), \( A(x) := \lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right) \) exists and \( A : X \to Y \) is a unique additive mapping such that

\[
(3.15) \quad \mu_{f(x) - A(x)}(t) \geq \Phi_{x,2x,x} \left( \frac{1 - 2\alpha t}{\alpha} \right)
\]

for all \( x \in X \) and \( t > 0 \).

**Proof.** Putting \( y = 2x \) and \( z = x \) in (3.14), we have

\[
(3.16) \quad \mu_{2f(\frac{x+y}{2}) - f(x)}(t) \geq \Phi_{x,2x,x}(t) \geq \Phi_{x,2x,x} \left( \frac{t}{\alpha} \right)
\]

for all \( x \in X \) and \( t > 0 \). Consider the set \( S := \{ g : X \to Y \} \) and the generalized metric \( d \) in \( S \) defined by

\[
(3.17) \quad d(f, g) = \inf_{u \in (0, \infty)} \left\{ \mu_{g(x) - h(x)}(ut) \geq \Phi_{x,2x,x}(t), \forall x \in X, t > 0 \right\},
\]

where \( \inf \emptyset = +\infty \). It is easy to show that \( (S, d) \) is complete (see [34], Lemma 2.1). Now, we consider a linear mapping \( J : (S, d) \to (S, d) \) such that

\[
(3.18) \quad Jh(x) := 2h \left( \frac{x}{2} \right)
\]
for all \(x \in X\). First, we prove that \(J\) is a strictly contractive mapping with the Lipschitz constant \(2\alpha\). In fact, let \(g, h \in S\) be such that \(d(g, h) < \epsilon\). Then we have \(\mu_{g(x)-h(x)}(\epsilon t) \geq \Phi_{x,2x,x}(t)\) for all \(x \in X\) and \(t > 0\) and so

\[
\mu_{Jg(x)-Jh(x)}(2\alpha \epsilon t) = \mu_{2g(x)-2h(x)}(2\alpha \epsilon t) = \mu_{g(x)-h(x)}(\epsilon t) \geq \Phi_{x,2x,x}(t) \geq \Phi_{x,2x,x}(t)
\]

for all \(x \in X\) and \(t > 0\). Thus \(d(g, h) < \epsilon\) implies that \(d(Jg, Jh) < 2\alpha\epsilon\). This means that \(d(Jg, Jh) \leq 2\alpha d(g, h)\) for all \(g, h \in S\). It follows from (3.16) that

\[
d(f, Jf) \leq \alpha.
\]

By Theorem 1.14, there exists a mapping \(A : X \to Y\) satisfying the following:

(1) \(A\) is a fixed point of \(J\), that is,

\[
A\left(\frac{x}{2}\right) = \frac{1}{2} A(x)
\]

for all \(x \in X\). The mapping \(A\) is a unique fixed point of \(J\) in the set \(\Omega = \{h \in S : d(g, h) < \infty\}\). This implies that \(A\) is a unique mapping satisfying (3.19) such that there exists \(u \in (0, \infty)\) satisfying \(\mu_{f(x)-A(x)}(ut) \geq \Phi_{x,2x,x}(t)\) for all \(x \in X\) and \(t > 0\).

(2) \(d(J^n f, A) \to 0\) as \(n \to \infty\). This implies the equality

\[
\lim_{n \to \infty} 2^n f\left(\frac{x}{2^n}\right) = A(x)
\]

for all \(x \in X\).

(3) \(d(f, A) \leq \frac{d(f, Jf)}{1-2\alpha}\) with \(f \in \Omega\), which implies the inequality \(d(f, A) \leq \frac{\alpha}{1-2\alpha}\) and so

\[
\mu_{f(x)-A(x)}\left(\frac{\alpha t}{1-2\alpha}\right) \geq \Phi_{x,2x,x}(t)
\]

for all \(x \in X\) and \(t > 0\). This implies that the inequality (3.15) holds. On the other hand

\[
\mu_{2^n f\left(\frac{x+y+z}{2^n}t\right)+2^n f\left(\frac{x+y+z}{2^n}t\right)} \geq \Phi_{x,2x,x}(t) \geq \Phi_{\frac{x}{2^n},\frac{y}{2^n},\frac{z}{2^n}}\left(\frac{t}{2^n}\right)
\]

for all \(x, y, z \in X\), \(t > 0\) and \(n \geq 1\). By (3.13), we know that

\[
\Phi_{\frac{x}{2^n},\frac{y}{2^n},\frac{z}{2^n}}\left(\frac{t}{2^n}\right) \geq \Phi_{x,y,z}\left(\frac{t}{(2\alpha)^n}\right).
\]
Since \( \lim_{n \to \infty} \Phi_{x,y,z} \left( \frac{t}{(2\alpha)^n} \right) = 1 \) for all \( x, y, z \in X \) and \( t > 0 \), we have
\[
\mu_{A(\frac{x+y+z}{2}) + A(\frac{x-y+z}{2}) - A(x) - A(z)}(t) = 1
\]
for all \( x, y, z \in X \) and \( t > 0 \). Thus the mapping \( A : X \to Y \) satisfying (0.1). Furthermore
\[
A(2x) - 2A(x) = \lim_{n \to \infty} 2^n f \left( \frac{x}{2^{n-1}} \right) - 2 \lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right)
\]
\[
= 2 \left[ \lim_{n \to \infty} 2^{n-1} f \left( \frac{x}{2^{n-1}} \right) - \lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right) \right] = 0.
\]
This completes the proof. \( \square \)

**Corollary 3.6.** Let \( X \) be a real normed space, \( \theta \geq 0 \) and \( r \) be a real number with \( r > 1 \). Let \( f : X \to Y \) be a mapping satisfying (3.20)
\[
\mu_{f(\frac{x+y+z}{2}) + f(\frac{x-y+z}{2}) - f(x) - f(z)}(t) \geq \frac{t}{t + \theta(\|x\|^r + \|y\|^r + \|z\|^r)}
\]
for all \( x, y, z \in X \) and \( t > 0 \). Then \( A(x) = \lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right) \) exists for all \( x \in X \) and \( A : X \to Y \) is a unique additive mapping such that
\[
\mu_{f(x) - A(x)}(t) \geq \frac{(2^r - 2)t}{(2^r - 2)t + (2^r + 2)\theta\|x\|^r}
\]
for all \( x \in X \) and \( t > 0 \).

**Proof.** The proof follows from Theorem 3.5 if we take
\[
\Phi_{x,y,z}(t) = \frac{t}{t + \theta(\|x\|^r + \|y\|^r + \|z\|^r)}
\]
for all \( x, y, z \in X \) and \( t > 0 \). In fact, if we choose \( \alpha = 2^{-r} \), then we get the desired result. \( \square \)

**Theorem 3.7.** Let \( X \) be a linear space, \( (Y, \mu, T_M) \) be a complete RN-space and \( \Phi \) be a mapping from \( X^3 \) to \( D^+ \) (\( \Phi(x,y,z) \) is denoted by \( \Phi_{x,y,z} \)) such that for some \( 0 < \alpha < 2 \)
\[
\Phi_{\frac{x+y+z}{2}, \frac{x-y+z}{2}, \frac{x+y-z}{2}}(t) \leq \Phi_{x,y,z}(\alpha t)
\]
for all \( x, y, z \in X \) and \( t > 0 \). Let \( f : X \to Y \) be a mapping satisfying (3.14). Then the limit \( A(x) := \lim_{n \to \infty} f \left( \frac{2^n x}{2^n} \right) \) exists for all \( x \in X \) and \( A : X \to Y \) is a unique additive mapping such that
\[
\mu_{f(x) - A(x)}(t) \geq \Phi_{2x,2x,2x}(\alpha t)
\]
for all \( x \in X \) and \( t > 0 \).
Proof. Putting $y = 2x$ and $z = x$ in (3.14), we have

\[(3.22) \quad \mu_{f(2x)} f(x)(t) \geq \Phi_{x,2x,x}(2t)\]

for all $x \in X$ and $t > 0$. Let $(S, d)$ be the generalized metric space defined in the proof of Theorem 3.1. Now, we consider a linear mapping $J : (S, d) \to (S, d)$ such that

\[(3.23) \quad Jh(x) := \frac{1}{2} h(2x)\]

for all $x \in X$. It follows from (3.22) that $d(f, Jf) \leq \frac{1}{2}$. By Theorem 1.14, there exists a mapping $A : X \to Y$ satisfying the following:

1. $A$ is a fixed point of $J$, that is,

\[(3.24) \quad A(2x) = 2A(x)\]

for all $x \in X$. The mapping $A$ is a unique fixed point of $J$ in the set $\Omega = \{ h \in S : d(g, h) < \infty \}$. This implies that $A$ is a unique mapping satisfying (3.24) such that there exists $u \in (0, \infty)$ satisfying $\mu_{f(x) - A(x)}(ut) \geq \Phi_{x,2x,x}(t)$ for all $x \in X$ and $t > 0$.

2. $d(J^n f, A) \to 0$ as $n \to \infty$. This implies the equality

\[\lim_{n \to \infty} \frac{f(2^n x)}{2^n} = A(x)\]

for all $x \in X$.

3. $d(f, A) \leq \frac{d(f,Jf)}{1-\frac{1}{2}}$ with $f \in \Omega$, which implies the inequality

\[\mu_{f(x) - A(x)} \left( \frac{t}{2 - \alpha} \right) \geq \Phi_{x,2x,x}(t)\]

for all $x \in X$ and $t > 0$. This implies that the inequality (3.21) holds. The rest of the proof is similar to the proof of Theorem 3.5. □

**Corollary 3.8.** Let $X$ be a real normed space, $\theta \geq 0$ and $r$ be a real number with $0 < r < 1$. Let $f : X \to Y$ be a mapping satisfying (3.20). Then the limit $A(x) = \lim_{n \to \infty} \frac{f(2^n x)}{2^n}$ exists for all $x \in X$ and $A : X \to Y$ is a unique additive mapping such that

\[\mu_{f(x) - A(x)}(t) \geq \frac{(2 - 2^r)t}{(2 - 2^r)t + (2^r + 2)\theta \|x\|^r}\]

for all $x \in X$ and $t > 0$.

**Proof.** The proof follows from Theorem 3.7 if we take

\[\Phi_{x,y}(t) = \frac{t}{t + \theta(\|x\|^r + \|y\|^r + \|z\|^r)}\]
for all $x, y, z \in X$ and $t > 0$. In fact, if we choose $\alpha = 2^r$, then we get the desired result. □

4. Fuzzy Stability of Functional Equation (0.1)

Throughout this section, using the fixed point and direct methods, we prove the generalized Hyers-Ulam-Rassias stability of functional equation (0.1) in fuzzy normed spaces.

4.1. a direct method.

In this section, using direct method, we prove the Hyers-Ulam-Rassias stability of functional equation (0.1) in fuzzy Banach spaces. Throughout this section, we assume that $X$ is a linear space, $(Y, N)$ is a fuzzy Banach space and $(Z, N')$ is a fuzzy normed spaces. Moreover, we assume that $N(x, .)$ is a left continuous function on $\mathbb{R}$.

**Theorem 4.1.** Assume that a mapping $f : X \to Y$ satisfies the inequality

$$N \left( f \left( \frac{x + y + z}{2} \right) + f \left( \frac{x - y + z}{2} \right) - f(x) - f(z), t \right) \geq N'(\varphi(x, y, z), t)$$

(4.1)

for all $x, y, z \in X, t > 0$ and $\varphi : X^3 \to Z$ is a mapping for which there is a constant $r \in \mathbb{R}$ satisfying $0 < |r| < \frac{1}{2}$ such that

$$N' \left( \varphi \left( \frac{x}{2}, \frac{y}{2}, \frac{z}{2} \right), t \right) \geq N' \left( \varphi(x, y, z), \frac{t}{|r|} \right)$$

(4.2)

for all $x, y, z \in X$ and all $t > 0$. Then we can find a unique additive mapping $A : X \to Y$ satisfying (0.1) and the inequality

$$N(f(x) - A(x), t) \geq N' \left( \frac{|r| \varphi(2x, x)}{1 - 2|r|}, t \right)$$

(4.3)

for all $x \in X$ and all $t > 0$.

**Proof.** It follows from (4.2) that

$$N' \left( \varphi \left( \frac{x}{2}, \frac{y}{2}, \frac{z}{2} \right), t \right) \geq N' \left( \varphi(x, y, z), \frac{t}{|r|^2} \right).$$

(4.4)
So $N'(\varphi(\frac{x}{2^n}, \frac{y}{2^n}, \frac{z}{2^n}), |r|^{j}t) \geq N'(\varphi(x, y, z), t)$ for all $x, y, z \in X$ and all $t > 0$.

Substituting $y = 2x$ and $z = x$ in (4.1), we obtain

$$N(f(2x) - 2f(x), t) \geq N'(\varphi(x, 2x, x), t)$$

(4.5)

So

$$N(f(x) - 2f\left(\frac{x}{2}\right), t) \geq N'(\varphi\left(\frac{x}{2}, \frac{x}{2}, \frac{x}{2}\right), t)$$

(4.6)

for all $x \in X$ and all $t > 0$. Replacing $x$ by $\frac{x}{2^n}$ in (4.6), we have

$$N\left(2^{j+1}f\left(\frac{x}{2^{j+1}}\right) - 2^jf\left(\frac{x}{2^j}\right), 2^jt\right) \geq N'(\varphi\left(\frac{x}{2^{j+1}}, \frac{x}{2^j}, \frac{x}{2^j}\right), t)$$

(4.7)

for all $x \in X$, all $t > 0$ and any integer $j \geq 0$. So

$$N\left(f(x) - 2^n f\left(\frac{x}{2^n}\right), \sum_{j=0}^{n-1} 2^j |r|^{j+1}t\right) = N\left(\sum_{j=0}^{n-1} \left[2^{j+1}f\left(\frac{x}{2^{j+1}}\right) - 2^jf\left(\frac{x}{2^j}\right)\right], \sum_{j=0}^{n-1} 2^j |r|^{j+1}t\right)$$

$$\geq \min_{0 \leq j \leq n-1} \left\{ N\left(2^{j+1}f\left(\frac{x}{2^{j+1}}\right) - 2^jf\left(\frac{x}{2^j}\right), 2^j |r|^{j+1}t\right) \right\}$$

$$\geq N'(\varphi(x, 2x, x), t)$$

which yields

$$N\left(2^n + pf\left(\frac{x}{2^n+p}\right) - 2^pf\left(\frac{x}{2^p}\right), \sum_{j=0}^{n-1} 2^j |r|^{j+1}t\right) \geq N'(\varphi\left(\frac{x}{2^n+p}, \frac{x}{2^p}, \frac{x}{2^p}\right), t)$$

$$\geq N'(\varphi(x, 2x, x), \frac{t}{|r|^p})$$

for all $x \in X, t > 0$ and any integers $n > 0, p \geq 0$. So

$$N\left(2^n + pf\left(\frac{x}{2^n+p}\right) - 2^pf\left(\frac{x}{2^p}\right), \sum_{j=0}^{n-1} 2^j |p|^{j+p+1}t\right) \geq N'(\varphi(x, 2x, x), t)$$

for all $x \in X, t > 0$ and any integers $n > 0, p \geq 0$. Hence one obtains

$$N\left(2^n + pf\left(\frac{x}{2^n+p}\right) - 2^pf\left(\frac{x}{2^p}\right), t\right)$$

(4.8)

$$\geq N'(\varphi(x, 2x, x), \sum_{j=0}^{n-1} \frac{t}{2^j |r|^{j+p+1}})$$
for all \( x \in X, t > 0 \) and any integers \( n > 0, p \geq 0 \). Since, the series
\[
\sum_{j=0}^{\infty} 2^j |r|^j
\]
is convergent series, we see by taking the limit \( p \to \infty \) in the last inequality that a sequence \( \{2^n f \left( \frac{x}{2^n} \right) \} \) is a Cauchy sequence in the fuzzy Banach space \((Y, N)\) and so it converges in \( Y \). Therefore a mapping \( A : X \to Y \) defined by \( A(x) := N - \lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right) \) is well defined for all \( x \in X \). It means that
\[
(4.9) \quad \lim_{n \to \infty} N \left( A(x) - 2^n f \left( \frac{x}{2^n} \right), t \right) = 1
\]
for all \( x \in X \) and all \( t > 0 \). In addition, it follows from (4.8) that
\[
N \left( 2^n f \left( \frac{x}{2^n} \right) - f(x), t \right) \geq N' \left( \varphi(x, 2x, x), \frac{t}{\sum_{j=0}^{n-1} 2^j |r|^j} \right)
\]
for all \( x \in X \) and all \( t > 0 \). So
\[
N(f(x) - A(x), t) \\
\geq \min \left\{ N \left( f(x) - 2^n f \left( \frac{x}{2^n} \right), (1 - \epsilon)t \right), N \left( A(x) - 2^n f \left( \frac{x}{2^n} \right), \epsilon t \right) \right\} \\
\geq N' \left( \varphi(x, 2x, x), \frac{t}{\sum_{j=0}^{n-1} 2^j |r|^j} \right) \geq N' \left( \varphi(x, 2x, x), \frac{(1 - 2|r|) \epsilon t}{|r|} \right)
\]
for sufficiently large \( n \) and for all \( x \in X, t > 0 \) and \( \epsilon \) with \( 0 < \epsilon < 1 \). Since \( \epsilon \) is arbitrary and \( N' \) is left continuous, we obtain
\[
N(f(x) - A(x), t) \geq N' \left( \varphi(x, 2x, x), \frac{(1 - 2|r|) t}{|r|} \right)
\]
for all \( x \in X \) and \( t > 0 \). It follows from (4.1) that
\[
N \left( 2^n f \left( \frac{x + y + z}{2^n + 1} \right) + 2^n f \left( \frac{x - y + z}{2^n + 1} \right) - 2^n f \left( \frac{x}{2^n} \right) - 2^n f \left( \frac{z}{2^n} \right), t \right) \\
\geq N' \left( \varphi \left( \frac{x}{2^n}, \frac{y}{2^n}, \frac{z}{2^n} \right), \frac{t}{2^n} \right) \geq N' \left( \varphi(x, y, z), \frac{t}{2^n |r|^n} \right)
\]
for all \( x, y, z \in X, t > 0 \) and all \( n \in \mathbb{N} \). Since
\[
\lim_{n \to \infty} N' \left( \varphi(x, y, z), \frac{t}{2^n |r|^n} \right) = 1
\]
and so
\[ N \left( 2^n f \left( \frac{x+y+z}{2^{n+1}} \right) + 2^n f \left( \frac{x-y+z}{2^{n+1}} \right) - 2^n f \left( \frac{x}{2^n} \right) - 2^n f \left( \frac{z}{2^n} \right), t \right) \to 1 \]
for all \( x, y, z \in X \) and all \( t > 0 \). Therefore, we obtain in view of (4.9)
\[
N \left( A \left( \frac{x+y+z}{2} \right) + A \left( \frac{x-y+z}{2} \right) - A(x) - A(z), t \right)
\geq \min \left\{ N \left( A \left( \frac{x+y+z}{2} \right) + A \left( \frac{x-y+z}{2} \right) - A(x) - A(z) \right), \right.
2^n f \left( \frac{x+y+z}{2^{n+1}} \right) + 2^n f \left( \frac{x-y+z}{2^{n+1}} \right) - 2^n f \left( \frac{x}{2^n} \right) - 2^n f \left( \frac{z}{2^n} \right), t \right\}
\]
\[
= N \left( 2^n f \left( \frac{x+y+z}{2^{n+1}} \right) + 2^n f \left( \frac{x-y+z}{2^{n+1}} \right) - 2^n f \left( \frac{x}{2^n} \right) - 2^n f \left( \frac{z}{2^n} \right), t \right) \to 1 \text{ as } n \to \infty
\]
which implies
\[ A \left( \frac{x+y+z}{2} \right) + A \left( \frac{x-y+z}{2} \right) = A(x) + A(z) \]
for all \( x, y, z \in X \). Thus \( A : X \to Y \) is a mapping satisfying the equation (0.1) and the inequality (4.3).
To prove the uniqueness, let there is another mapping \( L : X \to Y \) which satisfies the inequality (4.3). Since \( L(2^n x) = 2^n L(x) \) for all \( x \in X \), we have
\[
N(A(x) - L(x), t)
= N \left( 2^n A \left( \frac{x}{2^n} \right) - 2^n L \left( \frac{x}{2^n} \right), t \right)
\geq \min \left\{ N \left( 2^n A \left( \frac{x}{2^n} \right) - 2^n f \left( \frac{x}{2^n} \right), t \right), N \left( 2^n f \left( \frac{x}{2^n} \right) - 2^n L \left( \frac{x}{2^n} \right), t \right) \right\}
\geq N \left( \varphi \left( \frac{x}{2^n} \frac{2^n x}{2^n}, \frac{1-2|t|}{|t|} \right), \frac{1-2|t|}{|t|} \right) \to 1 \text{ as } n \to \infty
\]
for all \( t > 0 \). Therefore \( A(x) = L(x) \) for all \( x \in X \), this completes the proof. \( \square \)
Corollary 4.2. Let $X$ be a normed spaces and that $(\mathbb{R}, N')$ a fuzzy Banach space. Assume that there exists real number $\theta \geq 0$ and $0 < p < 2$ such that a mapping $f : X \to Y$ with $f(0) = 0$ satisfying the following inequality

$$N\left(f\left(\frac{x+y+z}{2}\right) + f\left(\frac{x-y+z}{2}\right) - f(x) - f(z), t\right) \geq N'(\theta (\|x\|^p + \|y\|^p + \|z\|^p), t)$$

for all $x, y, z \in X$ and $t > 0$. Then there is a unique additive mapping $A : X \to Y$ that satisfying (0.1) and the inequality

$$N(f(x) - A(x), t) \geq N'(\frac{(2r+2)\theta \|x\|^p}{2}, t)$$

Proof. Let $\varphi(x, y, z) := \theta (\|x\|^p + \|y\|^p + \|z\|^p)$ and $|r| = \frac{1}{4}$. Apply Theorem 4.1, we get desired results. □

Theorem 4.3. Assume that a mapping $f : X \to Y$ satisfies the inequality (4.1) and $\varphi : X^2 \to Z$ is a mapping for which there is a constant $r \in \mathbb{R}$ satisfying $0 < |r| < 2$ such that

$$N'(\varphi(x, y, z), |r| t) \geq N'(\varphi\left(\frac{x}{2}, \frac{y}{2}, \frac{z}{2}\right), t)$$

for all $x, y, z \in X$ and all $t > 0$. Then we can find a unique additive mapping $A : X \to Y$ that satisfying (0.1) and the following inequality

$$N(f(x) - A(x), t) \geq N'(\varphi(x, 2x, x), t)$$

for all $x \in X$ and all $t > 0$.

Proof. It follows from (4.5) that

$$N\left(f\left(\frac{2x}{2^n+1}\right) - f(x), \frac{t}{2^n+1}\right) \geq N'(\varphi(x, 2x, x), t)$$

for all $x \in X$ and all $t > 0$. Replacing $x$ by $2^n x$ in (4.12), we obtain

$$N\left(f\left(\frac{2^{n+1}x}{2^{n+1}}\right) - f(2^n x), \frac{t}{2^{n+1}}\right) \geq N'(\varphi(2^n x, 2^{n+1} x, 2^n x), t)$$

$$\geq N'(\frac{\varphi(x, 2x, x)}{|r|^n}, \frac{t}{|r|^n})$$

So

$$N\left(f\left(\frac{2^{n+1}x}{2^{n+1}}\right) - f(2^n x), \frac{|r|^n t}{2^{n+1}}\right) \geq N'(\varphi(x, 2x, x), t)$$
for all $x \in X$ and all $t > 0$. Proceeding as in the proof of Theorem 4.1, we obtain that

$$N \left( f(x) - f(2^nx) \right) \geq N'(\varphi(x, 2x, x), t) \geq N'(\varphi(x, 2x, x), \sum_{j=0}^{n-1} \frac{|r|^j}{2^n}, t)$$

for all $x \in X$, all $t > 0$ and any integer $n > 0$. So

$$N \left( f(x) - f(2^nx) \right) \geq N'(\varphi(x, 2x, x), \sum_{j=0}^{n-1} \frac{|r|^j}{2^n}, t) \geq N'(\varphi(x, 2x, x), (2 - |r|)t).$$

(4.15)

The rest of the proof is similar to the proof of Theorem 4.1.

**Corollary 4.4.** Let $X$ be a normed spaces and that $(\mathbb{R}, N')$ a fuzzy Banach space. Assume that there exists real number $\theta \geq 0$ and $0 < p = p_1 + p_2 + p_3 < 2$ such that a mapping $f : X \rightarrow Y$ satisfying the following inequality

$$N \left( f \left( \frac{x + y + z}{2} \right) + f \left( \frac{x - y + z}{2} \right) - f(x) - f(z), t \right) \geq N'(\varphi(x, 2x, x), \sum_{j=0}^{n-1} \frac{|r|^j}{2^n}, t)$$

for all $x, y, z \in X$ and $t > 0$. Then there is a unique additive mapping $A : X \rightarrow Y$ that satisfying (0.1) and the inequality

$$N(f(x) - A(x), t) \geq N'((2r + 2)\theta ||x||^p, t)$$

Proof. Let $\varphi(x, y, z) := \theta (||x||^{p_1} \cdot ||y||^{p_2} \cdot ||z||^{p_3})$ and $|r| = 1$. Apply Theorem 4.3, we get desired results. \qed

4.2. a fixed point method.

Throughout this subsection, using the fixed point alternative approach we prove the Hyers-Ulam-Rassias stability of functional equation (0.1) in fuzzy Banach spaces. In this subsection, assume that $X$ is a vector space and that $(Y, N)$ is a fuzzy Banach space.

**Theorem 4.5.** Let $\varphi : X^3 \rightarrow [0, \infty)$ be a function such that there exists an $L < 1$ with

$$\varphi \left( \frac{x}{2}, \frac{y}{2}, \frac{z}{2} \right) \leq \frac{L\varphi(x, y, z)}{2}$$
Stability of functional equations

for all $x, y, z \in X$. Let $f : X \to Y$ be a mapping satisfying

$$\tag{4.16} N \left( f \left( \frac{x + y + z}{2} \right) + f \left( \frac{x - y + z}{2} \right) - f(x) - f(z), t \right) \geq \frac{t}{t + \varphi(x, y, z)}$$

for all $x, y, z \in X$ and all $t > 0$. Then, the limit $A(x) := N \lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right)$ exists for each $x \in X$ and defines a unique additive mapping $A : X \to Y$ such that

$$\tag{4.17} N(f(x) - A(x), t) \geq \frac{(2 - 2L)t}{(2 - 2L)t + L\varphi(x, 2x, x)}.$$

Proof. Putting $y = 2x$ and $z = x$ in (4.16) and replacing $x$ by $\frac{x}{2}$, we have

$$\tag{4.18} N \left( 2f \left( \frac{x}{2} \right) - f(x), t \right) \geq \frac{t}{t + \varphi \left( \frac{x}{2}, x, \frac{x}{2} \right)}$$

for all $x \in X$ and $t > 0$. Consider the set $S := \{g : X \to Y\}$ and the generalized metric $d$ in $S$ defined by

$$d(f, g) = \inf \left\{ \mu \in \mathbb{R}^+ : N(g(x) - h(x), \mu t) \geq \frac{t}{t + \varphi(x, 2x, x)}, \forall x \in X, t > 0 \right\},$$

where $\inf \emptyset = +\infty$. It is easy to show that $(S, d)$ is complete (see [34, Lemma 2.1]). Now, we consider a linear mapping $J : S \to S$ such that

$$Jg(x) := 2g \left( \frac{x}{2} \right)$$

for all $x \in X$. Let $g, h \in S$ be such that $d(g, h) = \epsilon$. Then

$$N(g(x) - h(x), \epsilon t) \geq \frac{t}{t + \varphi(x, 2x, x)}$$

for all $x \in X$ and $t > 0$. Hence

$$N(Jg(x) - Jh(x), t) = N \left( 2g \left( \frac{x}{2} \right) - 2h \left( \frac{x}{2} \right), \frac{Lt}{2} \right)$$

$$= N \left( g \left( \frac{x}{2} \right) - h \left( \frac{x}{2} \right), \frac{Lt}{2} \right) \geq \frac{L\varphi(x, 2x, x)}{t} \geq \frac{Lt}{t + \varphi(x, 2x, x)} \geq \frac{Lt}{t + \varphi(x, 2x, x)} = \frac{t}{t + \varphi(x, 2x, x)}$$
for all \(x \in X\) and \(t > 0\). Thus \(d(g, h) = \epsilon\) implies that \(d(Jg, Jh) \leq L\epsilon\). This means that \(d(Jg, Jh) \leq Ld(g, h)\) for all \(g, h \in S\). It follows from (4.18) that

\[
N \left( f(x) - 2f \left( \frac{x}{2} \right), t \right) \geq \frac{t}{t + \varphi \left( \frac{x}{2}, x, \frac{x}{2} \right)} \geq \frac{t}{t + \frac{L\varphi(x, 2x, x)}{2}} = \frac{2t}{t + \varphi(x, 2x, x)}.
\]

Therefore

\[
(4.19) \quad N \left( f(x) - 2f \left( \frac{x}{2} \right), \frac{Lt}{2} \right) \geq \frac{t}{t + \varphi(x, 2x, x)}.
\]

This means that \(d(f, Jf) \leq \frac{Lt}{2}\). By Theorem 1.14, there exists a mapping \(A : X \to Y\) satisfying the following:

(1) \(A\) is a fixed point of \(J\), that is,

\[
(4.20) \quad A \left( \frac{x}{2} \right) = \frac{A(x)}{2}
\]

for all \(x \in X\). The mapping \(A\) is a unique fixed point of \(J\) in the set \(\Omega = \{h \in S : d(g, h) < \infty\}\). This implies that \(A\) is a unique mapping satisfying (4.20) such that there exists \(\mu \in (0, \infty)\) satisfying

\[
N(f(x) - A(x), \mu t) \geq \frac{t}{t + \varphi(x, 2x, x)}
\]

for all \(x \in X\) and \(t > 0\).

(2) \(d(J^n f, A) \to 0\) as \(n \to \infty\). This implies the equality \(N\)-\(lim_{n \to \infty} 2^n f \left( \frac{x}{2^n} \right) = A(x)\) for all \(x \in X\).

(3) \(d(f, A) \leq \frac{d(f, Jf)}{2 - 2L}\) with \(f \in \Omega\), which implies the inequality \(d(f, A) \leq \frac{L}{2 - 2L}\). This implies that the inequality (4.17) holds. Furthermore, since

\[
N \left( A \left( \frac{x + y + z}{2} \right) + A \left( \frac{x - y + z}{2} \right) - A(x) - A(z), t \right)
\]

\[
\geq N - \lim_{n \to \infty} \left( 2^n f \left( \frac{x + y + z}{2n+1} \right) + 2^n f \left( \frac{x - y + z}{2n+1} \right) - 2^n f \left( \frac{x}{2^n} \right) - 2^n f \left( \frac{z}{2^n} \right), t \right)
\]

\[
\geq \lim_{n \to \infty} \frac{t}{2^n + \varphi \left( \frac{x}{2n}, y, \frac{z}{2n} \right)} \geq \lim_{n \to \infty} \frac{t}{2^n + \frac{L^n \varphi(x, y, z)}{2n}} \to 1
\]

for all \(x, y, z \in X, t > 0\). So

\[
N \left( A \left( \frac{x + y + z}{2} \right) + A \left( \frac{x - y + z}{2} \right) - A(x) - A(z), t \right) = 1
\]

for all \(x, y, z \in X\) and all \(t > 0\). Thus the mapping \(A : X \to Y\) is additive, as desired. \(\square\)
Corollary 4.6. Let $\theta \geq 0$ and let $p$ be a real number with $p > 1$. Let $X$ be a normed vector space with norm $\|\cdot\|$. Let $f : X \to Y$ be a mapping satisfying

$$N\left( f\left( \frac{x+y+z}{2} \right) + f\left( \frac{x-y+z}{2} \right) - f(x) - f(z), t \right) \geq \frac{t}{t + \theta (\|x\|^p + \|y\|^p + \|z\|^p)}$$

for all $x, y, z \in X$ and all $t > 0$. Then, the limit

$$A(x) := \lim_{n \to \infty} 2^n f\left( \frac{x}{2^n} \right)$$

exists for each $x \in X$ and defines a unique additive mapping $A : X \to Y$ such that

$$N(f(x) - A(x), t) \geq \frac{(2^p + 1 - 2)Lt}{(2^p + 1 - 2)t + (2^r + 2)\theta \|x\|^p}$$

for all $x \in X$.

Proof. The proof follows from Theorem 4.5 by taking $\varphi(x, y, z) := \theta(\|x\|^p + \|y\|^p + \|z\|^p)$ for all $x, y, z \in X$. Then we can choose $L = 2^{-p}$ and we get the desired result.

Theorem 4.7. Let $\varphi : X^3 \to [0, \infty)$ be a function such that there exists an $L < 1$ with

$$\varphi(x, y, z) \leq 2L \varphi\left( \frac{x}{2}, \frac{y}{2}, \frac{z}{2} \right)$$

for all $x, y, z \in X$. Let $f : X \to Y$ be a mapping satisfying (4.16). Then

$$A(x) := \lim_{n \to \infty} \frac{f(2^n x)}{2^n}$$

exists for each $x \in X$ and defines a unique additive mapping $A : X \to Y$ such that

$$(4.21) \quad N(f(x) - A(x), t) \geq \frac{(2 - 2L)t}{(2 - 2L)t + \varphi(x, 2x, x)}$$

for all $x \in X$ and all $t > 0$.

Proof. Let $(S, d)$ be the generalized metric space defined as in the proof of Theorem 4.1. Consider the linear mapping $J : S \to S$ such that

$$Jg(x) := \frac{g(2x)}{2}$$

for all $x \in X$. Let $g, h \in S$ be such that $d(g, h) = \epsilon$. Then

$$N(g(x) - h(x), \epsilon t) \geq \frac{t}{t + \varphi(x, 2x, x)}$$
for all \( x \in X \) and \( t > 0 \). Hence

\[
N(Jg(x) - Jh(x), Let) = N\left( \frac{g(2x) - h(2x)}{2}, Let \right) \\
= N\left( g(2x) - h(2x), 2Let \right) \geq \frac{2Lt}{2Lt + \varphi(2x, 4x, 2x)} \\
\geq \frac{2Lt}{2Lt + 2L\varphi(2x, x)} = \frac{t}{t + \varphi(x, 2x, x)}
\]

for all \( x \in X \) and \( t > 0 \). Thus \( d(g, h) = \epsilon \) implies that \( d(Jg, Jh) \leq L\epsilon \).

This means that

\[
d(Jg, Jh) \leq Ld(g, h)
\]

for all \( g, h \in S \). It follows from (4.18) that

\[
N\left( \frac{f(2x) - f(x)}{2}, \frac{t}{2} \right) \geq \frac{t}{t + \varphi(x, 2x, x)}.
\]

Therefore

\[
d(f, Jf) \leq \frac{1}{2}.
\]

By Theorem 1.14, there exists a mapping \( A : X \rightarrow Y \) satisfying the following:

(1) \( A \) is a fixed point of \( J \), that is,

\[
2A(x) = A(2x)
\]

for all \( x \in X \). The mapping \( A \) is a unique fixed point of \( J \) in the set \( \Omega = \{ h \in S : d(g, h) < \infty \} \). This implies that \( A \) is a unique mapping satisfying (4.22) such that there exists \( \mu \in (0, \infty) \) satisfying

\[
N(f(x) - A(x), \mu t) \geq \frac{t}{t + \varphi(x, 2x, x)}
\]

for all \( x \in X \) and \( t > 0 \).

(2) \( d(J^n f, A) \rightarrow 0 \) as \( n \rightarrow \infty \). This implies the equality \( N-\lim_{n \rightarrow \infty} \frac{f(2^n x)}{2^n} \) for all \( x \in X \).

(3) \( d(f, A) \leq \frac{d(f, Jf)}{1 - L} \) with \( f \in \Omega \), which implies the inequality \( d(f, A) \leq \frac{1}{2 - 2L} \). This implies that the inequality (4.21) holds. The rest of the proof is similar to that of the proof of Theorem 4.5. \( \square \)

**Corollary 4.8.** Let \( \theta \geq 0 \) and let \( p \) be a real number with \( 0 < p < \frac{1}{3} \). Let \( X \) be a normed vector space with norm \( \| \cdot \| \). Let \( f : X \rightarrow Y \) be a
mapping satisfying
\[
N \left( f \left( \frac{x + y + z}{2} \right) + f \left( \frac{x - y + z}{2} \right) - f(x) - f(z), t \right) \geq \frac{t}{t + \theta \left( \|x\|^p \cdot \|y\|^p \cdot \|z\|^p \right)}
\]
for all \( x, y, z \in X \) and all \( t > 0 \). Then
\[
A(x) := \lim_{n \to \infty} f \left( \frac{2^n x}{2^n} \right)
\]
exists for each \( x \in X \) and defines a unique additive mapping \( A : X \to Y \) such that
\[
N(f(x) - A(x), t) \geq \frac{(2^{1+3p} - 2)t}{(2^{1+3p} - 2)t + 2^{3p} \theta \|x\|^{3p}}
\]
for all \( x \in X \).

Proof. The proof follows from Theorem 4.7 by taking
\[
\varphi(x, y, z) := \theta \left( \|x\|^p \cdot \|y\|^p \cdot \|z\|^p \right)
\]
for all \( x, y, z \in X \). Then we can choose \( L = 2^{-3p} \) and we get the desired result. \( \square \)
