Abstract

We investigate the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ production with a $f_0(980)$ decay into $\pi^+ \pi^-$ via the $K^{*0} K^- K^+$ and $K^{*-} K^0 \bar{K}^0$ triangle loops. These loops produce a peak around 1.42 GeV in the $\pi^- f_0(980)$ invariant mass distribution, which is the same mechanism as the one considered to explain the $a_1(1420)$ peak. In the $\pi^+ \pi^-$ distribution obtained by fixing the $\pi^- f_0(980)$ invariant mass to some values, a clear peak of $f_0(980)$ is seen, and the $\pi^- f_0(980)$ distribution has a peak around $M_{\pi^- f_0} = 1.42$ GeV, which is caused by the triangle mechanism of the $K^* \bar{K} K$ loop. The branching ratio of $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ with $f_0(980) \rightarrow \pi^+ \pi^-$ by the triangle mechanism, obtained by integrating the $\pi^- f_0(980)$ distribution from 1 to 1.6 GeV, is estimated to be the order 10^{-4} . Future measurements of the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ branching ratio and the $\pi^- f_0(980)$ invariant mass distribution predicted in this work would give further clues to clarify the nature of the $a_1(1420)$ peak.

FIG. 1. Triangle diagram relevant to the $\pi f_0(980)$ production.

I. INTRODUCTION

The role of triangle singularities (TSs) in hadronic reactions has been investigated for a long time. A general discussion on the emergence of singularities from loop amplitudes was given by Landau [1], and a physical picture of the singularity from triangle loops was provided in Ref. [2] and is known as the Coleman-Norton theorem; the TSs can show up when all the internal particles are on shell, the momenta of the particles in the loop are collinear, and the process can occur at the classical level. One can find a refined formulation and an intuitive picture of the TS in Ref. [3] (see also Ref. [4] for a recent review of the TS).

One interesting manifestation of the TS is the $\eta(1405/1475) \rightarrow \pi^0 f_0(980)$ decay. An anomalously large production of the $\pi^0 f_0(980)$ decay mode of $\eta(1405/1475)$, which is forbidden by isospin symmetry, was reported by the BESIII Collaboration [5], and that large amount production rate and the narrow $f_0(980)$ line shape in the $\pi\pi$ distribution, which is the order of the mass difference of the charged and neutral kaons due to the isospin symmetry breaking, are explained well by the triangle mechanism [6–9] (see also Ref. [10] for a review article). The triangle diagram considered in the work is composed of $K^* \bar{K} K$ and its charge conjugation shown in Fig. 1. The triangle loop diagram of Fig. 1 has a singularity around 1.42 GeV, which is in the $\eta(1405/1475)$ mass region. In the process, the $K^* \bar{K}$ pair is produced by $\eta(1405/1475)$ first, the K^* decays into πK , and the $K \bar{K}$ couple to $f_0(980)$. The position of the singularity can be obtained with a formula given in Ref. [3]. The triangle singularity plays an essential role in this process because the position of the TS is sensitive to the masses of the particles and the mass difference of K and K^* involved in the triangle loop introduces the isospin violation in this process. In practice, the singularity is turned into a peak by the width of the internal particles, and the detailed study on the width effect was done in Ref. [11]. In Refs. [12, 13], some other processes were studied for further investigation of the anomalous enhancement of the isospin-forbidden $\pi^0 f_0(980)$ production by the

FIG. 2. Triangle loops for the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ process.

triangle mechanism. The TS of the $K^* \bar{K} K$ loop was mentioned in Ref. [14], and the possible role of the $K^* \bar{K} K$ triangle loop has been investigated in many processes [6–9, 11–13, 15–22].

One important aim to study the TS is to clarify the origin of peaks in the invariant mass distribution. The peak of the TS has purely kinematical origin and cannot be associated with a resonant state. A peak of $a_1(1420)$, which is in the p -wave $\pi^- f_0(980)$ mode in the $\pi^- p \rightarrow \pi^+ \pi^- \pi^- p$ reaction, was found by the COMPASS Collaboration [23, 24] followed by the studies on the properties of $a_1(1420)$ [25–29] and the work on the explanation of the peak focusing on its production mechanism [30] (see Ref. [31] for a recent review article, and see also a mini review for mesons in the 1400 MeV region in the Particle Data Group (PDG) [32]). A possible understanding of the peak with the triangle mechanism was suggested in Refs. [17, 18]. The position of the singularity around 1.42 GeV stemming from the $K^* \bar{K} K$ loop coincides with the peak position of $a_1(1420)$. Despite the attempts to clarify the nature of the peak, a significant difference of the resonance and TS scenarios of the $a_1(1420)$ peak has not been found in the partial wave analysis so far [31]. Some predictions based on the TS scenario of the $a_1(1420)$ peak were made in Refs. [20, 21] in the B and τ decays.

In this work, we study the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ with $f_0(980) \rightarrow \pi^+ \pi^-$ via the triangle mechanism of the $K^* \bar{K} K$ loop producing a peak around 1.42 GeV in the $\pi^- f_0(980)$ distribution. We show in Fig. 2 the diagram of the $K^* \bar{K} K$ triangle loop contributing to the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ process. Apart from the $K^* \bar{K}$ production part, the mechanism producing a peak around 1.42 GeV is identical to the one considered in Refs. [17, 18] for the $a_1(1420)$ peak. With known theoretical and experimental information, we make the predictions on the branching ratio and the invariant mass distribution in the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ reaction. Such predictions, including the triangle mechanism, will be important for future experiments to clarify the nature of $a_1(1420)$ as an unavoidable peak of the kinematical effect.

FIG. 3. Quark-level diagrams for the Λ_b decay.

II. SETUP

The diagrams we consider in this study are shown in Fig. 2. Here, we focus on the diagram Fig. 2(a) in which a loop is formed by $K^{*0}K^-K^+$; Λ_b first decays into $\Lambda_c K^{*0}K^-$, and subsequently K^{*0} turns into the $\pi^- K^+$ with a merging of K^+ and K^- to give $f_0(980)$. The $f_0(980)$ finally decays into a $\pi^+\pi^-$ pair. Strictly speaking, this $K^*\bar{K}K$ loop for the $\pi^- f_0(980)$ production does not have the TS because the mass of $f_0(980)$ is slightly below the $K\bar{K}$ threshold; i.e., the $K\bar{K}$ in the loop cannot be on shell. However, in the distribution the remnant of the TS would be still expected due to the width of the particles. For example, by putting the $f_0(980)$ mass slightly above the $K\bar{K}$ threshold, with the formula in Ref. [3], the loop amplitude produces a TS around $M_{\pi^- f_0} = 1.42$ GeV in the $\pi^- f_0(980)$ invariant mass distribution.

In this section, the amplitude needed to evaluate the diagram in Fig. 2, the $\Lambda_b \rightarrow \Lambda_c K^* \bar{K}$, $K^* \rightarrow \pi K$, and $K\bar{K} \rightarrow \pi^+\pi^-$ transition amplitudes, will be explained, and the amplitude of the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ decay with $f_0(980) \rightarrow \pi^+\pi^-$ will be given at the end of this section.

A. $\Lambda_b \rightarrow \Lambda_c K^* \bar{K}$ amplitude

First, we consider the $\Lambda_b \rightarrow \Lambda_c K^{*0}K^-$ amplitude. At present, the data of the $\Lambda_b \rightarrow \Lambda_c K^{*0}K^-$ decay, such as the branching fraction or the Dalitz plot distribution, are not available; then, we make a microscopic derivation of the $\Lambda_b \rightarrow \Lambda_c K^* \bar{K}$ amplitude with some approximations. Some possible diagrams for the $\Lambda_b \rightarrow \Lambda_c K^* \bar{K}$ at quark level are depicted in Fig. 3. In this calculation, we take account of the diagram Fig. 3(a) with the external W^- emission, which is favored in terms of the color counting [33], and the diagrams with different topology shown in diagrams (b), (c), and (d) in the figure, suppressed in terms of the color counting, are not considered, and that can give, in general, the uncertainties of the

order of a few tens of percents.¹

For the baryonic part of the $\Lambda_b \rightarrow \Lambda_c W^-$ transition, B^μ ,

$$B^\mu = \langle \Lambda_c | \bar{c} \gamma^\mu (1 - \gamma_5) b | \Lambda_b \rangle, \quad (1)$$

we use a result of the QCD sum rule [35]. The $\Lambda_b \rightarrow \Lambda_c$ transition amplitude is parametrized as

$$\langle \Lambda_c | V^\mu | \Lambda_b \rangle = \langle \Lambda_c | \bar{c} \gamma^\mu b | \Lambda_b \rangle = \bar{u}_{\Lambda_c} [F_1(q^2) \gamma^\mu + F_2(q^2) v^\mu + F_3(q^2) v'^\mu] u_{\Lambda_b}, \quad (2)$$

$$\langle \Lambda_c | A^\mu | \Lambda_b \rangle = \langle \Lambda_c | \bar{c} \gamma^\mu \gamma_5 b | \Lambda_b \rangle = \bar{u}_{\Lambda_c} [G_1(q^2) \gamma^\mu + G_2(q^2) v^\mu + G_3(q^2) v'^\mu] \gamma_5 u_{\Lambda_b}, \quad (3)$$

where $v^\mu (v'^\mu) = p_{\Lambda_b(\Lambda_c)}^\mu / m_{\Lambda_b(\Lambda_c)}$ is the 4-velocity of Λ_b (Λ_c), $q^\mu = p_{\Lambda_b}^\mu - p_{\Lambda_c}^\mu$, $\mathcal{F}(q^2) = F_i(q^2)$ or $G_i(q^2)$ ($i = 1, 2, 3$) is parametrized as

$$\mathcal{F}(q^2) = \frac{\mathcal{F}(0)}{1 - \xi_1 \frac{q^2}{m_{\Lambda_b}^2} + \xi_2 \frac{q^4}{m_{\Lambda_b}^4} + \xi_3 \frac{q^6}{m_{\Lambda_b}^6} + \xi_4 \frac{q^8}{m_{\Lambda_b}^8}}, \quad (4)$$

with $\mathcal{F}(0)$ and ξ_i given in Ref. [35]. For later purposes, we give the spin sum and average of the baryonic part $\bar{B}^{\mu\nu} = \overline{\sum} \sum B^\mu B^{*\nu}$ (quantities with overline denote the spin summed and averaged ones in the following):

$$\begin{aligned} \bar{B}^{\mu\nu} = & \frac{1}{2} [g^{\mu\nu} \{ (F_1^2 - G_1^2) - (F_1^2 + G_1^2) w \} + (F_1^2 + F_1 F_2) (v^\mu v^\nu + v'^\mu v'^\nu) \\ & + 2F_1 F_2 v^\mu v^\nu + F_1 F_3 (v^\mu v'^\nu + v'^\mu v^\nu + 2v'^\mu v'^\nu) \\ & + w \{ (F_2^2 + G_2^2) v^\mu v^\nu + (F_2 F_3 + G_2 G_3) (v^\mu v'^\nu + v'^\mu v^\nu) + (F_3^2 + G_3^2) v'^\mu v'^\nu \} \\ & + F_2^2 v^\mu v^\mu + F_2 F_3 (v^\mu v'^\nu + v'^\mu v^\nu) + F_3^2 v'^\mu v'^\nu \\ & + G_1^2 (v^\mu v'^\nu + v'^\mu v^\nu) - G_1 G_2 (v^\mu v'^\nu + v'^\mu v^\nu) + 2G_1 G_2 v^\mu v^\nu \\ & - 2G_1 G_3 v'^\mu v'^\nu + G_1 G_3 (v^\mu v'^\nu + v'^\mu v^\nu) - G_2^2 v^\mu v^\nu \\ & - G_2 G_3 (v^\mu v'^\nu + v'^\mu v^\nu) - G_3^2 v'^\mu v'^\nu + 2i F_1 G_1 \epsilon^{\mu\nu\rho\sigma} v_\rho v'_\sigma] \end{aligned} \quad (5)$$

with $w = v \cdot v'$.

Let us move to the mesonic part producing $K^{*0} K^-$ or $K^{*-} K^0$, which is denoted by J_μ . Here, we assume the $a_1^-(1260)$ dominance for the $K^{*0} K^-$ and $K^{*-} K^0$ production and the

¹ Changing the u quark with the d quark, the diagrams (b), (c), and (d) in Fig. 3 can lead to the Σ_c production, which is reported to be small [32]. In addition, when one sees the $B \rightarrow K D^* \bar{D}^*$ branching fraction in the PDG [32], the branching fraction of the color favored process is about ten times larger than that of the color disfavored one [34]. These facts would imply the small corrections from the color disfavored processes.

effects of the rescatterings of the other pairs in the final-state particles are ignored. The observation of $\Lambda_b \rightarrow \Lambda_c a_1^-(1260)$ is reported in Ref. [36], and a peak around 1.3 GeV which may be associated with $a_1(1260)$ is seen in the $\pi^-\pi^+\pi^-$ distribution of $\Lambda_b \rightarrow \Lambda_c \pi^-\pi^+\pi^-$ [37], and we expect a large portion of $\Lambda_b \rightarrow \Lambda_c a_1^-(1260)$ in the $K^*\bar{K}$ production by taking into account a fairly strong coupling of $a_1(1260)$ to $K^*\bar{K}$ obtained theoretically in Refs. [38, 39]. Then, J_μ represents the amplitude of the $W^- \rightarrow a_1^-(1260) \rightarrow K^{*0}K^-$ or $K^{*-}K^0$ transition here. The effect of $a_1(1260)$ on the $\pi^-f_0(980)$ distribution will be checked later.

We write the conversion amplitude from W^- to $a_1^-(1260)$ as

$$-it_{W^-,a_1^-} = \frac{ig_W V_{ud}}{2} f_{a_1} m_{a_1} \epsilon_{W^-} \cdot \epsilon_{a_1}^* \quad (6)$$

with V_{ud} and g_W being the element of the Cabibbo-Kobayashi-Maskawa quark-mixing matrix and the coupling constant of the weak interaction, respectively, and the $a_1^-(1260) \rightarrow K^{*0}K^-$ amplitude is written as

$$-it_{a_1^-,K^{*0}K^-} = g_1 \epsilon_{a_1^-} \cdot \epsilon_{K^{*0}}^*, \quad (7)$$

where we take into account the amplitude with the lowest angular momentum which gives the dominant contribution in low energies. In the case of the $K^{*-}K^0$ pair in the final state, we just need an additional minus sign.

With the $\Lambda_b \rightarrow \Lambda_c$ form factor B^μ in Eq. (1), the $\Lambda_b \rightarrow \Lambda_c K^{*0}K^-$ transition amplitude given by the external W^- emission process is written as

$$\begin{aligned} -i\mathcal{M}_{\Lambda_b, \Lambda_c K^{*0}K^-} &= \left(\frac{ig_W}{2\sqrt{2}} V_{cb} \right) B^\mu \frac{i \left(-g_{\mu\nu} + \frac{q_\mu q_\nu}{m_W^2} \right)}{q^2 - m_W^2 + i\epsilon} \left(\frac{ig_W V_{ud}}{2} f_{a_1} m_{a_1} \right) \\ &\quad \cdot \frac{i \left(-g^{\nu\rho} + \frac{q^\nu q^\rho}{m_{a_1}^2} \right)}{q^2 - m_{a_1}^2 + im_{a_1} \Gamma_{a_1}} (+g_1) (\epsilon_{K^{*0}}^*)_\rho \\ &\sim g_1 G_F V_{cb} V_{ud} B^\mu g_{\mu\nu} \frac{f_{a_1} m_{a_1} \left(-g^{\nu\rho} + \frac{q^\nu q^\rho}{m_W^2} \right)}{q^2 - m_{a_1}^2 + im_{a_1} \Gamma} (\epsilon_{K^{*0}}^*)_\rho \\ &\equiv G_F V_{ud} V_{cb} B^\mu J_\mu, \end{aligned} \quad (8)$$

$$J^\mu = g_1 G_{a_1}^{\mu\nu} (\epsilon_{K^{*0}}^*)_\nu, \quad G_{a_1}^{\mu\nu} = \frac{f_{a_1} m_{a_1} \left(-g^{\mu\nu} + \frac{q^\mu q^\nu}{m_{a_1}^2} \right)}{q^2 - m_{a_1}^2 + im_{a_1} \Gamma_{a_1}}, \quad (9)$$

by taking the leading-order term of $1/m_W^2$. $G_F = g_W^2/(4\sqrt{2}m_W^2)$ is the Fermi coupling constant. The $\Lambda_b \rightarrow \Lambda_c K^{*-}K^0$ amplitude has the opposite sign relative to Eq. (8), which comes from the different sign of the $a_1^-(1260) \rightarrow K^{*0}K^-$ and $K^{*-}K^0$ vertices.

We fix the parameters in Eqs. (6) and (7) with the $\tau^- \rightarrow \nu_\tau K^{*0} K^-$ partial width given in the PDG [32], assuming the production is dominated by the $a_1(1260)$ meson. In the spectral function of $\tau \rightarrow 3\pi\nu_\tau$ [40, 41], one can see a significant peak at 1.2 GeV². The $K^- K^+ \pi^-$ distribution of the $\tau^- \rightarrow \nu_\tau K^- K^+ \pi^-$ decay, in which a large amount of $K^+ \pi^-$ comes from K^{*0} , is available [42], but the data are not enough for the analysis. The matrix element of the $\tau^- \rightarrow \nu_\tau K^{*0} K^-$ decay is written as

$$\begin{aligned} -i\mathcal{M}_\tau &= \left(\frac{ig_W}{2\sqrt{2}} \right) \bar{u}_\nu \gamma^\mu (1 - \gamma_5) u_\tau \frac{i \left(-g_{\mu\nu} + \frac{q_\mu q_\nu}{m_W^2} \right)}{q^2 - m_W^2 + i\epsilon} \left(\frac{ig_W V_{ud}}{2} f_{a_1} m_{a_1} \right) \\ &\quad \cdot \frac{i \left(-g^{\nu\rho} + \frac{q^\nu q^\rho}{m_{a_1}^2} \right)}{q^2 - m_{a_1}^2 + im_{a_1} \Gamma_{a_1}} (+g_1) (\epsilon_{K^{*0}}^*)_\rho \\ &\sim g_1 G_F V_{ud} \bar{u}_\nu \gamma^\mu (1 - \gamma_5) u_\tau g_{\mu\nu} \frac{f_{a_1} m_{a_1} \left(-g^{\nu\rho} + \frac{q^\nu q^\rho}{m_{a_1}^2} \right)}{q^2 - m_{a_1}^2 + im_{a_1} \Gamma_{a_1}} (\epsilon_{K^{*0}}^*)_\rho \end{aligned} \quad (10)$$

$$\equiv G_F V_{ud} \mathcal{L}^\mu J_\mu, \quad (11)$$

$$\mathcal{L}^\mu = \bar{u}_\nu \gamma^\mu (1 - \gamma_5) u_\tau. \quad (12)$$

For the $a_1(1260)$ mass and width, the central value of the PDG [32] is used; $m_{a_1} = 1.23$ GeV and $\Gamma_{a_1} = 0.425$ GeV.² The spin sum and average of the leptonic part \mathcal{L}^μ is given by

$$\mathcal{L}^{\alpha\beta} \equiv \overline{\mathcal{L}^\alpha \mathcal{L}^{\beta\dagger}} = \frac{4}{4m_\tau m_\nu} [p_\tau^\alpha p_\nu^\beta + p_\tau^\beta p_\nu^\alpha - g^{\alpha\beta} (p_\tau \cdot p_\nu) + i\epsilon^{\alpha\beta\rho\sigma} (p_\tau)_\rho (p_\nu)_\sigma], \quad (13)$$

with p_τ and p_ν being the momenta of the τ lepton and neutrino, respectively. Then, the matrix element squared with the spin sum and average is

$$\overline{|\mathcal{M}_\tau|^2} = g_1^2 G_F^2 V_{ud}^2 \mathcal{L}_{\mu\nu} G_{a_1}^{\mu\mu'} G_{a_1}^{*\nu\nu'} \left[-g_{\mu'\nu'} + \frac{(p_{K^{*0}})_{\mu'} (p_{K^{*0}})_{\nu'}}{m_{K^{*0}}^2} \right], \quad (14)$$

and the differential width is

$$\frac{d^2\Gamma_{\tau^- \rightarrow \nu_\tau K^{*0} K^-}}{dM_{K^- \nu_\tau}^2 dM_{K^{*0} K^-}^2} = \frac{4m_\tau m_\nu}{(2\pi)^3 32m_\tau^3} \overline{|\mathcal{M}_\tau|^2}. \quad (15)$$

In practice, we do not need to fix f_{a_1} and g_1 independently because a product $f_{a_1} m_{a_1} g_1$ appears in the amplitudes Eqs. (8) and (11). Finally, with the partial width of $\tau^- \rightarrow \nu_\tau K^{*0} K^-$, the product $f_{a_1} m_{a_1} g_1$ is fixed to $f_{a_1} m_{a_1} g_1 = 1.0$ GeV³.

² The peak in the spectral function in Refs. [40, 41] is a bit lower than the $a_1(1260)$ mass from the PDG [32].

See, e.g., Ref. [43] for a recent study on the $a_1(1260)$ meson in the τ decay, and see also Refs. [29, 38, 39, 44–55] and the references therein for the works concerning the $a_1(1260)$ properties.

B. $K^* \rightarrow \pi K$ and $\bar{K}^* \rightarrow \pi \bar{K}$ amplitudes

We move to the $K^{*-} \rightarrow \pi^- \bar{K}^0$ and $K^{*0} \rightarrow \pi^- K^+$ amplitudes. The p -wave amplitude of a vector meson decaying into two pseudoscalar mesons can be obtained from the effective Lagrangian [22, 56–59],

$$\mathcal{L}_{VPP} = -i\tilde{g} \langle V^\mu [P, \partial_\mu P] \rangle, \quad (16)$$

with

$$P = \begin{pmatrix} \frac{\pi^0}{\sqrt{2}} + \frac{1}{\sqrt{6}}\eta & \pi^+ & K^+ \\ \pi^- & -\frac{\pi^0}{\sqrt{2}} + \frac{1}{\sqrt{6}}\eta & K^0 \\ K^- & \bar{K}^0 & -\sqrt{\frac{2}{3}}\eta \end{pmatrix}, \quad V_\mu = \begin{pmatrix} \frac{\rho^0 + \omega}{\sqrt{2}} & \rho^+ & K^{*+} \\ \rho^- & \frac{-\rho^0 + \omega}{\sqrt{2}} & K^{*0} \\ K^{*-} & \bar{K}^{*0} & \phi \end{pmatrix}_\mu. \quad (17)$$

The brackets $\langle \dots \rangle$ stand for the trace of the flavor SU(3) matrices. From this Lagrangian, the amplitudes of $K^{*0} \rightarrow \pi^- K^+$ and $K^{*-} \rightarrow \pi^- \bar{K}^0$ are given by

$$\begin{aligned} -it_{K^{*0}, \pi^- K^+} &= +i\tilde{g}\epsilon_{K^{*0}} \cdot (p_{\pi^-} - p_{K^+}), \\ -it_{K^{*-}, \pi^- \bar{K}^0} &= -i\tilde{g}\epsilon_{K^{*-}} \cdot (p_{\pi^-} - p_{\bar{K}^0}). \end{aligned} \quad (18)$$

We fix the parameter \tilde{g} for the coupling of $K^* \rightarrow \pi K$ with the isospin averaged mass and width of mesons;

$$\Gamma_{K^*} = \frac{2\tilde{g}^2 p_K^3}{8\pi m_{K^*}^2}, \quad p_K = \frac{1}{2m_{K^*}} \lambda^{1/2}(m_{K^*}^2, m_K^2, m_\pi^2), \quad (19)$$

with the Källän function $\lambda(x, y, z) = x^2 + y^2 + z^2 - 2xy - 2yz - 2zx$, and Eq. (19) leads to $\tilde{g} = 4.5$.

C. $K\bar{K} \rightarrow \pi^+ \pi^-$ scattering amplitude

For the scattering t matrix of the $K\bar{K}$ to a meson pair MM' , $t_{MM', K\bar{K}}$, we use the amplitude calculated in the framework of chiral unitary approach. The $\pi\pi$ - $K\bar{K}$ - $\pi\eta$ coupled-channel system around 1 GeV was studied in this framework in Ref. [60] with a particular interest in the f_0 and a_0 resonances followed by the studies with similar approaches [61–63]³ and the applications to many reactions. In this work, we follow the setup of Ref. [69]; the

³ The scalar mesons around 1 GeV have been studied for a long time, and many studies were devoted for it from various viewpoints, e.g., as done in Refs. [64–67] (see also Ref. [68] for a review article).

FIG. 4. The $K^{*0}K^-K^+$ loop diagram for the $\pi^- f_0(980)$ transition amplitude T_μ .

$f_0(980)$ resonance is dynamically generated as a result of the nonperturbative meson-meson interaction, and it is found in Refs. [69–71] that the line shape of the $\pi^+\pi^-$ invariant mass distribution around 1 GeV is described fairly well. The amplitude is given by the scattering equation

$$t_{i,j} = [(1 - vg)^{-1}v]_{i,j} \quad (20)$$

with $i, j = \pi^+\pi^-, \pi^0\pi^0, K^+K^-, K^0\bar{K}^0, \eta\eta$. The interaction kernel v comes from the s -wave part of the leading-order chiral Lagrangian, and g is the meson-meson loop function with cutoff regularization given in Ref. [69], where the cutoff parameter Λ for g is chosen to be 0.6 GeV.

D. $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ amplitude via the $K^* \bar{K} K$ loop

Combining the amplitudes given above, we can obtain the loop amplitude given by the diagram in Fig. 4, which is denoted by T_μ . We can write the amplitude given by the diagram in Fig. 4 with the $K^{*0}K^-K^+$ triangle loop (a meson pair MM' in the final state comes from the K^+K^- rescattering) as follows:

$$\begin{aligned} T_\mu &= -i\tilde{g}t_{MM',K^+K^-} \int \frac{d^4l}{(2\pi)^4} \frac{\left(-g_{\mu\nu} + \frac{(k_1-l)_\mu(k_1-l)_\nu}{m_{K^{*0}}^2}\right) (k_1 - 2k_2 + l)^\nu}{[l^2 - m_{K^-}^2 + i\epsilon][(k_1-l)^2 - m_{K^{*0}}^2 + i\epsilon][(k_2-l)^2 - m_{K^+}^2 + i\epsilon]} \\ &\equiv -i\tilde{g}L_\mu(K^{*0}K^-K^+)t_{MM',K^+K^-}, \end{aligned} \quad (21)$$

with

$$\begin{aligned} L_\mu(K^{*0}K^-K^+) &= \int \frac{d^4l}{(2\pi)^4} \frac{\left(-g_{\mu\nu} + \frac{(k_1-l)_\mu(k_1-l)_\nu}{m_{K^{*0}}^2}\right) (k_1 - 2k_2 + l)^\nu}{[l^2 - m_{K^-}^2 + i\epsilon][(k_1-l)^2 - m_{K^{*0}}^2 + i\epsilon][(k_2-l)^2 - m_{K^+}^2 + i\epsilon]} \\ &= \int \frac{d^4l}{(2\pi)^4} \frac{1}{[l^2 - m_{K^-}^2 + i\epsilon][(l+k_1)^2 - m_{K^{*0}}^2 + i\epsilon][(l+k_2)^2 - m_{K^+}^2 + i\epsilon]} \end{aligned}$$

$$\cdot \left[-(k_1 - 2k_2)_\mu + \frac{k_1 \cdot (k_1 - 2k_2)}{m_{K^*0}^2} k_{1\mu} + \left(1 + \frac{k_1 \cdot (k_1 - 2k_2)}{m_{K^*0}^2} \right) l_\mu - \frac{2k_2 \cdot l}{m_{K^*0}^2} k_{1\mu} - \frac{2k_2 \cdot l}{m_{K^*0}^2} l_\mu - \frac{l^2}{m_{K^*0}^2} k_{1\mu} - \frac{l^2}{m_{K^*0}^2} l_\mu \right]. \quad (22)$$

A library for the one-loop integrals, LoopTools, is used [72]. In Eq. (22), the momenta k_1 and k_2 are defined as in Fig. 4. Now, the renormalization scale, μ , associated with the divergence of the loop integral is fixed to be 1 GeV, and the change of this parameter to $\mu = 0.5$ or 1.5 GeV gives just a tiny difference. The width effect of the K^*0 meson in the loop is included by replacing the squared mass of the K^*0 , $m_{K^*0}^2$, with $m_{K^*0}^2 - im_{K^*0}\Gamma_{K^*0}$ in this study.

Then, with the part of the $\Lambda_b \rightarrow \Lambda_c K^*0 K^-$ transition given in Eq. (8), the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980); f_0(980) \rightarrow MM'$ amplitude via the $K^*0 K^- K^+$ triangle loop is written as

$$-i\mathcal{M}_{\Lambda_b, \Lambda_c \pi^- MM'}^{(K^*0 K^- K^+)} = -i\tilde{g}g_1 G_F V_{ud} V_{cb} B_\mu G_{a_1}^{\mu\nu} t_{MM', K^+ K^-} L_\nu(K^*0 K^- K^+). \quad (23)$$

The amplitude of the $K^{*-} K^0 \bar{K}^0$ loop is obtained by just changing the label of the internal particles with the same sign relative to the $K^*0 K^- K^+$ loop taking into account the minus sign of $a_1^- K^* \bar{K}$ and $K^* \pi K$ vertices. Then, adding the contribution of the $K^{*-} K^0 \bar{K}^0$ and $K^*0 K^- K^+$ loops, we obtain

$$\begin{aligned} -i\mathcal{M}_{\Lambda_b, \Lambda_c \pi^- MM'} &= -i\mathcal{M}_{\Lambda_b, \Lambda_c \pi^- MM'}^{(K^*0 K^- K^+)} - i\mathcal{M}_{\Lambda_b, \Lambda_c \pi^- MM'}^{(K^{*-} K^0 \bar{K}^0)} \\ &= -i\tilde{g}g_1 G_F V_{ud} V_{cb} B_\mu G_{a_1}^{\mu\nu} [t_{MM', K^+ K^-} L_\nu(K^*0 K^- K^+) + t_{MM', K^0 \bar{K}^0} L_\nu(K^{*-} K^0 \bar{K}^0)]. \end{aligned} \quad (24)$$

In the following, we consider the case of $MM' = \pi^+ \pi^-$ in the final state to see $f_0(980)$. In the isospin symmetric case, where the isospin averaged mass and width of the mesons are used, the amplitude is reduced as follows⁴:

$$-i\mathcal{M}_{\Lambda_b, \Lambda_c \pi^- f_0} = -2i\tilde{g}g_1 G_F V_{ud} V_{cb} B_\mu G_{a_1}^{\mu\nu} L_\nu(K^*0 K^- K^+) t_{\pi^+ \pi^-, K^+ K^-}. \quad (25)$$

This isospin averaged amplitude will be used in the following calculation.

Using the formula of the phase space volume in Ref. [22], the differential distribution is given by

$$\frac{d^2\Gamma_{\Lambda_b \rightarrow \Lambda_c \pi^- f_0}}{dM_{\pi^+ \pi^-} dM_{\pi^- f_0}} = \frac{2m_{\Lambda_c} 2m_{\Lambda_b}}{2^5 (2\pi)^8 m_{\Lambda_b}^2} p_{\Lambda_c} p'_{\pi^-} p''_{\pi^+} \int d\Omega_{\Lambda_c} d\Omega'_{\pi^-} d\Omega''_{\pi^+} |\mathcal{M}_{\Lambda_b, \Lambda_c \pi^- f_0}|^2, \quad (26)$$

⁴ Note that $K^+ K^- = [-(K\bar{K})_{I=1} - (K\bar{K})_{I=0}]/\sqrt{2}$ and $K^0 \bar{K}^0 = [(K\bar{K})_{I=1} - (K\bar{K})_{I=0}]/\sqrt{2}$ with a phase convention $|K^-\rangle = -|I=1/2, I_z=-1/2\rangle$.

FIG. 5. The $\pi^+\pi^-$ invariant mass distribution $(d^2\Gamma_{\Lambda_b \rightarrow \Lambda_c \pi^- f_0}/dM_{\pi^- f_0} dM_{\pi^+\pi^-})/\Gamma_{\Lambda_b}$. $M_{\pi^- f_0}$ is fixed to 1.3 GeV (red dashed), 1.42 GeV (black solid), and 1.5 GeV (blue dotted).

with

$$p_{\Lambda_c} = \frac{1}{2m_{\Lambda_b}} \lambda^{1/2}(m_{\Lambda_b}^2, m_{\Lambda_c}^2, M_{\pi^- f_0}^2), \quad (27)$$

$$p'_{\pi^-} = \frac{1}{2M_{\pi^- f_0}} \lambda^{1/2}(M_{\pi^- f_0}^2, m_{\pi^-}^2, M_{\pi^+\pi^-}^2), \quad (28)$$

$$p''_{\pi^+} = \frac{1}{2M_{\pi^+\pi^-}} \lambda^{1/2}(M_{\pi^+\pi^-}^2, m_{\pi^+}^2, m_{\pi^-}^2). \quad (29)$$

The angles Ω_{Λ_c} , Ω'_{π^-} , and Ω''_{π^+} are those of Λ_c , π^- , and π^+ in the Λ_b rest frame, the $\pi^- f_0(980)$ c.m. frame, and the $\pi^+\pi^-$ c.m. frame, respectively.

III. RESULTS

We show in Fig. 5 the $\pi^+\pi^-$ invariant mass distribution given by Eq. (26) normalized with the Λ_b full width, Γ_{Λ_b} , with $M_{\pi^- f_0} = 1.3, 1.42$, and 1.5 GeV. A peak of $f_0(980)$ is clearly seen at $M_{\pi^+\pi^-} = 0.98$ GeV, and the largest strength is given with $M_{\pi^- f_0} = 1.42$ GeV by the virtue of the $K^* \bar{K} K$ triangle mechanism.

Integrating Eq. (26) over $M_{\pi^+\pi^-}$ in the range of $M_{\pi^+\pi^-} \in [0.9, 1.1]$ GeV, we obtain the

FIG. 6. The $\pi^- f_0(980)$ invariant mass distribution $(d\Gamma_{\Lambda_b \rightarrow \Lambda_c \pi^- f_0}/dM_{\pi^- f_0})/\Gamma_{\Lambda_b}$ as a function of $M_{\pi^- f_0}$.

$\pi^- f_0(980)$ invariant mass distribution, $(d\Gamma_{\Lambda_b \rightarrow \Lambda_c \pi^- f_0}/dM_{\pi^- f_0})/\Gamma_{\Lambda_b}$, shown in Fig. 6. The distribution is normalized with Γ_{Λ_b} again. In the $\pi^- f_0(980)$ distribution, a peak around 1.42 GeV with a width of the order of 0.1 GeV originating from the TS is clearly seen. The distribution is similar to the ones in the $a_1(1260)$ decay and the τ decay calculated in Refs. [18, 21]. Note that the $\pi^+\pi^-$ pair in the final-state $\pi^-\pi^+\pi^-$ is produced by $f_0(980)$ in this calculation. The $\pi^-\pi^+\pi^-$ in the final state would be mainly produced by the s -wave $\pi\rho$, which is a decay product of $a_1^-(1260)$, as studied in Refs. [17, 18] in the $\pi^- p \rightarrow \pi^+\pi^-\pi^- p$ reaction.

By integrating $(d\Gamma_{\Lambda_b \rightarrow \Lambda_c \pi^- f_0}/dM_{\pi^- f_0})/\Gamma_{\Lambda_b}$ in the range of $\Delta = [1.0, 1.6]$ GeV, we obtain the branching ratio Br_Δ ;

$$\text{Br}_\Delta(\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980); f_0(980) \rightarrow \pi^+\pi^-) \equiv \frac{1}{\Gamma_{\Lambda_b}} \int_\Delta dM_{\pi^- f_0} \frac{d\Gamma_{\Lambda_b \rightarrow \Lambda_c \pi^- f_0}}{dM_{\pi^- f_0}} \quad (30)$$

$$= 2.2 \times 10^{-4}, \quad (31)$$

which is the same order of magnitude obtained in the τ^- decay into $\nu_\tau \pi^- f_0(980)$ via the triangle mechanism [21].

To see the uncertainties from the $\Lambda_b \rightarrow \Lambda_c$ transition form factors, we show the plot in Fig. 7 with different parameter sets of the $\Lambda_b \rightarrow \Lambda_c$ form factors given in Refs. [35, 73]

FIG. 7. The $\pi^- f_0(980)$ invariant mass distribution $(d\Gamma_{\Lambda_b \rightarrow \Lambda_c \pi^- f_0}/dM_{\pi^- f_0})/\Gamma_{\Lambda_b}$ with different parameters in the $\Lambda_b \rightarrow \Lambda_c$ transition form factor. The lines (a) and (b), which are plotted with the black-solid and red-dashed curves, are the plots with the parameter set of the $\Lambda_b \rightarrow \Lambda_c$ form factor given in Ref. [35] and [73], respectively. The gray and red bands of the lines (a) and (b) reflect the uncertainties of the parameters in the $\Lambda_b \rightarrow \Lambda_c$ form factors in each model.

which are denoted by the lines (a) and (b), respectively. The gray and red bands are the uncertainties of the lines (a) and (b) originating from the parameters in the $\Lambda_b \rightarrow \Lambda_c$ form factors. The gray band for the uncertainties of the line (a) is obtained by using the errors of $\mathcal{F}(0)$ in Eq. (4) given in Ref. [35]. In Ref. [73], the errors of the form factors are estimated less than 5%, and here the uncertainties of the line (b) expressed with the red band are given by changing $\mathcal{F}(0)$ by $\pm 5\%$. One can see the relatively large uncertainties of the line (a) expressed with the gray band. The branching ratio Br_Δ is in the range from 1×10^{-4} to 5×10^{-4} , still the order 10^{-4} . Comparing the lines (a) and (b) in Fig. 7, one will see the similar line shapes with the different parameter sets; the peak structure around 1.42 GeV is stable. We note that, for the $\Lambda_b \rightarrow \Lambda_c$ transition amplitude, only the external W^- emission diagram is taken into account, and the approximation gives some further uncertainties which are not addressed in this study.

In the amplitude Eq. (8), the $a_1(1260)$ dominance in the $K^{*-} K^0$ and $K^{*0} K^-$ production

is assumed. For comparison, we show the plot without the intermediate $a_1(1260)$ resonance in the production.⁵ In terms of the $K^*\bar{K}$ interaction, if the $K^*\bar{K}$ interaction is weak or moderately attractive and the coupling to the $a_1(1260)$ is not so large, the $K^*\bar{K}$ rescattering amplitude is expected to have a moderate energy dependence, and the $K^*\bar{K}$ production from W^- can be approximated with a constant contact term involving all the short-range physics of the process. On the other hand, if the $K^*\bar{K}$ interaction is sufficiently strong, the $K^*\bar{K}$ generates a pole dynamically [38, 39, 46], and the $K^*\bar{K}$ rescattering can be represented approximately with the coupling to the pole, which may be related to $a_1(1260)$, and the details of the $K^*\bar{K}$ interaction is encoded in the coupling constant of the pole and the $K^*\bar{K}$ channel from the viewpoint of the Weinberg compositeness relation [75]. Comparing the $\pi^- f_0(980)$ distributions with and without $a_1(1260)$, we can see the effect of the different production mechanisms and the interaction of the initial $K^*\bar{K}$ pair on the $\pi^- f_0(980)$ distribution and the stability of the TS peak against it. In the case without the intermediate $a_1(1260)$, the decay amplitude of $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ is given by replacing the $a_1(1260)$ propagator $G_{a_1}^{\mu\nu}$ with $g^{\mu\nu}$ in Eq. (25). The $W^- \rightarrow K^*\bar{K}$ amplitude is given by Eq. (7) by replacing the $a_1^-(1260)$ polarization vector with the W^- one.

The $\pi^- f_0(980)$ invariant mass distributions with and without $a_1(1260)$ are compared in Fig. 8. The peak around 1.42 GeV can be seen in both cases, and the distribution without $a_1(1260)$ has a longer tail than that with $a_1(1260)$. The branching ratio defined in Eq. (30) is $\text{Br}_\Delta = 1.8 \times 10^{-4}$ without the intermediate $a_1(1260)$ resonance. The ratio is smaller compared to Eq. (31), but it is still the same order of magnitude.

To clarify the feature of the triangle mechanism in the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ process, we compare the invariant mass distribution of $\pi^- f_0(980)$ produced with and without the triangle mechanism. The amplitudes of $a_1(1260) \rightarrow \pi^- f_0(980)$ in the p wave and $f_0(980) \rightarrow \pi^+ \pi^-$ in the s wave, which are needed for the amplitude of the direct production of the p -wave $\pi^- f_0(980)$ pair from $a_1^-(1260)$, are written as

$$-it_{a_1^-, \pi^- f_0(980)} = g_1' \epsilon_{a_1^-} \cdot p_{\pi^-}, \quad (32)$$

$$-it_{f_0(980), \pi^+ \pi^-} = i g_{f_0, \pi\pi}. \quad (33)$$

The decay amplitude of $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ followed by $f_0(980) \rightarrow \pi^+ \pi^-$ with $\pi^- f_0(980)$

⁵ In Ref. [74], the effects of the $a_1(1260)$ meson in the $B^- \rightarrow K^- K^{*0} D^{(*)0}$ transition part of the $B^- \rightarrow K^- \pi^- D_{s0(s1)}^+$ decay with a $K^{*0} D^{(*)0} K^+$ triangle loop are studied, and it is found that the peak originating from the triangle mechanism is not changed with the inclusion of the $a_1(1260)$ contribution.

FIG. 8. The $\pi^- f_0(980)$ distribution $(d\Gamma_{\Lambda_b \rightarrow \Lambda_c \pi^- f_0}/dM_{\pi^- f_0})/\Gamma_{\Lambda_b}$ with and without $a_1(1260)$. The black-solid (red-dashed) line is the plot with (without) the $a_1(1260)$ resonance.

directly produced by $a_1^-(1260)$ is given by

$$-i\mathcal{M}'_{\Lambda_b, \Lambda_c \pi^- f_0} = -G_F V_{ud} V_{cb} B^\mu (G_{a_1})_{\mu\nu} \frac{g_{f_0, \pi\pi} g'_1 p_{\pi^-}^\nu}{M_{\pi^+ \pi^-}^2 - m_{f_0}^2 + im_{f_0} \Gamma_{f_0}}. \quad (34)$$

For simplicity, we just use a Breit-Wigner amplitude of the $f_0(980)$ resonance with the mass and width from the PDG [32].⁶

In Fig. 9, the $\pi^- f_0(980)$ invariant mass distribution with Eq. (34) is compared with the one with the triangle mechanism given by Eq. (25). The distribution with $\pi^- f_0(980)$ directly produced by $a_1(1260)$ has no structure around 1.4 GeV and just increases as a p wave. On the other hand, in the case with the triangle loop contribution, the peak of the TS is located around 1.42 GeV with the width about 0.2 GeV in the distribution. Thus, the triangle mechanism has the clear distinction from the other production mechanism we considered here.

⁶ In the studies of the $f_0(980)$ resonance, the Flatté(-like) amplitude [76] is used to analyze its properties due to the nearby $K\bar{K}$ threshold; see, e.g., Refs. [67, 77, 78].

FIG. 9. Comparison of the plots with different production mechanisms. The lines (a) and (b) are the plots with the $\pi^- f_0(980)$ pair via the triangle mechanism and the direct production by $a_1^-(1260)$, respectively. The amplitudes Eqs. (25) and (34) are used for the plot of lines (a) and (b), respectively. In the plot of the line (b), the parameters are fixed to be the same order as the line (a).

IV. CONCLUSIONS

We have studied the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ decay with $f_0(980) \rightarrow \pi^+ \pi^-$. For the $\Lambda_b \rightarrow \Lambda_c K^* \bar{K} (K \bar{K}^*)$ production part, the amplitude is factorized into the $\Lambda_b \rightarrow \Lambda_c$ transition and $K^{*-} K^0 (K^- K^{*0})$ production from the $a_1^-(1260)$ resonance which are connected with a W^- boson taking the leading contribution in terms of the color counting [33]. The $\Lambda_b \rightarrow \Lambda_c$ transition form factors are taken from the theoretical studies [35, 73], and the chiral unitary approach is employed for the $K \bar{K} \rightarrow \pi^+ \pi^-$ transition amplitude [69]. A coupling constant related to the production of $K^{*-} K^0$ is fixed with the $\tau^- \rightarrow \nu_\tau K^{*-} K^0$ branching ratio assuming the $a_1(1260)$ dominance.

A peak of the $f_0(980)$ resonance is seen in the $\pi^+ \pi^-$ invariant mass distribution, and the peak has the largest strength when the $\pi^- f_0(980)$ invariant mass is fixed to be 1.42 GeV. Integrating the $\pi^+ \pi^-$ distribution, we obtain the $\pi^- f_0(980)$ distribution which has a peak

around 1.42 GeV due to the triangle singularity of the $K^*\bar{K}K$ loop. With further integration over the $\pi^-f_0(980)$ invariant mass in the range of $M_{\pi^-f_0} \in [1.0, 1.6]$ GeV, the branching ratio of $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ with $f_0(980) \rightarrow \pi^+\pi^-$ by the $K^*\bar{K}K$ triangle mechanism is obtained as 2.2×10^{-4} . Considering the uncertainties from the parameters appearing in this calculation, the renormalization scale for the loop regularization, and the parameters in the $\Lambda_b \rightarrow \Lambda_c$ transition form factor, it is found that the branching ratio of $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980); f_0(980) \rightarrow \pi^+\pi^-$ is the order 10^{-4} and the peak position originating from the triangle mechanism is not changed although a more sophisticated treatment of the $\Lambda_b \rightarrow \Lambda_c K^*\bar{K}$ transition part may be needed in the future for more definite predictions. The comparison of the distributions with and without the intermediate $a_1(1260)$ is also done, and it is found that the peak around 1.42 GeV is not changed even if the $a_1(1260)$ is omitted, while some difference in the shape of the distribution can be seen. The branching ratio without the $a_1(1260)$ is still the order 10^{-4} . The distribution of $\pi^-f_0(980)$ directly produced by the $a_1(1260)$ meson without the triangle loop is also considered to compare it with the distribution including the triangle loop contribution, and it is found that the distribution without the triangle loop just increases without peak structures, which is quite different from the distribution with the $K^*\bar{K}K$ triangle mechanism.

The part of the $K^*\bar{K}K$ triangle loop is identical to the mechanism considered in Refs. [17, 18] to explain the $a_1(1420)$ peak in $\pi^-p \rightarrow \pi^-\pi^-\pi^+p$ observed by the COMPASS Collaboration [23]. Then, future measurements of the branching ratio of the $\Lambda_b \rightarrow \Lambda_c \pi^- f_0(980)$ and the $\pi^-f_0(980)$ invariant mass distribution, particularly the peak structure around 1.4 GeV, which are the predictions made in this work, can provide a support of the $a_1(1420)$ peak as a manifestation of the triangle singularity, and they also provide further knowledge about the role of the triangle singularities in the hadronic reactions.
