Abstract

Jacobian Conjecture states that for a polynomial map $P$ from $\mathbb{K}^n$ to itself, where $n \geq 2$ and $\mathbb{K}$ is a field of characteristic 0, if the determinant of its Jacobian matrix is a nonzero constant in $\mathbb{K}$, then the inverse $P^{-1}$ exists and is also a polynomial map. This conjecture was firstly posed by Keller in 1939 for $\mathbb{K}^n = \mathbb{C}^2$, and put in Smale’s 1998 list of Mathematical Problems for the Next Century. This study is going to present a proof for the conjecture. Our proof is based on Držkovski Map and Hadamard’s Diffeomorphism Theorem, and uses some optimization idea.

I. INTRODUCTION

Let $\mathbb{K}$ denote a number field, on which $\mathbb{K}[X] = \mathbb{K}[x_1, \ldots, x_n]$ be the polynomial ring in $n$ variables $X = (x_1, \ldots, x_n)$. Each polynomial vector $P(X) := (P_1(X), \ldots, P_n(X)) \in \mathbb{K}[X]^n$ defines a map from $\mathbb{K}^n$ to $\mathbb{K}^n$. The $n \times n$ Jacobian matrix $J_P(X)$ ($J_P$ for short) of $P(X)$ consists of the partial derivatives of $P_i$ with respect to $x_j$, that is, $J_P = [\frac{\partial P_i}{\partial x_j}, i, j = 1, \ldots, n]$. Then the determinant $\det(J_P)$ of $J_P$ is a polynomial function of $X$. Jacobian Condition is that $\det(J_P)$ is a nonzero constant in $\mathbb{K}$. A $P \in \mathbb{K}[X]^n$ is called Keller map \footnote{If it satisfies Jacobian Condition.} if it satisfies Jacobian Condition.

This work was partially supported by NSF of China (No. 61202131), CAS Youth Innovation Promotion Association (No. 2015615).
A polynomial map $P \in K[X]^n$ is an automorphism of $K^n$ if the inverse $P^{-1}$ exists and is also a polynomial map. Due to Osgood’s Theorem, the Jacobian Condition is necessary for $P$ being automorphism. Keller [2] posed the Jacobian Conjecture ($JC$) for $K^n = C^2$ in 1939, where $C$ is the complexity field. We refer the reader to [1], [3]–[6] for a nice survey paper containing some history and updated progresses of the Jacobian Conjecture. Abhyankar [7] gave its modern style as follows.

**Jacobian Conjecture — $JC(K, n)$**: If $P \in K[X]^n$ is a Keller map where $K$ is an arbitrary field of characteristic 0 and the integer $n \geq 2$, then $P$ is an automorphism.

$JC(K, 1)$ is trivially true. Besides, there are simple counterexamples [3], [8] for $JC(K, n)$ when the number field $K$ has characteristic $> 0$. So the characteristic 0 condition is necessary. These two assumptions are always supposed to be true in the rest of article unless a related statement is specified particularly.

Let $JC(K)$ stand for $JC(K, n)$ being true for all positive integers $n$. Due to Lefschetz Principle, it suffices to deal only with $JC(C)$. On the other side, $JC(R)$ implies $JC(C)$ [1], [9], where $R$ is the real number field. Therefore, it suffices to show $JC(R)$ for generic $JC(K)$. For $JC(R)$, there are many equivalent formulations [11]. Among them, D-map is a crucial equivalence in our approach. Given a matrix $A \in R^{n \times n}$, let $(AX)^{\ast 3}$ be the vector whose $i$-th element is $(A_i^T X)^{\ast 3}$, where $A_i^T$ is the $i$-th row vector of $A$. A Drużkowski map (D-map for short) is a Keller map of cubic linear form $D(X) := X + (AX)^{\ast 3}$ for some matrix $A \in R^{n \times n}$. Drużkowski [10] showed that

**Drużkowski Theorem 1.1**: If each D-map is an automorphism, then $JC(R)$ is true. Therefore, Jacobian Conjecture is true.

By Jacobian Condition, each Keller map is a local homeomorphism. Even for analytic maps, Hadamard’s Diffeomorphism Theorem presents a necessary and sufficient condition for local homeomorphism being diffeomorphism through proper map. A differentiable map $F : R^n \mapsto R^n$ is diffeomorphism if it is bijective and its inverse is also differentiable. A continuous map $H : R^n \mapsto R^n$ is proper if $H^{-1}(C)$ is compact for each compact set $C \subseteq R^n$. Equivalently, a map $H$ is proper iff it maps each unbounded set $B$ into an unbounded set $H(B)$. Based on these notions, in ( [11], [12]) it was showed that

**Hadamard Theorem 1.2**: For an analytic map $H : R^n \mapsto R^n$, $H$ is diffeomorphism iff $\det J_H(X) \neq 0$ for all $X \in R^n$ and $H$ is proper.

Therefore, for $JC(R)$ it suffices to show that each D-map is proper. As we are going to show
in the next section, this is actually true.

**Proper Map Theorem 1.3:** Each D-map is proper.

In consequence, $\mathcal{J}\mathcal{C}(\mathbb{R})$ is true. Therefore we can conclude

**Polynomial Automorphism Theorem 1.4:** For every $n \geq 2$ and any field $\mathbb{K}$ of characteristic 0, each Keller map $\mathcal{P} \in \mathbb{K}[X]^n$ is an automorphism.

In the rest of this article, we assume $n \geq 2$ for the dimension of $\mathbb{R}^n$ unless it is specified in particular. Capital letters denote vectors, blackboard bold letters denote sets of vector (point), fraktur letters denote vector functions, little letters denote integers, Greek letters denote real numbers and real functions.

II. **Proof of Proper Map Theorem**

Theorem 1.3 will be proved by contradiction. To this end, it needs to study the properties of D-map $\mathcal{D}(X) := X + (AX)^{*3}$ based on the matrix $\mathcal{A}$. Let’s start with some basic notions. A set $\mathcal{B} \subseteq \mathbb{R}^n$ is called unbunded if for any $\gamma \in \mathbb{R}$ there is an element $X \in \mathcal{B}$ such that $||X|| > \gamma$, where $|| \cdot ||$ is the Euclidean norm, that is, $||X|| := \sqrt{\sum_{1 \leq i \leq n} X_i^2}$.

Given a matrix $\mathcal{A} \in \mathbb{R}^{n \times n}$, let $(AX)^{\Delta 2}$ denote the diagonal matrix whose diagonals are $(A^T X)^2, \ldots, (A^T X)^2$. For a D-map $\mathcal{D}(X) := X + (AX)^{*3}$, its Jacobian matrix is $\mathcal{J}\mathcal{D} = \mathcal{I} + 3(AX)^{\Delta 2}A$ where $\mathcal{I}$ is the $n \times n$ identity matrix. In [10], it was showed that

**Theorem 2.1:** $\mathcal{D}(X) := X + (AX)^{*3}$ is a D-map iff $(AX)^{\Delta 2}A$ is a nilpotent matrix for each $X$. And each D-map has only one zero root: vector 0.

From this theorem, the following proposition is evident.

**Proposition 2.2:** If $\mathcal{D}(X) := X + (AX)^{*3}$ is a D-map, then for all $\lambda \in \mathbb{R}$, the map $\mathcal{D}_{\lambda}(X) := X + \lambda(AX)^{*3}$ is also a D-map, and for any nonzero $X$, $\mathcal{D}_{\lambda}(X) \neq 0$ or equivalently $||\mathcal{D}_{\lambda}(X)|| > 0$.

Immediately, we have

**Corollary 2.3:** For any D-map $\mathcal{D}(X) := X + (AX)^{*3}$, no $X$ satisfies $X^T (AX)^{*3} = \pm ||(AX)^{*3}|| \neq 0$. This means $\frac{X^T (AX)^{*3}}{||(AX)^{*3}||} \neq \pm 1$ for all $X$.

**Proof:** We prove this result by contradiction. Given a D-map $\mathcal{D}(X)$, suppose that there is some $X$ such that $X^T (AX)^{*3} = \delta ||(AX)^{*3}|| \neq 0$, where $\delta = -1$ if $X^T (AX)^{*3} < 0$ and $\delta = 1$ if $X^T (AX)^{*3} > 0$.

By Proposition 2.2, $\mathcal{D}_{\delta}(X) := X - \delta(AX)^{*3}$ is also a Keller map. Let’s consider the following equation

$$||\mathcal{D}_{\delta}(\sqrt[3]{\lambda}X)||^2 = \lambda - 2\lambda^2 \delta X^T (AX)^{*3} + \lambda^3 ||(AX)^{*3}||^2 = 0$$ (1)
It has a zero root \( \lambda = \frac{\delta X^T (AX)^{\ast 3}}{\| (AX)^{\ast 3} \|^2} > 0 \). That is, \( D_\delta(X) \) has a nonzero root, which contradicts with Proposition 2.2. Therefore, such \( X \) does not exist. ■

Given a matrix \( A \in \mathbb{R}^{n \times n} \), let \( \mathfrak{A}^\perp := \{ X \in \mathbb{R}^n \mid AX = 0 \} \) denote the linear space in which each element is a solution of \( AX = 0 \), and \( \mathfrak{A}^rSP \) stand for the linear space spanned by the row vectors of \( A \). Regarding the elements of \( \mathfrak{A}^rSP \) as column vectors, then \( \mathfrak{A}^rSP = \{ Y \mid Y = A^T Z, Z \in \mathbb{R}^n \} \). Furthermore, for any \( X \in \mathfrak{A}^\perp \) and \( Y = A^T Z \in \mathfrak{A}^rSP \), we have \( Y^T X = Z^T AX = 0 \), that is, \( Y \perp X \). In consequence,

**Proposition 2.4:** The spaces \( \mathfrak{A}^\perp \) and \( \mathfrak{A}^rSP \) have the following properties:

1) \( \mathfrak{A}^\perp \) and \( \mathfrak{A}^rSP \) are orthogonal to each other.

2) \( \mathfrak{A}^\perp \cap \mathfrak{A}^rSP = 0 \), and so \( ||AY|| \neq 0 \) for any nonzero \( Y \in \mathfrak{A}^rSP \).

3) Both \( \mathfrak{A}^\perp \) and \( \mathfrak{A}^rSP \) are closed sets.

4) For any nonzero \( Z \in \mathbb{R}^n \), it can be uniquely decomposed as \( Z = X + Y \) such that \( X \perp Y \), \( X \in \mathfrak{A}^\perp \) and \( Y \in \mathfrak{A}^rSP \).

Let \( \mathfrak{U} := \{ X \in \mathbb{R}^n \mid ||X|| = 1 \} \), which is a compact set in \( \mathbb{R}^n \). Then

**Proposition 2.5:** Both \( \mathfrak{U}(\mathfrak{A}^\perp) := \mathfrak{U} \cap \mathfrak{A}^\perp \) and \( \mathfrak{U}(\mathfrak{A}^rSP) := \mathfrak{U} \cap \mathfrak{A}^rSP \) are closed and so compact. Moreover, \( ||AY|| \neq 0 \) for any \( Y \in \mathfrak{U}(\mathfrak{A}^rSP) \), and furthermore \( \inf_{Y \in \mathfrak{U}(\mathfrak{A}^rSP)} \| (AY)^{\ast 3} \| = \epsilon > 0 \) and \( \sup_{Y \in \mathfrak{U}(\mathfrak{A}^rSP)} \| (AY)^{\ast 3} \| = \psi < \infty \) for some positive real numbers \( \epsilon \) and \( \psi \).

Fix an \( X \in \mathfrak{U} \), we consider \( D(\lambda, X) := D(\sqrt{\lambda} X) = \sqrt{\lambda} X + \left( \sqrt{\lambda} \right)^3 (AX)^{\ast 3} \) for \( \lambda > 0 \). We study the change of \( ||D(\lambda, X)|| \) with respect to \( \lambda > 0 \). First,

\[
||D(\lambda, X)||^2 = \lambda + 2\lambda^2 X^T (AX)^{\ast 3} + \lambda^3 \| (AX)^{\ast 3} \|^2
\]

As a result, \( ||D(\lambda, X)|| \to \infty \) as \( \lambda \to \infty \) no matter what is \( AX \). Suppose \( \| (AX)^{\ast 3} \| \neq 0 \), then it’s derivative with respect to \( \lambda \) is

\[
1 + 4\lambda X^T (AX)^{\ast 3} + 3\lambda^2 \| (AX)^{\ast 3} \|^2
\]

When \( 4(X^T (AX)^{\ast 3})^2 - 3\| (AX)^{\ast 3} \|^2 \geq 0 \), \( (3) \) has zero roots:

\[
\lambda(X) := \frac{-2X^T (AX)^{\ast 3} \pm \sqrt{4(X^T (AX)^{\ast 3})^2 - 3\| (AX)^{\ast 3} \|^2}}{3\| (AX)^{\ast 3} \|^2}
\]

Let \( \mathfrak{D} := \{ X \mid 4(X^T (AX)^{\ast 3})^2 - 3\| (AX)^{\ast 3} \|^2 \geq 0 \& X^T (AX)^{\ast 3} \leq 0 \} \cap \mathfrak{U} \). Suppose \( X \in \mathfrak{D} \), then the smaller solution of \( (3) \) is

\[
\lambda_1(X) := \frac{-2X^T (AX)^{\ast 3} - \sqrt{4(X^T (AX)^{\ast 3})^2 - 3\| (AX)^{\ast 3} \|^2}}{3\| (AX)^{\ast 3} \|^2}
\]
and the bigger solution of (3):
\[
\lambda_2(X) := \frac{-2X^T(AX)^{3} + \sqrt{4(X^T(AX)^{3})^2 - 3||(AX)^{3}||^2}}{3||(AX)^{3}||^2} \geq \lambda_1(X) \quad (6)
\]
Note that, for \( X \in \mathcal{D} \) it must be \( \lambda_2(X) \geq 0 \). For any fixed \( X \in \mathcal{D} \), if \( \lambda_2(X) > \lambda_1(X) \) then \( \lambda_2(X) \) is a local minimal point of \( ||\mathcal{D}(\lambda, X)|| \) with respect to \( \lambda > 0 \), since
(a) \( \lambda_1(X) < \lambda < \lambda_2(X) \) implies \( 1 + 4\lambda X^T(AX)^{3} + 3\lambda^2||(AX)^{3}||^2 < 0 \) and
(b) \( \lambda > \lambda_2(X) \) implies \( 1 + 4\lambda X^T(AX)^{3} + 3\lambda^2||(AX)^{3}||^2 > 0 \).
On the other side, if \( \lambda_2(X) = \lambda_1(X) \) then \( 1 + 4\lambda X^T(AX)^{3} + 3\lambda^2||(AX)^{3}||^2 \geq 0 \) for all \( \lambda \). As a result, \( ||\mathcal{D}(\lambda, X)||^2 \) is an increasing function with respect to \( \lambda \). In any case, we have

**Proposition 2.6:** For any \( X \in \mathcal{D} \) such that \( ||(AX)^{3}|| \neq 0 \), the following equation holds
\[
\inf_{\lambda > \lambda_1(X)} ||\mathcal{D}(\lambda, X)||^2 = ||\mathcal{D}(\lambda_2(X), X)||^2 \quad (7)
\]
\[
= \frac{16\theta_X^3 - 18\theta_X + 6\sqrt{4\theta_X^2 - 3} - 8\theta_X^2\sqrt{4\theta_X^2 - 3}}{27||(AX)^{3}||} \quad (8)
\]
where \( \theta_X := \frac{X^T(AX)^{3}}{||(AX)^{3}||}, \ X \in \mathcal{D} \).
Let \( \phi(\tau) := 16\tau^3 - 18\tau + 6\sqrt{4\tau^2 - 3} - 8\tau^2\sqrt{4\tau^2 - 3} \), then we have

**Proposition 2.7:** For \( \tau \in [-1, -\frac{\sqrt{3}}{2}] \), \( \phi(\tau) \geq 0 \) and is a strictly increasing function, herein the equality holds only when \( \tau = -1 \).

Let’s consider a subset \( \mathfrak{R} \) of \( \mathfrak{U}(\mathfrak{A}^\perp) \times \mathfrak{U}(\mathfrak{A}^r) \) defined by
\[
\mathfrak{R} := \{(V, W) \in \mathfrak{U}(\mathfrak{A}^\perp) \times \mathfrak{U}(\mathfrak{A}^r) | W^T(\mathcal{A}W)^{3} \leq 0 \ \& \ \frac{V^T(\mathcal{A}W)^{3}}{||(\mathcal{A}W)^{3}||} \leq -\frac{2\sqrt{3}}{3}\} \quad (9)
\]
By the definition, using Proposition 2.4 (2) can show that \( \mathfrak{R} \) is closed. By Proposition 2.5 both \( \mathfrak{U}(\mathfrak{A}^\perp) \) and \( \mathfrak{U}(\mathfrak{A}^r) \) are bounded. Therefore,

**Proposition 2.8:** \( \mathfrak{R} \) is a compact set of \( \mathbb{R}^{2n} \).
Note that, \( \mathfrak{R} \) has a clear topological structure. Because \( \mathfrak{U}(\mathfrak{A}^\perp) \) and \( \mathfrak{U}(\mathfrak{A}^r) \) are defined by algebraic inequalities, so they are semi-algebraic sets \[13\]. Because \( ||(\mathcal{A}W)^{3}|| > 0 \) for any \( W \in \mathfrak{U}(\mathfrak{A}^r) \), \( \mathfrak{R} \) is actually defined by several algebraic inequalities with existential quantifier. That is, \( \mathfrak{R} \) is the projection of a semi-algebraic set, which is a union of finitely many disjoint connected sets by Tarski’s Theorem.

Given a \( (V, W) \in \mathfrak{R} \), let \( X_\alpha := \alpha V + \sqrt{1 - \alpha^2}W \) for \( \alpha \in [0, 1] \) and define an arc \( \mathcal{A}(V, W, \alpha) \) by \( \mathcal{A}(V, W, \alpha) := \{X_\alpha | \alpha \in [0, 1]\} \) which is a curve on the unit sphere. For \( X_\alpha \in \mathcal{A}(V, W, \alpha) \) with \( (V, W) \in \mathfrak{R} \), we take \( \alpha^\# := \frac{3\sqrt{3}}{4\sqrt{2}} < 1 \) then \( \theta_{X_\alpha} := \frac{X_\alpha^T(AX_\alpha)^{3}}{||(AX_\alpha)^{3}||} \leq \frac{\alpha V^T(\mathcal{A}W)^{3}}{||(\mathcal{A}W)^{3}||} \leq -\frac{\sqrt{3}}{2} \) for all
\( \alpha \in [\alpha^#, 1) \neq \emptyset \) by (9). That is, \( \theta_{X_\alpha} \leq -\frac{\sqrt{2}}{\alpha} \) for all adequate large \( \alpha \in (0, 1) \). Based on this observation, we obtain the tendency of \( \inf_{\lambda > \lambda_1(X_\alpha)} \|D(\lambda, X_\alpha)\|^2 \) when \( \alpha \) tends to 1 as follows.

Lemma 2.9: For any fixed \( (V, W) \in \mathfrak{R} \), \( \lim_{\alpha \to 1} \inf_{\lambda > \lambda_1(X_\alpha)} \|D(\lambda, X_\alpha)\| = \infty \).

Proof: As \( (V, W) \in \mathfrak{R} \), for \( \alpha \in [\alpha^#, 1) \) it has \( X_\alpha \in \mathcal{D} \) and \( \|(AX_\alpha)^3\| \neq 0 \). So by Proposition 2.6 for \( \alpha \in [\alpha^#, 1) \) we have

\[
\inf_{\lambda > \lambda_1(X_\alpha)} \|D(\lambda, X_\alpha)\|^2 = \frac{16\theta X_\alpha^3 - 18\theta X_\alpha + 6\sqrt{4\theta X_\alpha^2 - 3} - 8\theta X_\alpha \sqrt{4\theta X_\alpha^2 - 3}}{27 (\sqrt{1 - \alpha^2})^3 \|D(W)^*\|} \tag{10}
\]

\[
= \frac{\phi(\theta X_\alpha)}{27 (\sqrt{1 - \alpha^2})^3 \|D(W)^*\|} \tag{11}
\]

where \( \theta X_\alpha = v\alpha + \omega \sqrt{1 - \alpha^2} \) with \( v := \frac{V^T(AX_\alpha)^3}{\|D(W)^*\|} \leq -\frac{2\sqrt{2}}{3} \) and \( \omega := \frac{W^T(AX_\alpha)^3}{\|D(W)^*\|} \leq 0 \), since \( (V, W) \in \mathfrak{R} \). By Proposition 2.4 (2), \( \inf_{\lambda > \lambda_1(X_\alpha)} \|D(\lambda, X_\alpha)\|^2 \) is always well defined and \( > 0 \) for any \( \alpha \in [\alpha^#, 1) \), since \( (V, W) \in \mathfrak{R} \). For a fixed \( (V, W) \in \mathfrak{R} \), \( \inf_{\lambda > \lambda_1(X_\alpha)} \|D(\lambda, X_\alpha)\|^2 \) is a function of \( \alpha \), precisely, a rational function of \( \alpha \) and \( \sqrt{1 - \alpha^2} \), in the interval \([\alpha^#, 1)\). So we can compute the limit by cases as follows.

Case I: \( v \in (-1, -\frac{2\sqrt{2}}{3}] \). By the method in [14], we have

\[
\lim_{\alpha \to 1} \inf_{\lambda > \lambda_1(X_\alpha)} \|D(\lambda, X_\alpha)\|^2 = \lim_{\alpha \to 1} \frac{\phi(v\alpha + \omega \sqrt{1 - \alpha^2})}{27 (\sqrt{1 - \alpha^2})^3 \|D(W)^*\|} \tag{12}
\]

\[
= \text{sign}(-4v^2\sqrt{4v^2 - 3} + 8v^3 + 3\sqrt{4v^2 - 3} - 9v) \cdot \infty \tag{13}
\]

wherein \( v \leq -\frac{2\sqrt{2}}{3} \) and \( \text{sign} \) is the sign function. Thus \( 4v^2 > 3 \). Note that, \( -4v^2\sqrt{4v^2 - 3} + 8v^3 + 3\sqrt{4v^2 - 3} - 9v > 0 \) for any \( v \in (-1, -\frac{\sqrt{3}}{2}] \) and so for all \( v \in (-1, -\frac{2\sqrt{2}}{3}] \).

Case II: \( v = -1 \), which implies \( V = \ell (AX_\alpha)^3 \) for some \( \ell < 0 \). As a result, it must be \( \omega = 0 \) since \( V \in \mathfrak{H}^\perp \) and \( W \in \mathfrak{H}^{sp} \). So \( \theta_{X_\alpha} = -\alpha \) and then

\[
\lim_{\alpha \to 1} \inf_{\lambda > \lambda_1(X_\alpha)} \|D(\lambda, X_\alpha)\|^2 = \lim_{\alpha \to 1} \frac{\phi(-\alpha)}{27 (\sqrt{1 - \alpha^2})^3 \|D(W)^*\|} \tag{14}
\]

\[
= \infty \tag{15}
\]

In summary, \( \lim_{\alpha \to 1} \inf_{\lambda > \lambda_1(X_\alpha)} \|D(\lambda, X_\alpha)\| = \infty \) for all \( (V, W) \in \mathfrak{R} \).

By Lemma 2.9 for any \( (V, W) \in \mathfrak{R} \) and \( \mu > 0 \) there is some \( \alpha \in [0, 1) \) such that

\[
\inf_{\lambda > \lambda_1(X_\alpha)} \|D(\lambda, X_\alpha)\| \geq \mu \tag{16}
\]

In fact, we have a more strong result as follows.
Lemma 2.10: For any \((V, W) \in \mathfrak{V}\) and \(\mu > 0\), there is an \(\alpha(V, W, \mu) < 1\) such that 
\[
\inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)|| \geq \mu \text{ for all } \alpha \in [\alpha(V, W, \mu), 1].
\]

Proof: For a fixed \((V, W) \in \mathfrak{V}\), by (11) \(\inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)||^2\) is a function of \(\alpha \in [\alpha^#, 1]\), precisely, is a rational function of \(\alpha\) and \(\sqrt{1 - \alpha^2}\). As a result, it’s derivative with respect to \(\alpha\) has at most finitely many zero in \([\alpha^#, 1]\). Therefore, it’s monotonicity can change at most finitely many times. Because

\[
\lim_{\alpha \to 1^+} \inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)|| = \infty
\]

there must exist \(\alpha(V, W) < 1\), which is the greatest zero root of the derivative, such that 
\(\inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)||\) is increasing in the interval \([\alpha(V, W), 1]\). Given a positive number \(\mu\), let \(\alpha(V, W, \mu)\) be the least number \(\alpha\) such that \(\alpha \geq \alpha(V, W)\) and \(\inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)|| \geq \mu\). Such \(\alpha(V, W, \mu)\) must exist and \(< 1\) by Lemma 2.9. So \(\inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)||\) is increasing with respect to \(\alpha \in [\alpha(V, W, \mu), 1]\). Therefore \(\inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)|| \geq \mu \) for all \(\alpha \in [\alpha(V, W, \mu), 1]\).

Given a \(\mu > 0\), let \(\alpha(\mathfrak{V}, \mu) = \max_{(V, W) \in \mathfrak{V}} \alpha(V, W, \mu)\), then we have

Lemma 2.11: \(\alpha(\mathfrak{V}, \mu) < 1\) for any \(\mu > 0\). Furthermore, for any \(\alpha \in [\alpha(\mathfrak{V}, \mu), 1]\) and \((V, W) \in \mathfrak{V}\), \(\inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)|| \geq \mu\).

Proof: In the proof of Lemma 2.10, it has shown that \(\alpha(V, W, \mu) < 1\) for each \((V, W) \in \mathfrak{V}\) and \(\mu > 0\). By (11), \(\inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)||\) is a continuous function with respect to \(V, W, \alpha\). So \(\alpha(V, W)\) in the proof of Lemma 2.10 is a continuous function with respect to \(V\) and \(W\). Thus, for any fixed \(\mu\), \(\alpha(V, W, \mu)\) is a continuous function with respect to \((V, W)\). Note that \(\mathfrak{V}\) is a compact set by Proposition 2.8. Therefore \(\alpha(\mathfrak{V}, \mu) = \alpha(V_{\mu}, W_{\mu}, \mu) < 1\) for some \((V_{\mu}, W_{\mu}) \in \mathfrak{V}\).

For any \(\alpha \in [\alpha(\mathfrak{V}, \mu), 1]\) and \((V, W) \in \mathfrak{V}\), we have \(\alpha \geq \alpha(\mathfrak{V}, \mu) \geq \alpha(V, W, \mu)\). That is, \(\alpha \in [\alpha(V, W, \mu), 1]\). By Lemma 2.10, \(\inf_{\lambda > \lambda_1(X_0)} ||D(\lambda, X_0)|| \geq \mu\).

Given a \(\mu > 0\) and \(Y \in \mathfrak{Y}(\mathfrak{V}^+\|\))\), we take an open neighbourhood \(\mathfrak{N}_\mu(Y)\) of \((\mu + 1)Y\) such that \(||D(X)|| > \mu\) for all \(X \in \mathfrak{N}_\mu(Y)\). This can be done, because \(||D((\mu + 1)Y)|| = ||(\mu + 1)Y|| = \mu + 1\) and \(||D(X)||\) is a continuous function about \(X\). Given a point \(P\) and \(\theta \in [0, 1)\), let \(\mathfrak{C}on(P, \alpha) = \{X | \frac{x^TP}{||X|| ||P||} > \theta\}\). Then \(\mathfrak{C}on(P, \alpha)\) is an open set, and contains \(P\) since \(\frac{p^TP}{||P||^2 ||P||} = 1 > \theta\). In the view of geometry, \(\mathfrak{C}on(P, \alpha)\) is an open cone with vertex \(0\) such that the angle \(\angle(P, X)\) between \(X\) and \(P\) is no more than \(arccos \theta\) for any \(X \in \mathfrak{C}on(P, \alpha)\). So \(\mathfrak{C}on(P, \alpha)\) is an unbounded open neighbourhood of \(P\). Note that, the cone \(\mathfrak{C}on(P, \alpha)\) is
symmetry in the sense that if $X = \lambda P + Y$ is in $\mathcal{C}on(P, \alpha)$ for some $Y \perp P$ and real number $\lambda$ then $X^* := \lambda P - Y$ is also in $\mathcal{C}on(P, \alpha)$. Another important property of $\mathcal{C}on(P, \alpha)$ is the following invariant.

**Proposition 2.12:** If $X \in \mathcal{C}on(P, \alpha)$ then $\lambda X \in \mathcal{C}on(P, \alpha)$ for all $\lambda > 0$. In particular, $\frac{X}{\|X\|} \in \mathcal{C}on(P, \alpha)$.

Now, we consider $\mathcal{S}_\mu(Y) := \mathcal{N}_\mu(Y) \cap \mathcal{C}on(Y, \alpha(\mathcal{R}, \mu)) \ni Y$ for $\mu > 0$ and $Y \in \mathcal{U}(\mathcal{A}^\perp)$. Note that $\mathcal{S}_\mu(Y)$ is an open set because $\alpha(\mathcal{R}, \mu) < 1$. Take an $X \in \mathcal{S}_\mu(Y)$, we decompose it as $X = \zeta(\mu + 1)Y + \beta Z$ for some $Z \perp Y$ with $Z \in \mathcal{U}$ and real numbers $\zeta, \beta \geq 0$. We further decompose $Z$ as $Z = \rho E + \xi H$ such that $E \in \mathcal{U}(\mathcal{A}^\perp)$ and $H \in \mathcal{U}(\mathcal{A}^{rSp})$ for some real numbers $\rho, \xi \geq 0$. Then

$$
X = \zeta(\mu + 1)Y + \beta Z
= \zeta(\mu + 1)Y + \beta \rho E + \beta \xi H
$$

(15)

As a result, $Y \perp E$, $Y \perp H$ and so $\zeta(\mu + 1)Y + \beta \rho E \in \mathcal{A}^\perp$. Now, we consider the decomposition $\frac{X}{\|X\|} = \alpha V + \sqrt{1 - \alpha^2}W$ such that $V \in \mathcal{U}(\mathcal{A}^\perp)$ and $W \in \mathcal{U}(\mathcal{A}^{rSp})$, with $\alpha \in [0, 1]$. Note that, such decomposition exists and is unique. As a result, we have $\alpha V = \frac{\zeta(\mu + 1)Y + \beta \rho E}{\|X\|}$, $W = \frac{H}{\|H\|}$ and

$$
\alpha = \frac{\sqrt{\zeta^2(\mu + 1)^2\|Y\|^2 + \beta^2 \rho^2 \|E\|^2}}{\|X\|}
\geq \frac{\zeta(\mu + 1)\|Y\|}{\|X\|}
\geq \frac{(\mu + 1)Y^T X}{\|X\| \cdot \|X\|}
\geq \alpha(\mathcal{R}, \mu)
$$

(17)

(18)

(19)

(20)

where equality (19) holds by (15) and inequality (20) holds by $X \in \mathcal{S}_\mu(Y)$. By inequalities (18)-(20), if $(V, W) \in \mathcal{R}$ then the corresponding $\alpha$ with the decomposition of $\frac{X}{\|X\|}$ satisfies $\alpha \geq \alpha(\mathcal{R}, \mu)$ and so $\inf_{\lambda > \lambda_1(X)} \|D(\lambda, \frac{X}{\|X\|})\| \geq \mu$ by Lemma 2.11. Note that, $X \in \mathcal{N}_\mu(Y)$ means $\|D(X)\| \geq \mu$. Furthermore,

**Lemma 2.13:** For a given $X \in \mathcal{S}_\mu(Y)$, if $\frac{X}{\|X\|} = \alpha V + \sqrt{1 - \alpha^2}W$ for some $\alpha \in [0, 1)$, $V \in \mathcal{U}(\mathcal{A}^\perp)$ and $W \in \mathcal{U}(\mathcal{A}^{rSp})$ such that $(V, W) \in \mathcal{R}$, then $\|D(\ell X)\| \geq \mu$ for all $\ell \geq 1$.

**Proof:** This result will be proved by cases. If $\|X\| \geq \lambda_2(\frac{X}{\|X\|})$, then $\|D(\ell \frac{X}{\|X\|})\|$ is increasing for $\ell \in \left[\lambda_2(\frac{X}{\|X\|}), \infty\right)$ and so for $\ell \in \left[\|X\|, \infty\right)$. Thus, $\|D(\ell X)\| \geq \|D(X)\|$ for all $\ell \geq 1$ by the monotonicity. As $X \in \mathcal{S}_\mu(Y)$, $\|D(X)\| \geq \mu$. Therefore $\|D(\ell X)\| \geq \mu$ for all $\ell \geq 1$. 
If \( ||X|| < \lambda_2(\frac{X}{||X||}) \), there are two subcases.

Subcase I: \( ||X|| < \lambda_1(\frac{X}{||X||}) \). Now \( ||D(\ell X)|| \) is increasing for \( \ell \in [1, \frac{\lambda_1(\frac{X}{||X||})}{||X||}] \). So \( ||D(\ell X)|| \geq D(X)|| > \mu \) for \( \ell \in [1, \frac{\lambda_1(\frac{X}{||X||})}{||X||}] \). For \( \ell \in [\frac{\lambda_1(\frac{X}{||X||})}{||X||}, \infty) \), \( ||\ell X|| \geq \lambda_1(\frac{X}{||X||}) \) and so \( ||D(\ell X)|| \geq \inf_{\lambda>\lambda_1(\frac{X}{||X||})} ||D(\lambda, \frac{X}{||X||})|| \geq \mu \) by \( Y \in \mathcal{G}_\mu(Y) \), \( (V, W) \in \mathcal{R} \) and Lemma 2.11 using \( \alpha \geq \alpha(\mathcal{R}, \mu) \).

In summary, \( ||D(\ell X)|| \geq \mu \) for all \( \ell \geq 1 \) in this subcase.

Subcase II: \( ||X|| \geq \lambda_1(\frac{X}{||X||}) \). In this case, \( ||D(\ell X)|| \geq \inf_{\lambda>\lambda_1(\frac{X}{||X||})} ||D(\lambda, \frac{X}{||X||})|| \geq \mu \) for all \( \ell \in [1, \infty) \), by \( Y \in \mathcal{G}_\mu(Y) \), \( (V, W) \in \mathcal{R} \) and Lemma 2.11 using \( \alpha \geq \alpha(\mathcal{R}, \mu) \).

Now, we are ready to prove Theorem 1.3. By Hadamard Theorem 1.2, if a D-map \( D(X) := X + (AX)_{*3} \) is not an automorphism, then there must be an unbounded sequence \( \{Y_i \in \mathbb{R}^n \mid i = 1, 2, \ldots, \infty\} \) (\( \{Y_i\}_i \) for simplicity, and such notation applied for other similar set in the article) such that \( \{D(Y_i)\}_i \) is a bounded sequence. Without loss of generality, we suppose that \( ||Y_{i+1}|| > ||Y_i|| \) for all \( i \). By the boundness of \( \{D(Y_i)\}_i \), there is some real number \( \sigma < \infty \) such that

\[
Y_i^T Y_i + 2Y_i^T (AY_i)_{*3} + ||(AY_i)_{*3}||^2 \leq \sigma^2 \tag{21}
\]

for all \( i \). Because \( \{Y_i\}_i \) is unbounded and \( D(X) \) has a unique zero root, it must be \( Y_i^T (AY_i)_{*3} < 0 \) for almost all \( i \). Without loss of generality, we suppose \( Y_i^T (AY_i)_{*3} < 0 \) for all \( i \). As a result, \( (AY_i)_{*3} \neq 0 \) and so \( ||(AY_i)_{*3}|| > 0 \) for all \( i \). Then by optimization theory [15], we have

\[
|| (AY_i)_{*3} ||^2 \gamma^2 + 2Y_i^T (AY_i)_{*3} \gamma + Y_i^T Y_i \geq Y_i^T Y_i - \frac{(Y_i^T (AY_i)_{*3})^2}{|| (AY_i)_{*3} ||^2} \tag{22}
\]

for any \( \gamma \in \mathbb{R} \) and all \( i \). When \( \gamma = 1 \), we get

\[
Y_i^T Y_i - \frac{(Y_i^T (AY_i)_{*3})^2}{|| (AY_i)_{*3} ||^2} \leq Y_i^T Y_i + 2Y_i^T (AY_i)_{*3} + ||(AY_i)_{*3}||^2 \leq \sigma^2 \tag{23}
\]

Therefore,

\[
\lim_{i \to \infty} \left( 1 - \frac{(Y_i^T (AY_i)_{*3})^2}{|| (AY_i)_{*3} ||^2} \right) \leq \lim_{n \to \infty} \frac{\sigma^2}{Y_i^T Y_i} = 0 \tag{24}
\]

since \( \{Y_i\}_i \) is unbounded. Let \( X_i = \frac{Y_i}{||Y_i||} \), then \( X_i \in \mathcal{U} \), \( (AX_i)_{*3} \neq 0 \) by the assumption \( Y_i^T (AY_i)_{*3} < 0 \) for all \( i \), and then

**Lemma 2.14:**

\[
\lim_{i \to \infty} \frac{X_i^T (AX_i)_{*3}}{|| (AX_i)_{*3} ||} = \lim_{i \to \infty} \frac{Y_i^T (AY_i)_{*3}}{|| (AY_i)_{*3} ||} = -1 \tag{25}
\]

For each \( i \), we decompose \( X_i \) as \( X_i = \alpha_i V_i + \sqrt{1 - \alpha_i^2} W_i \) such that \( V_i \in \mathcal{U}(\mathbb{1}^+, W_i \in \mathcal{U}(\mathbb{2}^{*S^p}) \), and \( \alpha_i \in [0, 1] \). By assumption \( Y_i^T (AY_i)_{*3} < 0 \) for all \( i \), we have
Corollary 2.15: \( \alpha_i < 1 \) for all \( i \).

Because \( V_i, W_i \in \mathcal{U} \) for all \( i \), we can choose a subsequence \( \{X_{i_k}\}_k \) of \( \{X_i\}_i \) such that
\[
\lim_{k \to \infty} V_{i_k} = V_{\infty} \in \mathbb{R}^n \quad \text{and} \quad \lim_{k \to \infty} W_{i_k} = W_{\infty} \in \mathbb{R}^n.
\]
As \( \mathcal{U}(\mathbb{R}^+) \) and \( \mathcal{U}(\mathbb{R}^{rSp}) \) are closed, it must be \( V_{\infty} \in \mathcal{U}(\mathbb{R}^+) \) and \( W_{\infty} \in \mathcal{U}(\mathbb{R}^{rSp}) \). Furthermore, we can choose a subsequence \( \{X_{i_{k_j}}\}_j \) of \( \{X_{i_k}\}_k \) such that \( \lim_{j \to \infty} \alpha_{i_{k_j}} = \alpha_{\infty} \in [0, 1] \). Without loss of generality, we assume \( \{X_i\}_i \) has such properties of \( \{X_{i_{k_j}}\}_j \), that is,

(i) \( \lim_{i \to \infty} \alpha_i = \alpha_{\infty} \in [0, 1] \).

(ii) \( \lim_{i \to \infty} V_i = V_{\infty} \in \mathcal{U}(\mathbb{R}^+) \) and \( \lim_{i \to \infty} W_i = W_{\infty} \in \mathcal{U}(\mathbb{R}^{rSp}) \)

Then
\[
\lim_{i \to \infty} \frac{X_i^T(AX_i)^{k_3}}{||((AX_i)^{k_3})||} = \lim_{i \to \infty} \frac{\alpha_i V_i + \sqrt{1 - \alpha_i^2} W_i}{||((AX_i)^{k_3})||} \tag{26}
\]
\[
= \frac{(\alpha_{\infty} V_{\infty} + \sqrt{1 - \alpha_{\infty}^2} W_{\infty})^3}{||((AX_{\infty})^{k_3})||} \tag{27}
\]
\[
= -1 \tag{28}
\]

Now, let \( X_{\infty} = \alpha_{\infty} V_{\infty} + \sqrt{1 - \alpha_{\infty}^2} W_{\infty} \). There are two cases.

Case (i): \( \alpha_{\infty} < 1 \). In this case \( X_{\infty} \not\in \mathcal{U}^+ \). Thus \( \frac{X_{\infty}^T(AX_{\infty})^{k_3}}{||((AX_{\infty})^{k_3})||} = -1 \) by (27) and (28). This contradicts with Corollary 2.3.

Case (ii): \( \alpha_{\infty} = 1 \). Because \( \lim_{i \to \infty} \frac{X_i^T(AX_i)^{k_3}}{||((AX_i)^{k_3})||} = -1 \), there must exist an integer \( i^# \) such that \( \frac{V_i^T(AW_i)^{k_3}}{||((AW_i)^{k_3})||} < -\frac{2\sqrt{2}}{3} \) for all \( i \geq i^# \). Without loss of generality, we suppose that \( \frac{V_i^T(AW_i)^{k_3}}{||((AW_i)^{k_3})||} < -\frac{2\sqrt{2}}{3} \) for all \( i \). There are two subcases.

Subcase (ii.a): There are infinitely many \( i \) such that \( \frac{W_i^T(AW_i)^{k_3}}{||((AW_i)^{k_3})||} \geq 0 \), say \( i_s \) for \( s = 1, 2, \ldots, \infty \).

By definition, \( Y_{i_s} = \|Y_{i_s}\|X_{i_s} \), and so \( Y_{i_s} = \rho_{i_s} V_{i_s} + \tau_{i_s} W_{i_s} \) where \( \rho_{i_s} = \|Y_{i_s}\|\alpha_{i_s} \) and \( \tau_{i_s} = \|Y_{i_s}\|\sqrt{1 - \alpha_{i_s}^2} \). As a result,
\[
\|D(Y_{i_s})\|^2 = \rho_{i_s}^2 + \tau_{i_s}^2 + \tau_{i_s}^6 ||(AW_{i_s})^{k_3}||^2 + 2\rho_{i_s} \tau_{i_s}^3 V_{i_s}^T(AX_{i_s})^{k_3} + 2\tau_{i_s}^4 W_{i_s}^T(AX_{i_s})^{k_3} \tag{29}
\]
\[
\geq \rho_{i_s}^2 + \tau_{i_s}^2 + \tau_{i_s}^6 ||(AW_{i_s})^{k_3}||^2 + 2\rho_{i_s} \tau_{i_s}^3 V_{i_s}^T(AX_{i_s})^{k_3} \tag{30}
\]
\[
= \rho_{i_s}^2 + \tau_{i_s}^2 + \tau_{i_s}^6 ||(AW_{i_s})^{k_3}||^2 \tag{31}
\]

Wherein, inequality (29) holds since \( \frac{W_i^T(AW_i)^{k_3}}{||((AW_i)^{k_3})||} \geq 0 \) by assumption, and inequality (31) holds because \( \frac{X_i^T Y_i}{||X_i|| Y_i} \geq -1 \) for any vector \( X \) and \( Y \) by its geometric meaning. By the unboundedness assumption on \( \{Y_{i_s}\}_s \), \( \rho_{i_s}^2 + \tau_{i_s}^2 \to \infty \) as \( s \to \infty \). If \( \{\tau_{i_s}\}_s \) is unbounded, then \( \{D(Y_{i_s})\}_s \) must
be unbounded by (31). If \( \{ \tau_i \}_s \) is bounded, then \( \{ \rho_i \}_s \) must be unbounded. Thus \( \{(\rho_i - \tau_i^3||AW_i^3||)^2\}_s \) must be unbounded since \( \{(\rho_i - \tau_i^3||AW_i^3||)_s \) is bounded by Proposition 2.4. Therefore \( \{D(Y_i)\}_s \) is unbounded again by (31). In consequence, \( \{D(Y_i)\}_i \) is unbounded.

Subcase (ii.b): There are only finitely many \( i \) such that \( W_i^T(\rho_i - \tau_i^3||AW_i^3||) \geq 0 \), i.e., \( W_i^T(\rho_i - \tau_i^3||AW_i^3||) \geq 0 \). Without loss of generality, we suppose \( W_i^T(\rho_i - \tau_i^3||AW_i^3||) < 0 \) for all \( i \). Then \( (V_i, W_i) \in \mathfrak{A} \) for all \( i \). In this subcase, we can still show that

**Lemma 2.16:** \( \{D(Y_i)\}_i \) must be unbounded.

**Proof:** For any \( \mu > 0 \), set \( Y := X_\infty \) and for which let’s take a neighbourhood \( \mathfrak{S}_\mu(Y) \) as before. Because \( \lim_{i \to \infty} \frac{Y_i^T Y}{||Y_i||} = \lim_{i \to \infty} X_i^TY = \lim_{i \to \infty} X_i^TX_\infty = 1 \), there must exist an integer \( i_\mu \) such that \( Y_i \in \mathfrak{C} \mathfrak{o} \mathfrak{n} (Y, \alpha(\mathfrak{A}, \mu)) \) for all \( i \geq i_\mu \). For each \( i \geq i_\mu \), by Proposition 2.12 we have \( (\mu + 1) \frac{Y_i}{||Y_i||} \in \mathfrak{C} \mathfrak{o} \mathfrak{n} (Y, \alpha(\mathfrak{A}, \mu)) \). \( \lim_{i \to \infty} \frac{X_i}{||X_i||} = Y \) implies \( \lim_{i \to \infty} (\mu + 1) \frac{Y_i}{||Y_i||} = (\mu + 1)Y \), therefore for the neighbourhood \( \mathfrak{N}_\mu(Y) \) there is some integer \( i_\# \) such that \( (\mu + 1) \frac{Y_i}{||Y_i||} \in \mathfrak{N}_\mu(Y) \) for all \( i \geq i_\# \). So, \( (\mu + 1) \frac{Y_i}{||Y_i||} \in \mathfrak{S}_\mu(Y) \) for all \( i \geq i_\# \). As \( \{Y_i\}_i \) is unbounded, there must exist some \( i_\# > i_\mu \) such that \( ||Y_i|| \geq \mu + 1 \). Then by Lemma 2.13 and Corollary 2.15 \( ||D(Y_i)\|| \geq \mu \). By the arbitrariness of \( \mu \), \( \{D(Y_i)\}_i \) must be unbounded.

Lemma 2.16 contradicts with the assumption again. So, for a given D-map \( D(X) \) there must have no unbounded sequence \( \{Y_i\}_i \) such that \( \{D(Y_i)\}_i \) is bounded. Therefore, each D-map must be a proper map.

This completes the proof of Theorem 1.3.

### III. Discussion and Related Work

Recall the history of \( J\mathcal{C} \), there are many excellent work. First of all, Keller posed \( J\mathcal{C} \) for \( \mathbb{K}^n = \mathbb{C}^2 \) in 1939 [2]. And Abhyankar gave its modern style in his lectures [7], [8]. Let \( (J\mathcal{C})^k \) denote \( J\mathcal{C}(\mathbb{K}, n) \) in which the polynomial degrees are not greater than \( k \). A remarkable progress is Wang’s result [16] that \( (J\mathcal{C})^2 \) is true for arbitrary field of characteristic \( \neq 2 \). This led to the studies on the reduction of \( J\mathcal{C} \) to specific \( (J\mathcal{C})^k \) for some small integer \( k \). In the line of this, Yagžev [17] and independently Bass et al. [3] showed that \( (J\mathcal{C})^3 \) implies \( J\mathcal{C} \). Furthermore, Družkowski [10] showed that it suffices to show D-maps being automorphism for \( J\mathcal{C} \). Anyway, it cannot make a reduction of \( J\mathcal{C} \) to \( (J\mathcal{C})^2 \) [18] on the field \( \mathbb{C} \). That is, we must solve \( (J\mathcal{C})^3 \) to the end of \( J\mathcal{C} \). Anyway, many studies [19], [20] showed that it suffices to prove specific structure D-maps for \( J\mathcal{C} \). Furthermore, \( J\mathcal{C} \) also appeared to be connected to questions in noncommutative algebra, for example, \( J\mathcal{C} \) is equivalent to the Dixmier Conjecture which
asserts that each endomorphism of the Weyl algebra is surjective (hence an automorphism) \[21\]– \[23\]. \(JC\) is proved equivalent to various conjectures, such as, Kernel Conjecture \[5\], Hessian Conjecture \[20\], \[24\], Eulerian Conjecture \[25\], etc. There are many partial results of \(JC\) on special categories of polynomials, for instance, the “non-negative coefficients” D-map \[9\], D-maps in low dimension space \[26\], \[27\], a special class of D-maps in dimension \(9\) \[28\], tame automorphisms \[29\]–\[31\], etc, refer to surveys \[1\], \[3\]–\[6\] for more related results. There were some studies about \(JC\) for fixed number of variables, even for 2-variables, such as, \(JC\) \[32\] for 2-variables \(\leq 100\)-degree, sufficient conditions via polynomial flows in \[33\] for \(JC(\mathbb{R}, 2)\), a Hamiltonian flows approach in \[34\] for \(JC(\mathbb{C}, 2)\).

\(JC\) must depend on Jacobian Condition, polynomial type and the zero characteristic of number field. For Keller map over fields of characteristic zero, injectivity always implies subjectivity \[3\], \[17\], \[35\]–\[37\]. But, this property completely fails for nonpolynomial map, already for \(n = 2\). There is a counterexample in \[3\]: \(F_1(X) = e^{x_1}, F_2 = x_2 e^{-x_1}\) whose Jacobian is 1, but \(F(\mathbb{C}^2)\) excludes exactly the axis \(x_1 = 0\). That is, injectivity does not means surjectivity for analytic map. Even for rational maps, there are counterexamples in \[38\]. As to the zero characteristic condition, there are counterexamples in \[3\], \[8\] for \(JC\) of characteristic \(> 0\). The Jacobian Condition also cannot be relaxed. A generalization of \(JC\) is the real Jacobian problem \[39\] (also called strong Jacobian Conjecture in \[40\]), that is, whether a polynomial mapping \(F : \mathbb{R}^2 \mapsto \mathbb{R}^2\) with a nonvanishing Jacobian determinant is an automorphism. The strong Jacobian Conjecture has a negative answer \[40\]. Pinchuk presented a beautiful example of a non-injective polynomial mapping \(F(x_1, x_2)\) of \(\mathbb{R}^2\) into itself, of degree \((x_1, x_2) = (10, 40)\), whose Jacobian determinant is everywhere positive on \(\mathbb{R}^2\). Therefore, Polynomial Automorphism Theorem (PAT for short) is the best in all of what we can get.

From PAT, it immediately gets that the Roll Theorem is true for polynomial functions over algebraic closed field. Let \(K\) be an algebraically closed field of characteristic zero, \(P \in K[X]^n\). Then the determinant \(det(J_P(X))\) is a polynomial and must have an \(X_0 \in K^n\) such that \(det(J_P(X_0)) = 0\) if \(det(J_P(X))\) is not a constant. By Theorem \[1.4\] using contradiction argument we can obtain

**High Dimension Roll Theorem 3.1:** If there are \(X \neq Y \in K^n\) such that \(P(X) = P(Y)\) then there is some \(X_0\) such that \(det(J_P(X_0)) = 0\).

In this theorem, the requirement “algebraically closed” is necessary. Otherwise, the Pinchuk’s counterexample will be a counterexample over \(\mathbb{R}^2\).
Another immediate result of PAT is that the inverse flows are actually polynomials in $X$ and $t$. So, high order Lie derivatives vanish at some stages. That is, the Lie derivatives are locally nilpotent or finite \cite{41, 42}. Therefore, it actually give a termination criterion for computing inverse polynomial through Lie derivatives \cite{43}.

When a polynomial map is automorphisme, there are several different approaches to the inversion formulas. An early one is the Abhyankar-Gurjar inversion formula \cite{8}. In \cite{3} Bass et al. presented a formal expansion for the inverse. Nousiainen and Sweedler \cite{43} provided a inversion formula through Lie derivatives. For specific polynomials, Wright \cite{44} and respectively Zhao \cite{45, 46} gave advanced inversion formals. Anyway, the degree of inverse polynomial is bounded by $\deg(F^{-1}) \leq \deg(F)^{n-1}$ \cite{3, 47, 48}.

Besides Jacobian Condition, van den Essen \cite{49} using Gröbner base gave an algebraic criterion for the invertibility of polynomial maps.

\textit{Essen Theorem 3.2 (49):} Any map $F = (F_1(X), \ldots, F_n(X)) \in \mathbb{K}[X]$ on arbitrary field $\mathbb{K}$ is an automorphism iff there are polynomials $G_1(Y), \ldots, G_n(Y) \in \mathbb{K}[Y]$ such that $Y_1 - F_1(X), \ldots, Y_n - F_n(X)$ and $X_1 - G_1(Y), \ldots, X_n - G_n(Y)$ generate the same polynomial idea in $\mathbb{K}[X,Y]$.

This criterion is not limited to the characteristic zero case but holds in all characteristics. At the same time Theorem 3.2 also provides an algorithm to decide if a polynomial map has an inverse and compute the inverse if it exists. Theory of Gröbner bases for polynomial ideals \cite{50} is the foundation of Essen Theorem. In contrast with this, PAT is an analytic criterion for the global invertibility of polynomial maps. In particular, PAT can be efficiently implemented for sparse polynomial maps, by testing the Jacobian Condition through random inputs.

\textbf{IV. CONCLUDING REMARKS}

In this study, we respond to Jacobian Conjecture affirmatively. Based on D-map, our proof used (1) algebraic property like nilpotency property in Case (i), and (2) geometric properties like open cone, arc and cosines between vectors as showed in Subcase (ii.a). To study the direction changing tendency of unbounded sequence $\{Y_i\}_i$, we used optimization method to obtain the key limit equation (25). To obtain the unboundedness of the images, we used optimization idea again in Subcase (ii.b). Jacobian Conjecture is an algebraic geometry problem. It is no surprising to use algebraic and geometric methods in the proof, but the optimization method is really an extra auxiliary. So, this proof is said an optimization based method. Our proof takes much advantage
of D-maps’ nice algebraic and geometric properties. Although Yag\v{z}ev map is a little extension of D-map, it has no such good properties. At least, so far our proof does not work on Yag\v{z}ev map for which we cannot construct something like \( \mathfrak{r} \). By the way, in the definition of \( \mathfrak{r} \), \(-\frac{2\sqrt{2}}{3}\) can be replaced by any real number \( \eta \) in the interval \((-1, -\frac{\sqrt{3}}{2})\). Such numbers still work for the proof. We would like to stress that such \( \eta \) can not be \(-1\) or \(-\frac{\sqrt{3}}{2}\) for the sake of getting Lemma 2.11. From our proof, it can see if a cubic linear form \( C(X) := X + (AX)^3 \) has only finitely many zero roots then nonproperness of \( C(X) \) will imply Lemma 2.14. For D-map, the Jacobian Condition implies a unique zero root. But for a general cubic linear form \( C(X) \), the finiteness of zero roots is not necessarily true. In Case (i), Jacobian Condition is used again. From the proof, we can clearly see how and why Jacobian Condition makes D-map being automorphism.

Given a polynomial map \( P(X) := (P_1(X), \ldots, P_n(X)) \in \mathbb{K}[X]^n \), \( P(X) \) is an automorphism from \( \mathbb{K}^n \) onto \( \mathbb{K}^n \) iff the deduced endomorphism \( R_P : \mathbb{K}[X]^n \rightarrow \mathbb{K}[X]^n \) by \( R_P(X_i) = P_i(X) \) for \( i = 1, \ldots, n \) is an automorphism from ring \( \mathbb{K}[X]^n \) into itself. If we consider derivatives as algebraic operators, then Jacobian Conjecture is purely an algebraic problem. So a purely algebraic proof is really an interested thing. It is already known that an analytic map satisfying Jacobian Condition is not necessarily a diffeomorphism. In fact, even for rational maps Jacobian Condition is not a sufficient condition to this type map being diffeomorphism. For analytic maps over Euclidean space, Hadamard’s Diffeomorphism Theorem has provided a nice criterion for diffeomorphism. However, this is not a computable approach like Jacobian Condition. To my best knowledge, so far there is no computable method to check the properness of a map. In practice, we may need to computably determine whether a given concrete map is diffeomorphism. In such context, Hadamard’s Diffeomorphism Theorem helps a little and Jacobian Condition is not a correct criterion for nonpolynomial maps. In physical world, we are usually concerned with elementary maps which are composed of elementary expressions like \( e^X, X^p, \sin X, \cos X \), etc. So for analytic maps, it is natural to ask whether there is some computable diffeomorphism criterion. Another basic question about polynomial automorphisms is how many of them, or what is the ratio of polynomial automorphisms to all polynomials, or what is their distribution. By Weierstrass Approximation Theorem, each continuous real function on some closed interval can be uniformly approximated by polynomials. In comparison with this, we are interested whether the automorphism polynomials are dense in the set of all analytic diffeomorphisms. Over finite fields, by Lagrange’s Interpolation Formula each map can be expressed as a polynomial [51]. And over \( \mathbb{R} \), each analytic function can be expressed as a power series which can be regarded
as a limit of polynomial sequence. We are not clear about the relation among automorphisms of space, the types of automorphism and the underlying number fields. An interesting question is: does there exist a number field $K$ of characteristic 0 such that each analytic diffeomorphism of $K^n$ must be a polynomial?
