Abstract This paper deals with the possibility of transforming a weakly measurable function in a Hilbert space into a continuous frame by a metric operator, i.e., a strictly positive self-adjoint operator. A necessary condition is that the domain of the analysis operator associated to the function be dense. The study is done also with the help of the generalized frame operator associated to a weakly measurable function, which has better properties than the usual frame operator. A special attention is given to lower semi-frames: indeed if the domain of the analysis operator is dense, then a lower semi-frame can be transformed into a Parseval frame with a (special) metric operator.

1 Introduction

In recent papers, one of us (RC) \cite{21, 22} has analyzed sesquilinear forms defined by sequences in Hilbert spaces and operators associated to them by means of representation theorems. In particular, he derived results about lower semi-frames and duality.

It turns out that most results from \cite{21, 22} can be extended to the continuous case and that is one of the aims of this present paper. The results are reported in Sect.3, but we give here a brief summary. The continuous case involves a locally compact space \((X, \mu)\) with a Radon measure \(\mu\). A function \(\phi : X \to H, x \mapsto \phi_x\) is said to be weakly measurable if for every \(f \in H\) the function \(x \mapsto \langle f | \phi_x \rangle\) is measurable. A weakly measurable function \(\phi\) is said to be \(\mu\)-total if \(\langle f | \phi_x \rangle = 0\) for a.e. \(x \in X\) implies that \(f = 0\). A weakly measurable function \(\phi\) is a continuous frame of \(H\) if there exist constants \(0 < m \leq M < \infty\) (the frame bounds) such that

\[
m \|f\|^2 \leq \int_X |\langle f | \phi_x \rangle|^2 \, d\mu(x) \leq M \|f\|^2, \quad \forall f \in H. \tag{1.1}
\]

If a weakly measurable function \(\phi\) satisfies

\[
\int_X |\langle f | \phi_x \rangle|^2 \, d\mu(x) \leq M \|f\|^2, \quad \forall f \in H,
\]

then we say that \(\phi\) is a Bessel mapping of \(H\). On the other hand, \(\phi\) is a lower semi-frame of \(H\) if there exists a constant \(m > 0\) such that

\[
m \|f\|^2 \leq \int_X |\langle f | \phi_x \rangle|^2 \, d\mu(x), \quad \forall f \in H. \tag{1.2}
\]

Given a weakly measurable function \(\phi\), the operator \(C_{\phi} : D(C_{\phi}) \subseteq H \to L^2(X, d\mu)\) with domain

\[
D(C_{\phi}) := \left\{ f \in H : \int_X |\langle f | \phi_x \rangle|^2 \, d\mu(x) < \infty \right\}
\]
and \((C_\phi f)(x) = \langle f|\phi_x\rangle\), \(f \in D(C_\phi)\), is called the analysis operator of \(\phi\). We can define the sesquilinear form
\[
\Omega_\phi(f, g) = \int_X \langle f|\phi_x\rangle \langle \phi_x|g\rangle d\mu(x), \quad f, g \in D(C_\phi)
\]
and associate a positive self-adjoint operator \(T_\phi\) in the space \(\mathcal{H}_\phi\), the closure of \(D(C_\phi)\) in \(\mathcal{H}\), by Kato’s representation theorem [26], which we call generalized frame operator. When \(\phi\) is a lower semi-frame of \(\mathcal{H}\), then the range of \(T_\phi\) is \(\mathcal{H}_\phi\) and the function \(\psi: X \to \mathcal{H}\), defined by \(\psi_x = T_\phi^{-1} P_\phi \phi_x, x \in X\), where \(P_\phi\) is the orthogonal projection onto \(\mathcal{H}_\phi\), is a Bessel mapping and the reconstruction formula
\[
f = \int_X \langle f|\phi_x\rangle \psi_x d\mu(x),
\]
holds for every \(f \in D(C_\phi)\) in a weak sense.

In this paper we do not confine ourselves to extend results of [21, 22], but actually we set two more goals. From one hand, given a lower semi-frame \(\phi: X \to \mathcal{H}\) with \(D(C_\phi)\) dense in \(\mathcal{H}\), we consider general powers \(T_\phi^{-k}\) with \(k \geq 0\). These functions are Bessel mappings, frames or lower semi-frames in the space \(\mathcal{H}(T_\phi^m)\) (given by the domain of \(T_\phi^m\) and the inner product \(\langle T_\phi^m f, T_\phi^m g \rangle\)) with \(m \geq 0\) according to a simple relation between \(k\) and \(m\) (see Theorem 4.1).

When \(\phi: X \to \mathcal{H}\) is a \(\mu\)-total weakly measurable function with \(D(C_\phi)\) dense, then \(T_\phi\) is in particular a metric operator, i.e., a strictly positive self-adjoint operator. Metric operators are a topic familiar in the theory of the so-called \(\mathcal{P}\mathcal{T}\)-symmetric quantum mechanics [19, 27]. In our previous works [10, 11, 14], we have analyzed thoroughly the structure generated by such a metric operator, bounded or unbounded, namely a lattice of Hilbert spaces.

As particular case of Theorem 4.1 if \(\phi: X \to \mathcal{H}\) is a lower semi-frame with \(D(C_\phi)\) dense, then \(T_\phi^{-1/2}\) is a Parseval frame of \(\mathcal{H}\). This inspired us to consider the following more general problem.

**Question:** for which weakly measurable functions \(\phi: X \to \mathcal{H}\) there exists a metric operator \(G\) on \(\mathcal{H}\) such that \(\phi_x \in D(G)\) for all \(x \in X\) and \(G\phi\) is a frame?

Partial answers to this problem are given in Theorem 5.1. In particular, necessary conditions are that \(D(C_\phi)\) is dense, and that \(\phi\) is \(\mu\)-total if \(\phi\) is in addition a Bessel mapping. In the discrete case, if \(\phi: \mathbb{N} \to \mathcal{H}\) is a Schauder basis, then the problem has a positive solution (more precisely, one can again take \(G = T_\phi^{-1/2}\) and \(T_\phi^{-1/2}\) is actually an orthonormal basis).

The paper is organized as follows. After reviewing the conventional definitions about frames and semi-frames in Sec.2, we introduce in Sec.3 the generalized frame operator \(T_\phi\), whose properties are more convenient than those of the standard frame operator \(S_\phi\). In Sec.4, we investigate the various (semi)-frames generated by a lower semi-frame. In Sec.5, we review the lattice of Hilbert spaces generated by a metric operator. In Sec.6, we face the question of transforming functions in frames. We conclude in Sec.7 by several examples.

## 2 Preliminaries

Before proceeding, we list further definitions and conventions. The framework is a (separable) Hilbert space \(\mathcal{H}\), with the inner product \(\langle \cdot|\cdot \rangle\) linear in the first factor. \(GL(\mathcal{H})\) denotes the set of all invertible bounded operators on \(\mathcal{H}\) with bounded inverse. Throughout the paper, we will consider weakly measurable functions \(\phi: X \to \mathcal{H}\), where \((X, \mu)\) is a locally compact space with a Radon measure \(\mu\).

Given a continuous frame \(\phi\), the analysis operator is defined and bounded on \(\mathcal{H}\), i.e. \(C_\phi: \mathcal{H} \to L^2(X, d\mu)\) \(^1\) and the corresponding synthesis operator \(C_\phi^*: L^2(X, d\mu) \to \mathcal{H}\) is defined as

\(^1\) As usual, we identify a function \(\xi\) with its residue class in \(L^2(X, d\mu)\).
(the integral being understood in the weak sense, as usual)

\[ C_\phi^* \xi = \int_X \xi(x) \phi_x \, d\mu(x), \text{ for } \xi \in L^2(X, d\mu). \]  

(2.1)

Moreover, we set \( S_\phi := C_\phi^* C_\phi \), which is self-adjoint. Then it follows that

\[ \langle S_\phi f | g \rangle = \langle C_\phi^* C_\phi f | g \rangle = \langle C_\phi f | C_\phi g \rangle = \int_X \langle f | \phi_x \rangle \langle \phi_x | g \rangle \, d\mu(x). \]

Thus, for continuous frames, \( S_\phi \) and \( S_\phi^{-1} \) are both bounded, that is, \( S_\phi \in GL(H) \).

Following [6, 7], we will say that a function \( \phi \) is a semi-frame if it satisfies only one of the frame inequalities in (1.1). We already introduced the lower semi-frames (if \( \phi \) satisfies (1.2), then it could still be a frame, hence we say that the lower semi-frame \( \phi \) is proper if it is not a frame). Notice that the lower frame inequality automatically implies that \( \phi \) is \( \mu \)-total. On the other hand, a weakly measurable function \( \phi \) is an upper semi-frame if it is \( \mu \)-total, that is, \( N(C_\phi) = \{0\} \), and there exists \( M < \infty \) such that

\[
0 < \int_X |\langle f | \phi_x \rangle|^2 \, d\mu(x) \leq M \|f\|^2, \ \forall \ f \in H, \ f \neq 0.
\]  

(2.2)

Thus an upper semi-frame is a total Bessel mapping [24]. Notice this definition does not forbid \( \phi \) to be a frame. Thus we say that \( \phi \) is a proper upper semi-frame if it is not a frame.

If \( \phi \) is a proper upper semi-frame \( S_\phi \) is bounded and \( S_\phi^{-1} \) is unbounded, as follows immediately from (2.2). In the lower case, however, the definition of \( S_\phi \) must be changed, since the domain \( D(C_\phi) \) need not be dense, so that \( C_\phi^* \) may not exist. Instead, following [6, Sec.2] one defines the synthesis operator as

\[ D_\phi F = \int_X F(x) \phi_x \, d\mu(x), \ F \in L^2(X, d\mu), \]  

(2.3)

on the domain of all elements \( F \) for which the integral in (2.3) converges weakly in \( H \), and then \( S_\phi := D_\phi C_\phi \). With this definition, it is shown in [6, Sec.2] that if \( \phi \) is a proper lower semi-frame then \( S_\phi \) is unbounded and \( S_\phi^{-1} \) is bounded. All these objects are studied in detail in our previous papers [6, 7]. In particular, it is shown there that a natural notion of duality exists, namely, two measurable functions \( \phi, \psi \) are dual to each other (the relation is symmetric) if one has

\[ \langle f | g \rangle = \int_X \langle f | \phi_x \rangle \langle \psi_x | g \rangle \, d\mu(x), \ \forall \ f, g \in H. \]  

(2.4)

This duality property extends to lower semi-frames and Bessel mappings, as shown in Proposition 3.2 below.

Consider the following sesquilinear form on the domain \( D_1 \times D_2 \):

\[ \Omega_{\psi, \phi}(f, g) = \int_X \langle f | \phi_x \rangle \langle \psi_x | g \rangle \, d\mu(x), \ f \in D_1, g \in D_2. \]  

(2.5)

If \( D_1 = D_2 = H \) and the form \( \Omega_{\psi, \phi} \) is bounded on \( H \times H \), that is, \( |\Omega_{\psi, \phi}(f, g)| \leq c \|f\| \|g\| \), for some \( c > 0 \), then the couple of weakly measurable functions \( (\psi, \phi) \) is called a reproducing pair if the corresponding bounded operator \( S_{\psi, \phi} \) given weakly by

\[ \langle S_{\psi, \phi} f | g \rangle = \int_X \langle f | \phi_x \rangle \langle \psi_x | g \rangle \, d\mu(x), \ \forall \ f, g \in H, \]

belongs to \( GL(H) \). If \( \psi = \phi \), we recover the notion of continuous frame.

Under certain conditions, boundedness of \( \Omega_{\psi, \phi} \) is automatic, as shown in [24, Prop. 7]
Proposition 2.1 If $D_1 = D_2 = \mathcal{H}$, $X$ is locally compact and $\sigma$-compact, that is, $X = \bigcup_n K_n, K_n \subset K_{n+1}$, with $K_j$ compact for every $j$, and $\sup_{x \in X} (\|\phi_x\|_\mathcal{H} \|\psi_x\|_\mathcal{H}) < \infty$, then the form $\Omega_{\psi,\phi}$ is bounded on $\mathcal{H} \times \mathcal{H}$.

Proof. Define

$$\Omega^n_{\psi,\phi}(f,g) := \int_{K_n} \langle f|\phi_x\rangle \langle \phi_x|g \rangle \, d\mu(x), \quad f, g \in \mathcal{H}.$$ 

By assumption, there exists $c > 0$ such that

$$|\Omega^n_{\psi,\phi}(f,g)| \leq c \left\| f \right\| \left\| g \right\| \left| \int_{K_n} d\mu(x) \right| < \infty$$

Hence there exists a bounded operator $T_n$ such that $\Omega^n_{\psi,\phi}(f,g) = \langle T_n f | g \rangle$. Applying the Banach-Steinhaus theorem to the functional $g \mapsto \Omega_{\psi,\phi}(f,g)$, one gets that the operator $T_{\psi,\phi}$ associated to $\Omega_{\psi,\phi}$ is defined on the whole of $\mathcal{H}$. Doing the same with $T_n$, as in [21, Prop. 7], we conclude that the form $\Omega_{\psi,\phi}$ is bounded on $\mathcal{H} \times \mathcal{H}$. \hfill \Box

The converse of Proposition 2.1 does not hold, as shown in the following example (which is based on [17, Example 2.5]), in the sense that boundedness of the form $\Omega$ does not imply the supremum condition.

Example 2.2 Let $h \in \mathcal{H}\setminus\{0\}$ and let $a : \mathbb{R} \to \mathbb{C}$ be such that $a \in L^2(\mathbb{R}) \backslash L^\infty(\mathbb{R})$. Define $\phi_x = a(x)h$ for all $x \in \mathbb{R}$. Then $\phi : \mathbb{R} \to \mathcal{H}$ is a weakly-measurable function and a Bessel mapping because

$$\int_{\mathbb{R}} |\langle f|\phi_x\rangle|^2 \, dx \leq \|a\|^2_{L^2(\mathbb{R})} \|h\|^2 \|f\|^2, \quad f \in \mathcal{H}.$$ 

In conclusion, the sesquilinear form $\Omega_{\psi,\phi}$, where $\psi = \phi$, is defined and bounded on $\mathcal{H} \times \mathcal{H}$, but $\sup_{x \in X} (\|\phi_x\|_\mathcal{H} \|\psi_x\|_\mathcal{H}) = \infty$.

3 The generalized frame operator $T_\phi$

In the previous section we defined the frame operator $S_\phi$ for a lower semi-frame. However, this operator lacks good properties, in general (for instance $S_\phi$ need not be self-adjoint like in the case of an upper semi-frame, even if $S_\phi$ is non-negative). In this section, we are going to construct a new operator associated to $\phi$ which plays the rôle of $S_\phi$ for lower-semi-frames. We show its main properties, in particular, concerning the definition of a Bessel dual mapping in a natural way.

We note that if $\phi$ is a proper lower semi-frame, the r.h.s. of (1.2) actually diverges for some $f$. As already said, the domain $D(C_\phi)$ need not be dense in $\mathcal{H}$. It is useful to work with the Hilbert space $\mathcal{H}_\phi$ made of the closure of $D(C_\phi)$ endowed with the topology of $\mathcal{H}$.

The analysis operator $C_\phi$ is closed [6, Lemma 2.1]. Therefore the sesquilinear form

$$\Omega_\phi(f,g) = \langle C_\phi f | C_\phi g \rangle = \int_X \langle f|\phi_x\rangle \langle \phi_x|g \rangle \, d\mu(x), \quad f, g \in D(C_\phi)$$

is non-negative and closed. By Kato’s second representation theorem [26, Theorem 2.23] there exists an operator $T_\phi : D(T_\phi) \subset \mathcal{H}_\phi \to \mathcal{H}_\phi$, with $D(T_\phi) \subset D(C_\phi)$, such that

- $\Omega_\phi(f,g) = \langle T_\phi f | g \rangle$ for all $f \in D(T_\phi)$ and $g \in D(C_\phi)$;

\footnote{We use this sans serif font in order to avoid confusion with the generalized synthesis operator $T_\phi$ introduced in our papers about reproducing pairs [12, 13, 15].}
• if $T : D(T) \subset \mathcal{H}_\phi \rightarrow \mathcal{H}_\phi$ is such that $\Omega_\phi(f,g) = \langle Tf|g \rangle$ for all $f \in D(T)$ and $g \in D(C_\phi)$, then $T \subset T_\phi$;
• $T_\phi$ is non-negative and self-adjoint in $\mathcal{H}_\phi$;
• $\Omega_\phi(f,g) = \langle T_\phi^{1/2}f|T_\phi^{1/2}g \rangle$, for all $f,g \in D(C_\phi)$.

We call $T_\phi$ the generalized frame operator of $\phi$. The motivation behind this name is that when $\phi$ is a continuous frame then $T_\phi = S_\phi$. The generalized frame operator has been studied in [21, 22] in the discrete case and a preliminary extension to the continuous setting has been given in [18].

If $D(C_\phi)$ is dense, then of course $\mathcal{H}_\phi = \mathcal{H}$ (i.e., $T_\phi$ is a non-negative self-adjoint operator on $\mathcal{H}$) and $S_\phi \subset T_\phi$. In [22], it was proved that in the discrete setting ($X = \mathbb{N}$) we may have a strict inclusion $S_\phi \subsetneq T_\phi$ (recall that in our paper $S_\phi$ is weakly defined, therefore in the discrete setting it corresponds to the operator $W_\phi$ in [22]).

Since $\Omega_\phi(f,g) = \langle C_\phi f|C_\phi g \rangle$ we have $T_\phi := |C_\phi|^2 = C_\phi^\times C_\phi$ where $C_\phi^\times$ and $|C_\phi|$ are the adjoint and the modulus of $C_\phi$ when we think of it as an operator $C_\phi : \mathcal{H}_\phi \rightarrow L^2(X,\mu)$.

The following characterization can be proved as in [21].

**Proposition 3.1** Let $\phi$ be a weakly measurable function and $m > 0$. The following statements are equivalent.

(i) $\phi$ is a lower semi-frame of $\mathcal{H}$ with lower bound $m$;
(ii) $\Omega_\phi$ is bounded from below by $m$, i.e.,
\[ \Omega_\phi(f,f) \geq m\|f\|^2, \quad \forall f \in D(C_\phi); \]
(iii) $C_\phi$ is bounded from below by $\sqrt{m}$, i.e.
\[ \|C_\phi f\| \geq \sqrt{m}\|f\|, \quad \forall f \in D(C_\phi); \]
(iv) $T_\phi$ is bounded from below by $m$, i.e.,
\[ \|T_\phi f\| \geq m\|f\|, \quad \forall f \in D(T_\phi); \]
(v) $T_\phi$ is invertible and $T_\phi^{-1} \in \mathcal{B}(\mathcal{H}_\phi)$ with $\|T_\phi^{-1}\| \leq m$.

**Proof.** (i) $\iff$ (ii) and (i) $\iff$ (iii) By definition.
(ii) $\implies$ (iv) Let $f \in D(T_\phi)$. Then $\|T_\phi f\| \geq \langle T_\phi f|f \rangle \geq m\|f\|^2$. Thus $\|T_\phi f\| \geq m\|f\|$.
(iv) $\implies$ (ii) For $f \in D(T_\phi)$ we have $\Omega_\phi(f,f) = \langle T_\phi^{1/2}f|T_\phi^{1/2}f \rangle \geq m\|f\|^2$ by hypothesis. The inequality now extends to every $f \in D(C_\phi)$ noting that $D(T_\phi)$ is a core of $\Omega_\phi$ (see [26] Theorem 2.1).
(iv) $\iff$ (v) This is clear since $T_\phi$ is self-adjoint.

Now assume that $\phi$ is a lower semi-frame of $\mathcal{H}$. By [6, Proposition 2.6] there exists a Bessel mapping $\psi : X \rightarrow \mathcal{H}$ dual to $\phi$, i.e. for some $M > 0$
\[ \int_X |\langle f|\psi_x \rangle|^2 \, d\mu(x) \leq M\|f\|^2, \quad \forall f \in \mathcal{H}, \]
and
\[ f = \int_X \langle f|\phi_x \rangle \psi_x \, d\mu(x), \quad \forall f \in D(C_\phi) \text{ in weak sense.} \quad (3.1) \]
A proof may be found in [6, Lemma 2.5 and Proposition 2.6]. Note that the proof given there is incomplete, in the sense there is no guarantee that $\psi$ is total, see Item (4) in Proposition 3.2 below. Here we give a different proof involving the operator $T_\phi$ using the same argument as in [22, Theorem 4.1].
Proposition 3.2  Let $\phi$ be a lower semi-frame of $H$. Let $\psi$ be the function defined by $\psi = T^{-1}_\phi P_\phi \phi$, i.e. $\psi_x = T^{-1}_\phi P_\phi \phi_x$ for $x \in X$, where $P_\phi : H \rightarrow H_\phi$ is the orthogonal projection of $H$ onto $H_\phi$. The following statements hold.

(1) $\psi$ is a weakly measurable function;
(2) $\psi$ a Bessel mapping of $H$;
(3) $\psi$ is dual to $\phi$, i.e. satisfies (3.1);
(4) If $D(C_\phi)$ is dense, then $\psi$ is an upper semi-frame of $H$.

Proof. We recall that $T_\phi$ is invertible with $T^{-1}_\phi \in B(H_\phi)$.

(1) This is immediate.

(2) Let $f \in H$. Then

$$
\int_X |\langle f | T^{-1}_\phi P_\phi \phi_x \rangle|^2 \, d\mu(x) = \int_X |\langle P_\phi f | T^{-1}_\phi P_\phi \phi_x \rangle|^2 \, d\mu(x) = \int_X |\langle T^{-1}_\phi P_\phi f | \phi_x \rangle|^2 \, d\mu(x)
$$

$$
= \|T^{1/2}_\phi T^{-1}_\phi P_\phi f\|^2 = \|T^{-1/2}_\phi P_\phi f\|^2 \leq \|T^{-1/2}_\phi\|^2 \|f\|^2. \tag{3.2}
$$

(3) Let $f \in D(C_\phi)$ and $h \in H$. Then

$$
\langle f | h \rangle = \langle f | P_\phi h \rangle = \langle f | T_\phi T^{-1}_\phi P_\phi h \rangle = \int_X \langle f | \phi_x \rangle \langle \phi_x | T^{-1}_\phi P_\phi h \rangle \, d\mu(x)
$$

$$
\quad = \int_X \langle f | \phi_x \rangle \langle P_\phi \phi_x | T^{-1}_\phi P_\phi h \rangle \, d\mu(x) = \int_X \langle f | \phi_x \rangle \langle T^{-1}_\phi P_\phi \phi_x | h \rangle \, d\mu(x).
$$

(4) This is immediate from (3.1). \qed

Remark 3.3 Part (3) of the above proposition comes from general properties of semi-bounded operators. If $H, K$ are Hilbert spaces, and $C : D(C) \subset H \rightarrow K$ is a closed operator such that $D(C)$ is dense and $\| Cf \| \geq \gamma \| f \|$, for every $f \in D(C)$, then by Kato’s theorem there exists $T \geq 0$, with the properties described at the beginning of Section 3, such that $\langle Cf | Cg \rangle = \langle T^{1/2} f | T^{1/2} g \rangle$ for every $f, g \in D(C)$; as before $T$ is invertible with bounded inverse. On the other hand,

$$
|\langle f | g \rangle| \leq \frac{1}{\gamma^2} \| f \| \| g \| C, \quad \forall f, g \in D(C), \text{where } \| f \| C := \| Cf \|.
$$

Hence, there exists an operator $X$, bounded in $H(C) := D(C)[| \cdot | C]$, such that

$$
\langle f | g \rangle = \langle Cf | CXg \rangle, \quad \forall f, g \in D(C).
$$

Then,

$$
\langle C f | CXg \rangle = \langle T^{1/2} f | T^{1/2} Xg \rangle = \langle f | g \rangle, \quad \forall f, g \in D(C).
$$

This implies that $T^{1/2} Xg \in D(T^{1/2}) = D(C)$, for every $g \in D(C)$ and $TXg = g$, $\forall g \in D(C)$. Thus $X \subset T^{-1}$. In conclusion, $\langle f | g \rangle = \langle C f | CT^{-1} g \rangle$, for all $f, g \in D(C)$. So, if $C = C_\phi$ is densely defined, the dual is found. If $D(C_\phi)$ is not dense we can proceed with the projection $P_\phi$ as before.

Finally, as mentioned in [22] for the discrete case, calculations similar to (3.2) show the next result.

Proposition 3.4  Let $\phi$ be a lower semi-frame of $H$. Then the function $\psi = T^{-1/2}_\phi P_\phi \phi$ is a Parseval frame for $H_\phi$. 

6
Thus, following the standard terminology in frame theory, we can call $T^{-1}_\phi P_\phi$ and $T^{-1/2}_\phi P_\phi$ the canonical dual Bessel mapping and the canonical tight frame of $\phi$.

Now we exploit Proposition 5 of [21] and the discussion after it.

**Proposition 3.5** Let $\phi$ be a weakly measurable function of $\mathcal{H}$. Then $\phi$ is a lower semi-frame of $\mathcal{H}$ if and only if there exists an inner product $\langle \cdot | \cdot \rangle$ inducing a norm $\| \cdot \|_+$ on $D(C_\phi)$ for which $D(C_\phi)[\| \cdot \|_+]$ is complete, continuously embedded into $\mathcal{H}$ and for some $m, M > 0$ one has

$$m \|f\|_+^2 \leq \int_X |\langle f|\phi_x \rangle|^2 \, d\mu(x) \leq M \|f\|_+^2, \forall f \in D(C_\phi).$$

**Proof.** It is sufficient to take $\|f\|_+^2 = \|f\|_{C_\phi}^2 = \int_X |\langle f|\phi_x \rangle|^2 \, d\mu(x)$, for $f \in D(C_\phi)$. \hfill $\Box$

Let $\phi$ be a lower semi-frame in the Hilbert space $\mathcal{H}$, with domain $D(C_\phi)$, assumed to be dense. For every $x \in X$, the map $f \mapsto \langle f|\phi_x \rangle$ is a bounded linear functional on the Hilbert space $\mathcal{H}(C_\phi) := D(C_\phi)[\| \cdot \|_+]$. By the Riesz Lemma, there exists an element $\chi^\phi_x \in D(C_\phi)$ such that

$$\langle f|\phi_x \rangle = \langle f|\chi^\phi_x \rangle_+ \forall f \in D(C_\phi). \quad (3.3)$$

By Prop. 3.5 $\chi^\phi$ is a frame.

We can explicitly determine the element $\chi^\phi$ when $\| \cdot \|_+$ is the norm $\|f\|_{1/2}^2 = \left\| T^{1/2}_\phi f \right\|^2$. Notice that, by Prop. 3.1(iv), this norm is equivalent to the the graph norm of $T^{1/2}_\phi$.

Then we have $\langle f|\phi_x \rangle = \langle f|\chi^\phi_x \rangle_{1/2} = \langle f|T_\phi\chi^\phi_x \rangle$ for all $f \in D(C_\phi)$. Thus $\chi^\phi_x = T^{-1}_\phi \phi_x$ for all $x \in X$, i.e. $\chi^\phi$ is the canonical dual Bessel mapping of $\phi$.

Following the notation of [8], denote by $\mathcal{H}(T^{1/2}_\phi)$ the Hilbert space $D(T^{1/2}_\phi)$ with the norm $\| \cdot \|_{1/2}$. In the same way, denote by $\mathcal{H}(C_\phi)$ the Hilbert space $D(C_\phi)$ with inner product $\langle C_\phi, C'_\phi \rangle$. Hence we have proved the following result.

**Proposition 3.6** Let $\phi$ be a lower semi-frame of $\mathcal{H}$ with $D(C_\phi)$ dense. Then the canonical dual Bessel mapping of $\phi$ is a tight frame for the Hilbert space $\mathcal{H}(C_\phi) = \mathcal{H}(T^{1/2}_\phi)$.

We can proceed in the converse direction, i.e. starting with a frame $\chi \in D(C_\phi)$, does there exist a lower semi-frame $\eta$ of $\mathcal{H}$ such that $\chi$ is the frame $\chi^\eta$ constructed from $\eta$ in the way described above? The answer is formulated in the following

**Proposition 3.7** ([21, Prop. 6]) Let $\chi$ be a frame of $\mathcal{H}(C_\phi) = \mathcal{H}(T^{1/2}_\phi)$. Then

(i) There exists a lower semi-frame $\eta$ of $\mathcal{H}$ such that $\chi = \chi^\eta$ if, and only if, $\chi \in D(T_\phi)$.

(ii) If $\chi = \chi^\eta$ for some lower semi-frame $\eta$ of $\mathcal{H}$, then $\eta = T_\phi \chi$.

4 The functions generated by a lower semi-frame

Throughout this section we continue to consider a lower semi-frame $\phi$ in $\mathcal{H}$, with $D(C_\phi)$ dense.

Since $T^{-1}_\phi$ is defined on $\mathcal{H}$ we can actually apply different powers of $T^{-1}_\phi$ on $\phi$ and get the functions $T^{-k}_\phi \phi$, $k \in [0, \infty)$. Hence we can ask for the properties of $T^{-k}_\phi \phi$. Of course the answer depends on the Hilbert space where $T^{-k}_\phi \phi$ is considered. For instance, for $k = 0$ we have a lower semi-frame of $\mathcal{H}$ and, as seen in the previous section, for $k = \frac{1}{2}$ we have a frame for $\mathcal{H}$, while for $k = 1$ we have a frame for $\mathcal{H}(T^{1/2}_\phi)$. When we have powers of an unbounded, closed, densely
Then the following statements hold.

Let \( m \) comparing 2 semi-frame \( \phi \in D \) sufficient condition for \( T \) holds by the same estimate.

defined operator, then we can consider scales and lattices of Hilbert spaces, which we will consider in more detail in Section 5. For a while, let us simply denote by \( \mathcal{H}(T_m) \), \( m \geq 0 \), the domain of \( T_m^k \) considered as a Hilbert space with norm \( \|f\|_m = \|T_m^k f\| \), \( f \in D(T_m^k) \). Then, if \( m > n \geq 0 \), we have \( \mathcal{H}(T_m^k) \subset \mathcal{H}(T_n^k) \subset \mathcal{H} \). The function \( T_m^{-k} \phi \) is not always a well-defined function of \( \mathcal{H}(T_m^k) \); a sufficient condition for \( T_m^{-k} \phi \in \mathcal{H}(T_m^k) \) is that \( k \geq m \).

Having at our disposal the notion of scale of Hilbert spaces, we now come back to a lower semi-frame \( \phi \) with \( D(C) \) dense and to the functions \( T_m^{-k} \phi \) with \( k \geq 0 \). For simplicity of notation, we write in a compact way the inner product of \( \mathcal{H}(T_m^k) \) in the following way \( \langle f \mid g \rangle_m := \langle f \mid g \rangle_{T_m^k} = \langle T_m^k f \mid T_m^k g \rangle \).

**Theorem 4.1** Let \( \phi \) be a lower semi-frame of \( \mathcal{H} \) with \( D(C) \) dense and \( m, k \in [0, \infty) \), \( k \geq m \). Then the following statements hold.

(i) \( T_m^{-k} \phi \) is a Bessel mapping of \( \mathcal{H}(T_m^k) \) if and only if \( k \geq m + \frac{1}{2} \);

(ii) \( T_m^{-k} \phi \) is a lower semi-frame of \( \mathcal{H}(T_m^k) \) if and only if \( m \leq k \leq m + \frac{1}{2} \);

(iii) \( T_m^{-k} \phi \) is a frame of \( \mathcal{H}(T_m^k) \) if and only if \( T_m^{-k} \phi \) is a Parseval frame of \( \mathcal{H}(T_m^k) \), if and only if \( k = m + \frac{1}{2} \).

**Proof.** We have for \( f \in \mathcal{H}(T_m^k) \)

\[
\int_X |\langle f \mid T_m^{-k} \phi \rangle_m|^2 d\mu(x) = \int_X |\langle T_m^k f \mid T_m^{-k} \phi \rangle|^2 d\mu(x) = \int_X |\langle T_m^{2m-k} f \mid \phi \rangle|^2 d\mu(x) = \|T_m^{1/2} T_m^{2m-k} f\|^2 = \|T_m^{2m-k+1/2} f\|^2.
\]

Hence, taking into account that \( 0 \in \rho(T_m^k) \) and that \( \|f\|_m^2 = \|T_m^k f\|^2 \), (i) and (ii) follow by comparing \( 2m-k+1 \) and \( m \). We give the details for (i) as example.

Assume that \( T_m^{-k} \phi \) is a Bessel mapping of \( \mathcal{H}(T_m^k) \), then there exists \( B > 0 \) such that for all \( f \in \mathcal{D}(T_m^k) \) we have \( \|T_m^{2m-k+1/2} f\|^2 \leq B \|T_m^k f\|^2 \). Rewriting the inequality as \( \|T_m^{m-k+1/2} f\|^2 \leq B \|T_m^k f\|^2 \), we find that \( T_m^{m-k+1/2} \) is bounded, i.e. \( m-k+1/2 \leq 0 \). The other implication trivially holds by the same estimate.

Finally, combining the two cases above, we obtain that \( T_m^{-k} \phi \) is a frame of \( \mathcal{H}(T_m^k) \) if and only if \( k = m + \frac{1}{2} \). Moreover, in this case \( T_m^{-k} \phi \) is actually a Parseval frame, as one can see in 4.11. \( \square \)

In particular, we recover some cases we discussed in the previous section, namely \( (k, m) = (1, \frac{1}{2}) \) and \( (k, m) = (1, 0) \) (corresponding to the canonical Bessel mapping of \( \phi \)) and \( (k, m) = (1, 0) \) (corresponding to the canonical tight frame of \( \phi \)).

It is possible to generalize Theorem 4.1 by considering more general functions than powers of \( T_\phi \). For instance we could take the set \( \Sigma \) of real valued functions \( g \) defined on the spectrum \( \sigma(T_\phi) \), which are measurable with respect to the spectral measure of \( T_\phi \) and such that \( g \) and \( \tilde{g} := 1/g \) are bounded on compact subsets of \( \sigma(T_\phi) \). For every \( g \in \Sigma \) we denote by \( \mathcal{H}_g \) the Hilbert space completion of \( D(g(T_\phi)) \) with respect to the norm \( \|f\|_g = \|g(T_\phi) f\| \), \( f \in D(g(T_\phi)) \). As shown in Sec.10.4], we get a LHS if the order is defined by \( h \leq g \iff \exists \gamma > 0 \) such that \( h \leq \gamma g \). We put \( i(t) := t, t \in \sigma(T_\phi) \). Then we get

**Theorem 4.2** Let \( \phi \) be a lower semi-frame of \( \mathcal{H} \) with \( D(C) \) dense and \( g, h \) non-negative functions from \( \Sigma \), with \( g \geq h \). Suppose that \( \tilde{g} \) and \( h \tilde{g} \) are bounded functions. Then the following statements hold.
Thus, for instance, if $\varphi > 0$ and $\varphi \in H$, then $\int_X |\varphi|^2 \, d\mu(x)$ is a Bessel mapping of $X$. Hence, we have $\int_X |\varphi|^2 \, d\mu(x) = 0$ if and only if $\varphi = 0$. In addition, $D(|\varphi|) = D(S)$ and $N(S^*S) = N(S)$ [28, Theor.5.39 and 5.40].

Given $S$ as above, the operator $R_S := I + S^*S$ is self-adjoint, with domain $D(S^*S)$, and $R_S \geq 1$. Hence $R_S$ is an unbounded metric operator, with bounded inverse $R_S^{-1} = (I + S^*S)^{-1}$. In our previous works [10, 11, 14], we have analyzed the lattice of Hilbert spaces generated by such a metric operator. In the sequel, we summarize this discussion, keeping the same notations.

In the general case where both the metric operator $G$ and its inverse $G^{-1}$ are unbounded, the lattice is given in Fig. 1. Given the metric operator $G$, equip the domain $D(G^{1/2})$ with the following norm

$$\|f\|_{R_G}^2 = \|(I + G)^{1/2}f\|^2, \quad f \in D(G^{1/2}).$$

(5.1)

Since this norm is equivalent to the graph norm of $G^{1/2}$, this makes $D(G^{1/2})$ into a Hilbert space, denoted $H(R_G)$, dense in $H$. Next, we equip $H(R_G)$ with the norm $\|f\|^2_G := \|G^{1/2}f\|^2$ and denote by $H(G)$ the completion of $H(R_G)$ in that norm and corresponding inner product $\langle \cdot, \cdot \rangle_G := \langle G^{1/2}, \cdot|G^{1/2}, \cdot \rangle$. Hence, we have $H(R_G) = H \cap H(G)$, with the so-called projective norm [3, Sec.I.2.1], which here is simply the graph norm of $G^{1/2}$. 

5 Metric Operators

The generalized frame operator of a total weak measurable function $\varphi$ with $D(C_\varphi)$ dense is an example of metric operator in the sense of the following definition [10].

Definition 5.1 By a metric operator in a Hilbert space $H$, we mean a strictly positive self-adjoint operator $G$, that is, $G > 0$ or $\langle Gf, f \rangle \geq 0$ for every $f \in D(G)$ and $\langle Gf, f \rangle = 0$ if and only if $f = 0$.

Let $S$ be an unbounded closed operator with dense domain $D(S)$. As usual, define the graph norm of $S$:

$$\langle f|g \rangle_{gr} := \langle f|g \rangle + \langle Sf|Sg \rangle, \quad f, g \in D(S),$$

$$\|f\|_{gr}^2 = \|f\|^2 + \|Sf\|^2.$$ Then the norm $\|\cdot\|_{gr}$ makes $D(S)$ into a Hilbert space continuously embedded into $H$. For $f \in D(S^*S)$, we may write $\|f\|_{gr}^2 = \langle f|(I + S^*S)f \rangle$. Note that the operator $S^*S = |S|^2$ is self-adjoint and non-negative: $|S|^2 \geq 0$. In addition, $D(|S|) = D(S)$ and $N(S^*S) = N(S)$ [28, Theor.5.39 and 5.40].

Given $S$ as above, the operator $R_S := I + S^*S$ is self-adjoint, with domain $D(S^*S)$, and $R_S \geq 1$. Hence $R_S$ is an unbounded metric operator, with bounded inverse $R_S^{-1} = (I + S^*S)^{-1}$. In our previous works [10, 11, 14], we have analyzed the lattice of Hilbert spaces generated by such a metric operator. In the sequel, we summarize this discussion, keeping the same notations.

In the general case where both the metric operator $G$ and its inverse $G^{-1}$ are unbounded, the lattice is given in Fig. 1. Given the metric operator $G$, equip the domain $D(G^{1/2})$ with the following norm

$$\|f\|_{R_G}^2 = \|(I + G)^{1/2}f\|^2, \quad f \in D(G^{1/2}),$$

(5.1)
Next we proceed in the same way with the inverse operator $G^{-1}$, and we obtain another Hilbert space, $\mathcal{H}(G^{-1})$. Then we consider the lattice generated by $\mathcal{H}(G)$ and $\mathcal{H}(G^{-1})$ with the operations

\begin{align}
\mathcal{H}_1 \land \mathcal{H}_2 &= \mathcal{H}_1 \cap \mathcal{H}_2, \\
\mathcal{H}_1 \lor \mathcal{H}_2 &= \mathcal{H}_1 + \mathcal{H}_2,
\end{align}

shown on Fig. 1. Here every embedding, denoted by an arrow, is continuous and has dense range. Taking conjugate duals, it is easy to see that one has

\begin{align}
\mathcal{H}(R_G)^\times &= \mathcal{H}(R_G^{-1}) = \mathcal{H} + \mathcal{H}(G^{-1}), \\
\mathcal{H}(R_{G^{-1}})^\times &= \mathcal{H}(R_{G^{-1}}) = \mathcal{H} + \mathcal{H}(G).
\end{align}

In these relations, the r.h.s. is meant to carry the inductive norm (and topology) [5, Sec.I.2.1], so that both sides are in fact unitary equivalent, hence identified.

![Diagram](image)

Figure 1: The lattice of Hilbert spaces generated by a metric operator.

At this stage, we return to the construction in terms of the closed unbounded operator $S$. We have to envisage two cases.

(i) An unbounded metric operator

We take as metric operator $G_1 = I + S^*S$, which is unbounded, with $G_1 > 1$ and bounded inverse. Then the norm $\|\cdot\|_{G_1}$ is equivalent to the norm $\|\cdot\|_{R_G}$ on $D(G_1^{1/2}) = D(S)$, so that $\mathcal{H}(G_1) = \mathcal{H}(R_{G_1})$ as vector spaces and thus also $\mathcal{H}(G_1^{-1}) = \mathcal{H}(R_{G_1^{-1}})$. On the other hand, $G_1^{-1}$ is bounded. Hence we get the triplet

\begin{equation}
\mathcal{H}(G_1) \subset \mathcal{H} \subset \mathcal{H}(G_1^{-1}) = \mathcal{H}(G_1)^\times.
\end{equation}

Actually, the triplet (5.6) is the central part of the discrete scale of Hilbert spaces $V_G$ built on the powers of $G_1^{1/2}$. This means that $V_G := \{\mathcal{H}_n, n \in \mathbb{Z}\}$, where $\mathcal{H}_n = D(G_1^{n/2}), n \in \mathbb{N}$, with a norm equivalent to the graph norm, and $\mathcal{H}_n = \mathcal{H}_n^\times$:

\begin{equation}
\ldots \subset \mathcal{H}_2 \subset \mathcal{H}_1 \subset \mathcal{H} \subset \mathcal{H}_{-1} \subset \mathcal{H}_{-2} \subset \ldots
\end{equation}

Thus $\mathcal{H}_1 = \mathcal{H}(G_1^{1/2}) = D(S)$, $\mathcal{H}_2 = \mathcal{H}(G_1) = D(S^*S)$, and $\mathcal{H}_{-1} = \mathcal{H}(G_1^{-1})$. Then $G_1^{1/2}$ is a unitary operator from $\mathcal{H}_1$ onto $\mathcal{H}$ and, more generally, from $\mathcal{H}_n$ onto $\mathcal{H}_{n-1}$. In the same way, $G_1$ is a unitary operator from $\mathcal{H}_n$ onto $\mathcal{H}_{n-2}$ and $G_1^{-1}$ a unitary operator from $\mathcal{H}_n$ onto $\mathcal{H}_{n+2}$.

Moreover, one may add the end spaces of the scale, namely,

\begin{equation}
\mathcal{H}_\infty(G_1) := \bigcap_{n \in \mathbb{Z}} \mathcal{H}_n, \quad \mathcal{H}_{-\infty}(G_1) := \bigcup_{n \in \mathbb{Z}} \mathcal{H}_n.
\end{equation}
In this way, we get a genuine Rigged Hilbert Space:

$$\mathcal{H}_\infty(G_1) \subset \mathcal{H} \subset \mathcal{H}_{-\infty}(G_1).$$

(5.9)

In fact, one can go one more step. Namely, following [5, Sec. 5.1.2], we can use quadratic interpolation theory [20] and build a continuous scale of Hilbert spaces \( \mathcal{H}_\alpha, 0 \leq \alpha \leq 1 \), between \( \mathcal{H}_1 \) and \( \mathcal{H} \), where \( \mathcal{H}_\alpha = D(G_1^{\alpha/2}) \), with the graph norm \( \|\xi\|_\alpha^2 = \|\xi\|^2 + \|G_1^{\alpha/2}\xi\|^2 \) or, equivalently, the norm \( \|(I + G_1)^{\alpha/2}\xi\|^2 \). Indeed every \( G_1^\alpha, \alpha \geq 0 \), is an unbounded metric operator.

Next we define \( \mathcal{H}_{-\alpha} = \mathcal{H}_\alpha^\times \) and iterate the construction to the full continuous scale \( V_{\mathcal{G}_1} := \{\mathcal{H}_\alpha, \alpha \in \mathbb{R}\} \). Then, of course, one can replace \( \mathbb{Z} \) by \( \mathbb{R} \) in the definition (5.8) of the end spaces of the scale.

In the general case, \( R_{G_1} = I + G_1 > 1 \) is also an unbounded metric operator. Thus we have

$$\mathcal{H}(R_{G_1}) \subset \mathcal{H} \subset \mathcal{H}(R_{G_1}^{-1}) = \mathcal{H}(R_{G_1})^\times,$$

(5.10)

and we get another Hilbert-Gel’fand triplet. Then one can repeat the construction and obtain the Hilbert scale built on the powers of \( R_{G_1}^{1/2} \).

Now, if \( S \) is injective, i.e. \( N(S) = \{0\} \), then \( |S|^2 > 0 \) is also an unbounded metric operator. Since \( |S| > 0, R_S = I + |S|^2 > 1 \) and it is another unbounded metric operator, with bounded inverse \( R_S^{-1} \). In both cases, one may build the corresponding Hilbert scale corresponding to the powers of \( S \) or \( R_S^{1/2} \).

At this stage, we have recovered the formalism based on metric operators that we have developed for the theory of quasi-Hermitian operators, in particular non-self-adjoint Hamiltonians, as encountered in the so-called \( \mathcal{PT} \)-symmetric quantum mechanics. We refer to [10, 11, 14] for a complete treatment. However, the case of an unbounded metric operator does not lead to many results, unless one considers a quasi-Hermitian operator [9, Def.3.1].

(ii) A bounded metric operator

We take as metric operator \( G_2 = (I + S^*S)^{-1} \), which is bounded, with unbounded inverse.

Since \( G_2 \) is bounded, things simplify, because now \( D(G_2) = \mathcal{H} \). Similarly, one gets \( \mathcal{H}(R_{G_2}^{-1}) = \mathcal{H}(G_2^{-1}) \) and \( \mathcal{H}(R_{G_2}^{-1}) = \mathcal{H}(G_2) \). So we are left with the triplet

$$\mathcal{H}(G_2^{-1}) \subset \mathcal{H} \subset \mathcal{H}(G_2).$$

(5.11)

Then \( G_2^{1/2} \) is a unitary operator from \( \mathcal{H}(G_2) \) onto \( \mathcal{H} \) and from \( \mathcal{H} \) onto \( \mathcal{H}(G_2^{-1}) \), whereas \( G_2^{-1/2} \) is a unitary operator \( \mathcal{H}(G_2^{-1}) \) onto \( \mathcal{H} \) and from \( \mathcal{H} \) onto \( \mathcal{H}(G_2) \).

(iii) A bounded metric operator with bounded inverse

There is a third case, which is almost trivial. If the operator \( S \) is bounded, \( G_1 = I + S^*S \) and \( G_2 = (I + S^*S)^{-1} \) are both bounded metric operators, with bounded inverse. Then all nine Hilbert spaces in the lattice of Fig. 1 coincide as vector spaces, with equivalent, but different, norms.

The advantage of this situation is that it leads to strong results on the similarity of two operators. As mentioned in [8, Sec.3], up to unitary equivalence, one may always consider that the intertwining operator defining the similarity is in fact a metric operator. Let us briefly recall these notions.

Let \( \mathcal{H}, \mathcal{K} \) be Hilbert spaces, \( D(A) \) and \( D(B) \) dense subspaces of \( \mathcal{H} \) and \( \mathcal{K} \), respectively, \( A : D(A) \to \mathcal{H}, B : D(B) \to \mathcal{K} \) two linear operators. A (metric) bounded operator \( T : \mathcal{H} \to \mathcal{K} \) is called an intertwining operator for \( A \) and \( B \) if
(i) \( T : D(A) \to D(B) \);
(ii) \( B^*T \xi = T A \xi, \forall \xi \in D(A) \).

We say that \( A \) and \( B \) are similar, and write \( A \sim B \), if there exists an intertwining operator \( T \) for \( A \) and \( B \) with bounded inverse \( T^{-1} : K \to \mathcal{H} \), intertwining for \( B \) and \( A \).

A parallel definition (quasi-similarity) may be given in case the inverse \( T^{-1} \) of the intertwining operator \( T \) is not bounded.

From the relation \( A \sim B \), there follows many interesting results about the respective spectra of \( A \) and \( B \), as described in detail in [8].

6 Transforming functions into frames by metric operators

This section concerns the second main aim of our paper. By Proposition 3.4 and Theorem 4.1, we get the following result: If \( \phi \) is a lower semi-frame of \( \mathcal{H} \) and \( D(C_\phi) \) is dense, then \( T_{\phi}^{-1/2} : \mathcal{H} \to \mathcal{H} \) and \( \psi = T_{\phi}^{-1/2} \phi \) is a Parseval frame for \( \mathcal{H}_\phi = \mathcal{H} \). As we already remarked, \( T_{\phi}^{-1/2} : \mathcal{H} \to \mathcal{H} \) is a metric operator. We now want to relax the condition for \( \phi \) of being a lower semi-frame. Thus we ask the following question: for which weakly measurable functions \( \phi : X \to \mathcal{H} \) does there exist a metric operator \( G \) on \( \mathcal{H} \) such that \( G\phi \) is a frame? \[3\]

The motivation of this question is that in general one tries to pass from a less regular situation to a more regular, possibly in a smaller space.

In the next result we find some necessary or sufficient conditions for an answer to our question. As we are going to see, the recourse of the generalized frame operator is again useful.

**Theorem 6.1** Let \( \phi : X \to \mathcal{H} \) be a weakly measurable function with generalized frame operator \( T_{\phi} \). The following statements hold.

(i) If \( \phi \) is not total, then there does not exist a metric operator \( G \) on \( \mathcal{H} \) such that \( G\phi \) is a frame and \( G^{-1} \) is bounded.

(ii) If \( \phi \) is a Bessel mapping and not total, then there does not exist a metric operator \( G \) on \( \mathcal{H} \) such that \( G\phi \) is a frame.

(iii) If \( D(C_\phi) \) is not dense, then there does not exist a metric operator \( G \) on \( \mathcal{H} \) such that \( G\phi \) is a frame.

(iv) If \( D(C_\phi) \) is dense and \( \phi \) is a lower semi-frame, then there exists a metric operator \( G \) on \( \mathcal{H} \) such that \( G\phi \) is a Parseval frame. In particular, a possible choice is \( G = T_{\phi}^{-1/2} \).

(v) If \( \phi \) is total, \( D(C_\phi) \) is dense and \( \phi_x \in R(T_{\phi}) \) for all \( x \in X \), then there exists a metric operator \( G \) on \( \mathcal{H} \) such that \( G\phi \) is a Parseval frame. In particular, a possible choice is \( G = T_{\phi}^{-1/2} \).

**Proof.**

(i) Suppose that there exists a metric operator \( G \) on \( \mathcal{H} \) such that \( G\phi \) is a frame and \( G^{-1} \) is bounded. By hypothesis, there exists \( f \in \mathcal{H} : f \neq 0 \) such that \( \langle \phi_x | f \rangle = 0 \) for a.e. \( x \in X \). Since \( G \) is self-adjoint and \( G^{-1} \) is bounded, then \( G^{-1} \) is defined on \( \mathcal{H} \). Hence \( \langle G\phi_x | G^{-1}f \rangle = \langle \phi_x | GG^{-1}f \rangle = 0 \) for a.e. \( x \in X \), which implies that \( G^{-1}f = 0 \), i.e. the contradiction \( f = 0 \).

(ii) Suppose that there exists a metric operator \( G \) such that \( G\phi \) is a frame, and let \( m \) be a lower bound of \( G\phi \). Then for all \( f \in D(G) \)

\[
m\|f\|^2 \leq \int_X |\langle f | G\phi_x \rangle|^2 d\mu(x) = \int_X |\langle Gf | \phi_x \rangle|^2 d\mu(x) \leq M\|Gf\|^2 \tag{6.1}
\]

\[3\] Here and in the rest of paper, writing \( G\phi \) means implicitly that \( \phi_x \in D(G) \) for all \( x \in X \).
where $M$ is an upper bound of $\phi$. Thus (6.1) implies that $G^{-1}$ is bounded. By the previous point, we get then a contradiction.

(iii) Suppose that there exists a metric operator $G$ on $\mathcal{H}$ such that $G\phi$ is a frame. Then $\int_X |\langle f | G\phi_x \rangle|^2 d\mu(x) < \infty$ for all $f \in \mathcal{H}$. In particular, for $f \in D(G)$ we have

$$\int_X |\langle f | \phi_x \rangle|^2 d\mu(x) < \infty,$$

so $R(G) \subseteq D(C_\phi)$. This means that $N(G) \supseteq D(C_\phi) \perp \neq \{0\}$ which contradicts the property that $G$ is a metric operator.

(iv) This follows by Proposition 3.4.

(v) The statement can be proved with a similar argument to that of Proposition 3.4 (Proposition 3.2), thus we give only a sketch of the proof. First of all, we note that $T_\phi$ has domain dense in $\mathcal{H}$, $D(T_\phi) \subseteq D(T_\phi^{1/2})$ and also that $T_\phi$ is injective ($\phi$ is total). Let $f \in D(T_\phi)$, then

$$\int_X |\langle f | T_\phi^{-1/2} \phi_x \rangle|^2 d\mu(x) = \|T_\phi^{1/2} T_\phi^{-1/2} f\|^2 = \|f\|^2.$$

Now, a standard argument of density concludes that $\psi$ is a Parseval frame of $\mathcal{H}$.

**Example 6.2** Let $\{e_n\}_{n \in \mathbb{N}}$ be an orthonormal basis, $\phi = \{e_1 + e_n\}_{n \geq 2}$ and $\psi = \{e_n\}_{n \geq 2}$. Both $\phi$ and $\psi$ cannot be transformed into frames of $\mathcal{H}$ by a metric operator. Indeed, $D(C_\phi) = \{e_1\} \perp$ and $\psi$ is a Bessel sequence but not total.

We will consider more examples (concerning, in particular, lower semi-frames) in the next section. As an immediate consequence of Theorem 6.1 we get the following result (compare with [25, Corollary II.1]). We recall that two sequences $\{\phi_n\}_{n \in \mathbb{N}}, \{\psi_n\}_{n \in \mathbb{N}}$ are said bi-orthogonal if $\langle \psi_n | \phi_m \rangle = \delta_{n,m}$, the Kronecker symbol.

**Corollary 6.3** Let $\phi := \{\phi_n\}_{n \in \mathbb{N}}, \psi := \{\psi_n\}_{n \in \mathbb{N}}$ be bi-orthogonal and total sequences of $\mathcal{H}$. Then $D(C_\phi)$ is dense. Moreover, if $T_\phi$ is the generalized frame operator of $\phi$, then $\phi_n \in R(T_\phi) \subseteq R(T_\phi^{1/2})$ for all $n \in \mathbb{N}$ and $\{T_\phi^{-1/2} \phi_n\}_{n \in \mathbb{N}}$ is an orthonormal basis of $\mathcal{H}$.

**Proof.** Then $D(C_\phi)$ is dense because it contains the total sequence $\psi$ and moreover $\psi_n \in D(T_\phi)$ and $T_\phi \psi_n = \phi_n$ for all $n \in \mathbb{N}$ (which also gives $\phi_n \in R(T_\phi) \subseteq R(T_\phi^{1/2})$). Now by Theorem 6.1(iv) $\{T_\phi^{-1/2} \phi_n\}_{n \in \mathbb{N}}$ is a Parseval frame of $\mathcal{H}$, but since $\langle T_\phi^{-1/2} \phi_n | T_\phi^{-1/2} \phi_m \rangle = \langle \psi_n | \phi_m \rangle = \delta_{n,m}$ we conclude that $\{T_\phi^{-1/2} \phi_n\}_{n \in \mathbb{N}}$ is in particular an orthonormal basis of $\mathcal{H}$.

The problem about transforming functions in frames is still open. However, in the light of Theorem 6.1 one may formulate a new version of the problem: given a weakly measurable function $\phi : X \rightarrow \mathcal{H}$, is it true that there exists a metric operator $G$ on $\mathcal{H}$ such that $G\phi$ is a frame if and only if $\phi$ is total and $D(C_\phi)$ is dense?

**7 Examples**

In this final section, we exhibit several examples of lower semi-frames, mostly taken from our previous works.
(1) Sequences of exponential functions

Let \( \mathcal{H} = L^2(0, 1) \) and \( g \in L^2(0, 1) \). A weighted exponential sequence of \( g \) is \( \mathcal{E}(g, b) := \{g_n\}_{n \in \mathbb{Z}} = \{g(x)e^{2\pi ibx}\}_{n \in \mathbb{Z}} \) with \( b > 0 \). In [22] Remark 6.6 it was proved that if \( 0 < b \leq 1 \), then \( \mathcal{E}(g, b) \) is a lower semi-frame if and only if \( g \) is bounded away from zero, i.e. \( |g(x)| \geq A \) for some \( A > 0 \) and a.e. \( x \in (0, 1) \). Moreover, by [22] Corollary 6.5, the analysis operator of \( \mathcal{E}(g, b) \) is densely defined and the generalized frame operator \( T_g \) of \( \mathcal{E}(g, b) \) is the multiplication operator by \( \frac{1}{b}|g|^2 \), i.e.

\[
D(T_g) = \{f \in L^2(0, 1) : |f|g|^2 \in L^2(0, 1)\} \quad \text{and} \quad T_g f = \frac{1}{b}|g|^2 f, \ \forall f \in D(T_g).
\]

Thus, for \( k \geq 0 \) and \( n \in \mathbb{Z} \), \( (T_g^{-k}g_n)(x) = g(x)/|g(x)|^{-2k}e^{2\pi inbx} \), i.e. \( T_g^{-k}\mathcal{E}(g, b) = \mathcal{E}(g/|g|^{-2k}, b) \). It is not difficult to check that the conclusions of Theorem 4.1 hold.

(2) A Reproducing Kernel Hilbert space

Following [13], we consider a reproducing kernel Hilbert space of (nice) functions on a measure space \((X, \mu)\), with kernel function \( k_x, x \in X \), that is, \( f(x) = \langle f|k_x\rangle_K, \forall f \in \mathcal{H}_{k} \). Choose the weight function \( m(x) > 1 \) and define the Hilbert scale \( \mathcal{H}_k \), \( k \in \mathbb{Z} \), determined by the multiplication operator \( Af(x) = m(x)f(x), \forall x \in X \). Thus we have, for \( n \geq 1 \) \((\Omega = -n)\),

\[
\mathcal{H}_{2n} \subset \mathcal{H}_n \subset \mathcal{H}_{K} \subset \mathcal{H}_{\Omega} \subset \mathcal{H}_{\Omega}.
\]

Then define the measurable functions \( \phi_x = k_x m^n(x), \psi_x = k_x m^{-n}(x) \), so that \( C_\psi : \mathcal{H}_K \rightarrow \mathcal{H}_m, C_\phi : \mathcal{H}_K \rightarrow \mathcal{H}_m \) continuously, and they are dual of each other. One has indeed \( \langle \phi_x|g\rangle_K = \overline{\langle g|x\rangle}_m \) and \( \langle \psi_x|g\rangle_K = \langle g|x\rangle_m \), which implies duality. Thus \( (\psi, \phi) \) is a reproducing pair with \( S_{\psi, \phi} = I \), where \( \psi \) is an upper semi-frame and \( \phi \) a lower semi-frame.

Now we concentrate on the lower semi-frame \( \phi \). First we have \( D(C_\phi) = \mathcal{H}_n \), which is dense, so that \( \mathcal{H}_\phi = \mathcal{H} \). Let us compute the sesquilinear form

\[
\Omega_\phi(f, g) = \langle C_\phi f|C_\phi g\rangle_K = \int_X f(x)m(x)|g(x)|m(x)\,d\mu(x), \quad f, g \in D(C_\phi)
\]

\[
= \langle T_{\phi}^{1/2} f|T_{\phi}^{1/2} g\rangle_K.
\]

Therefore we have \( (T_{\phi}^{1/2} f)(x) = f(x)m(x)^n \) and therefore \( (T_{\phi} f)(x) = f(x)m(x)^{2n} \). Hence \( D(T_{\phi}) = \mathcal{H}_{2n} \subset D(C_{\phi}) = \mathcal{H}_n \) and \( D(T_{\phi}^{1/2}) = \mathcal{H}_n \), see (7.1) above.

Next \( T_{\phi}^{-1/2} \) is the operator of multiplication by \( m^{-n} \), and indeed it is bounded in \( \mathcal{H} \). Finally, since \( \phi \) is a lower semi-frame, \( \chi := T_{\phi}^{-1/2} \phi \) is a frame in \( \mathcal{H} \), by Proposition 3.2.

(3) Wavelets on the sphere

The continuous wavelet transform on the 2-sphere \( S^2 \) has been analyzed in [4]. For an axissymmetric (zonal) mother wavelet \( \phi \in \mathcal{H} = L^2(S^2, d\mu) \), define the family of spherical wavelets

\[
\phi_{\theta, a} := R_{\theta} D_a \phi, \quad \text{where} \quad (\theta, a) \in X := SO(3) \times \mathbb{R}^+.
\]

Here, \( D_a \) denotes the stereographic dilation operator and \( R_{\theta} \) the unitary rotation on \( S^2 \).
Given the wavelet $\phi$, it is known that the operator $S_\phi$ is diagonal in Fourier space (harmonic analysis on the 2-sphere reduces to expansions in spherical harmonics $Y_l^m$, $l \in \mathbb{N}_0$, $m = -l, \ldots, l$), thus it is given by a Fourier multiplier $\hat{S}_\phi f(l,n) = s_\phi(l) \hat{f}(l,n)$ with the symbol $s_\phi$ given by

$$s_\phi(l) := \frac{8\pi^2}{2l+1} \sum_{|m| \leq l} \int_0^\infty |\hat{D}_\phi(l,m)|^2 \frac{da}{a^3}, \ l \in \mathbb{N}_0.$$  

where $\hat{D}_\phi(l,m) := \langle Y_l^m | D_\phi \rangle$ is the Fourier coefficient of $D_\phi$.

If one has $d \leq s_\phi(l) \leq c$, for every $l \in \mathbb{N}$, then the wavelet $\phi$ is admissible and a frame in $L^2(\mathbb{S}^2, d\mu)$. However, it has been shown in [29] that the reconstruction formula converges under the weaker condition $d \leq s_\phi(l) < \infty$ for all $l \in \mathbb{N}_0$. In that case, $\phi$ is not admissible and is a lower semi-frame, with $S_\phi$ unbounded and densely defined. The domain of $S_\phi$ is the following:

$$D(S_\phi) = \{ f \in L^2(\mathbb{S}^2, d\mu) : |\hat{f}(l,n)| \leq \frac{1}{s_\phi(l)} |\hat{h}(l,n)|, \text{ for some } h \in L^2(\mathbb{S}^2, d\mu) \}.$$  

This domain contains, in particular, the set of band-limited functions, i.e. functions $f$ such that $\hat{f}(l,n) = 0$, $\forall l \geq N_1$, for some $N_1 < \infty$, which is dense in $L^2$. Since $S_\phi = D_\phi C_\phi$, it follows that $D(S_\phi) \subset D(C_\phi)$, hence $D(C_\phi)$ is dense as well and $\mathcal{H}_\phi = \mathcal{H}$.

We proceed as in Case (2) and consider the sequilinear form

$$\Omega_\phi(f,g) = \langle C_\phi f | C_\phi g \rangle = \langle T_\phi^{1/2} f | T_\phi^{1/2} g \rangle, \ f,g \in D(C_\phi).$$  

Since $D(C_\phi)$ is dense, we get $T_\phi := |C_\phi|^2 = C_\phi^* C_\phi$, $T_\phi^{1/2} = |C_\phi|$ and $D(T_\phi) \subset D(T_\phi^{1/2}) = D(C_\phi)$.

Finally, since $\phi$ is a lower semi-frame, $\chi := T_\phi^{-1/2} \phi$ is a frame in $\mathcal{H}$, by Proposition 3.2 as before.
