Moniqua: Modulo Quantized Communication in Decentralized SGD

Yucheng Lu* and Christopher De Sa†
Department of Computer Science, Cornell University

Abstract
Running Stochastic Gradient Descent (SGD) in a decentralized fashion has shown promising results. In this paper we propose Moniqua, a technique that allows decentralized SGD to use quantized communication. We prove in theory that Moniqua communicates a provably bounded number of bits per iteration, while converging at the same asymptotic rate as the original algorithm does with full-precision communication. Moniqua improves upon prior works in that it (1) requires zero additional memory, (2) works with 1-bit quantization, and (3) is applicable to a variety of decentralized algorithms. We demonstrate empirically that Moniqua converges faster with respect to wall clock time than other quantized decentralized algorithms. We also show that Moniqua is robust to very low bit-budgets, allowing 1-bit-per-parameter communication without compromising validation accuracy when training ResNet20 and ResNet110 on CIFAR10.

1 Introduction
Stochastic gradient descent (SGD), as a widely adopted optimization algorithm for machine learning, has shown promising performance when running at large scale [1, 2, 3, 4]. However, the communication bottleneck among workers can substantially slow down the training [5]. State-of-the-art frameworks such as TensorFlow [6], CNTK [7] and MXNet [8] are built in a centralized fashion, where workers exchange gradients either via a centralized parameter server [9, 10] or the MPI AllReduce operation [11]. Such a design, however, puts heavy pressure on the central server and strict requirements on the underlying network. In other words, when the underlying network is poorly constructed, i.e. high latency or low bandwidth, it can easily cause degradation of training performance due to communication congestion in the central server or stragglers (slow workers) in the system.

There are two general approaches to deal with these problems: (1) decentralized training [12, 13, 14, 15] and (2) quantized communication [16, 17, 18]. In decentralized training, all the workers are connected to form a graph and each worker communicates only with neighbors by averaging model parameters between two adjacent optimization steps. This balances load and is robust to scenarios where workers can only be partially connected or the communication latency is high. On the other hand, quantized communication reduces the amount of data exchanged among workers, leading to faster convergence with respect to wall clock time [16, 17, 19, 20, 21]. This is especially useful when the communication bandwidth is restricted.

At this point, a natural question is: Can we apply quantized communication to decentralized training, and thus benefit from both of them? Unfortunately, directly combining them together negatively affects the convergence rate [22]. This happens because existing quantization techniques are mostly designed for centralized SGD, where workers communicate via exchanging gradients [17, 19, 23]. Gradients are robust to quantization since they get smaller in magnitude near local optima and in some sense carry less information, causing quantization error to approach zero [24]. In contrast, decentralized workers are communicating the...
model parameters, which do not necessarily approach zero and thus quantization error does not diminish without explicitly increasing precision \[25\]. Previous work solved this problem by adding an error tracker to compensate quantization errors \[26\] or adding replicas of neighboring models and focusing on quantizing model-difference which does approach zero \[22, 27\]. However, these methods have limitations in that: (1) the extra replicas or error tracking incurs substantial memory overhead that is proportional to size of models and the graph (more details in Section 2); and (2) these methods are either limited to constant step size or biased quantizers \[22, 26, 27\].

To address these problems, in this paper we propose Moniqua, an additional-memory-free method for decentralized training to use quantized communication. Moniqua supports non-constant step size and biased quantizers. Our contribution can be summarized as follows:

- We show by example that naively quantizing communication in decentralized training can fail to converge asymptotically. (Section 3)
- We propose Moniqua, a general algorithm that uses modular arithmetic for communication quantization in decentralized training. We prove applying Moniqua achieves the same asymptotic convergence rate as the baseline full-precision algorithm (D-PSGD) while supporting extreme low bit-budgets. (Section 4)
- We apply Moniqua to decentralized algorithms with variance reduction and asynchronous communication (D^2 and AD-PSGD) and prove Moniqua enjoys the same asymptotic rate as with full-precision communication when applied to these cases. (Section 5)
- We empirically evaluate Moniqua and show it outperforms all the related algorithms given an identical quantizer. We also show Moniqua is scalable and works with 1-bit quantization. (Section 6)

### Intuition behind Moniqua.

In decentralized training, workers communicate to average their model parameters \[12\]. As the algorithm converges, all the workers will approach the same stationary point as they reach consensus \[22\]. As a result, the difference in the same coordinate of models on two workers is becoming small. Suppose \(x\) and \(y\) are the \(i\)th coordinates of models on workers \(w_x\) and \(w_y\), respectively. If we somehow know in advance that \(|x - y| < \theta\), then if \(w_y\) needs to obtain \(x\), it suffices to fetch \(x \mod 2\theta\) rather than \(x\) from \(w_x\). Note that \(x \mod 2\theta\) is generally a smaller number than \(x\), which means to obtain the same absolute error, fewer bits are needed compared to fetching \(x\) directly. Formally, this intuition is captured in the following lemma.

**Lemma 1** Define the modulo operation mod as the follows. For any \(z \in \mathbb{R}\) and \(a \in \mathbb{R}^+\),

\[
\{z \mod a\} = \{z + na | n \in \mathbb{N}\} \cap [-a/2, a/2)
\]

then for any \(x, y \in \mathbb{R}\), if \(|x - y| < \theta\), then

\[
x = (x \mod 2\theta - y \mod 2\theta) \mod 2\theta + y.
\]

### 2 Related Work

**Decentralized Stochastic Gradient Descent (SGD).** Decentralized algorithms \[28, 29, 30, 31\] have been widely studied with consideration of communication efficiency, privacy and scalability. In the domain of large-scale machine learning, D-PSGD was the first Decentralized SGD algorithm that was proven to enjoy the same asymptotic convergence rate \(O(1/\sqrt{Kn})\) (where \(K\) is the number of total iterations and \(n\) is the number of workers) as centralized algorithms \[12\]. After D-PSGD came D^2, which improves D-PSGD and is applicable to the case where workers are not sampling from identical data sources \[14\]. Another extension was AD-PSGD, which lets workers communicate *asynchronously* and has a convergence rate of \(O(1/\sqrt{K})\) \[13\]. Other relevant work includes: He et al. \[32\], which investigates decentralized learning on linear models; Nazari et al. \[33\], which introduces decentralized algorithms with online learning; Zhang and You \[34\], which analyzes the case when workers cannot mutually communicate; and Assran et al. \[35\], which investigates Decentralized SGD specifically for deep learning.

**Quantized Communication in Centralized SGD.** Prior research on quantized communication is often focused on centralized algorithms, such as randomized quantization \[18, 20, 26\] and randomized sparsification \[21, 23, 37, 38\]. Many examples of prior work focus on studying quantization in the communication of
Table 1: Comparison among Moniqua and baseline algorithms, where workers form a graph with \( n \) vertices and \( m \) edges. \( d \) refers to the model dimension. Detailed discussion can be found in Section 2. The additional memory refers to the space complexity required additional to the baseline full-precision communication decentralized training algorithm (D-PSGD).

Deep learning tasks specifically \[18, 39, 40\]. Alistarh et al. \[17\] proposes QSGD, which uses an encoding-efficient scheme, and discusses its communication complexity. Another method, 1bitSGD, quantizes exchanged gradients with one bit per parameter and shows great empirical success on speech recognition \[19\]. Other work discusses the convergence rate under sparsified or quantized communication \[37, 41\]. Acharya et al. \[42\] theoretically analyzes sublinear communication for distributed training.

**Quantized Communication in Decentralized SGD.** Quantized communication for decentralized algorithms is a rising topic in the optimization community. Previous work has proposed decentralized algorithms with quantized communication for strongly convex objectives \[43\]. Following that, Tang et al. \[22\] proposes DCD/ECD-PSGD, which quantizes communication via estimating model difference. Furthermore, Tang et al. \[22\] proposes DeepSqueeze, which applies an error-compensation method \[44\] to decentralized setting. Koloskova et al. \[27\] proposed ChocoSGD, a method that lets workers estimate remote models with a local estimator, which supports arbitrary quantization by tuning the communication matrix.

**How Moniqua improves on prior works.** We summarize the comparison among Moniqua and other baseline algorithms in Table 1. Specifically, Moniqua supports biased quantizer and arbitrary quantization. It requires no additional memory (compared to full-precision algorithms) while other algorithms incur substantial memory overhead as shown in Table 1. Considering the fact that model size and networks are large in practice, the baseline algorithms have significant memory overhead. Furthermore, Moniqua has theoretical guarantees even with asynchronous communication and non-i.i.d. data sources. Finally, Moniqua gives theoretical guarantees for non-constant step size schemes, while other baselines only support constant step size in their theory.

### 3 Setting and Notation

In this section, we introduce our notation and the general assumptions we will make about the quantizers for our results to hold. Then we describe D-PSGD \[12\], the basic algorithm for Decentralized SGD, and we show how naive quantization can fail in decentralized training.

**Quantizers.** Throughout this paper, we assume that we use a quantizer \( Q_\delta \) that has bounded error

\[
\|Q_\delta(x) - x\|_\infty \leq \delta \quad \text{when} \quad x \in \left[-\frac{1}{2}, \frac{1}{2}\right]^d
\]

where \( \delta \) is some constant. Note that in this assumption, we do not assume any bound for \( x \) outside \( \left[-\frac{1}{2}, \frac{1}{2}\right]^d \): as will be shown later, a bound in this region is sufficient for our theory. This assumption holds for both linear \[45, 46\] and non-linear \[17, 47\] quantizers. In general, a smaller \( \delta \) denotes more fine-grained quantization.
Decentralized parallel stochastic gradient descent (D-PSGD). D-PSGD \cite{12} is the first and most basic Decentralized SGD algorithm. In D-PSGD, \( n \) workers are connected to form a graph. Each worker \( i \) stores a copy of model \( x \in \mathbb{R}^d \) and a local dataset \( D_i \) and collaborates to optimize

\[
\min_{x \in \mathbb{R}^d} f(x) = \frac{1}{n} \sum_{i=1}^{n} \mathbb{E}_{\xi \sim D_i} f_i(x; \xi). \tag{3}
\]

where \( \xi \) is a data sample from \( D_i \). In each iteration of D-PSGD, worker \( i \) computes a local gradient sample using \( D_i \). Then it averages its model parameters with its neighbors according to a symmetric and doubly stochastic matrix \( W \), where \( W_{ij} \) denotes the ratio worker \( j \) averages from worker \( i \). Formally: Let \( x_{k,i} \) and \( \tilde{y}_{k,i} \) denote local model and sampled gradient on worker \( i \) at \( k \)-th iteration, respectively. Let \( \alpha_k \) denote the step size. The update rule of D-PSGD can be expressed as:

\[
x_{k+1,i} = \sum_{j=1}^{n} x_{k,j} W_{ji} - \alpha_k \tilde{y}_{k,i} = x_{k,i} - \sum_{j=1}^{n} (x_{k,i} - x_{k,j}) W_{ji} - \alpha_k \tilde{y}_{k,i}
\]

From \( \text{(3)} \) we can see the update of a single local model contains two parts: communication to reduce model difference and a gradient step. Lian et al. \cite{12} shows that all local models in D-PSGD reach the same stationary point.

Failure with naive quantization. Here, we illustrate why naively quantizing communication in decentralized training — directly quantizing the exchanged data — can fail to converge asymptotically even on a simple problem. This naive approach with quantizer \( Q_\delta \) can be represented by

\[
x_{k+1,i} = x_{k,i} W_{ii} + \sum_{j \neq i} Q_\delta(x_{k,j}) W_{ji} - \alpha_k \tilde{y}_{k,i} \tag{4}
\]

Based on Equation \( \text{(4)} \) we obtain the following theorem.

**Theorem 1** For some constant \( \delta \), suppose that we use an unbiased linear quantizer \( Q \) with representable points \( \{\delta n \mid n \in \mathbb{Z}\} \) to learn on the quadratic objective function \( f(x) = (x - \delta/2)^\top (x - \delta/2)/2 \) with the direct quantization approach \( \text{(3)} \). Let \( \phi \) denote the smallest value of a non-zero entry in \( W \). Regardless of what step size we adopt, it will always hold for all iterations \( k \) and local model indices \( i \) that \( \mathbb{E} \| \nabla f(x_{k,i}) \|^2 \geq \frac{\phi^2}{8(2 + \phi)} \).

That is, the local iterates will fail to asymptotically converge to a region of small gradient magnitude in expectation.

Theorem \( \text{1} \) shows that naively quantizing communication in decentralized SGD, even with an unbiased quantizer, any local model can fail to converge on a simple quadratic objective. This is not satisfying, since, it implies we would need more advanced quantizers which are likely to require more system resources such as memory. In the following section, we propose a technique, Moniqua, that solves this problem.

## 4 Moniqua

In Section \( \text{1} \) we described the basic idea behind Moniqua: to use modular arithmetic to decrease the magnitude of the numbers we are quantizing. We now describe how Moniqua implements this intuition with a given quantizer \( Q_\delta \). Consider the two-scalar example from Section \( \text{1} \). Suppose we know \( y \) and \( |x - y| < \theta \) and need to fetch \( x \) from a remote host via a quantizer \( Q_\delta \) to recover \( x \). We’ve shown in Section \( \text{3} \) that fetching and using \( Q_\delta(x) \) leads to divergence. Instead, we define a parameter \( B_\theta = (2\theta)/(1 - 2\delta) \) and then use the modulo operation and fetch \( Q_\delta ((x/B_\theta) \mod 1) \) from the remote host, from which we can approximately recover \( x \) as

\[
\hat{x} = (B_\theta Q_\delta ((x/B_\theta) \mod 1) - y) \mod B_\theta + y. \tag{5}
\]
Algorithm 1 Pseudo-code of Moniqua on worker $i$

**Input:** initial point $x_{0,i} = x_0$, step size $\{\alpha_k\}_{k \geq 0}$, the a priori bound $\{\theta_k\}_{k \geq 0}$, communication matrix $W$, number of iterations $K$, quantizer $Q_\delta$, neighbor list $\mathcal{N}_i$

1. for $k = 0, 1, 2, \ldots, K - 1$ do
2. Compute a local stochastic gradient $\tilde{g}_{k,i}$ with data sample $\xi_{k,i}$ and current weight $x_{k,i}$
3. Send modulo-ed model to neighbors:
   $$q_{k,i} = Q_\delta \left( (x_{k,i}/B_\theta_k) \mod 1 \right)$$
4. Compute local biased term $\hat{x}_{k,i}$ as:
   $$\hat{x}_{k,i} = q_{k,i}B_\theta_k - x_{k,i} \mod B_\theta_k + x_{k,i}$$
5. Recover model received from worker $j$ as:
   $$\hat{x}_{k,j} = (q_{k,j}B_\theta_k - x_{k,i}) \mod B_\theta_k + x_{k,i}$$
6. Average with neighboring workers:
   $$x_{k+\frac{1}{2},i} \leftarrow x_{k,i} + \sum_{j \in \mathcal{N}_i} (\hat{x}_{k,j} - \hat{x}_{k,i})W_{ji}$$
7. Update the local weight with local gradient:
   $$x_{k+1,i} \leftarrow x_{k+\frac{1}{2},i} - \alpha_k \tilde{g}_{k,i}$$
8. end for
9. return averaged model $\bar{X}_K = \frac{1}{n} \sum_{i=1}^{n} x_{K,i}$

Note that inside the quantizer we rescale $x$ to $x/B_\theta$, which is required for (2) to apply. This approach has quantization error bounded proportional to the original bound $\theta$, as shown in the following lemma.

**Lemma 2** For any scalars $x, y \in \mathbb{R}$, if $|x - y| < \theta$ and if $\delta < \frac{1}{2}$, then if we set $B_\theta = (2\theta)/(1 - 2\delta)$ and $\hat{x}$ as in (5),
$$|\hat{x} - x| \leq \delta B_\theta = \theta \cdot (2\delta)/(1 - 2\delta).$$

Importantly, since the quantization error is decreasing with $\theta$, if we are able to prove a decentralized algorithm approaches consensus and use this proof to give a bound of the form $|x - y| < \theta$, this bound will give us a compression procedure with smaller error as our consensus bound improves. We formalize this approach as Moniqua (Algorithm 1). (Note that all the division and mod operations in Algorithm 1 act element-wise.)

Note that in line 4 and 6, we compute and cancel out a local biased term, this is to cancel out the extra noise which may be brought to the global model. As we will show in the supplementary material, cancelling out this local biased term reduces extra noise to the algorithm. And in Algorithm 1 we consider the general case where $\theta$ can be an iteration dependent bound. As will be shown later, a constant $\theta$ also guarantees convergence.

We now proceed to analyze the convergence rate of Algorithm 1. We use the following common assumptions for analyzing decentralized optimization algorithms [12, 22, 27).

(A1) **Lipschitzian gradient.** All the functions $f_i$ have $L$-Lipschitzian gradients.
$$||\nabla f_i(x) - \nabla f_i(y)|| \leq L ||x - y||, \forall x, y \in \mathbb{R}^d$$

(A2) **Spectral gap.** The communication matrix $W$ is a symmetric doubly stochastic matrix and
$$\max \{||\lambda_2(W)||, ||\lambda_n(W)||\} = \rho < 1,$$
where $\lambda_i(W)$ denotes the the $i$th eigenvalue of $W$. 

5
(A3) Bounded variance. There exist non-negative constants \( \sigma \) and \( \varsigma \in \mathbb{R} \) such that
\[
\mathbb{E}_{\xi_i \sim D_i} \left\| \nabla \tilde{f}_i(x; \xi_i) - \nabla f_i(x) \right\|^2 \leq \sigma^2
\]
\[
\mathbb{E}_{i \sim \{1, \ldots, n\}} \left\| \nabla f_i(x) - \nabla f(x) \right\|^2 \leq \varsigma^2
\]
where \( \nabla \tilde{f}_i(x; \xi_i) \) denotes the gradient sample on worker \( i \) computed via data sample \( \xi_i \).

(A4) Initialization. All the local models are initialized with the same weight: \( x_{0,i} = x_0 \) for all \( i \), and without loss of generality \( x_0 = 0 \).

(A5) Bounded gradient magnitude. For some constant \( G_\infty \), the norm of a sampled gradient is bounded by \( \| \tilde{g}_{k,i} \|_\infty \leq G_\infty \), for all \( i \) and \( k \).

Lemma \ref{lemma:quantization-bound} states that the error bound from quantization is proportional to \( \theta \). In other words, a tight estimation or choice on the \( \theta \) will lead to smaller quantization error in the algorithm. We present these parameter choices in Theorem \ref{theorem:moniqua-convergence} along with the resulting convergence rate for Moniqua.

Theorem 2 Consider adopting a non-increasing step size scheme \( \{ \alpha_t \}_{t \geq 0} \) such that there exists constant \( C_\alpha > 0 \) and \( \eta (0 < \eta \leq 1) \) that for any \( k, t \geq 0 \), \( \frac{\alpha_k}{\alpha_{k+t}} \leq C_\alpha \eta^t \), set \( \theta_k = \frac{2 \alpha_k G_\infty C_\alpha \log(16n)}{1-\eta \rho} \) and \( \delta = \frac{C_\alpha^{-1}}{8C_\alpha^2 \eta \log(16n)+2(1-\eta \rho)} \), then Algorithm 1 converges at the following rate:
\[
\sum_{k=0}^{K-1} \alpha_k \mathbb{E} \left\| \nabla f(\bar{\mathbf{X}}_k) \right\|^2 \leq 4(\mathbb{E} f(0) - \mathbb{E} f^*) + \frac{2 \sigma^2 L}{n} \sum_{k=0}^{K-1} \alpha_k^2 + \frac{8 (\sigma^2 + 3 \varsigma^2) L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3 + \frac{8 G_\infty^2 d L^2}{(1-\rho)^2 C_\alpha^2} \sum_{k=0}^{K-1} \alpha_k^3
\]

Theorem \ref{theorem:moniqua-convergence} shows that the priori bound \( \theta_k \) is proportional to the step size and increases at the logarithmic speed when system size \( n \) increases. The two-constant assumption on the step size prevents it from decreasing too fast. As a rapidly decreasing step size would prevent us from obtaining such a priori bound in theory. This assumption generally holds for most of the step size schemes. Just as baseline algorithms, by setting step size to a constant, we can obtain a concrete convergence bound as shown in the following corollary.

Corollary 1 If we run Algorithm 1 in a setting where \( \alpha_k = \frac{1}{\varsigma^2/3 K^{1/3} + \sigma \sqrt{K/n} + 2L} \) then the output of Algorithm 1 converges at the asymptotic rate
\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(\bar{\mathbf{X}}_k) \right\|^2 \lesssim \frac{1}{K} + \frac{\sigma}{\sqrt{nK} \varsigma} + \frac{\varsigma^2}{K^2} + \frac{(\sigma^2 + G_\infty^2 d n)}{\sigma^2 K + n}.
\]

Consistent with D-PSGD. Note that D-PSGD converges at the asymptotic rate of \( O(\sigma/\sqrt{nK} + \varsigma^2/K^2 + n/K) \), and thus Moniqua has the same asymptotic rate as D-PSGD \[12\]. That is, the asymptotic convergence rate is not negatively impacted by the quantization.

Robust to large \( d \). In Assumptions (A3) and (A5) we use \( l_2 \)-norm and \( l_\infty \)-norm to bound sample variance and gradient magnitude, respectively. Note that, when \( d \) gets larger, the variance \( \sigma^2 \) will also tend to grow proportionally. So, the last term will tend to remain \( n/K \) asymptotically with large \( d \).

Bound on the Bits. The specific number of bits required by Moniqua depends on the underlying quantizer (\( \mathbb{Q}_\delta \)). If we use nearest neighbor rounding \[35\] with a linear quantizer as \( \mathbb{Q}_\delta \) in Theorem \ref{theorem:moniqua-convergence} it suffices to use at each step a number of bits \( B \) for each parameter sent, where
\[
B \leq \left\lceil \log_2 \left( \frac{1}{\delta} + 1 \right) \right\rceil = \left\lceil \log_2 \left( \frac{4 \log_2(16n)}{1-\rho} + 3 \right) \right\rceil
\]
Note that this bound is independent of model dimension \( d \). When the system scales up, the number of required bits grows at a rate of \( O(\log \log n) \). Note that, this is a general bound on the number of bits required by Moniqua using the same communication matrix \( W \) as the baseline. To enforce a even more restricted bit-budget (e.g. 1 bit), Moniqua can still converge at the same rate by adjusting the communication matrix.
1-bit Quantization. We can also add a consensus step \[20\] [27] to allow Moniqua to use 1 bit per parameter. Specifically, we adopt a slack communication matrix \[W = \gamma W + (1 - \gamma)I\] and tune \(\gamma\) as a hyperparameter. We formalize this result in the following Theorem.

**Theorem 3** Consider using a communication matrix in the form of \(W = \gamma W + (1 - \gamma)I\). If we set \(\theta = \frac{2\alpha G_\infty \log(16n)}{\gamma(1 - \rho)}\), \(\gamma = \frac{1 - \rho + \frac{1}{1 - 2\delta^2} \log(32\gamma) + \log(K)}{1 - \rho}\), and \(\alpha = \frac{1}{\bar{\varsigma} K \hat{z} + \sigma \sqrt{4n + 2L}}\), then the output of Algorithm 1 converges at the asymptotic rate

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(\hat{x}_k) \right\|^2 \lesssim \frac{\sigma}{\sqrt{nK}} + \frac{1}{K} + \frac{\varsigma \delta^4 \log^2(n) \log^2(K)}{K \hat{z} (1 - 2\delta)^4} + \frac{\sigma^2 n \delta^4 \log^2(n) \log^2(K)}{(\sigma^2 K + n)(1 - 2\delta)^4} + \frac{n \delta^6 \log^4(n) \log^2(K)}{(\sigma^2 K + n)(1 - 2\delta)^6}
\]

Note that the dominant term in **Theorem 3** is still \(O(\sigma/\sqrt{nK})\), which means Moniqua converges at the asymptotic rate the same as full precision D-PSGD [12] even with more restricted bits-budget. Note that in **Theorem 3** the only requirement on the quantizer is \(\delta < \frac{1}{2}\). Considering the properties of our quantizer [2], this version of Moniqua allows us to use 1 bit in general per parameter.

### 5 Scalable Moniqua

So far, we have discussed how Moniqua, along with baseline algorithms, modifies D-PSGD to use communication quantization. In this section, we show Moniqua is general enough to be applied on other decentralized algorithms that are beyond D-PSGD. Previous work has extended D-PSGD to \(D^2\) [14] (to make Decentralized SGD applicable to workers sampling from different data sources) and AD-PSGD [13] (an asynchronous version of D-PSGD). In this section, we prove Moniqua is applicable to both of these algorithms.

**Moniqua with Decentralized Data** Decentralized data refers to the case where all the local datasets \(D_i\) are not identically distributed [14]. More explicitly, the outer variance \(\mathbb{E}_{i \sim \{1, ..., n\}} \| \nabla f_i(x) - \nabla f(x) \|^2\) is no longer bounded by \(\varsigma^2\) as assumed in D-PSGD (Assumption [A3]). We apply Moniqua to \(D^2\) [14], a decentralized algorithm designed to tackle this problem by reducing the variance over time. Applying Moniqua on \(D^2\) can be explicitly expressed \[\footnote{For brevity, the detailed pseudo code can be found in the supplementary material.}\] as:

\[
\begin{align*}
X_{k+\frac{1}{2}} &= 2X_k - X_{k-1} - \alpha_k \tilde{G}_k + \alpha_{k-1} \tilde{G}_{k-1} \\
X_{k+1} &= X_{k+\frac{1}{2}} W + (X_{k+\frac{1}{2}} - X_{k+\frac{1}{2}}) (W - I)
\end{align*}
\]

where \(X_k\), \(\tilde{G}_k\) and \(X_{k+\frac{1}{2}}\) are matrix in the shape of \(\mathbb{R}^{d \times n}\), where their \(i\)-th column are \(x_{k,i}\), \(\tilde{g}_{k,i}\) and \(\tilde{x}_{k+\frac{1}{2},i}\) respectively. And \(X_{-1}\) and \(\tilde{G}_{-1}\) are \(0^{d \times n}\) by convention. Based on this, we obtain the following convergence theorem.

**Theorem 4** If we apply Moniqua on \(D^2\) in a setting where \(\theta = (6D_1n + 8)\alpha G_\infty\), \(\alpha = \frac{1}{\sigma \sqrt{K/n + 2L}}\) where \(D_1\) and \(D_2\) are two constants\[\footnote{\text{they only depend on the eigenvalues of } W \text{ (definition can be found in supplementary material)}}\], applying Moniqua on \(D^2\) has the following asymptotic convergence rate:

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \| \nabla f(\hat{x}_k) \|^2 \lesssim \frac{1}{K} + \frac{\sigma}{\sqrt{nK}} + \frac{(\sigma^2 + G_\infty^2) n}{\sigma^2 K + n}.
\]

Note that \(D^2\) [14] with full-precision communication has the asymptotic convergence rate of \(O \left( \frac{1}{K} + \frac{\sigma}{\sqrt{nK}} + \frac{n}{K} \right)\). Moniqua on \(D^2\) has the same asymptotic rate.
Moniqua with Asynchronous Communication  Both D-PSGD and $D^2$ are synchronous algorithms as they require global synchronization at the end of each iteration, which can become a bottleneck when such synchronization is not cheap. Another algorithm, AD-PSGD, avoids this overhead by letting workers communicate asynchronously [13]. In the analysis of AD-PSGD, an iteration represents a single gradient update on one randomly-chosen worker, rather than a synchronous bulk update of all the workers. This single-worker-update analysis models the asynchronous nature of the algorithm. Applying Moniqua on AD-PSGD can be explicitly expressed as:

$$X_{k+1} = X_k W_k + (\tilde{X}_k - X_k)(W_k - I) - \alpha_k \tilde{G}_{k-\tau_k}$$

where $W_k$ describes the communication behaviour between the $k$th and $(k+1)$th gradient update, and $\tau_k$ denotes the delay (measured as a number of iterations) between when the gradient is computed and updated to the model. Note that unlike D-PSGD, here $W_k$ can be different at each update step and usually each individually has $\rho = 1$, so we can’t expect to get a bound in terms of a bound on the spectral gap, as we did in Theorems 2 and 4. Instead, we require the following condition, which is inspired by the literature on Markov chain Monte Carlo methods: for some constant $t_{\text{mix}}$ and for any $k$, $\forall \mu \in \mathbb{R}^n$, if $\mu_i \geq 0$ and $\mu^\top \mu = 1$, it must hold that $\left\| \left( \prod_{t=1}^{t_{\text{mix}}} W_{k+1} \right) \mu - \frac{1}{n} \right\|_2 \leq \frac{1}{2}$. We call this constant $t_{\text{mix}}$ because it is effectively the mixing time of the time-inhomogeneous Markov chain with transition probability matrix $W_k$ at time $k$ [19]. Note that this condition is more general than those used in previous work on AD-PSGD because it does not require that the $W_k$ are sampled independently or in an unbiased manner. Using this, we obtain the following convergence theorem.

**Theorem 5** If we apply Moniqua on AD-PSGD in a setting where $\theta = 16 t_{\text{mix}}^d G_{\infty}$, $\delta = \frac{1}{64 t_{\text{mix}}^d + 2}$ and $\alpha_k = \alpha = \frac{n}{2L + \sqrt{K(\sigma^2 + 6\varsigma^2)}}$, applying Moniqua on AD-PSGD has the following asymptotic convergence rate:

$$\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 \lesssim \frac{1}{K} + \frac{\sqrt{\sigma^2 + 6\varsigma^2}}{\sqrt{K}} + \frac{(\sigma^2 + 6\varsigma^2) t_{\text{mix}}^d n^2}{(\sigma^2 + 6\varsigma^2) K + 1} + \frac{n^2 t_{\text{mix}}^d G_{\infty}^2 d}{(\sigma^2 + 6\varsigma^2) K + 1}$$

Note that AD-PSGD [13] with full-precision communication has the asymptotic convergence rate of $O \left( \frac{1}{K} + \frac{\sqrt{\sigma^2 + 6\varsigma^2}}{\sqrt{K}} + \frac{\varsigma^2}{K} \right)$. Moniqua obtains the same asymptotic rate.

Since adopting a slack matrix to enable 1-bit quantization in these two algorithms will be similar to the case in Theorem 3 we omit the discussion here for brevity.

### 6 Experiments

In this section, we evaluate Moniqua empirically. First, we compare Moniqua and other quantized decentralized training algorithms’ convergence under different network configurations. Second, we compare the validation performance of them under extreme bit-budget. Then we investigate Moniqua’s scalability on $D^2$ and AD-PSGD. Finally, we introduce several useful techniques for running Moniqua efficiently.

**Setting and baselines.** All the models and training scripts in this section are implemented in PyTorch and run on Google Cloud Platform. We launch an instance as one worker, each configured with a 2-core CPU with 4 GB memory and an NVIDIA Tesla P100 GPU. We use MPICH as the communication backend. All the instances are running Ubuntu 16.04, and latency and bandwidth on the underlying network are configured using the tc command in Linux. Throughout our experiments, we adopt the commonly used [15] stochastic rounding. We compare Moniqua with the following baselines: Centralized (implemented as a standard AllReduce operation), D-PSGD [12] with full-precision communication, DCD/ECD-PSGD [22], ChocoSGD [22] and DeepSqueeze [26].

---

5 For brevity, the detailed pseudo code can be found in the supplementary material.

6 Since several baselines are not applicable to biased quantizer, for fair comparison we consistently use stochastic rounding (unbiased).
Wall-clock time evaluation. We start by evaluating the performance of Moniqua and other baseline algorithms under different network configurations. We launch 8 workers connected in a ring topology and train a ResNet20 [50] model on CIFAR10 [51]. For all the algorithms, we quantize each parameter into 8-bit representation.

We plot our results in Figure 1. We can see from Figures 1(a) to 1(b) that when the network bandwidth decreases, the curves begin to separate. AllReduce and full-precision D-PSGD suffer the most, since they require a large volume of high-precision exchanged data. And from Figure 1(b) to Figure 1(c) when the network latency increases, AllReduce is severely delayed since it needs to transfer large volume of messages (such as handshakes between hosts to send data). On the other hand, from Figure 1(a) to Figure 1(b) and Figure 1(c) curves of all the quantized baselines (DCD/ECD-PSGD, ChocoSGD and DeepSqueeze) are getting closer to Moniqua. This is because, as shown in Figure 1(a), the extra updating of the replicas in DCD/ECD-PSGD and ChocoSGD as well as the error tracking in DeepSqueeze counteract the benefits from accelerated communication. However, when network bandwidth decreases or latency increases, communication becomes the bottleneck and makes these algorithms diverge from centralized SGD and D-PSGD. Delay between Moniqua and quantized baselines does not vary with the network since that only depends on the their extra local computation (error tracking and replica update). Figure 1(d) shows an extremely poor network, and we can see that all the quantized baselines are having similar convergence speed since now network is a serious overhead.
Table 2: Final test accuracy of ResNet20 and ResNet110 on CIFAR10 trained by different algorithms. (“diverge” means the algorithm cannot converge. “extra memory” means the extra memory required by different algorithms compared to full precision D-PSGD.)

Extremely low bit-budget. We proceed to evaluate whether Moniqua and other baselines are able to achieve state-of-the-art accuracy under extremely low bit budgets. We train two different models: ResNet20 and ResNet110 on CIFAR10. State-of-the-art results [50] show that ResNet20 can achieve test accuracy of 91.25% while ResNet110 can achieve 93.57%. We enforce two strict bit-budget: 1bit and 2bit (per parameter). We plot the final test accuracy under different algorithms in Table 6. We can see that DCD-PSGD and ECD-PSGD are generally not able to converge. Among all the other algorithms, Moniqua achieves slightly better test accuracy while requiring no additional memory. By comparison, ChocoSGD and DeepSqueeze are able to get close to state-of-the-art accuracy, but at the cost of incurring substantial memory overhead.

Scalability of Moniqua. We evaluate the performance of Moniqua when applied to $D^2$ [14] and AD-PSGD [13]. First, we demonstrate how applying Moniqua to $D^2$ can handle decentralized data. We launch 10 workers, collaborating to train a VGG16 [52] model on CIFAR10. State-of-the-art results [30] show that ResNet20 can achieve test accuracy of 91.25% while ResNet110 can achieve 93.57%. We let each worker have exclusive access to 1 label (of the 10 labels total in CIFAR10). In this way, the data variance among workers is maximized. We plot the results in Figure 2(a). We observe that applying Moniqua on $D^2$ does not affect the convergence rate while D-PSGD can no longer converge because of the outer variance. Here we omit the wall clock time comparison since the communication volume is the same in comparison of Moniqua and Centralized algorithm in Figure 1.

Next, we evaluate Moniqua on AD-PSGD. We launch 6 workers organized in a ring topology, collaborating to train a ResNet110 model on CIFAR10. We set the network bandwidth to be 20Mbps and latency to be 0.15ms. We plot the results in Figure 2(b). We can see that both AD-PSGD and asynchronous Moniqua outperform D-PSGD. Besides, Moniqua outperforms AD-PSGD in that communication is reduced, which is
aligned with the intuition and theory.

Choosing $\theta$ empirically. We can see that the $\theta$ chosen will largely affect the running of Moniqua. In practice, there are several methods to effectively tune $\theta$. The first method is to directly compute $\theta$ via its expression. Specifically, we could first run a few epochs and keep track of the infinity norm of the gradient and then use expression in Theorem 2 to obtain $\theta$. Note that gradient is usually decreasing in magnitude as algorithm proceeds. In general the computed $\theta$ can be used throughout the training. The second method is to treat $\theta$ as a hyperparameter and use standard methods such as random search or grid search [53] to tune $\theta$ until we find the correct $\theta$. The third method is to add verification. For instance, consider using stochastic rounding with quantization step being $\delta$. Suppose we have $x \in \mathbb{R}^d$ and need to send it to machine $M$ with $y$. If $|x - y| < \theta$, then if we send $Q_\delta(x/\delta)$ mod $\theta/\delta$ to $M$, it will recover $Q_\delta(x/\delta)$ based on $y$. In addition, we can also send $H(Q_\delta(x/\delta))$, where $H$ is a hash function that takes the un-modded vector. When $M$ recovers $Q_\delta(x/\delta)$, it can detect whether the thing it recovered has the correct hash. If the $\theta$ is mistakenly chosen, $M$ will detect any errors with high probability [54]. Note that compared to the model parameters, the output of hash function will not cause any overhead in general.

More efficient Moniqua. There are two techniques we have observed to improve the performance of Moniqua when using stochastic rounding: $Q_\delta(x) = \delta[\frac{x}{\delta} + u]$ (where $u$ is uniformly sampled from $[0, 1]$), $\forall x \in \mathbb{R}^d$. The first is to use shared randomness, in which the same random seed is used for stochastic rounding on all the workers. That is, if two workers are exchanging tensors $x$ and $y$ respectively, then the floored tensors $[\frac{x}{\delta} + u]$ and $[\frac{y}{\delta} + u]$ they send use the same randomly sampled value $u$. This provably reduces the error due to quantization (more details are in the supplementary material). The second technique is to use a standard entropy compressor like bzip to further compress the communicated tensors. This can help further reduce the number of bits because the modulo operation in Moniqua can introduce some redundancy in the higher-order bits, which a traditional compression algorithm can easily remove.

7 Conclusions

In this paper we propose Moniqua, a simple unified method of quantizing the communication in decentralized training algorithms. Theoretically, Moniqua supports biased quantizer and non-convex problems, while enjoying the same asymptotic convergence rate as full-precision-communication algorithms without incurring storage or computation overhead. Empirically, we observe Moniqua converges faster than other related algorithms with respect to wall clock time. Additionally, Moniqua is robust to very low bits-budget.

Supplementary Material

A Overview

This supplementary material contains proof to all the theoretical results. It is organized as follows: In Section B, we analyze how to work with Modulo and quantization, as proofs to Lemma 1 and Lemma 2 in the paper. In Section C, we provably explain why using shared randomness in communication with stochastic rounding can improve performance. In Section D, we illustrate why directly quantizing communication in D-PSGD fails to converge asymptotically, as a proof to Theorem 1. In Section E, we introduce some useful tools of modeling communication as a Markov Chain for the rest of the proof (part of the intuition is illustrated in the paper). We recommend to go through this before getting into Section F to H. Finally we will provide proof to Theorem 2 to 5 from Section F to H.

B Modulo Operation with Quantization

Proof to Lemma 1

Proof Rewrite $x$ and $y$ as

$x = N_x a + r_x, -\frac{a}{2} \leq r_x < \frac{a}{2}$

$y = N_y a + r_y, -\frac{a}{2} \leq r_y < \frac{a}{2}$

where $N_x, N_y \in \mathbb{Z}$ then,

$LHS = (r_x - r_y) \mod a$

$RHS = ((N_x - N_y)a + r_x - r_y) \mod a = (r_x - r_y) \mod a = LHS$

Thus we complete the proof.

Proof to Lemma 2

Proof We start from

$B_\theta Q_\delta \left( \frac{x}{B_\theta} \mod 1 \right) - B_\theta \left( \frac{x}{B_\theta} \mod 1 \right) + x = B_\theta Q_\delta \left( \frac{x}{B_\theta} \mod 1 \right) - B_\theta \left( \frac{x}{B_\theta} \mod 1 \right) + x - y + y$

If $B_\theta$ is sufficiently large such that $B_\theta \geq 2\theta + 2\delta B_\theta > 2|x-y| + 2\delta B_\theta$, we could put a "mod $B_\theta$" to the first four terms as follows:

$B_\theta Q_\delta \left( \frac{x}{B_\theta} \mod 1 \right) - B_\theta \left( \frac{x}{B_\theta} \mod 1 \right) + x - y + y$

$= \left( B_\theta Q_\delta \left( \frac{x}{B_\theta} \mod 1 \right) - B_\theta \left( \frac{x}{B_\theta} \mod 1 \right) + x - y \right) \mod B_\theta + y$

$\overset{\text{Lemma 1}}{=} \left[ \left( B_\theta Q_\delta \left( \frac{x}{B_\theta} \mod 1 \right) - B_\theta \left( \frac{x}{B_\theta} \mod 1 \right) + x \right) \mod B_\theta - y \mod B_\theta \right] \mod B_\theta + y$

$\overset{\text{Lemma 1}}{=} \left\{ \left[ B_\theta Q_\delta \left( \frac{x}{B_\theta} \mod 1 \right) \mod B_\theta - \left( B_\theta \left( \frac{x}{B_\theta} \mod 1 \right) - x \right) \mod B_\theta \right] \mod B_\theta - y \mod B_\theta \right\} \mod B_\theta + y$

Note that the term $\left( B_\theta \left( \frac{x}{B_\theta} \mod 1 \right) - x \right) \mod B_\theta = 0$, then we can proceed as:

$\left\{ \left[ B_\theta Q_\delta \left( \frac{x}{B_\theta} \mod 1 \right) \mod B_\theta - \left( B_\theta \left( \frac{x}{B_\theta} \mod 1 \right) - x \right) \mod B_\theta \right] \mod B_\theta - y \mod B_\theta \right\} \mod B_\theta + y$
By moving $x$ to the right side we obtain
$$\left| B_\theta Q_3\left(\frac{x}{B_\theta} \mod 1\right) - y \mod B_\theta \right| \leq \delta B_\theta$$
That completes the proof.

C Shared Randomness

In this section, we provide a theoretical explanation why using shared randomness in the stochastic rounding is able to improve the performance. Without the loss of generality, in the following analysis, we let the quantization step associated with stochastic rounding quantizer $Q_3$ be $\delta = 1$. For any $z$ quantized using $Q_3$, let $z_f = z - \lfloor z \rfloor$, the variance of quantization error can be expressed as
$$\mathbb{E}\|Q_3(z) - z\|^2 = (1 - z_f)(-z_f)^2 + z_f(1 - z_f)^2 = z_f(1 - z_f)$$

(6)

Note that in Moniqua, the term associate with quantization error is
$$\mathbb{E}\|(q_{k,j} - x_{k,j}) - (q_{k,i} - x_{k,i})\|^2$$
We now show for $\forall x, y \in \mathbb{R}^d$

$$\mathbb{E}\|\left(Q_3(x) - x\right) - (Q_3(y) - y)\|^2 = \mathbb{E}\|Q_3(y - x) - (y - x)\|^2$$

With out the loss of generality, let $x - \lfloor x \rfloor \leq y - \lfloor y \rfloor$. Let $x_f = x - \lfloor x \rfloor$ and $y_f = y - \lfloor y \rfloor$, then
$$\lfloor x + u \rfloor = \lfloor x \rfloor \quad \text{and} \quad \lfloor y + u \rfloor = \lfloor y \rfloor, \text{with probability } \lfloor y \rfloor - y$$
$$\lfloor x + u \rfloor = \lfloor x \rfloor \quad \text{and} \quad \lfloor y + u \rfloor = \lfloor y \rfloor, \text{with probability } x - \lfloor x \rfloor$$
Then we have
$$\mathbb{E}\|\left(Q_3(x) - x\right) - (Q_3(y) - y)\|^2$$
$$= \mathbb{E}\left\|\left(\delta \left\lfloor \frac{x + u}{\delta} \right\rfloor - x\right) - \left(\delta \left\lfloor \frac{y + u}{\delta} \right\rfloor - y\right)\right\|^2$$
$$= ((\lfloor y \rfloor - y)((\lfloor x \rfloor - x) - (\lfloor y \rfloor - y))^2 + (x - \lfloor x \rfloor)(\lfloor x \rfloor - x) - (\lfloor y \rfloor - y))^2$$
$$+ ((\lfloor x \rfloor - x) - (\lfloor y \rfloor - y))((\lfloor x \rfloor - x) - (\lfloor y \rfloor - y))^2$$
$$= (1 - y_f)(x_f - y_f)^2 + (x_f)(x_f - y_f) + (y_f - x_f)(y_f - x_f - 1)^2$$
$$= (1 - y_f + x_f)(y_f - x_f)^2 + (y_f - x_f)(y_f - x_f - 1)^2$$
$$= (1 - y_f + x_f)(y_f - x_f)$$
$$= \mathbb{E}\|Q_3(y - x) - (y - x)\|^2$$
The last equality holds due to equation (6) Next, let
$$\Delta = y - x$$
$$r = Q_3(\Delta) - \Delta$$
And let $r_h$ denote $h$-th entry of $r$, let $\Delta_h$ denote $h$-th entry of $\Delta$. We obtain
$$r_h = Q_3(\Delta_h) - \Delta_h$$
\[ \delta \left\{ \begin{array}{ll} -\frac{\Delta h}{\delta} + \left\lfloor \frac{\Delta h}{\delta} \right\rfloor + 1, & \text{if } p_t \leq \frac{\Delta h}{\delta} - \left\lfloor \frac{\Delta h}{\delta} \right\rfloor \\ -\frac{\Delta h}{\delta} + \left\lfloor \frac{\Delta h}{\delta} \right\rfloor, & \text{otherwise} \end{array} \right. \]

\[ = \delta \left\{ \begin{array}{ll} -q + 1, & \text{if } p_t \leq q \\ -q, & \text{otherwise} \end{array} \right. \]

where

\[ q = \frac{\Delta h}{\delta} - \left\lfloor \frac{\Delta h}{\delta} \right\rfloor, \quad q \in [0, 1) \]

Based on that, we have

\[ \mathbb{E} \left[ r_h^2 \right] \leq \delta^2 \left( (q - 1)^2 q + (q)^2 (1 - q) \right) \]

\[ \leq \delta^2 q (1 - q) \leq \delta^2 \min\{q, 1 - q\} \]

Since \( \min\{q, 1 - q\} \leq \left| x_h \delta \right| \), we have

\[ \mathbb{E} \left[ r_h^2 \right] \leq \delta^2 \left( \frac{\Delta h}{\delta} \right) \leq \delta |\Delta h| \]

Summing over the index \( h \) yields,

\[ \mathbb{E} \left[ \| r \|_2^2 \right] \leq \delta \mathbb{E} \| \Delta \|_1 \leq \sqrt{d} \delta \mathbb{E} \| \Delta \|_2 \]

Pushing back \( x \) and \( r \), we have

\[ \mathbb{E} \left[ \| Q \delta (y - x) - (y - x) \|_2^2 \right] \leq \sqrt{d} \delta \mathbb{E} \| y - x \| = \sqrt{d} \delta \mathbb{E} \| x - y \| \]

Putting it back we have

\[ \mathbb{E} \left[ \| Q \delta (x - x^*) \|_2^2 \right] \leq \sqrt{d} \delta \mathbb{E} \| x - y \| \]

Now we can see that the error term is bounded by the distance of two quantized tensors, which, in decentralized training, refers to the distance between two models on adjacent workers. In such a way, the error bound can be reduced since the workers are getting close to each other.

## D Why Naive Quantization Fails in D-PSGD (Proof to Theorem 1)

The update rule of naive quantization on D-PSGD is

\[ x_{k+1,i} = x_{k,i} W_{ii} + \sum_{j=1, j \neq i}^{n} Q_{\delta}(x_{k,j}) W_{ji} - \alpha_k \tilde{g}_{k,i} = x_{k,i} + \sum_{j=1, j \neq i}^{n} (Q_{\delta}(x_{k,j}) - x_{k,i}) W_{ji} - \alpha_k \tilde{g}_{k,i} \]

where \( \alpha_k \) is allowed to vary with any policy. Let

\[ X_k = [x_{k,1}, \ldots, x_{k,n}] \in \mathbb{R}^{d \times n} \]

\[ \Omega_k = \left[ \sum_{j \neq 1} W_{j1} (Q_{\delta}(x_{k,j}) - x_{k,1}), \ldots, \sum_{j \neq n} W_{jn} (Q_{\delta}(x_{k,j}) - x_{k,n}) \right] \in \mathbb{R}^{d \times n} \]

\[ \tilde{G}_k = [\tilde{g}_{k,1}, \ldots, \tilde{g}_{k,n}] \in \mathbb{R}^{d \times n} \]

by rewriting the update rule, we obtain

\[ X_{k+1} = X_k + \Omega_k - \alpha_k \tilde{G}_k \]

Let \( Y_k = X_k - x^* 1_n^T \), and considering the fact that \( \nabla f(x) = x - \delta/2 = x - x^* \), we can rewrite the update rule as

\[ Y_{k+1} e_i = Y_k e_i + \Omega_k e_i - \alpha_k Y_k e_i + \alpha_k \left( \tilde{G}_k - G_k \right) e_i \]
where \( \bar{G}_k - G_k \) denotes variance in the gradient sampling.

Suppose that by using the update rule of naive quantization, worker \( i \) converges to \( x^* \). Then there must exist a \( K \) such that \( \forall k \geq K \),

\[
E\|Y_{k+1}e_i\|^2 \leq E\|Y_k e_i\|^2 < \frac{\phi^2\delta^2}{8(1 + \phi^2)}
\]  

(7)

Next we show that this assumption lets us derive a contradiction. Firstly, considering the property of linear quantizer,

\[
\frac{\delta^2}{4} \leq E \| Q_\delta(x_{k,i}) - x^* \|^2 \leq 2E \| Q_\delta(x_{k,i}) - x_{k,i} \|^2 + 2E \| x_{k,i} - x^* \|^2
\]

As a result,

\[
E \| Q_\delta(x_{k,i}) - x_{k,i} \|^2 \geq \frac{\delta^2}{8} - \frac{\phi^2\delta^2}{8(1 + \phi^2)} = \frac{\delta^2}{8(1 + \phi^2)}
\]

Since \( Q_\delta \) is unbiased, that means \( E[Q_\delta(x) - x] = 0 \), then we have

\[
E\|\Omega_k e_i\|^2
\]

\[
= E \left\| \sum_{j \neq i} W_{ji} (Q_\delta(x_{k,j}) - x_{k,i}) \right\|^2
\]

\[
= \sum_{j \in N_i} W_{ji}^2 E \| (Q_\delta(x_{k,j}) - x_{k,i}) \|^2 + \sum_{m \neq n \neq i} E \langle (Q_\delta(x_{k,m}) - x_{k,i}) W_{mi}, (Q_\delta(x_{k,n}) - x_{k,i}) W_{ni} \rangle
\]

\[
\geq \phi^2 \sum_{j \in N_i} E \| (Q_\delta(x_{k,j}) - x_{k,i}) \|^2 + \sum_{m \neq n \neq i} E \langle (Q_\delta(x_{k,m}) - x_{k,i}) W_{mi}, (Q_\delta(x_{k,n}) - x_{k,i}) W_{ni} \rangle
\]

\[
\geq \phi^2 \sum_{j \in N_i} E \| Q_\delta(x_{k,j}) - x_{k,i} \|^2
\]

\[
\geq \frac{\phi^2\delta^2}{8(1 + \phi^2)}
\]

where step (\( \ast \)) holds due to unbiased quantizer. Putting it back to the update rule, we obtain

\[
E\|Y_{k+1}e_i\|^2
\]

\[
= E \left\| (Y_k + \Omega_k - \alpha_k Y_k + \alpha_k (\bar{G}_k - G_k)) e_i \right\|^2
\]

\[
\geq \frac{\phi^2\delta^2}{8(1 + \phi^2)}
\]

where cross terms in the (\( \ast \)) step are all 0 due to the unbiased quantizer and unbiased sampling of the gradient. Her we obtain the contradictory that \( \frac{\phi^2\delta^2}{8(1 + \phi^2)} \leq E \| x_{k+1} - x^* \|^2 < \frac{\phi^2\delta^2}{8(1 + \phi^2)} \). That being said, for \( \forall k, i \)

\[
E\|x_{k,i} - x^*\|^2 = E\|\nabla f(x_{k,i})\|^2 \geq \frac{\phi^2\delta^2}{8(1 + \phi^2)}
\]

Thus we complete the proof.
E A Markov Chain Analysis on the Communication

To better understand how the parallel workers reach consensus over a communication matrix, in this section we use theory from the analysis of Markov Chains to obtain some useful lemmas for proof of Moniqua on D-PSGD and AD-PSGD.

Since the communication matrix $W$ is doubly stochastic (each row and column sum to 1), it has the same structure as the transition matrix of a Markov Chain with $\frac{1}{n}$ as its the stationary distribution $(W \frac{1}{n} = \frac{1}{n})$. Now let $t_{\text{mix}}$ and $d(t)$ denote the mixing time and maximal distance between initial state and stationary distribution as defined in Markov Chain theory.[7]

E.1 D-PSGD

In D-PSGD, the communication matrix is fixed during the training. That makes it perfectly aligned with the structure of a Markov Chain. As a result, we obtain the following lemma:

Lemma 3

$$\left\|W^t \left(I - \frac{1}{n} \frac{1}{n}^T\right)\right\|_1 \leq 2 \cdot 2^{-\left\lceil \frac{t}{t_{\text{mix}}} \right\rceil}$$

Proof For $\forall x \in \mathbb{R}^d$, let $u \in \mathbb{R}^d$ be such a vector that every entry of $u$ is the positive entry of $x$ and 0 otherwise. Let $v \in \mathbb{R}^d$ be such a vector that every entry of $v$ is the absolute value of negative entry of $x$ and 0 otherwise. The setting above means $x = u - v$. For example,

$x = [2, -1]^T$

$u = [2, 0]^T$

$v = [0, 1]^T$

And we have

$$\left\|W^t \left(I - \frac{1}{n} \frac{1}{n}^T\right)\right\|_1 x \leq \left\|W^t \left(I - \frac{1}{n} \frac{1}{n}^T\right) (u - v)\right\|_1$$

$$= \left\|W^t \left(I - \frac{1}{n} \frac{1}{n}^T\right) u\right\|_1 + \left\|W^t \left(I - \frac{1}{n} \frac{1}{n}^T\right) v\right\|_1$$

$$= \frac{1}{n}^T u \left\|W^t u - \frac{1}{n} \frac{1}{n}^T\right\|_1 + \frac{1}{n}^T v \left\|W^t v - \frac{1}{n} \frac{1}{n}^T\right\|_1$$

$$\leq 2 \left(\frac{1}{n}^T u + \frac{1}{n}^T v\right) d(t)$$

$$\leq 2d(t) \|x\|_1$$

Considering the definition of $L_1$-norm, we have

$$\left\|W^t \left(I - \frac{1}{n} \frac{1}{n}^T\right)\right\|_1 = \max_{\|x\|_1} \left\|W^t \left(I - \frac{1}{n} \frac{1}{n}^T\right) x\right\|_1 \leq 2d(t)$$

According to a well-known results on the theory of Markov Chains,[8] $d(t_{\text{mix}}) \leq 2^{-l}$ holds for any non-negative integer $l$, so we have

$$\left\|W^t \left(I - \frac{1}{n} \frac{1}{n}^T\right)\right\|_1 \leq 2d(t) \leq 2d \left(\frac{t}{t_{\text{mix}}} \cdot t_{\text{mix}}\right) \leq 2d \left(\frac{t}{t_{\text{mix}}} \right) t_{\text{mix}} \leq 2 \cdot 2^{-\left\lceil \frac{t}{t_{\text{mix}}} \right\rceil}$$

That completes the proof.

[7]Here we are using notation from Chapter 4.5 of Markov Chains and Mixing Times (Levin 2009), available at https://pages.uoregon.edu/dlevin/MARKOV/markovmixing.pdf

[8]Again, see Markov Chains and Mixing Times for more details.
Additionally, based on standard results in the theory of reversible Markov Chains, we also have:

\[ t_{\text{mix}} \leq \log \left( \frac{1}{1 - \frac{1}{n^2}} \right) \frac{1}{1 - \rho} \leq \frac{\log(4n)}{1 - \rho}. \]

### E.2 AD-PSGD

Note that unlike D-PSGD, here \( W_k \) can be different at each update step and usually each individually have spectral radius \( \rho = 1 \), so we can’t expect to get a bound in terms of a bound on the spectral gap as we did in Theorems 2 and 4. Instead, we require the following condition, which is inspired by the literature on Markov chain Monte Carlo methods: for some constant \( t_{\text{mix}} \) (here \( t_{\text{mix}} \) is the same as \( t_{\text{mix}} \) in the paper) and for any \( k \) and any non-negative vector \( \mu \in \mathbb{R}^d \) such that \( \mathbb{1}_n \mu = 1 \), it must hold that

\[
\left\| \left( \prod_{i=1}^{t_{\text{mix}}} W_{k+i} \right) \mu - \frac{\mathbb{1}_n}{n} \right\|_1 \leq \frac{1}{2}.
\]

We call this constant \( t_{\text{mix}} \) because it is effectively the mixing time of the time-inhomogeneous Markov chain with transition probability matrix \( W_k \) at time \( k \). Note that this condition is more general than those used in previous work on AD-PSGD because it does not require that the \( W_k \) are sampled independently or in an unbiased manner. Based on the above analysis, we can prove the following lemma, which is analogous to the lemma used in the synchronous case.

**Lemma 4** For any \( k \geq 0 \) and for any \( b \geq a \geq 0 \), there exists \( t_{\text{mix}} \) such that

\[
\left\| b \prod_{q=a}^{b} W_q \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) \right\|_1 \leq 2 \cdot 2^{-\frac{b-a+1}{t_{\text{mix}}}}.
\]

**Proof** Note that for any \( x \in \mathbb{R}^d \), and let \( u \) and \( v \) be two vectors having same definition as in Lemma 3 with respect to \( x \), then we have for any \( k \)

\[
\left\| \prod_{q=1}^{t_{\text{mix}}} W_{q+k} \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) x \right\|_1 = \left\| \prod_{q=1}^{t_{\text{mix}}} W_{q+k} \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) (u - v) \right\|_1 \\
\leq \left\| \prod_{q=1}^{t_{\text{mix}}} W_{q+k} \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) u \right\|_1 + \left\| \prod_{q=1}^{t_{\text{mix}}} W_{q+k} \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) v \right\|_1 \\
= \mathbb{1}_n^\top u \left\| \prod_{q=1}^{t_{\text{mix}}} W_{q+k} \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) \frac{u}{n} \right\|_1 + \mathbb{1}_n^\top v \left\| \prod_{q=1}^{t_{\text{mix}}} W_{q+k} \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) \frac{v}{n} \right\|_1 \\
\leq \frac{1}{2} (\mathbb{1}_n^\top u + \mathbb{1}_n^\top v) \\
\leq \frac{1}{2} \|x\|_1
\]

Considering the definition of the induced \( \ell_1 \) operator norm, we have

\[
\left\| \prod_{q=1}^{t_{\text{mix}}} W_{q+k} \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) \right\|_1 = \max_x \left\| \prod_{q=1}^{t_{\text{mix}}} W_{q+k} \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) x \right\|_1 \leq \frac{1}{2}
\]

\[\text{9} \text{Detailed analysis and proofs of this result can be found in chapter 12.2 of Markov Chains and Mixing Times.}\]
As a result, from the submultiplicativity of the matrix induced norm, we obtain

\[
\left\| \prod_{q=a}^{b} W_q \left( I - \frac{1_n 1_n^T}{n} \right) \right\|_1 \\
\leq \left\| \prod_{q=1}^{t_{\text{mix}}} W_{a-1+q} \left( I - \frac{1_n 1_n^T}{n} \right) \right\|_1 \cdots \left\| \prod_{q=1}^{t_{\text{mix}}} W_{a+q} \left( I - \frac{1_n 1_n^T}{n} \right) \right\|_1 \\
\leq 2^{-\left\lfloor \frac{b-a+1}{t_{\text{mix}}} \right\rfloor} \left\| \prod_{q=1}^{t_{\text{mix}}} W_{a+q} \left( I - \frac{1_n 1_n^T}{n} \right) \right\|_1
\]

where \( t_r = (b - a + 1) \mod t_{\text{mix}} \). Note that

\[
\left\| \prod_{q=1}^{t_r} W_q \left( I - \frac{1_n 1_n^T}{n} \right) \right\|_1 \leq 1 - \frac{1}{n} + (n - 1) \frac{1}{n} = 2 - \frac{2}{n} \leq 2
\]

Putting it back we obtain

\[
\left\| \prod_{q=a}^{b} W_{a+q} \left( I - \frac{1_n 1_n^T}{n} \right) \right\|_1 \leq 2 \cdot 2^{-\left\lfloor \frac{b-a+1}{t_{\text{mix}}} \right\rfloor}
\]

That completes the proof.

Note that in the analysis of Moniqua on AD-PSGD (Section H), we will use this lemma as an assumption.

F Moniqua on D-PSGD (Proof to Theorem 2 and 3)

F.1 Notations

For convenience, we adopt the following notation

\[ X_k = [x_{k,1}, \ldots, x_{k,n}], \quad \hat{X}_k = [\hat{x}_{k,1}, \ldots, \hat{x}_{k,n}] \]
\[ \tilde{G}_k = [\tilde{g}_{k,1}, \ldots, \tilde{g}_{k,n}], \quad G_k = [g_{k,1}, \ldots, g_{k,n}] \]
\[ \tilde{X} = \frac{1_n}{n}, \quad \forall X \in \mathbb{R}^{d \times n}, \quad \Omega_k = (\hat{X}_k - X_k)(W - I) \]

where \( g_{k,i} \) denotes gradient computed via the whole dataset \( D_i \) and \( x_{k,i} \).

From a local view, the update rule on worker \( i \) at iteration \( k \) can be written as

\[ x_{k+1,i} \leftarrow x_{k,i} + \sum_{j \in N_i} (\hat{x}_{k,j} - \hat{x}_{k,i}) W_{ji} - \alpha_k \tilde{g}_{k,i} \]

which is equivalent to

\[ x_{k+1,i} = \sum_{j=1}^{n} x_{k,j} W_{ji} - \alpha_k \tilde{g}_{k,i} + \sum_{j=1}^{n} ((\hat{x}_{k,j} - x_{k,j}) - (\hat{x}_{k,i} - x_{k,i})) W_{ji} \quad (8) \]

From a global view, the update rule can be written as

\[ X_{k+1} = X_k + \hat{X}_k(W - I) - \alpha_k \tilde{G}_k = X_k W - \alpha_k \tilde{G}_k + (\hat{X}_k - X_k)(W - I) \quad (9) \]
F.2 Proof to Theorem [2].

Proof From Lemma [3], we have
\[
\sum_{k=0}^{K-1} \alpha_k \| \nabla f(\mathbf{x}_k) \|^2 \leq 4(\mathbb{E} f(0) - Ef^*) + \frac{2\alpha^2 L}{n} \sum_{k=0}^{K-1} \alpha_k^2 + \frac{8\sigma^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3 + \frac{24\kappa^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3
\]
\[
+ \frac{8L^2}{n(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k \| \Omega_k \|_F^2
\]

Note that
\[
\sum_{k=0}^{K-1} \alpha_k \| \Omega_k \|_F^2 = \sum_{k=0}^{K-1} \alpha_k \sum_{i=1}^{n} \left| \sum_{j=1}^{n} ((\hat{x}_{k,j} - x_{k,j}) - (\hat{x}_{k,i} - x_{k,i})) W_{ji} \right|^2 \leq 4 \sum_{k=0}^{K-1} \alpha_k \delta^2 \sigma_k^2 \Omega
\]

By using Lemma [4] and by assigning \( \delta = \frac{1-\eta}{\sigma \sqrt{\log(1+2(1-\eta \rho))}} \), we obtain
\[
\sum_{k=0}^{K-1} \alpha_k \| \Omega_k \|_F^2 \leq \frac{8G^2 \sigma^2 \Omega}{C^2} \sum_{k=0}^{K-1} \alpha_k^3
\]

Pushing it back we obtain
\[
\sum_{k=0}^{K-1} \alpha_k \| \nabla f(\mathbf{x}_k) \|^2 \leq 4(\mathbb{E} f(0) - Ef^*) + \frac{2\alpha^2 L}{n} \sum_{k=0}^{K-1} \alpha_k^2 + \frac{8\sigma^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3 + \frac{24\kappa^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3
\]
\[
+ \frac{8L^2}{(1-\rho)^2 C^2} \sum_{k=0}^{K-1} \alpha_k^3
\]

That completes the proof.

F.3 Proof to Corollary [1].

Proof When \( \alpha_k = \alpha, C_a = \eta = 1 \), and we have:
\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \| \nabla f(\mathbf{x}_k) \|^2 \leq \frac{4f(0) - f^*)}{\alpha K} + \frac{2\alpha L}{n} \sigma^2 + \frac{8\sigma^2 L^2 (\sigma^2 + 3\kappa^2)}{(1-\rho)^2} + \frac{8\alpha^2 G^2 \sigma^2 \Omega}{(1-\rho)^2}
\]

By setting \( \alpha = \frac{1}{\zeta^2 K^{1+\sigma \sqrt{2L}}} \), we have
\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \| \nabla f(\mathbf{x}_k) \|^2 \leq \frac{8(f(0) - f^*)L}{K} + \frac{4\sigma f(0) - f^* + L/2}{\sqrt{nK}} + \frac{4\zeta^2 (f(0) - f^*)}{\zeta^2 K^{1+\sigma \sqrt{2L}}}
\]
\[
+ \frac{8L^2 \sigma^2 n}{(1-\rho)^2 (\sigma^2 K + 4n L^2)} + \frac{24L^2 \zeta^2}{(1-\rho)^2 K^{1+\sigma \sqrt{2L}}} + \frac{8G^2 \sigma^2 \Omega}{(1-\rho)^2 (\sigma^2 K + 4n L^2)}
\]
\[
\leq \frac{1}{\sqrt{nK}} + \frac{\sigma}{\sqrt{nK}} + \frac{\zeta^2}{K^{1+\sigma \sqrt{2L}}} + \frac{\sigma^2 n}{\sigma^2 K + n} + \frac{G^2 \sigma^2 \Omega}{\sigma^2 K + n}
\]

That completes the proof of Corollary 1.

F.4 Lemma for Moniqua on D-PSGD

Lemma 5 If \( \| x_{t,i} - x_{t,j} \|_\infty < \theta_t, \forall i, j \) holds at iteration \( t \), then
\[
\left\| \sum_{j=1}^{n} ((\hat{x}_{t,j} - x_{t,j}) - (\hat{x}_{t,i} - x_{t,i})) W_{ji} \right\|_\infty \leq \frac{4\delta}{1 - 2\delta} \theta_t
\]
Proof Let \( B_\theta = \frac{2}{1 - 2\delta} \theta \), based on the algorithm, we obtain

\[
\hat{x}_{t,j} = \left( B_\theta Q_\delta \left( \frac{x_{t,j} + 1}{B_\theta} \right) - x_{t,i} \right) \mod B_\theta + x_{t,i} \]

\[
\hat{x}_{t,i} = B_\theta Q_\delta \left( \frac{x_{t,i} + 1}{B_\theta} \right) - B_\theta \left( \frac{x_{t,i} + 1}{B_\theta} \right) + x_{t,i}
\]

We start from

\[
\left\| \sum_{j=1}^{n} ((\hat{x}_{t,j} - x_{t,j}) - (\hat{x}_{t,i} - x_{t,i})) W_{ji} \right\|_\infty \leq \sum_{j=1}^{n} W_{ji} \left\| (\hat{x}_{t,j} - x_{t,j}) - (\hat{x}_{t,i} - x_{t,i}) \right\|_\infty
\]

\[
\leq \sum_{j=1}^{n} W_{ji} \left\| \hat{x}_{t,j} - x_{t,j} \right\|_\infty + \sum_{j=1}^{n} W_{ji} \left\| \hat{x}_{t,i} - x_{t,i} \right\|_\infty
\]

On the first hand, due to Lemma 2 we obtain

\[
\left\| \hat{x}_{t,j} - x_{t,j} \right\|_\infty \leq \delta B_\theta
\]

on the other hand,

\[
\left\| \hat{x}_{t,i} - x_{t,i} \right\|_\infty = \left\| B_\theta Q_\delta \left( \frac{x_{t,i} + 1}{B_\theta} \right) - B_\theta \left( \frac{x_{t,i} + 1}{B_\theta} \right) \right\|_\infty \leq \delta B_\theta
\]

Putting it back, we obtain

\[
\left\| \sum_{j=1}^{n} ((\hat{x}_{t,j} - x_{t,j}) - (\hat{x}_{t,i} - x_{t,i})) W_{ji} \right\|_\infty \leq 2\delta B_\theta = \frac{4\delta}{1 - 2\delta} \theta
\]

which completes the proof.

Lemma 6 For any \( X_t \in \mathbb{R}^{d \times n} \), we have

\[
\left\| \sum_{t=0}^{k-1} X_t \left( \frac{1}{n} \mathbb{1}_n \mathbb{1}_n^\top - W^k - 1 \right) \right\|_F^2 \leq \left( \sum_{t=0}^{k-1} \rho^k \left\| X_t \right\|_F \right)^2
\]

Proof

\[
\left\| \sum_{t=0}^{k-1} X_t \left( \frac{1}{n} \mathbb{1}_n \mathbb{1}_n^\top - W^k - 1 \right) \right\|_F^2 = \left( \left\| \sum_{t=0}^{k-1} X_t \left( \frac{1}{n} \mathbb{1}_n \mathbb{1}_n^\top - W^k - 1 \right) \right\|_F \right)^2
\]

\[
\leq \left( \sum_{t=0}^{k-1} \left\| X_t \right\|_F \left\| \frac{1}{n} \mathbb{1}_n \mathbb{1}_n^\top - W^k - 1 \right\|_F \right)^2
\]

\[
\leq \left( \sum_{t=0}^{k-1} \left\| X_t \right\|_F \left\| \frac{1}{n} \mathbb{1}_n \mathbb{1}_n^\top - W^k - 1 \right\|_F \right)^2
\]

That completes the proof.

Lemma 7 In any iteration \( k \geq 0 \), and for any two worker \( i \) and \( j \), when \( \delta = \frac{1 - \eta \rho}{8C_\delta \eta \log(16n) + 2(1 - \eta \rho)} \) we have:

\[
\left\| X_k (e_i - e_j) \right\|_\infty \leq \frac{2\alpha_k G_\infty C_\eta \log(16n)}{1 - \eta \rho} = \theta_k
\]

23
Proof We use mathematical induction to prove this:

I. When $k = 0$, $\|X_0(e_i - e_j)\|_{\infty} = 0 < \theta_0, \forall i, j$

II. Suppose $\|X_t(e_i - e_j)\|_{\infty} < \theta_t, \forall t \leq k, \forall i, j$, we obtain

$$
\|X_{k+1}(e_i - e_j)\|_{\infty} = \left\| \sum_{t=0}^{k} (-\alpha_t G_t + \Omega_t) W^{k-t}(e_i - e_j) \right\|_{\infty}
$$

$$
\leq \sum_{t=0}^{k} \| -\alpha_t G_t \|_{1,\infty} \| W^{k-t}(e_i - e_j) \|_1 + \sum_{t=0}^{k} \| \Omega_t \|_{1,\infty} \| W^{k-t}(e_i - e_j) \|_1
$$

By Lemma

$$
\leq \alpha_{k+1} G_{\infty} \sum_{t=0}^{k} \frac{\alpha_{k-t}}{\alpha_{k+1}} \| W^{t}(e_i - e_j) \|_1 + \frac{4\delta}{1 - 2\delta} \sum_{t=0}^{k} \theta_t \| W^{k-t}(e_i - e_j) \|_1
$$

$$
< \alpha_{k+1} G_{\infty} C_{\alpha, \eta} \sum_{t=0}^{\infty} \eta^t \| W^{t}(e_i - e_j) \|_1 + \frac{4\delta C_{\alpha, \eta}}{1 - 2\delta} \sum_{t=0}^{\infty} \eta^t \| W^{t}(e_i - e_j) \|_1
$$

For any $t \geq 0$, on one hand

$$
\| W^{t}(e_i - e_j) \|_1 \leq \sqrt{n} \| W^{t}(e_i - e_j) \|_2 \leq \sqrt{n} \left( \| W^{t} e_i - \frac{I_n}{n} \| + \sqrt{n} \| W^{t} e_j - \frac{I_n}{n} \| \right) \leq 2\sqrt{n} \eta^t
$$

where the last step holds due to the diagonalizability of $W$. On the other hand,

$$
\| W^{t}(e_i - e_j) \|_1 \leq \| W^{t} e_i + I_n^T W^{t} e_i = I_n^T e_i + I_n^T e_j = 2
$$

As a result

$$
\eta^t \| W^{t}(e_i - e_j) \|_1 \leq \min\{2\sqrt{n}(\eta^t), 2\}
$$

Let $T_0 = \left[ -\log(\sqrt{n}) \right]$, so that $\sqrt{n}(\eta^t)^{T_0} \leq 1$, then we have

$$
\sum_{t=0}^{\infty} \eta^t \| W^{t}(e_i - e_j) \|_1 = \sum_{t=0}^{T_0-1} \eta^t \| W^{t}(e_i - e_j) \|_1 + \sum_{t=T_0}^{\infty} \eta^t \| W^{t}(e_i - e_j) \|_1
$$

$$
\leq \sum_{t=0}^{T_0-1} 2 + \sum_{t=0}^{\infty} 2\sqrt{n}(\eta^t)^{t+T_0}
$$

$$
\leq 2 \left[ \frac{-\log(\sqrt{n})}{\log(\eta)} \right] + \sum_{t=0}^{\infty} 2 \left( \sqrt{n}(\eta^t)^{T_0} \right) (\eta^t)^{t}
$$

$$
\leq \frac{2 \log(\sqrt{n})}{1 - \eta} + 2 + \frac{2}{1 - \eta}
$$

$$
\leq \frac{\log(16n)}{1 - \eta}
$$

As a result, we have

$$
\| X_{k+1}(e_i - e_j) \|_{\infty} < \frac{\alpha_{k+1} G_{\infty} C_{\alpha} \eta \log(16n)}{1 - \eta} + \frac{4\delta C_{\alpha}}{1 - 2\delta} \cdot \frac{\log(16n)}{1 - \eta} \cdot \theta_k
$$

with $\delta = \frac{1 - \eta}{8C_{\alpha}^2 \eta \log(16n) + 2(1 - \eta \delta)}$,

$$
\| X_{k+1}(e_i - e_j) \|_{\infty} < \frac{\alpha_{k+1} G_{\infty} C_{\alpha} \eta \log(16n)}{1 - \eta} + \frac{4\delta C_{\alpha}}{1 - 2\delta} \cdot \frac{\log(16n)}{1 - \eta} \cdot \frac{2\alpha k G_{\infty} C_{\alpha} \eta \log(16n)}{1 - \eta}
$$

24
And by Taylor Expansion, we have
\[
\frac{\alpha_{k+1} G_\infty C_\alpha \eta \log(16n)}{1 - \eta \rho} + \frac{4\delta C_\alpha}{1 - \eta \rho} \log(16n) - \frac{2\alpha_{k+1} C_\alpha \eta G_\infty C_\alpha \eta \log(16n)}{1 - \eta \rho}
\]
\[
\leq 2\alpha_{k+1} G_\infty C_\alpha \eta \log(16n)
\]

Combining I and II, we complete the proof.

**Lemma 8** The running average of the gradient norm has the following bound:
\[
\sum_{k=0}^{K-1} \alpha_k \mathbb{E} \left\| \nabla f(\overline{x}_k) \right\|^2 \leq 4(\mathbb{E} f(0) - \mathbb{E} f^*) + \frac{2\alpha^2 L^2}{n} \sum_{k=0}^{K-1} \alpha_k^2 + 8\sigma^2 L^2 \left( \frac{1}{(1 - \rho)^2} \right) \sum_{k=0}^{K-1} \alpha_k^3 + \frac{24\sigma^2 L^2}{(1 - \rho)^2} \sum_{k=0}^{K-1} \alpha_k^3
\]
\[
+ \frac{8L^2}{n(1 - \rho)^2} \sum_{k=0}^{K-1} \alpha_k \mathbb{E} \left\| \Omega_k \right\|^2_P
\]

**Proof** Let 1 denote a n-dimensional vector with all the entries be 1. And we have
\[
\overline{x}_{k+1} = (X_k W - \alpha_k \overline{G}_k + \Omega_k) \frac{1}{n} = \overline{x}_k - \alpha_k \overline{G}_k + (\overline{x}_k - X_k)(W - I) \frac{1}{n} = \overline{x}_k - \alpha_k \overline{G}_k
\]

And by Taylor Expansion, we have
\[
\mathbb{E} f(\overline{x}_{k+1}) = \mathbb{E} f \left( \left( X_k W - \alpha_k \overline{G}_k + \Omega_k \right) \frac{1}{n} \right)
\]
\[
= \mathbb{E} f \left( \overline{x}_k - \alpha_k \overline{G}_k \right)
\]
\[
\leq \mathbb{E} f(\overline{x}_k) - \alpha_k \mathbb{E} \left( \nabla f(\overline{x}_k), \overline{G}_k \right) + \frac{\alpha_k^2 L}{2} \mathbb{E} \left\| \overline{G}_k \right\|^2
\]

And for the last term, we have
\[
\mathbb{E} \left\| \overline{G}_k \right\|^2 = \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2
\]
\[
= \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} - \sum_{i=1}^{n} \frac{g_{k,i}}{n} + \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2
\]
\[
= \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} - \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2 + \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2 + \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2
\]
\[
= \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} - \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2 + \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2 + \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2
\]
Assumption 3 \[
\leq \frac{1}{n^2} \sum_{i=1}^{n} \mathbb{E} \left\| g_{k,i} - g_{k,i} \right\|^2 + \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2
\]
Assumption 3 \[
\leq \frac{\sigma^2}{n} + \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2
\]

Putting it back, we obtain
\[
\mathbb{E} f(\overline{x}_{k+1}) \leq \mathbb{E} f(\overline{x}_k) - \alpha_k \mathbb{E} \left( \nabla f(\overline{x}_k), \overline{G}_k \right) + \frac{\alpha_k^2 L}{2n} \sigma^2 + \frac{\alpha_k^2 L}{2} \mathbb{E} \left\| \sum_{i=1}^{n} \frac{g_{k,i}}{n} \right\|^2
\]
\[
= \mathbb{E} f(\overline{x}_k) - \frac{\alpha_k - \frac{\alpha_k^2 L}{2} \mathbb{E} \left\| \overline{G}_k \right\|^2}{2} - \frac{\alpha_k \mathbb{E} \left\| \nabla f(\overline{x}_k) \right\|^2}{2} + \frac{\alpha_k^2 L}{2n} \sigma^2 + \frac{\alpha_k}{2} \mathbb{E} \left\| \nabla f(\overline{x}_k) - \overline{G}_k \right\|^2
\]
where the last step comes from 2(a, b) = \|a\|^2 + \|b\|^2 = \|a - b\|^2 And
\[
\mathbb{E} \left\| \nabla f(\overline{x}_k) - \overline{G}_k \right\|^2 \leq \frac{1}{n} \sum_{i=1}^{n} \mathbb{E} \left\| \nabla f_i \left( \sum_{i=1}^{n} \frac{x_{k,i}}{n} \right) - \nabla f_i(x_{k,i}) \right\|^2
\]

25
Assumption \( t \) \( \frac{L^2}{n} \sum_{i=1}^{n} E \left\| \sum_{i \neq i'}^{n} \frac{x_{k,i'}}{n} - x_{k,i} \right\|^2 \leq 0 \)

by Lipschitz assumption, we obtain

\[
\frac{\alpha_k - \alpha_k^2 L}{2} E \left\| G_k \right\|^2 + \frac{\alpha_k}{2} E \left\| \nabla f(X_k) \right\|^2 \leq E f(X_k) - E f(X_{k+1}) + \frac{\alpha_k^2 L}{2n} \sigma^2 + \alpha_k L^2 \sum_{i=1}^{n} E \left\| X_k - x_{k,i} \right\|^2
\]

summing over from \( k = 0 \) to \( K - 1 \) on both sides, we have

\[
\sum_{k=0}^{K-1} \left( \frac{\alpha_k - \alpha_k^2 L}{2} E \left\| G_k \right\|^2 + \frac{\alpha_k}{2} E \left\| \nabla f(X_k) \right\|^2 \right) \leq 2(E f(X_0) - E f(X_K)) + \frac{\sigma^2 L}{n} \sum_{k=0}^{K-1} \alpha_k^2
\]

From Lemma 9, we have

\[
\sum_{k=0}^{K-1} \left( \frac{\alpha_k - \alpha_k^2 L}{2} E \left\| G_k \right\|^2 + \frac{\alpha_k}{2} E \left\| \nabla f(X_k) \right\|^2 \right) \leq 2(E f(X_0) - E f(X_K)) + \frac{\sigma^2 L}{n} \sum_{k=0}^{K-1} \alpha_k^2 + \frac{L^2}{n} \sum_{k=0}^{K-1} \sum_{i=1}^{n} \alpha_k E \left\| X_k - x_{k,i} \right\|^2
\]

Rearrange the terms, we have

\[
\sum_{k=0}^{K-1} \alpha_k E \left\| \nabla f(X_k) \right\|^2 \leq 4(E f(0) - E f^*) + \frac{2\sigma^2 L}{n} \sum_{k=0}^{K-1} \alpha_k^2 + \frac{8\sigma^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3 + \frac{24\sigma^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3 + \frac{24\sigma^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3 E \left\| \nabla f(X_k) \right\|^2
\]

and that completes the proof

Lemma 9

\[
\frac{L^2}{n} \sum_{k=0}^{K-1} \sum_{i=1}^{n} \alpha_k E \left\| X_k - x_{k,i} \right\|^2 \leq \frac{4\sigma^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^2 + \frac{12\sigma^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3 + \frac{12\sigma^2 L^2}{(1-\rho)^2} \sum_{k=0}^{K-1} \alpha_k^3 E \left\| \nabla f(X_k) \right\|^2
\]

Proof

\[
\sum_{k=0}^{K-1} \sum_{i=1}^{n} \alpha_k E \left\| X_k - x_{k,i} \right\|^2
\]
That completes the proof.

Proof

Lemma 10
\[
\sum_{k=0}^{K-1} \alpha_k \mathbb{E} \left\| \mathbf{G}_k \right\|_F^2 \leq n \sigma^2 \sum_{k=0}^{K-1} \alpha_k^3 + 3L^2 \sum_{k=0}^{K-1} \sum_{i=1}^{n} \alpha_k^3 \mathbb{E} \left\| \mathbf{X}_k - x_{k,i} \right\|^2 + 3n \alpha_k^2 \sum_{k=0}^{K-1} \alpha_k + 3n \sum_{k=0}^{K-1} \alpha_k^2 \mathbb{E} \left\| \nabla f(\mathbf{X}_k) \right\|^2
\]

Proof From the property of Frobenius norm, we have
\[
\mathbb{E} \left\| \mathbf{G}_k \right\|_F^2 = \sum_{i=1}^{n} \mathbb{E} \left\| \mathbf{g}_{k,i} \right\|^2
\]
From Lemma, we know
\[ \mathbb{E} \| \tilde{y}_{k,i} \|^2 \leq \sigma^2 + 3L^2 \mathbb{E} \| X_k - x_{k,i} \|^2 + 3\kappa^2 + 3\mathbb{E} \| \nabla f(X_k) \|^2 \]

Summing from \( k = 0 \) to \( K - 1 \), we obtain
\[
\sum_{k=0}^{K-1} \alpha_k^3 \mathbb{E} \| \tilde{G}_k \|^2 \\
= \sum_{k=0}^{K-1} \alpha_k^3 \sum_{i=1}^{n} \mathbb{E} \| \tilde{y}_{k,i} \|^2 \\
\leq \sum_{k=0}^{K-1} \alpha_k^3 \sum_{i=1}^{n} \sigma^2 + 3L^2 \sum_{k=0}^{K-1} \sum_{i=1}^{n} \mathbb{E} \| X_k - x_{k,i} \|^2 + 3\sum_{k=0}^{K-1} \alpha_k^3 \sum_{i=1}^{n} \kappa^2 + 3\sum_{k=0}^{K-1} \alpha_k^3 \sum_{i=1}^{n} \mathbb{E} \| \nabla f(X_k) \|^2 \\
= n\sigma^2 \sum_{k=0}^{K-1} \alpha_k^3 + 3L^2 \sum_{k=0}^{K-1} \sum_{i=1}^{n} \alpha_k^3 \mathbb{E} \| X_k - x_{k,i} \|^2 + 3n\kappa^2 \sum_{k=0}^{K-1} \alpha_k^3 + 3n \sum_{k=0}^{K-1} \alpha_k^3 \mathbb{E} \| \nabla f(X_k) \|^2
\]

That completes the proof.

Lemma 11 Given \( 0 \leq \rho < 1 \) and \( T \), a positive integer. Also given non-negative sequences \( \{a_t\}_{t=1}^{\infty} \) and \( \{b_t\}_{t=1}^{\infty} \) with \( \{a_t\}_{t=1}^{\infty} \) being non-increasing, the following inequalities holds:
\[
\sum_{t=1}^{k} a_t \left( \sum_{s=1}^{t} \rho^{- \lfloor \frac{s}{\gamma} \rfloor} b_s \right) \leq \frac{T}{1 - \rho} \sum_{s=1}^{k} a_s b_s \\
\sum_{t=1}^{k} a_t \left( \sum_{s=1}^{t} \rho^{- \lfloor \frac{s}{\gamma} \rfloor} b_s \right)^2 \leq \frac{T^2}{(1 - \rho)^2} \sum_{s=1}^{k} a_s b_s^2
\]

Proof Firstly,
\[
S_k = \sum_{t=1}^{k} a_t \left( \sum_{s=1}^{t} \rho^{- \lfloor \frac{s}{\gamma} \rfloor} b_s \right) = \sum_{s=1}^{k} \sum_{t=s}^{k} a_t \rho^{- \lfloor \frac{s}{\gamma} \rfloor} b_s \leq \sum_{s=1}^{k} \alpha_s b_s \sum_{t=0}^{T-1} \sum_{m=0}^{\infty} \rho^m \leq \frac{T}{1 - \rho} \sum_{s=1}^{k} a_s b_s
\]

further we have
\[
\sum_{t=1}^{k} a_t \left( \sum_{s=1}^{t} \rho^{- \lfloor \frac{s}{\gamma} \rfloor} b_s \right)^2 = \sum_{t=1}^{k} a_t \sum_{s=1}^{t} \rho^{- \lfloor \frac{s}{\gamma} \rfloor} b_s \sum_{r=1}^{t} \rho^{- \lfloor \frac{r}{\gamma} \rfloor} b_r = \sum_{t=1}^{k} a_t \sum_{s=1}^{t} \sum_{r=1}^{t} \rho^{- \lfloor \frac{s}{\gamma} \rfloor} \lfloor \frac{r}{\gamma} \rfloor b_s b_r \\
\leq \sum_{t=1}^{k} a_t \sum_{s=1}^{t} \sum_{r=1}^{t} \rho^{- \lfloor \frac{s}{\gamma} \rfloor} \lfloor \frac{r}{\gamma} \rfloor + \lfloor \frac{s}{\gamma} \rfloor \cdot \frac{b_s^2 + b_r^2}{2} = \sum_{t=1}^{k} a_t \sum_{s=1}^{t} \sum_{r=1}^{t} \rho^{- \lfloor \frac{s}{\gamma} \rfloor} \lfloor \frac{r}{\gamma} \rfloor b_s b_r \\
\leq \sum_{t=1}^{k} a_t \sum_{s=1}^{t} b_s^2 \rho^{- \lfloor \frac{s}{\gamma} \rfloor} \sum_{r=1}^{t} \rho^{- \lfloor \frac{r}{\gamma} \rfloor} \sum_{r=0}^{T-1} \sum_{m=0}^{\infty} \rho^m \\
\leq \frac{T^2}{(1 - \rho)^2} \sum_{s=1}^{k} a_s b_s^2 \]

That completes the proof.

F.5 Proof to Theorem 3.

Proof Let \( \overline{\rho} \) denote the spectral gap of matrix \( \mathbf{W} \), it is straightforward to know that \( \overline{\rho} = \gamma \rho + (1 - \gamma) \). we first use mathematical induction to prove at iteration \( \forall k \leq K \), for any worker \( i \) and \( j \), with probability \( (1 - \epsilon)^k \)
\[
\| X_k(e_i - e_j) \|_\infty < \theta = \frac{2 \alpha \log(16n) G_\infty}{\gamma (1 - \rho)}
\]
where $\gamma = \frac{1-\rho}{1-2\rho} \frac{2\log(2n)}{1-\rho} \log(\frac{1}{\delta})$.

I. When $k = 0$, $\|X_0(e_i - e_j)\|_\infty = 0 < \theta$

II. Suppose $\|X_t(e_i - e_j)\|_\infty < \theta$ holds for $\forall t \leq k$, then for $k + 1$ we have

$$\|X_{k+1}(e_i - e_j)\|_\infty = \left\| \left( X_k \mathbf{W} - \alpha \tilde{G}_k + \gamma \Omega_k \right) (e_i - e_j) \right\|_\infty$$

$$x_{k+1} \equiv \left\| \sum_{t=0}^{k} \left( -\alpha \tilde{G}_t + \gamma \Omega_t \right) \mathbf{W}^{k-t}(e_i - e_j) \right\|_\infty$$

$$\leq \left\| \sum_{t=0}^{k} \alpha \tilde{G}_t \mathbf{W}^{k-t}(e_i - e_j) \right\|_\infty + \left\| \sum_{t=0}^{k} \gamma \Omega_t \mathbf{W}^{k-t}(e_i - e_j) \right\|_\infty$$

We bound these terms separately. First from Lemma we know that

$$\sum_{t=0}^{\infty} \left\| \mathbf{W}^t(e_i - e_j) \right\|_1 < \frac{\log(16n)}{1-\rho} = \frac{\log(16n)}{\gamma(1-\rho)}$$

then we have for the first term,

$$\left\| \sum_{t=0}^{k} \alpha \tilde{G}_t \mathbf{W}^{k-t}(e_i - e_j) \right\|_\infty \leq \sum_{t=0}^{k} \left\| \alpha \tilde{G}_t \right\|_1 \left\| \mathbf{W}^{k-t}(e_i - e_j) \right\|_1$$

$$\leq \alpha \gamma \sum_{t=0}^{\infty} \left\| \mathbf{W}^t(e_i - e_j) \right\|_1$$

$$< \frac{\alpha \log(16n) G_\infty}{\gamma(1-\rho)}$$

Next, we bound the second term. Suppose the infinity norm of the term $\sum_{t=0}^{k} \gamma \Omega_t \mathbf{W}^{k-t}(e_i - e_j)$ is taken at coordinate $h$, then we have

$$\left\| \sum_{t=0}^{k} \gamma \Omega_t \mathbf{W}^{k-t}(e_i - e_j) \right\|_\infty = \gamma \left( \sum_{t=0}^{k} \Omega_t \mathbf{W}^{k-t}(e_i - e_j) \right)$$

$$= \gamma \sum_{t=0}^{k} e_h^T \left( \Omega_t \mathbf{W}^{k-t}(e_i - e_j) \right)$$

Let

$$u_t = \sum_{m=0}^{t} e_h^T \left( \Omega_{k-m} \mathbf{W}^m(e_i - e_j) \right)$$

from the induction hypothesis we know that $\{u_t\}_{t=0}^{k}$ is a martingale sequence. Note that,

$$|u_t - u_{t-1}| = \left| e_h^T \left( \Omega_{k-t} \mathbf{W}^t(e_i - e_j) \right) \right|$$

$$\leq \left\| \Omega_{k-t} \mathbf{W}^t(e_i - e_j) \right\|_\infty$$

Equation

$$\leq \left\| \Omega_{k-t} \right\|_{1,\infty} \min\{2\sqrt{n\theta}, 2\}$$

$$\leq 2\delta B_\theta \min\{2\sqrt{n\theta}, 2\}$$

where $B_\theta = \frac{2^2}{1-2\theta} \theta$, then by using Azuma’s inequality we obtain

$$\mathbb{P} \left[ \sum_{t=0}^{k} e_h^T \left( \Omega_t \mathbf{W}^{k-t}(e_i - e_j) \right) > a \right] \leq \exp \left( -\frac{a^2}{8\delta^2 B_\theta^2 \sum_{t=0}^{k} \min\{2\sqrt{n\theta}, 2\}^2} \right)$$
Combining I and II, we complete the proof.

Here we use the induction hypothesis. Similar as before, let $T_0 = \left\lfloor \frac{-\log(n)}{2\log(p)} \right\rfloor$, so that $n\bar{p}^{2T_0} \leq 1$, then we have

$$\sum_{t=0}^{\infty} \min\{n\bar{p}^{2t}, 1\} = \sum_{t=0}^{T_0-1} \min\{n\bar{p}^{2t}, 1\} + \sum_{t=T_0}^{\infty} \min\{n\bar{p}^{2t}, 1\} < \sum_{t=0}^{T_0-1} 1 + \sum_{t=0}^{\infty} n\bar{p}^{2t+2T_0} \leq \frac{-\log(n)}{2\log(p)} + \sum_{t=0}^{\infty} (n\bar{p}^{2T_0}) \bar{p}^{2t} \leq \frac{\log(n)}{1 - \bar{p}^2} + 1 + \frac{1}{1 - \bar{p}^2} \leq \frac{\log(4n)}{1 - \bar{p}^2}.$$

Putting it back, we obtain

$$\mathbb{P} \left[ \left\| \sum_{t=k}^{\infty} \gamma_t \Omega_t \bar{W}^{k-t} (e_i - e_j) \right\|_\infty > a \right] \leq \exp \left( -\frac{a^2(1 - \rho)(2 - \gamma(1 - \rho))}{32\delta^2\bar{p}^2 \log(4n)} \right)$$

In other words, with probability $1 - \epsilon$,

$$\left\| \sum_{t=k}^{\infty} \gamma_t \Omega_t \bar{W}^{k-t} (e_i - e_j) \right\|_\infty < \frac{a \log(16n)G\infty}{\gamma(1 - \rho)} + \delta \bar{B}_\rho \sqrt{\frac{32 \log(4n)\gamma}{(1 - \rho)(2 - \gamma(1 - \rho))} \log \left( \frac{1}{\epsilon} \right)}.$$

Combine them together, we obtain

$$\left\| X_{k+1}(e_i - e_j) \right\|_\infty < \frac{\alpha \log(16n)G\infty}{\gamma(1 - \rho)} + \frac{2\delta}{1 - 2\theta} \sqrt{\frac{32 \log(4n)\gamma}{(1 - \rho)(2 - \gamma(1 - \rho))} \log \left( \frac{1}{\epsilon} \right)}.$$

Let $\gamma = \frac{1}{1 - \rho + \frac{16\delta^2}{32\log(4n)}} \cdot \frac{1}{1 - \rho - \frac{16\delta^2}{32\log(4n)} \log \left( \frac{1}{\epsilon} \right)}$.

$$\left\| X_{k+1}(e_i - e_j) \right\|_\infty < \frac{\alpha \log(16n)G\infty}{\gamma(1 - \rho)} + \frac{1}{2} \theta \leq \theta.$$

Combining I and II, we complete the proof.

We proceed to obtain the convergence rate. From Theorem 2 we have with $\alpha_k = \alpha$

$$\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left[ \left\| \nabla f(X_k) \right\|_2^2 \right] \leq \frac{4(Ef(0) - Ef^*)}{\alpha K} + \frac{2\alpha^2L^2}{n} + \frac{8\alpha^2\bar{p}^2L^2}{(1 - \bar{p})^2} + \frac{24\alpha^2\gamma^2L^2}{(1 - \bar{p})^2} + \frac{8\alpha L^2}{n(1 - \bar{p})^2 K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \gamma\Omega_k \right\|_F^2.$$

Note that with probability $(1 - \epsilon)^K$

$$\sum_{k=0}^{K-1} \mathbb{E} \left\| \gamma\Omega_k \right\|_F^2 = \gamma^2 \sum_{k=0}^{K-1} \sum_{i=1}^{n} \left\| \sum_{j=1}^{n} ((\hat{x}_{k,j} - x_{k,j}) - (\hat{x}_{k,i} - x_{k,i})) W_{ji} \right\|_2^2 \leq \frac{16\delta^2\gamma^2}{(1 - 2\delta)^2} \theta^2 d nK.$$

30
Fit in $\theta = \frac{2a \log(16n) G_\infty}{(1-\rho)}$, we obtain

$$\sum_{k=0}^{K-1} \mathbb{E}\|\gamma \Theta_k\|_F^2 \leq \frac{64a^2 \delta^2 \log^2(16n) G_\infty^2}{(1-2\delta)^2(1-\rho)^2} d n K$$

Let $\mathcal{E}$ denote the event that the bound $\theta$ holds for all $0 \leq t \leq T - 1$, then,

$$\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\|\nabla f(X_k)\|^2 = \left[ \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\|\nabla f(X_k)\|^2 | \mathcal{E} \right] \mathbb{P}(\mathcal{E}) + \left[ \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\|\nabla f(X_k)\|^2 | \neg \mathcal{E} \right] \mathbb{P}(\neg \mathcal{E})$$

$$\leq \frac{4(f(0) - f^*)}{\alpha K} + \frac{2aL}{n} \sigma^2 + \frac{8a^2 L^2 (\sigma^2 + 3\kappa^2)}{(1-\rho)^2} + \frac{8L^2}{nK(1-\rho)^2} \sum_{k=1}^{K-1} \mathbb{E}\|\Gamma \Omega_k\|_F^2 + G_\infty^2 d (1 - (1 - \epsilon)^K)$$

$$\leq \frac{4(f(0) - f^*)}{\alpha K} + \frac{2aL}{n} \sigma^2 + \frac{8a^2 L^2 (\sigma^2 + 3\kappa^2)}{\gamma^2 (1-\rho)^2} + \frac{512a^2 \delta^2 L^2 \log^2(16n) G_\infty^2 d}{\gamma^2 (1-\rho)^4 (1-2\delta)^2} + G_\infty^2 d (1 - (1 - \epsilon)^K)$$

Assign $\epsilon = \frac{1}{K^*}$ and set $\alpha = \frac{1}{\zeta + \sqrt{\zeta^2 + \sigma^2 L^2} + 2L}$, we have

$$\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\|\nabla f(X_k)\|^2 \lesssim \frac{\sigma}{\sqrt{nK}} + \frac{\zeta \delta^2 \log^2(n) \log^2(K)}{K^* (1-2\delta)^4} + \frac{\sigma^2 n \delta^4 \log^2(n) \log^2(K)}{(\sigma^2 K + n)(1-2\delta)^4} + \frac{n \delta^6 \log^2(n) \log^2(K)}{(\sigma^2 K + n)(1-2\delta)^6}$$

That completes the proof

G  Moniqua on $D^2$ (Proof to Theorem 4)

G.1 Setting

We first show the pseudo code in Algorithm 2.

$D^2$ makes the following assumptions (1-4), and we add the additional assumption (5):

1. **Lipschitzian Gradient**: All the function $f_i$ have L-Lipschitzian gradients.

2. **Communication Matrix**: Communication matrix $W$ is a symmetric doubly stochastic matrix. Let the eigenvalues of $W \in \mathbb{R}^{n \times n}$ be $\lambda_1 \geq \cdots \geq \lambda_n$. We assume $\lambda_2 < 1, \lambda_n > -\frac{1}{2}$.

3. **Bounded Variance**: $E_{\xi_i \sim D_i} \mathbb{E}\|\nabla f_i(x; \xi_i) - \nabla f_i(x)\|^2 \leq \sigma^2, \forall i$

   where $\nabla f_i(x; \xi_i)$ denotes gradient sample on worker $i$ computed via data sample $\xi_i$.

4. **Initialization**: All the models are initialized by the same parameters: $x_{0,i} = x_0, \forall i$ and with out the loss of generality $x_0 = 0$.

5. **Gradient magnitude**: The norm of a sampled gradient is bounded by $\|\tilde{g}_k\|_\infty \leq G_\infty$ for some constant $G_\infty$.

G.2 Proof to Theorem 4

**Proof**  From a local view, define $x_{-1} = \tilde{g}_{-1} = 0$, the update rule of Moniqua on $D^2$ on worker $i$ in iteration $k$ can be written as

$$x_{k+\frac{1}{2},i} = 2x_{k,i} - x_{k-1,i} - \alpha \tilde{g}_{k,i} + \alpha \tilde{g}_{k-1,i}$$

$$x_{k+1,i} = \frac{1}{\alpha} \left( \frac{1}{2} x_{k+\frac{1}{2},i} + \alpha \tilde{g}_{k,i} \right)$$

$$x_{k+2} = \frac{1}{\alpha} \left( \frac{1}{2} x_{k+1} + \alpha \tilde{g}_{k+1} \right)$$
Algorithm 2 Moniqua with Variance Reduction on worker $i$

**Input:** initial point $x_{0,i} = x_0$, step size $\alpha$, the discrepancy bound $B_0$, communication matrix $W$, number of iterations $K$, neighbor list of worker $i$: $\mathcal{N}_i$, quantizer $Q_\delta$

1. **for** $k = 0, 1, 2, \cdots, K - 1$ **do**
2. Randomly sample data $\xi_k,i$ from local memory
3. Compute a local stochastic gradient based on $\xi_k,i$ and current weight $x_{k,i}$: $\bar{g}_{k,i}$
4. **if** $k = 0$ **then**
5. Update local weight: $x_{k+\frac{1}{2},i} \leftarrow x_{k,i} - \alpha \bar{g}_{k,i}$
6. **else**
7. Update local weight: $x_{k+\frac{1}{2},i} \leftarrow 2x_{k,i} - x_{k-1,i} - \alpha \bar{g}_{k,i} + \alpha \bar{g}_{k-1,i}$
8. **end if**
9. Send modulo-ed model to neighbors: $q_{k+\frac{1}{2},i} \leftarrow Q_\delta \left( \frac{x_{k+\frac{1}{2},i}}{B_0} \mod 1 \right)$
10. Compute local biased term $\hat{x}_{k+\frac{1}{2},i}$ as:
    \[
    \hat{x}_{k+\frac{1}{2},i} = q_{k+\frac{1}{2},i} B_0 - x_{k+\frac{1}{2},i} \mod B_0 + x_{k+\frac{1}{2},i}
    \]
11. Recover model received from worker $j$ as:
    \[
    \hat{x}_{k+\frac{1}{2},j} = (q_{k+\frac{1}{2},j} B_0 - x_{k+\frac{1}{2},j}) \mod B_0 + x_{k+\frac{1}{2},i}
    \]
12. Average with neighboring workers: $x_{k+1,i} \leftarrow x_{k+\frac{1}{2},i} + \sum_{j \in \mathcal{N}_i} (\hat{x}_{k+\frac{1}{2},j} - \hat{x}_{k+\frac{1}{2},i}) W_{ji}$
13. **end for**

**Output:** $X_K = \frac{1}{n} \sum_{i=1}^{n} x_{K,i}$

\[
x_{k+1,i} = \sum_{j=1}^{n} x_{k+\frac{1}{2},j} W_{ji} + \sum_{j=1}^{n} \left( (\hat{x}_{k+\frac{1}{2},j} - x_{k+\frac{1}{2},j}) - (\hat{x}_{k+\frac{1}{2},i} - x_{k+\frac{1}{2},i}) \right) W_{ji}
\]

From a global view, the update rule can be written as

\[
X_{k+1} = 2X_k - X_{k-1} - \alpha \bar{G}_k + \alpha \bar{G}_{k-1}
\]

\[
X_{k+1} = X_{k+\frac{1}{2}} W + (\bar{X}_{k+\frac{1}{2}} - X_{k+\frac{1}{2}}) (W - I)
\]

Define

\[
\Omega_k = (\bar{X}_{k+\frac{1}{2}} - X_{k+\frac{1}{2}}) (W - I)
\]

Since $W$ is symmetric, it can be diagonalized as $W = P \Lambda P^T$, where the $i$-th column of $P$ and $\Lambda$ are $W$’s $i$-th eigenvector and eigenvalue, respectively. And we obtain

\[
X_{k+1} = 2X_k P \Lambda P^T - X_{k-1} P \Lambda P^T - \alpha \bar{G}_k P \Lambda P^T + \alpha \bar{G}_{k-1} P \Lambda P^T + \Omega_k
\]

and

\[
X_{k+1} = 2X_k P \Lambda - X_{k-1} P \Lambda - \alpha \bar{G}_k P \Lambda + \alpha \bar{G}_{k-1} P \Lambda + \Omega_k P
\]

Denote $Y_k = X_k P$, $H(X_k; \xi_k) = \bar{G}_k P$, and denote $y_{k,i}$, $h_{k,i}$, and $r_{k,i}$ as the $i$-th column of $Y_k$, $H_k$ and $\Omega_k$, respectively. Then we have

\[
y_{k+1,i} = \lambda_i (2y_{k,i} - y_{k-1,i} - \alpha h_{k,i} + \alpha h_{k-1,i}) + r_{k,i}
\]

From Lemma 10 (Constants $C_1$, $C_2$, $C_3$ and $C_4$ are defined in the Lemma 12), Constants $D_1$ and $D_2$ are defined in Lemma 16) we get

\[
\left( 1 - \frac{3C_1 \alpha^2 L^2}{C_4} \right) E \| \nabla f(0) \| + \left( 1 - \alpha L - \frac{3C_2}{C_4} \alpha^4 L^4 \right) \frac{1}{K} \sum_{k=1}^{K-1} E \| \nabla f(X_k) \|^2 + \frac{1}{K} \sum_{k=0}^{K-1} E \| \nabla f(X_k) \|^2
\]

32
Let $\alpha = \frac{1}{\sigma \sqrt{K/n+2L}}$, we have

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 \leq \frac{2(f(0) - f^\star)}{\alpha K} + \frac{\alpha L}{n} \sigma^2 + \frac{3C_1 \alpha^2 L^2 (\sigma^2 + \sigma_i^2)}{C_4 K} + \frac{6C_2}{C_4} \alpha^2 L^2 + \frac{6C_2}{nC_4} \alpha^2 L^4 + \frac{3C_2}{C_4} \frac{C_3 L^2}{C_4} \left( \frac{6D_1 n + 8}{6D_2 n + 1} \right)^2 \alpha^2 G_\infty^2 d\alpha^2
\]

That completes the proof.

**G.3 Lemma for $D^2$**

**Lemma 12** Define

\[
D_1 = \max \left\{ \left\| v_n \right\| + \frac{2|\lambda_n|}{1 - |v_n|}, \sqrt{\frac{\lambda_2}{1 - \lambda_2}} + \frac{2\lambda_2}{1 - \lambda_2} \right\}
\]

\[
D_2 = \max \left\{ \frac{2}{1 - |v_n|}, \frac{2}{\sqrt{1 - \lambda_2}} \right\}
\]

\[
v_n = \lambda_n - \sqrt{\lambda_n^2 - \lambda_2}
\]

Let $\delta = \frac{1}{12nD_2}$, and we have for $\forall i, j$

\[
\left\| x_{k+\frac{1}{2}} (e_i - e_j) \right\| < \theta = (6D_1 n + 8)\alpha G_\infty
\]

**Proof** We use mathematical induction to prove this:

I. When $k = 0$,\n
\[
\left\| X_{0+\frac{1}{2}} (e_i - e_j) \right\| = \left\| -\alpha G_0 (e_i - e_j) \right\| < \alpha \left\| G_0 \right\|_{1,\infty} \left\| e_i - e_j \right\|_1 < 2\alpha G_\infty \leq (6D_1 n + 8)\alpha G_\infty
\]

II. Suppose for $k \geq 0$, $\forall t \leq k$, we have $\left\| X_{t+\frac{1}{2}} (e_i - e_j) \right\| < (6D_1 n + 8)\alpha G_\infty$, then for $\forall i, j$

\[
\left\| X_{k+1} (e_i - e_j) \right\|_{\infty} \leq \left\| X_{k+1} \left( \frac{1}{n} - e_i \right) \right\|_{\infty} + \left\| X_{k+1} \left( \frac{1}{n} - e_j \right) \right\|_{\infty}
\]

\[
= X_{k+1} PP^T e_i - X_{k+1} P + X_{k+1} PP^T e_j - X_{k+1} P
\]

\[
= \begin{bmatrix}
1 & 0 & 0 & \ldots & 0 \\
0 & 0 & 0 & \ldots & 0 \\
0 & 0 & 0 & \ldots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & \ldots & 0 \\
\end{bmatrix}
\begin{bmatrix}
P^T e_i \\
P^T e_j \\
\end{bmatrix}
\]

\[
= \begin{bmatrix}
1 & 0 & 0 & \ldots & 0 \\
0 & 0 & 0 & \ldots & 0 \\
0 & 0 & 0 & \ldots & 0 \\
\vdots & \vdots & \ddots & \ddots & \vdots \\
0 & 0 & 0 & \ldots & 0 \\
\end{bmatrix}
\begin{bmatrix}
P^T e_i \\
P^T e_j \\
\end{bmatrix}
\]

33
where $\beta_{k,i} = -\alpha h_{k,i} + \alpha h_{k-1,i}$, for all $y_i$ with $-\frac{1}{3} < \lambda_i < 0$, from Lemma 14 we have

$$y_{k+1,i} = y_{1,i} \left( \frac{u_i^{k+1} - v_i^{k+1}}{u_i - v_i} \right) + \sum_{s=1}^{k} (\lambda_i \beta_{s,i} + r_{s,i}) \frac{u_i^{k-s+1} - v_i^{k-s+1}}{u_i - v_i}$$

where $u_i = \lambda_i + \sqrt{\lambda_i^2 - \lambda_i}$ and $v_i = \lambda_i - \sqrt{\lambda_i^2 - \lambda_i}$, we obtain

$$\|y_{k+1,i}\|_\infty \leq \|y_{1,i}\|_\infty \|v_i\|^k + |\lambda_i| \sum_{s=1}^{k} \|\beta_{s,i}\|_\infty \|v_i\|^{k-s} + \sum_{s=1}^{k} \|r_{s,i}\|_\infty \|v_i\|^{k-s}$$

Since

$$\left| \frac{u_i^{n+1} - v_i^{n+1}}{u_i - v_i} \right| \leq \|v_i\|^n$$

We obtain

$$\|y_{k+1,i}\|_\infty \leq \|y_{1,i}\|_\infty \|v_i\|^k + |\lambda_i| \sum_{s=1}^{k} \|\beta_{s,i}\|_\infty \|v_i\|^{k-s} + \sum_{s=1}^{k} \|r_{s,i}\|_\infty \|v_i\|^{k-s}$$

For $\beta_{s,i}$, we have

$$\|\beta_{s,i}\|_\infty = \|\alpha h_{k,i} + \alpha h_{k-1,i}\|_\infty \leq 2\alpha (\|h_{k,i}\|_\infty + \|h_{k-1,i}\|_\infty)$$

$$\leq 2\alpha (\|G_k\|_{1,\infty} \|Pe_i\|_1 + \|G_{k-1}\|_{1,\infty} \|Pe_i\|_1)$$

$$\leq 2\alpha \sqrt{\pi} G_\infty$$

For $r_{s,i}$, we have

$$\|r_{k,i}\|_\infty = \|\Omega_k Pe_i\|_\infty \leq \|\Omega_k\|_{1,\infty} \|Pe_i\|_1 \leq 2\sqrt{n}\delta \bar{B}_0$$

when $\lambda_i < 0$, we have

$$\|y_{k+1,i}\|_\infty \leq \|y_{1,i}\|_\infty \|v_i\|^k + |\lambda_i| \sum_{s=1}^{k} \|\beta_{s,i}\|_\infty \|v_i\|^{k-s} + \sum_{s=1}^{k} \|r_{s,i}\|_\infty \|v_i\|^{k-s}$$

$$\leq \|y_{1,i}\|_\infty \|v_i\|^k + |\lambda_i| \sum_{s=1}^{k} \|\beta_{s,i}\|_\infty \|v_i\|^{k-s} + \sum_{s=1}^{k} \|r_{s,i}\|_\infty \|v_i\|^{k-s}$$

$$\leq \alpha \sqrt{n} G_\infty \|v_i\|^k + 2\alpha \sqrt{n} G_\infty |\lambda_i| \sum_{s=1}^{\infty} \|v_i\|^{k-s} + 2\sqrt{n}\delta \bar{B}_0 \sum_{s=1}^{\infty} |v_i|^{k-s}$$
The last step is because
As a result
where
By taking norm, we get
Putting it back we have
such that
Since
On the other hand, when \(0 \leq \lambda < 1\), from Lemma 12 we have

\[
y_{k+1,i} \sin \phi_i = y_{1,i} \lambda_{i}^k \sin[(t+1)\phi_i] + \lambda_i \sum_{s=1}^{k} \beta_{s,i} \lambda_{i}^{s+k} \sin[(k-s)\phi_i] + \sum_{s=1}^{k} r_{s,i} \lambda_{i}^{s+k} \sin[(k-s)\phi_i]
\]

By taking norm, we get

\[
\|y_{k+1,i}\|_{\infty} |\sin \phi_i| = \|y_{1,i}\|_{\infty} \lambda_i^k |\sin[(t+1)\phi_i]| + \lambda_i \sum_{s=1}^{k} \|\beta_{s,i}\|_{\infty} |\lambda_i^{s+k}| |\sin[(k-s)\phi_i]|
\]

\[
+ \sum_{s=1}^{k} \|r_{s,i}\|_{\infty} |\lambda_i^{s+k}| |\sin[(k-s)\phi_i]|
\]

\[
< \|y_{1,i}\|_{\infty} \lambda_i^k + 2\alpha \sqrt{n\lambda_2} \lambda_2 \sum_{s=1}^{\infty} \lambda_2^s + 2\sqrt{n\delta} B_0 \sum_{s=1}^{\infty} \lambda_2^s
\]

\[
\leq \alpha \sqrt{n\lambda_2} \sqrt{\lambda_2} + \frac{2\alpha \sqrt{n\lambda_2} \lambda_2 + 2\sqrt{n\delta} B_0}{\sqrt{1-\lambda_2}}
\]

Since \(|\sin \phi_i| \geq \sqrt{1-\lambda_2}\), putting it back, we get

\[
\|y_{k+1,i}\|_{\infty} < \alpha \sqrt{n\lambda_2} \sqrt{\lambda_2} + \frac{2\alpha \sqrt{n\lambda_2} \lambda_2 + 2\sqrt{n\delta} B_0}{1-\lambda_2}
\]

So there exists \(D_1, D_2\)

\[
D_1 = \max \left\{ \frac{|v_n|}{1-|v_n|}, \sqrt{\lambda_2} \frac{2\lambda_2}{1-\lambda_2} \right\}
\]

\[
D_2 = \max \left\{ \frac{1}{1-|v_n|}, \lambda_2 \frac{2}{\lambda_2} \right\}
\]

such that

\[
\|y_{k+1,i}\|_{\infty} < D_1 \alpha \sqrt{n\lambda_2} + D_2 \sqrt{n\delta} B_0
\]

Putting it back we have \(\forall i, j\)

\[
\|X_{k+1}(e_i - e_j)\|_{\infty} < D_1 \alpha \sqrt{n\lambda_2} + D_2 \sqrt{n\delta} B_0
\]

As a result

\[
\|X_{k+1}^{1/2}(e_i - e_j)\|_{\infty}
\]

\[
= \|\left(2X_{k+1} - X_k - \alpha G_{k+1} + \alpha G_k\right)(e_i - e_j)\|_{\infty}
\]

\[
\leq 2 \|X_{k+1}(e_i - e_j)\|_{\infty} + \|X_k(e_i - e_j)\|_{\infty} + \alpha \|G_{k+1}\|_{1,\infty} \|e_i - e_j\|_1 + \alpha \|G_k\|_{1,\infty} \|e_i - e_j\|_1
\]

\[
< 3(D_1 \alpha \sqrt{n\lambda_2} + D_2 \sqrt{n\delta} B_0) + 4\alpha G_\infty
\]

\[
\leq (6D_1 n + 8)\alpha G_\infty
\]

The last step is because \(\delta = \frac{1}{12nD_2+2}\)

Combining I and II we complete the proof.
Lemma 13 By defining

\[ C_1 = \max \left\{ \frac{3}{1 - |v_n|^2}, \frac{3}{(1 - \lambda_2)^2} \right\} \]
\[ C_2 = \max \left\{ \frac{3\lambda_n^2}{(1 - |v_n|^2)^2}, \frac{3\lambda_n^2}{(1 - \sqrt{\lambda_2})^2(1 - \lambda_2)} \right\} \]
\[ C_3 = \max \left\{ \frac{3}{(1 - |v_n|^2)^2}, \frac{3}{(1 - \sqrt{\lambda_2})^2(1 - \lambda_2)} \right\} \]

we have

\[(1 - 12C_2\alpha^2L^2) \sum_{i=1}^{n} \sum_{k=1}^{K} \mathbb{E} \left| X_k - x_{k,i} \right|^2 \leq 3C_1\alpha^2n\sigma^2 + 3C_1\alpha^2n\sigma_0^2 + 3C_1\alpha^2n\mathbb{E} \left| \nabla f(0) \right| + 6C_2\alpha^2n\sigma^2 K + 3C_2\alpha^4\sigma^2 L^2 K \]
\[+ 3C_2\alpha^4nL^2 \sum_{k=1}^{K-1} \mathbb{E} \left| C_k \right|^2 + C_3 \sum_{k=1}^{K-1} \mathbb{E} \left| \Omega_k \right|^2 \]

Proof

\[
\sum_{i=1}^{n} \left| X_k - x_{k,i} \right|^2 = \sum_{i=1}^{n} \left| X_k \left( e_i - \frac{1}{n} I \right) \right|^2 = \left| X_k \left( I - \frac{1}{n} I \right)^T \right|^2 \]
\[= \left| X_k PP^T - X_k v_1 v_1^T \right|^2 \]
\[= \sum_{i=2}^{n} \left| y_{k,i} \right|^2 \]

From the update rule, we obtain,

\[ y_{k+1,i} = \lambda_i (2y_{k,i} - y_{k-1,i} - \alpha h_{k,i} + \alpha h_{k-1,i}) + r_{k,i} = \lambda_i (2y_{k,i} - y_{k-1,i}) + \lambda_i \beta_{k,i} + r_{k,i} \]

where \( \beta_{k,i} = -\alpha h_{k,i} + \alpha h_{k-1,i} \), for all \( y_i \) with \( -\frac{1}{3} < \lambda_i < 0 \), from Lemma 14 we have

\[ y_{k+1,i} = \lambda_i (u_{k,i}^{-1} - u_{i}^{-1}) + \sum_{s=1}^{k} (\lambda_i \beta_{s,i} + r_{k,i}) \frac{u_{k,s+1}^{-1} - u_{i}^{-1}}{u_{i}^{-1} - v_i} \]

where \( u_i = \lambda_i + \sqrt{\lambda_2} - \lambda_i \) and \( v_i = \lambda_i - \sqrt{\lambda_2} - \lambda_i \), we obtain

\[ \left| y_{k+1,i} \right|^2 \leq 3 \left| y_{k,i} \right|^2 \left( \frac{u_{k+1}^{-1} - u_{k}^{-1}}{u_{i}^{-1} - v_i} \right)^2 + 3\lambda_i^2 \left( \sum_{s=1}^{k} \left| \beta_{s,i} \right| \frac{u_{k,s+1}^{-1} - u_{i}^{-1}}{u_{i}^{-1} - v_i} \right)^2 \]
\[+ 3 \left( \sum_{s=1}^{k} \left| r_{s,i} \right| \frac{u_{k,s+1}^{-1} - u_{i}^{-1}}{u_{i}^{-1} - v_i} \right)^2 \]
Since

\[
\left| \frac{u_i^{n+1} - v_i^{n+1}}{u_i - v_i} \right| \leq |v_i|^n \left| \frac{u_i \left( \frac{u_i}{v_i} \right)^n - v_i}{u_i - v_i} \right| \leq |v_i|^n
\]

We obtain

\[
\|y_{k+1,i}\|^2 \leq 3 \|y_{1,i}\|^2 |v_i|^2 + 3\lambda_i^2 \left( \sum_{s=1}^{K} \|\beta_{s,i}\| |v_i|^{k-s} \right)^2 + 3 \left( \sum_{s=1}^{K} \|r_{s,i}\| |v_i|^{k-s} \right)^2
\]

Summing from \( k = 0 \) to \( t = K - 1 \), we obtain

\[
\sum_{k=0}^{K-1} \|y_{k+1,i}\|^2 = \sum_{k=1}^{K} \|y_{k,i}\|^2
\]

\[
\leq 3 \|y_{1,i}\|^2 \sum_{k=0}^{K-1} |v_i|^{2k} + 3\lambda_i^2 \sum_{k=1}^{K-1} \left( \sum_{s=1}^{K} \|\beta_{s,i}\| |v_i|^{k-s} \right)^2 + 3 \left( \sum_{s=1}^{K} \|r_{s,i}\| |v_i|^{k-s} \right)^2
\]

where \( v_n = \lambda_n - \sqrt{\lambda_n^2 - \lambda_i} \).

On the other hand, when \( 0 \leq \lambda_i < 1 \), from Lemma \( I4 \) we have

\[
y_{k+1,i} \sin \phi_t = y_{1,i} \lambda_i^k \sin[(t+1)\phi_i] + \lambda_i \sum_{s=1}^{K} \beta_{s,i} \lambda_i^{k-s} \sin[(k+1-s)\phi_i] + \sum_{s=1}^{K} r_{s,i} \lambda_i^{k-s} \sin[(k+1-s)\phi_i]
\]

And we have

\[
\|y_{k+1,i}\|^2 \sin^2 \phi_i \leq 3 \|y_{1,i}\|^2 \lambda_i \sin^2[(t+1)\phi_i] + 3\lambda_i^2 \left( \sum_{s=1}^{K} \beta_{s,i} \lambda_i^{k-s} \sin[(k+1-s)\phi_i] \right)^2
\]

\[
+ 3 \left( \sum_{s=1}^{K} r_{s,i} \lambda_i^{k-s} \sin[(k+1-s)\phi_i] \right)^2
\]

\[
\leq 3 \|y_{1,i}\|^2 \lambda_i + 3\lambda_i^2 \left( \sum_{s=1}^{K} \beta_{s,i} \lambda_i^{k-s} \right)^2 + 3 \left( \sum_{s=1}^{K} r_{s,i} \lambda_i^{k-s} \right)^2
\]

Summing from \( k = 0 \) to \( K - 1 \), we have

\[
\sum_{k=0}^{K-1} \|y_{k+1,i}\|^2 \sin^2 \phi_i = \sum_{k=1}^{K} \|y_{k,i}\|^2 \sin^2 \phi_i
\]

\[
\leq 3 \|y_{1,i}\|^2 \sum_{k=0}^{K-1} \lambda_i + 3\lambda_i^2 \sum_{k=1}^{K-1} \left( \sum_{s=1}^{K} \|\beta_{s,i}\| \lambda_i^{k-s} \right)^2 + 3 \left( \sum_{s=1}^{K} \|r_{s,i}\| \lambda_i^{k-s} \right)^2
\]

\[
\leq \frac{3 \|y_{1,i}\|^2}{1 - \lambda_i} + \frac{3\lambda_i^2}{(1 - \sqrt{\lambda_i})^2} \sum_{k=1}^{K-1} \|\beta_{k,i}\|^2 + \frac{3}{(1 - \sqrt{\lambda_i})^2} \sum_{k=1}^{K-1} \|r_{k,i}\|^2
\]

Since \( \sin^2 \phi_i = 1 - \lambda_i \), we have

\[
\sum_{k=1}^{K} \|y_{k,i}\|^2 \leq \frac{3 \|y_{1,i}\|^2}{(1 - \lambda_i)^2} + \frac{3\lambda_i^2}{(1 - \sqrt{\lambda_i})^2 (1 - \lambda_i)} \sum_{k=1}^{K-1} \|\beta_{k,i}\|^2 + \frac{3}{(1 - \sqrt{\lambda_i})^2 (1 - \lambda_i)} \sum_{k=1}^{K-1} \|r_{k,i}\|^2
\]
We next analyze

By taking expectation we have

So there exists $C_1, C_2, C_3$

By taking expectation we have

We next analyze $\beta_{k,i}$:

Le scenic

\begin{align*}
\sum_{i=1}^{n} \mathbb{E} \| \beta_{k,i} \|^2 \\
= \alpha^2 \sum_{i=1}^{n} \mathbb{E} \| \tilde{G}_k e_i - \tilde{G}_{k-1} e_i \|^2 \\
\leq 3 \alpha^2 \sum_{i=1}^{n} \mathbb{E} \| \tilde{G}_k e_i - \tilde{G}_{k-1} e_i \|^2 + 3 \alpha^2 \sum_{i=1}^{n} \mathbb{E} \| \tilde{G}_{k-1} e_i - G_{k-1} e_i \|^2 \\
\leq 6 \alpha^2 n \sigma^2 + 3 \alpha^2 \sum_{i=1}^{n} \mathbb{E} \| G_k e_i - G_{k-1} e_i \|^2 \\
\leq 6 \alpha^2 n \sigma^2 + 3 \alpha^2 L^2 \sum_{i=1}^{n} \mathbb{E} \| x_{k,i} - x_{k-1,i} \|^2 \\
\leq 6 \alpha^2 n \sigma^2 + 3 \alpha^2 L^2 \sum_{i=1}^{n} \mathbb{E} \| Y_k P^T e_i - Y_{k-1} P^T e_i \|^2 \\
\leq 38
\end{align*}
\[
\leq 6\alpha^2 n\sigma^2 + 3\alpha^2 L^2 E \| Y_k P^T - Y_{k-1} P^T \|_F^2
\]

**Lemma**
\[
\leq 6\alpha^2 n\sigma^2 + 3\alpha^2 L^2 E \| Y_k - Y_{k-1} \|_F^2
\]
\[
\leq 6\alpha^2 n\sigma^2 + 3\alpha^2 L^2 \sum_{i=1}^n E \| y_{k,i} - y_{k-1,i} \|^2
\]

And Putting it back, we have
\[
\sum_{i=2}^n \sum_{k=1}^K E \| y_{k,i} \|^2
\]
\[
\leq C_1 E \| Y_1 \|_F^2 + C_2 \sum_{i=2}^n \sum_{k=1}^{K-1} E \| \beta_{k,i} \|^2 + C_3 \sum_{k=1}^{K-1} \sum_{i=2}^n E \| r_{k,i} \|^2
\]
\[
\leq C_1 E \| Y_1 \|_F^2 + C_2 \sum_{k=1}^{K-1} \left( 6\alpha^2 n\sigma^2 + 3\alpha^2 L^2 \sum_{i=1}^n E \| y_{k,i} - y_{k-1,i} \|^2 \right) + C_3 \sum_{k=1}^{K-1} \sum_{i=2}^n E \| r_{k,i} \|^2
\]

**Lemma**
\[
\leq C_1 E \| Y_1 \|_F^2 + 6C_2\alpha^2 n\sigma^2 K + 3C_2\alpha^2 L^2 \sum_{k=1}^{K-1} \sum_{i=1}^n E \| y_{k,i} - y_{k-1,i} \|^2 + C_3 \sum_{k=1}^{K-1} E \| \Omega_k \|_F^2
\]

Since
\[
E \| y_{k,1} - y_{k-1,1} \|^2 = E \| X_k Pe_1 - X_{k-1} Pe_1 \|^2 = E \| X_k v_1 - X_{k-1} v_1 \|^2
\]
\[
= E \left\| X_k \frac{1}{\sqrt{n}} 1_n - X_{k-1} \frac{1}{\sqrt{n}} 1_n \right\|^2 = n E \left\| X_k - X_{k-1} \right\|^2 = n\alpha^2 E \| \overline{G}_k \|^2
\]
\[
\leq n\alpha^2 E \| \overline{G}_k - \overline{C}_k \|^2 + n\alpha^2 E \| \overline{C}_k \|^2 \leq n\alpha^2 \sigma^2 \frac{\alpha}{n} + n\alpha^2 E \| \overline{C}_k \|^2
\]
\[
= \alpha^2 \sigma^2 + n\alpha^2 E \| \overline{C}_k \|^2
\]

Putting it back, and we obtain
\[
\sum_{i=2}^n \sum_{k=1}^K E \| y_{k,i} \|^2
\]
\[
\leq C_1 E \| Y_1 \|_F^2 + 6C_2\alpha^2 n\sigma^2 K + 3C_2\alpha^4 \sigma^2 L^2 K + 3C_2\alpha^4 nL^2 \sum_{k=1}^{K-1} E \| \overline{C}_k \|^2
\]
\[
+ 3C_2\alpha^2 L^2 \sum_{k=1}^{K-1} \sum_{i=2}^n E \| y_{k,i} - y_{k-1,i} \|^2 + C_3 \sum_{k=1}^{K-1} E \| \Omega_k \|_F^2
\]
\[
\leq C_1 E \| Y_1 \|_F^2 + 6C_2\alpha^2 n\sigma^2 K + 3C_2\alpha^4 \sigma^2 L^2 K + 3C_2\alpha^4 nL^2 \sum_{k=1}^{K-1} E \| \overline{G}_k \|^2
\]
\[
+ 6C_2\alpha^2 L^2 \sum_{k=1}^{K-1} \sum_{i=2}^n E \left( \| y_{k,i} \|^2 + \| y_{k-1,i} \|^2 \right) + C_3 \sum_{k=1}^{K-1} E \| \Omega_k \|_F^2
\]
\[
\leq C_1 E \| Y_1 \|_F^2 + 6C_2\alpha^2 n\sigma^2 K + 3C_2\alpha^4 \sigma^2 L^2 K + 3C_2\alpha^4 nL^2 \sum_{k=1}^{K-1} E \| \overline{C}_k \|^2
\]
\[
+ 12C_2\alpha^2 L^2 \sum_{k=1}^{K-1} \sum_{i=2}^n E \| y_{k,i} \|^2 + C_3 \sum_{k=1}^{K-1} E \| \Omega_k \|_F^2
\]

39
Rearrange the terms, we get
\[
(1 - 12C_2a^2L^2) \sum_{i=2}^{n} \sum_{k=1}^{K} E \|y_{k,i}\|^2 \\
\leq C_1 E \|Y_1\|_F^2 + 6C_2a^2n\sigma^2K + 3C_2a^4\sigma^2L^2K + 3C_2a^4nL^2 \sum_{k=1}^{K-1} E \|G_k\|^2 + C_3 \sum_{k=1}^{K-1} E \|\Omega_k\|^2_F \]
\leq C_1 E \|X_1\|_F^2 + 6C_2a^2n\sigma^2K + 3C_2a^4\sigma^2L^2K + 3C_2a^4nL^2 \sum_{k=1}^{K-1} E \|G_k\|^2 + C_3 \sum_{k=1}^{K-1} E \|\Omega_k\|^2_F 
\]

Considering
\[
E \|X_1\|_F^2 = \alpha^2 E \|\tilde{G}_0\|^2_F \\
= \alpha^2 \sum_{i=1}^{n} E \left\| G_{0,i} - G_{0,i} + G_0 - \nabla f(0) + \nabla f(0) \right\|^2 \\
\leq 3\alpha^2 \sum_{i=1}^{n} E \left\| G_{0,i} - G_{0,i} \right\|^2 + 3\alpha^2 \sum_{i=1}^{n} E \left\| G_0 - \nabla f(0) \right\|^2 + 3\alpha^2 \sum_{i=1}^{n} E \left\| \nabla f(0) \right\|^2 \\
\leq 3\alpha^2 n\sigma^2 + 3\alpha^2 n\sigma^2 + 3\alpha^2 nE \left\| \nabla f(0) \right\| 
\]

We finally get
\[
(1 - 12C_2a^2L^2) \sum_{i=2}^{n} \sum_{k=1}^{K} E \|y_{k,i}\|^2 \\
\leq (1 - 12C_2a^2L^2) \sum_{i=1}^{n} \sum_{k=1}^{K} E \|X_k - x_{k,i}\|^2 \\
\leq 3C_1 \alpha^2 n\sigma^2 + 3C_2a^2n\sigma^2 + 3C_1 \alpha^2 nE \left\| \nabla f(0) \right\| + 6C_2a^2n\sigma^2K + 3C_2a^4\sigma^2L^2K \\
+ 3C_2a^4nL^2 \sum_{k=1}^{K-1} E \|G_k\|^2 + C_3 \sum_{k=1}^{K-1} E \|\Omega_k\|^2_F 
\]

That completes the proof.

**Lemma 14** Given $\rho \in (-\frac{1}{3}, 0) \cup (0, 1)$, for any two sequence $\{a_t\}_{t=1}^{\infty}$, $\{b_t\}_{t=1}^{\infty}$ and $\{c_t\}_{t=1}^{\infty}$ that satisfying $a_0 = b_0 = 0$, $a_{t+1} = \rho (2a_t - a_{t-1}) + b_t - b_{t-1} + c_t, \forall t \geq 1$ we have
\[
a_{t+1} = a_1 \left( \frac{u^{t+1} - v^{t+1}}{u - v} \right) + \sum_{s=1}^{t} (b_s - b_{s-1} + c_s) \left( \frac{u^{t-s+1} - v^{t-s+1}}{u - v} \right), \forall t \geq 0 
\]
where $u = \rho + \sqrt{\rho^2 - \rho}, v = \rho - \sqrt{\rho^2 - \rho}$

Moreover, if $0 < \rho < 1$, we have
\[
a_{t+1} = a_1 \rho^t \frac{\sin[(t + 1)\phi]}{\sin \phi} + \sum_{s=1}^{t} (b_s - b_{s-1} + c_s) \rho^{t-s} \frac{\sin[(t - s + 1)\phi]}{\sin \phi} 
\]
where $\phi = \arccos \sqrt{\rho}$
**Proof** when \( t \geq 1 \), we have

\[
a_{t+1} = 2\rho a_t - \rho a_{t-1} + b_t - b_{t-1} + c_t
\]

since,

\[
u = \rho + \sqrt{\rho^2 - \rho}, v = \rho - \sqrt{\rho^2 - \rho}
\]

we obtain

\[
a_{t+1} - ua_t = (a_t - ua_{t-1})v + b_t - b_{t-1} + c_t
\]

Recursively we have

\[
a_{t+1} - ua_t = (a_t - ua_{t-1})v + b_t - b_{t-1} + c_t = (a_{t-1} - ua_{t-2})v^2 + (b_{t-1} - b_{t-2} + c_{t-1})v + b_t - b_{t-1} + c_t = (a_1 - ua_0)v^t + \sum_{s=1}^{t} (b_s - b_{s-1} + c_s)v^{t-s}
\]

\[
= a_1v^t + \sum_{s=1}^{t} (b_s - b_{s-1} + c_s)v^{t-s}
\]

Dividing both sides by \( u^{t+1} \), we have

\[
\frac{a_{t+1}}{u^{t+1}} = \frac{a_t}{u^t} + u^{-(t+1)} \left( a_1v^t + \sum_{s=1}^{t} (b_s - b_{s-1} + c_s)v^{t-s} \right) = \frac{a_{t-1}}{u^{t-1}} + u^{-t} \left( a_1v^{t-1} + \sum_{s=1}^{t-1} (b_s - b_{s-1} + c_s)v^{t-1-s} \right)
\]

\[
+ u^{-(t+1)} \left( a_1v^t + \sum_{s=1}^{t} (b_s - b_{s-1} + c_s)v^{t-s} \right) = \frac{a_1}{u} + \sum_{k=1}^{t} u^{-k-1} \left( a_1v^k + \sum_{s=1}^{k} (b_s - b_{s-1} + c_s)v^{k-s} \right)
\]

Multiplying both sides by \( u^{t+1} \)

\[
a_{t+1} = a_1u^t + \sum_{k=1}^{t} u^{-k} \left( a_1v^k + \sum_{s=1}^{k} (b_s - b_{s-1} + c_s)v^{k-s} \right) = a_1u^t \left( 1 + \sum_{k=1}^{t} \left( \frac{v}{u} \right)^k \right) + u^t \sum_{k=1}^{t} \sum_{s=1}^{k} (b_s - b_{s-1} + c_s)v^{-s} \left( \frac{v}{u} \right)^k
\]

\[
= a_1u^t \sum_{k=0}^{t} \left( \frac{v}{u} \right)^k + u^t \sum_{k=1}^{t} \sum_{s=1}^{k} (b_s - b_{s-1} + c_s)v^{-s} \left( \frac{v}{u} \right)^k
\]

\[
= a_1u^t \left( \frac{1 - \left( \frac{v}{u} \right)^{t+1}}{1 - \frac{v}{u}} \right) + u^t \sum_{s=1}^{t} (b_s - b_{s-1} + c_s)v^{-s} \left( \frac{v}{u} \right)^s \frac{1 - \left( \frac{v}{u} \right)^{t-s-1}}{1 - \frac{v}{u}}
\]

\[
= a_1 \left( \frac{u^{t+1} - v^{t+1}}{u - v} \right) + \sum_{s=1}^{t} (b_s - b_{s-1} + c_s) \frac{u^{t-s+1} - v^{t-s+1}}{u - v}
\]

Note that when \( 0 < \rho < 1 \), both \( u \) and \( v \) are complex numbers, we have

\[
u = \sqrt{\rho}e^{i\phi}, v = \sqrt{\rho}e^{-i\phi}
\]

where \( \phi = \arccos \sqrt{\rho} \). And under this context, we have

\[
a_{t+1} = a_1\rho^t \frac{\sin[(t+1)\phi]}{\sin \phi} + \sum_{s=1}^{t} (b_s - b_{s-1} + c_s)\rho^{t-s} \frac{\sin[(t-s+1)\phi]}{\sin \phi}
\]
That completes the proof.

**Lemma 15** For any matrix $X \in \mathbb{R}^{N \times n}$, we have

$$
\sum_{i=2}^{n} \|Xv_i\|^2 \leq \sum_{i=1}^{n} \|Xv_i\|^2 = \|X\|_F^2
$$

$$
\sum_{i=1}^{n} \|XP^T e_i\|^2 = \|XP\|_F^2 = \|X\|_F^2
$$

**Proof**

$$
\sum_{i=2}^{n} \|Xv_i\|^2 \leq \sum_{i=1}^{n} \|Xv_i\|^2 = \|Xv\|^2 = \text{Tr}(XvPP^TXv^T) = \text{Tr}(XvXv^T) = \|Xv\|^2
$$

And similarly,

$$
\sum_{i=1}^{n} \|XP^T e_i\|^2 = \|XP\|_F^2 = \text{Tr}(XP^TPXv^T) = \text{Tr}(XvXv^T) = \|Xv\|^2
$$

That completes the proof.

**Lemma 16** If we run Algorithm 2 for $K$ iterations the following inequality holds:

$$
\left( 1 - \frac{3C_1 \alpha^2 L^2}{C_4} \right) \mathbb{E}\|\nabla f(0)\| + \left( 1 - \alpha L - \frac{3C_2}{C_4} \alpha^4 L^4 \right) \frac{1}{K} \sum_{k=1}^{K-1} \mathbb{E}\|G_k\|^2 + \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E}\|\nabla f(X_k)\|^2
$$

$$
\leq \frac{2(f(0) - f^*)}{\alpha K} + \frac{\alpha L}{n} \sigma^2 + \frac{3C_1 \alpha^2 L^2 (\sigma^2 + \varsigma_0^2)}{C_4 K} + \frac{6C_2}{C_4} \alpha^2 \sigma^2 L^2 + \frac{3C_2}{nC_4} \alpha^4 \sigma^2 L^4
$$

$$
+ \frac{C_3 L^2}{C_4} \left( \frac{12D_1 n + 8}{6D_2 n + 1} \right) \alpha^2 \sigma_\infty^2 d
$$

where

$$
C_1 = \max \left\{ \frac{3}{1 - |v_n|^2}, \frac{3}{1 - \lambda_2^2} \right\}
$$

$$
C_2 = \max \left\{ \frac{3\lambda_n^2}{(1 - |v_n|^2)^2}, \frac{3\lambda_2^2}{(1 - \sqrt{\lambda_2})^2(1 - \lambda_2)} \right\}
$$

$$
C_3 = \max \left\{ \frac{3}{(1 - |v_n|^2)^2}, \frac{3}{(1 - \sqrt{\lambda_2})^2(1 - \lambda_2)} \right\}
$$

$$
C_4 = 1 - 12C_2 \alpha^2 L^2
$$

**Proof** Since

$$
\overline{X}_{k+1} = (2X_k - X_{k-1} - \alpha \overline{G}_k + \alpha \overline{G}_{k-1})W \frac{1}{n} + (\overline{X}_{k+\frac{1}{2}} - X_{k+\frac{1}{2}})(W - I) \frac{1}{n}
$$

$$
= 2\overline{X}_k - X_{k-1} - \alpha \overline{G}_k + \alpha \overline{G}_{k-1}
$$

and we have

$$
\overline{X}_{k+1} - \overline{X}_k = \overline{X}_k - X_{k-1} - \alpha \overline{G}_k + \alpha \overline{G}_{k-1}
$$

$$
= \overline{X}_1 - X_0 - \alpha \sum_{t=1}^{k} (\overline{G}_t - \overline{G}_{t-1})
$$

$$
= -\alpha \overline{G}_k
$$

42
Note that the update of the averaged model is exactly the same as D-PSGD, thus we can reuse the result from D-PSGD for $D^2$ as follows:

$$\frac{1 - \alpha L}{K} \sum_{k=0}^{K-1} \mathbb{E} \| G_k \|^2 + \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \| \nabla f(X_k) \|^2 \leq \frac{2(f(0) - f^*)}{\alpha K} + \frac{\alpha L}{n} \sigma^2 + 2 \frac{L^2}{nK} \sum_{k=0}^{K-1} \sum_{i=1}^{n} \mathbb{E} \| X_k - x_{k,i} \|^2$$

From Lemma 13 we obtain

$$\frac{1 - \alpha L}{K} \sum_{k=0}^{K-1} \mathbb{E} \| G_k \|^2 + \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \| \nabla f(X_k) \|^2 \leq \frac{2(f(0) - f^*)}{\alpha K} + \frac{\alpha L}{n} \sigma^2 + \frac{3C_1 \alpha^2 L^2 \sigma^2 + \sigma_0^2 + \mathbb{E} \| \nabla f(0) \|}{C_4K} + 6 \frac{C_2}{C_4} \alpha^2 \sigma^2 L^2 + 3 \frac{C_2}{nC_4} \alpha^4 \sigma^2 L^4 + \frac{C_3 L^2}{C_4 n K} \sum_{k=1}^{K-1} \mathbb{E} \| \Omega_k \|^2$$

Rearrange the terms, we get

$$\left(1 - \frac{3C_1 \alpha^2 L^2}{C_4}\right) \mathbb{E} \| \nabla f(0) \| + \left(1 - \alpha L - 3 \frac{C_2}{C_4} \alpha^4 L^4\right) \frac{1}{K} \sum_{k=1}^{K-1} \mathbb{E} \| G_k \|^2 + \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \| \nabla f(X_k) \|^2 \leq \frac{2(f(0) - f^*)}{\alpha K} + \frac{\alpha L}{n} \sigma^2 + \frac{3C_1 \alpha^2 L^2 \sigma^2 + \sigma_0^2}{C_4K} + 6 \frac{C_2}{C_4} \alpha^2 \sigma^2 L^2 + 3 \frac{C_2}{nC_4} \alpha^4 \sigma^2 L^4 + \frac{C_3 L^2}{C_4 n K} \sum_{k=1}^{K-1} \mathbb{E} \| \Omega_k \|^2$$

Similar to the case in D-PSGD, we have

$$\sum_{k=0}^{K-1} \mathbb{E} \| \Omega_k \|^2 \leq \sum_{k=0}^{K-1} \sum_{i=1}^{n} \mathbb{E} \left\| \bar{x}_{k+\frac{1}{2},j} - x_{k+\frac{1}{2},j} - (\bar{d}_{k+\frac{1}{2},i} - x_{k+\frac{1}{2},i}) W_{ji} \right\|^2$$

Putting it back, we obtain

$$\left(1 - \frac{3C_1 \alpha^2 L^2}{C_4}\right) \mathbb{E} \| \nabla f(0) \| + \left(1 - \alpha L - 3 \frac{C_2}{C_4} \alpha^4 L^4\right) \frac{1}{K} \sum_{k=1}^{K-1} \mathbb{E} \| G_k \|^2 + \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \| \nabla f(X_k) \|^2 \leq \frac{2(f(0) - f^*)}{\alpha K} + \frac{\alpha L}{n} \sigma^2 + \frac{3C_1 \alpha^2 L^2 \sigma^2 + \sigma_0^2}{C_4K} + 6 \frac{C_2}{C_4} \alpha^2 \sigma^2 L^2 + 3 \frac{C_2}{nC_4} \alpha^4 \sigma^2 L^4 + \frac{C_3 L^2}{C_4} \left(\frac{6D_1 n + 8}{6D_2 n + 1}\right)^2 \alpha^2 G_\infty^2 d n K$$

That completes the proof.

## H Moniqua on AD-PSGD (Proof to Theorem 5)

### H.1 Definition and Notation

In the original analysis of AD-PSGD, to better capture the nature of workers computing at different speed, the objective function is expressed as

$$f(x) = \sum_{i=1}^{n} p_i f_i(x)$$

where $p_i$ is a parameter denoting the speed of $i$-th worker gradient updates. In the rest of the proof, we denote $p = \max_i \{p_i\}$
Algorithm 3 Moniqua with Asynchronous Communication

Input: initial point $x_{0,i} = x_0$, step size $\alpha$, the discrepancy bound $B_\theta$, number of iterations $K$, quantization function $Q_\delta$, initial random seed

1: for $k = 0, 1, 2, \ldots, K-1$ do
2: \hspace{1cm} worker $i_k$ is updating the gradient while during this iteration the global communication behaviour is written in the form of $W_k$.
3: \hspace{1cm} Compute a local stochastic gradient with model delayed by $\tau_k$: $\tilde{g}_{k,i_k}$
4: \hspace{1cm} Send modulo-ed model to one randomly selected neighbor $j_k$: $q_{k,i_k} \leftarrow Q_\delta \left( \frac{x_{k,i_k}}{B_\theta} \mod 1 \right)$
5: \hspace{1cm} Compute local biased term $\hat{x}_{k,i_k}$ as:
6: \hspace{1cm} Randomly select one neighbor $j_k$ and recover its model as:
7: \hspace{1cm} Average with neighboring workers: $x_{k+1,i_k} \leftarrow x_{k,i_k} + \sum_{j \in N(i)} (\hat{x}_{k,j_k} - \hat{x}_{k,i_k}) W_{ji}$
8: \hspace{1cm} Update the local weight with local gradient: $x_{k+1,i_k} \leftarrow x_{k,i_k} - \alpha \tilde{g}_{k,i_k}$
9: end for

Output: $X_K = \frac{1}{n} \sum_{i=1}^n x_{K,i}$

For simplicity, we also define the following terms

\[ \nabla F(X_k) = n \left[ p_1 g_{k,1}, \ldots, p_n g_{k,n} \right] \in \mathbb{R}^{d \times n} \]
\[ \nabla \tilde{F}(X_k) = n \left[ \tilde{p}_1 \tilde{g}_{k,1}, \ldots, \tilde{p}_n \tilde{g}_{k,n} \right] \in \mathbb{R}^{d \times n} \]
\[ \tilde{G}_k = \begin{bmatrix} \cdots & \tilde{g}_{k,i_k} & \cdots \end{bmatrix} \]
\[ G_k = \begin{bmatrix} \cdots & g_{k,i_k} & \cdots \end{bmatrix} \]
\[ \Lambda_b^a = \frac{1}{n} \mathbb{1}_n \mathbb{1}_n^\top - \frac{b}{q=a} \prod_{q=a}^{b} W_q \]

H.2 Setting

The pseudo code can be found in Algorithm 3. We makes the following assumptions:

1. Lipschitzian Gradient: All the function $f_i$ have L-Lipschitzian gradients.

2. Communication Matrix

   The communication matrix $W_k$ is doubly stochastic for any $k \geq 0$ and for any $b \geq a \geq 0$, there exists $t_{\text{mix}}$ such that

   \[ \left\| \prod_{q=a}^{b} W_q \left( I - \frac{\mathbb{1}_n \mathbb{1}_n^\top}{n} \right) \right\|_1 \leq 2 \cdot 2^{-\left\lfloor \frac{b-a+1}{t_{\text{mix}}} \right\rfloor} \]

3. Bounded Variance:

   \[ \mathbb{E}_{\xi_i \sim D_i} \left\| \nabla \tilde{f}_i(x_i; \xi_i) - \nabla f_i(x) \right\|^2 \leq \sigma^2, \forall i \]
   \[ \mathbb{E}_{i \sim \{1, \ldots, n\}} \left\| \nabla f_i(x) - \nabla f(x) \right\|^2 \leq \varsigma^2, \forall i \]

   where $\nabla \tilde{f}_i(x_i; \xi_i)$ denotes gradient sample on worker $i$ computed via data sample $\xi_i$.

\footnote{Please refer to Section 3 for more details}
4. Bounded Staleness: There exists $T$ such that $\tau_k \leq T, \forall k$

5. Gradient magnitude: The norm of a sampled gradient is bounded by $\|\tilde{g}_{k,i}\|_\infty \leq G_\infty$ for some constant $G_\infty$.

H.3 Proof to Theorem 5

Proof We start from

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 + \left( 1 - \frac{2\alpha L}{n} \right) \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla F(X_k - \tau_k) \right\|^2 \\
\leq \frac{2n(f(0) - f^*)}{\alpha K} + \frac{(\sigma^2 + 6\kappa^2)\alpha L}{n} + \left( 2L^2 + \frac{12\alpha L^3}{n} \right) \frac{1}{K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i \mathbb{E} \left\| X_k - \tau_k \left( \frac{1}{n} - e_i \right) \right\|^2 \\
+ \frac{2L^2}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \frac{X_k}{n} - \frac{X_k - \tau_k}{n} \right\|^2 \\
\leq \frac{2n(f(0) - f^*)}{\alpha K} + \frac{(\sigma^2 + 6\kappa^2)\alpha L}{n} + \frac{2\alpha^2 T^2(\sigma^2 + 6\kappa^2)L^2}{n^2} + \frac{4\alpha^2 T^2 L^2}{n^2 K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i \mathbb{E} \left\| X_k - \tau_k \left( \frac{1}{n} - e_i \right) \right\|^2 \\
+ \left( 2L^2 + \frac{12\alpha L^3}{n^2} + \frac{24\alpha^2 \kappa^2 T^2}{n^2} \right) \frac{1}{K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i \mathbb{E} \left\| X_k - \tau_k \left( \frac{1}{n} - e_i \right) \right\|^2 \\
\leq \frac{2n(f(0) - f^*)}{\alpha K} + \frac{(\sigma^2 + 6\kappa^2)\alpha L}{n} + \frac{2\alpha^2 T^2(\sigma^2 + 6\kappa^2)L^2}{n^2} + \frac{4\alpha^2 T^2 L^2}{n^2 K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i \mathbb{E} \left\| X_k - \tau_k \left( \frac{1}{n} - e_i \right) \right\|^2 \\
+ \frac{128\alpha^2 L^2}{A_1} \left( (\sigma^2 + 6\kappa^2)p + \frac{2p}{K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i g_{k-\tau_k,i} \right) + G_\infty^2 d
\]

where $A_1 = 1 - 192p\alpha^2 L^2$ as defined in Lemma 19.

Rearrange the terms, we get

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 \leq \frac{2n(f(0) - f^*)}{\alpha K} + \frac{(\sigma^2 + 6\kappa^2)\alpha L}{n} + \frac{2\alpha^2 T^2(\sigma^2 + 6\kappa^2)L^2}{n^2} \\
+ \frac{128p\alpha^2 L^2}{A_1} (\sigma^2 + 6\kappa^2) + \frac{128\alpha^2 L^2}{A_1} G_\infty^2 d
\]

By setting $\alpha = \frac{n}{2L + \sqrt{K(\sigma^2 + 6\kappa^2)}}$

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 \lesssim \frac{1}{K} \left[ \sqrt{\alpha^2 + 6\kappa^2} + \frac{p t_{\text{mix}}^2 (\sigma^2 + 6\kappa^2)n^2}{(\sigma^2 + 6\kappa^2)K + 4L^2} + \frac{n^2 t_{\text{mix}} G_\infty^2 d}{(\sigma^2 + 6\kappa^2)K + 4L^2} \right] \lesssim \frac{1}{K} \left[ \sqrt{\alpha^2 + 6\kappa^2} + \frac{(\sigma^2 + 6\kappa^2)t_{\text{mix}}^2 n^2}{(\sigma^2 + 6\kappa^2)K + 1} + \frac{n^2 t_{\text{mix}} G_\infty^2 d}{(\sigma^2 + 6\kappa^2)K + 1} \right]
\]

H.4 Lemma for Moniqua on AD-PSGD

Lemma 17

\[
\mathbb{E} \left\| \tilde{g}_{k-\tau_k} \frac{1}{n} \right\|^2 \leq \frac{\sigma^2}{n^2} + \frac{1}{n^2} \sum_{i=1}^{n} p_i \mathbb{E} \| g_{k-\tau_k,i} \|^2, \forall k \geq 0.
\]
Proof

\[ E \left\| \tilde{G}_{k-\tau_k} \frac{1_n}{n} \right\|^2 \leq \sum_{i=1}^{n} p_i E \left\| \frac{\tilde{g}_{k-\tau_k,i}}{n} \right\|^2 \]

\[ = \sum_{i=1}^{n} p_i E \left\| \frac{\tilde{g}_{k-\tau_k,i} - g_{k-\tau_k,i}}{n} \right\|^2 + \sum_{i=1}^{n} p_i E \left\| \frac{g_{k-\tau_k,i}}{n} \right\|^2 \]

\[ \leq \sigma^2 + \frac{1}{n^2} \sum_{i=1}^{n} p_i E \left\| g_{k-\tau_k,i} \right\|^2 \]

Lemma 18

\[ \sum_{i=1}^{n} p_i E \left\| g_{k-\tau_k,i} \right\|^2 \leq 12L^2 \sum_{i=1}^{n} p_i E \left\| X_{k-\tau_k} \left( \frac{1_n}{n} - c_i \right) \right\|^2 + 6\varsigma^2 + 2E \sum_{i=1}^{n} p_i g_{k-\tau_k,i} \]

Proof

\[ \sum_{i=1}^{n} p_i E \left\| g_{k-\tau_k,i} \right\|^2 = \sum_{i=1}^{n} p_i E \left\| g_{k-\tau_k,i} - \sum_{i=1}^{n} p_i g_{k-\tau_k,i} + \sum_{i=1}^{n} p_i g_{k-\tau_k,i} \right\|^2 \]

\[ \leq 2 \sum_{i=1}^{n} p_i E \left\| g_{k-\tau_k,i} - \sum_{i=1}^{n} p_i g_{k-\tau_k,i} \right\|^2 + 2 \sum_{i=1}^{n} p_i E \left\| \sum_{i=1}^{n} p_i g_{k-\tau_k,i} \right\|^2 \]

\[ = 2 \sum_{i=1}^{n} p_i E \left\| g_{k-\tau_k,i} - \sum_{i=1}^{n} p_i g_{k-\tau_k,i} \right\|^2 + 2E \left\| \sum_{i=1}^{n} p_i g_{k-\tau_k,i} \right\|^2 \]

And

\[ \sum_{i=1}^{n} p_i E \left\| g_{k-\tau_k,i} - \sum_{i=1}^{n} p_i g_{k-\tau_k,i} \right\|^2 \]

\[ \leq 3 \sum_{i=1}^{n} p_i E \left\| g_{k-\tau_k,i} \right\|^2 + 3 \sum_{i=1}^{n} p_i E \left\| \nabla f_i (\overline{X}_{k-\tau_k}) - \sum_{j=1}^{n} p_j \nabla f_j (\overline{X}_{k-\tau_k}) \right\|^2 \]

\[ + 3 \sum_{i=1}^{n} p_i E \left\| \sum_{j=1}^{n} p_j \nabla f_j (\overline{X}_{k-\tau_k}) \right\|^2 \]

\[ \leq 3L^2 \sum_{i=1}^{n} p_i E \left\| x_{k-\tau_k,i} - \overline{X}_{k-\tau_k} \right\|^2 + 3 \sum_{i=1}^{n} p_i E \left\| \nabla f_i (\overline{X}_{k-\tau_k}) - \sum_{j=1}^{n} p_j \nabla f_j (\overline{X}_{k-\tau_k}) \right\|^2 \]

\[ + 3E \left\| \sum_{i=1}^{n} p_i g_{k-\tau_k,i} - \sum_{j=1}^{n} p_j \nabla f_j (\overline{X}_{k-\tau_k}) \right\|^2 \]

\[ \leq 3L^2 \sum_{i=1}^{n} p_i E \left\| X_{k-\tau_k} \left( \frac{1_n}{n} - c_i \right) \right\|^2 + 3 \sum_{i=1}^{n} p_i E \left\| \nabla f_i (\overline{X}_{k-\tau_k}) - \nabla f (\overline{X}_{k-\tau_k}) \right\|^2 \]

\[ + 3 \sum_{j=1}^{n} p_j E \left\| g_{k-\tau_k,j} - \nabla f_j (\overline{X}_{k-\tau_k}) \right\|^2 \]

\[ \leq 6L^2 \sum_{i=1}^{n} p_i E \left\| X_{k-\tau_k} \left( \frac{1_n}{n} - c_i \right) \right\|^2 + 3\varsigma^2 \]

That completes the proof.
Lemma 19  Let $A_1 = 1 - 192p^2 \sigma^2 L^2$, 
\[
\sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i \mathbb{E} \left[ X_{k-\tau_k} \left( \frac{1}{n} - e_i \right) \right]^2 \leq \frac{32 \sigma^2 \nu \max}{A_1} \left( (\sigma^2 + 6\sigma^2) pK + 2p \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i g_{k-\tau_k, i} \right)^2 + G_\infty^2 dK 
\]

Proof
\[
\sum_{i=1}^{n} p_i \mathbb{E} \left[ X_k \left( \frac{1}{n} - e_i \right) \right]^2 = \sum_{i=1}^{n} p_i \mathbb{E} \left[ X_{k-1} W_{k-1} - \alpha \tilde{G}_{k-1} - \Omega_{k-1} \right] \left( \frac{1}{n} - e_i \right)^2 
\]
\[
X_{i=0} = \sum_{i=1}^{n} p_i \mathbb{E} \left[ \sum_{t=0}^{k-1} \left( -\alpha \tilde{G}_{t-\tau_t} + \Omega_t \right) \Lambda_{t+1}^{-1} e_i \right]^2 \leq 2 \sum_{i=1}^{n} p_i \mathbb{E} \left[ \sum_{t=0}^{k-1} \alpha \tilde{G}_{t-\tau_t} \Lambda_{t+1}^{-1} e_i \right]^2 + 2 \sum_{i=1}^{n} p_i \mathbb{E} \left[ \sum_{t=0}^{k-1} \Omega_t \Lambda_{t+1}^{-1} e_i \right]^2 
\]

Now for the first term, we have
\[
2 \sum_{i=1}^{n} p_i \mathbb{E} \left[ \sum_{t=0}^{k-1} \alpha \tilde{G}_{t-\tau_t} \Lambda_{t+1}^{-1} e_i \right]^2 \leq 2 p \sigma^2 \mathbb{E} \left[ \sum_{t=0}^{k-1} \tilde{G}_{t-\tau_t} \Lambda_{t+1}^{-1} \right]^2 
\]
\[
\leq 2 p \sigma^2 \mathbb{E} \left( \sum_{t=0}^{k-1} \left\| \tilde{G}_{t-\tau_t} \right\|_F \left\| \Lambda_{t+1}^{-1} \right\|_1 \right)^2 
\]
\[
\leq 8 p \sigma^2 \mathbb{E} \left( \sum_{t=0}^{k-1} \left\| \tilde{G}_{t-\tau_t} \right\|_F 2^{t-1} \left\| \Lambda_{t+1}^{-1} \right\|_1 \right)^2 
\]

Now we replace $k$ with $k - \tau_k$, that is
\[
\sum_{i=1}^{n} p_i \mathbb{E} \left[ X_{k-\tau_k} \left( \frac{1}{n} - e_i \right) \right]^2 \leq 8 p \sigma^2 \mathbb{E} \left( \sum_{t=0}^{k-\tau_k - 1} \left\| \tilde{G}_{t-\tau_t} \right\|_F 2^{t-1} \left\| \Lambda_{t+1}^{-1} \right\|_1 \right)^2 + 2 \sum_{i=1}^{n} p_i \mathbb{E} \left[ \sum_{t=0}^{k-\tau_k - 1} \Omega_t \Lambda_{t+1}^{-1} e_i \right]^2 
\]

Summing from $k = 0$ to $K - 1$ on both sides, we obtain
\[
\sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i \mathbb{E} \left[ X_{k-\tau_k} \left( \frac{1}{n} - e_i \right) \right]^2 \leq 8 p \sigma^2 \sum_{k=0}^{K-1} \mathbb{E} \left( \sum_{t=0}^{k-\tau_k - 1} \left\| G_{t-\tau_t} \right\|_F 2^{t-1} \left\| \Lambda_{t+1}^{-1} \right\|_1 \right)^2 + 2 \sum_{i=1}^{n} p_i \sum_{k=0}^{K-1} \mathbb{E} \left[ \sum_{t=0}^{k-\tau_k - 1} \Omega_t \Lambda_{t+1}^{-1} e_i \right]^2 
\]
Note that for the first term, we have

\[ \sum_{k=0}^{K-1} E \left( \sum_{t=0}^{k-\tau_k-1} \left\| \tilde{G}_{t-\tau_k} \right\|_F^2 \right) \]

\[ \leq 8\sigma^2 \sum_{k=0}^{K-1} E \left( \sum_{t=0}^{k-\tau_k-1} \left\| \tilde{G}_{t-\tau_k} \right\|_F^2 \right)^2 \]

\[ + 2 \sum_{i=1}^{n} \sum_{k=0}^{K-1} E \left( \sum_{t=0}^{k-\tau_k-1} \left\| \Omega_t \right\|_{1,2} \left\| \Lambda_{t+1}^{k-\tau_k-1} \right\|_1 \left\| e_i \right\|_1 \right)^2 \]

\[ \leq 8\sigma^2 \sum_{k=0}^{K-1} E \left( \sum_{t=0}^{k-\tau_k-1} \left\| \tilde{G}_{t-\tau_k} \right\|_F^2 \right)^2 \]

\[ + 8 \sum_{i=1}^{n} \sum_{k=0}^{K-1} E \left( \sum_{t=0}^{k-\tau_k-1} \left\| \Omega_t \right\|_{1,2} \left\| \Lambda_{t+1}^{k-\tau_k-1} \right\|_1 \left\| e_i \right\|_1 \right)^2 \]

Note that for the first term, we have

\[ \sum_{k=0}^{K-1} \left\| \tilde{G}_{k-\tau_k} \right\|_F^2 \]

\[ = \sum_{k=0}^{K-1} \left\| \tilde{g}_{k-\tau_k} \right\|^2 \]

\[ = \sum_{k=0}^{K-1} \left\| \tilde{g}_{k-\tau_k} - g_{k-\tau_k} \right\|^2 + \sum_{k=0}^{K-1} \left\| g_{k-\tau_k} \right\|^2 \]

\[ \leq \sigma^2 K + \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i E \left\| g_{t-\tau_k} - i \right\|^2 \]

\[ \leq (\sigma^2 + 6\sigma^2) K + 12L^2 \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i E \left\| X_{k-\tau_k} \left( \frac{I_n}{n} - e_i \right) \right\|^2 + 2 \sum_{k=0}^{K-1} E \sum_{i=1}^{n} p_i \left\| g_{k-\tau_k} - i \right\|^2 \]

Putting these two terms back, we obtain

\[ \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i E \left\| X_{k-\tau_k} \left( \frac{I_n}{n} - e_i \right) \right\|^2 \]

\[ \leq 32\sigma^2 t^2 \left( (\sigma^2 + 6\sigma^2) K + 12L^2 \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i E \left\| X_{k-\tau_k} \left( \frac{I_n}{n} - e_i \right) \right\|^2 + 2 \sum_{k=0}^{K-1} E \sum_{i=1}^{n} p_i \left\| g_{k-\tau_k} - i \right\|^2 \right) \]

\[ + 12\delta^2 B^2 \sigma^2 \tau^2 \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i E \left\| X_{k-\tau_k} \left( \frac{I_n}{n} - e_i \right) \right\|^2 + 2 \sum_{k=0}^{K-1} E \sum_{i=1}^{n} p_i \left\| g_{k-\tau_k} - i \right\|^2 \]

Rearrange the terms, we obtain

\[ (1 - 192\sigma^2 t^2 \frac{L^2}{K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i E \left\| X_{k-\tau_k} \left( \frac{I_n}{n} - e_i \right) \right\|^2 \]

\[ \leq 32\sigma^2 t^2 \left( (\sigma^2 + 6\sigma^2) K + 2 \sum_{k=0}^{K-1} E \sum_{i=1}^{n} p_i \left\| g_{k-\tau_k} - i \right\|^2 \right) + 12\delta^2 B^2 \sigma^2 \tau^2 \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i E \left\| X_{k-\tau_k} \left( \frac{I_n}{n} - e_i \right) \right\|^2 \]

48
Lemma 20

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \|\nabla f(X_k)\|^2 + \left( 1 - \frac{2\alpha L}{n} \right) \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \|\nabla \mathcal{F}(X_{k-\tau})\|^2 \\
\leq 2n(f(0) - f^*) \frac{1}{\alpha K} + \frac{2L^2}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \left( \frac{X_k - X_{k-\tau}}{n} \right) \right\|^2 \\
+ \left( 2L^2 + \frac{12\alpha L^3}{n} \right) \frac{1}{K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i \mathbb{E} \left\| X_{k-\tau} \left( \frac{1}{n} - e_i \right) \right\|^2 + \frac{(\sigma^2 + 6\gamma^2)\alpha L}{n}
\]

Proof: We start from \( f(X_{k+1}) \) since

\[
X_{k+1} = X_k W_k \frac{1}{n} + (Q_k - X_k)(W_k - I) \frac{1}{n} - \alpha \overline{G}_{k-\tau} = X_k - \alpha \overline{G}_{k-\tau}
\]

Then from Taylor Expansion, we have

\[
\mathbb{E} f(X_{k+1}) \\
= \mathbb{E} f(X_k - \alpha \overline{G}_{k-\tau}) \\
\leq \mathbb{E} f(X_k) - \alpha \mathbb{E} \langle \nabla f(X_k), \overline{G}_{k-\tau} \rangle - \frac{\alpha^2 L}{2} \mathbb{E} \left\| \overline{G}_{k-\tau} \right\|^2 \\
= \mathbb{E} f(X_k) - \alpha \mathbb{E} \langle \nabla f(X_k), \overline{G}_{k-\tau} \rangle - \alpha \mathbb{E} \langle \nabla f(X_k), \overline{G}_{k-\tau} - \overline{G}_{k-\tau} \rangle + \frac{\alpha^2 L}{2} \mathbb{E} \left\| \overline{G}_{k-\tau} \right\|^2 \\
= \mathbb{E} f(X_k) - \frac{\alpha^2 L}{2} \mathbb{E} \left\| \overline{G}_{k-\tau} \right\|^2 \\
= \mathbb{E} f(X_k) - \frac{\alpha^2 L}{2} \mathbb{E} \left\| \overline{g}_{k-\tau,i} \right\|^2 \\
+ \frac{\alpha^2 L}{2} \sum_{i=1}^{n} p_i \mathbb{E} \left\| \tilde{g}_{k-\tau,i} - g_{k-\tau,i} \right\|^2 \\
\leq \mathbb{E} f(X_k) - \frac{\alpha^2 L}{2} \mathbb{E} \left\| \nabla f(X_k) - \nabla \mathcal{F}(X_{k-\tau}) \right\|^2 - \frac{\alpha^2 L}{2} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 - \frac{\alpha^2 L}{2} \mathbb{E} \left\| \nabla \mathcal{F}(X_{k-\tau}) \right\|^2 \\
+ \frac{\alpha^2 L\sigma^2}{2n^2} + \frac{\alpha^2 L}{2n^2} \sum_{i=1}^{n} p_i \mathbb{E} \left\| g_{k-\tau,i} \right\|^2 \\
\leq \mathbb{E} f(X_k) - \frac{\alpha^2 L}{2n^2} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 + \frac{\alpha^2 L}{2n^2} \mathbb{E} \left\| \nabla \mathcal{F}(X_{k-\tau}) \right\|^2 \\
\leq \mathbb{E} f(X_k) - \mathbb{E} f(X_{k+1}) + \frac{\alpha^2 L}{2n^2} \mathbb{E} \left\| \nabla f(X_k) - \nabla \mathcal{F}(X_{k-\tau}) \right\|^2
\]
Summing over \( k = 0 \) to \( K - 1 \) on both sides, we can get

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 + \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla F(X_{k-\tau_k}) \right\|^2 \\
\leq 2n(f(0) - f^*) + \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) - \nabla f(X_{k-\tau_k}) \right\|^2 + 2 \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_{k-\tau_k}) - \nabla F(X_{k-\tau_k}) \right\|^2
\]

For \( \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) - \nabla F(X_{k-\tau_k}) \right\|^2 \), we have

\[
\sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) - \nabla F(X_{k-\tau_k}) \right\|^2 \\
\leq 2 \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) - \nabla f(X_{k-\tau_k}) \right\|^2 + 2 \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_{k-\tau_k}) - \nabla F(X_{k-\tau_k}) \right\|^2
\]

Putting it back, we have

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 + \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla F(X_{k-\tau_k}) \right\|^2 \\
\leq 2n(f(0) - f^*) + \frac{12L^2}{nK} \sum_{k=0}^{K-1} \mathbb{E} \left\| \frac{X_k - X_{k-\tau_k}}{n} \right\|^2 \\
+ \frac{2L^2}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \frac{X_{k-\tau_k}}{n} \right\|^2 + 6 \mathbb{E} \left\| \frac{1}{n} - e_i \right\|^2 + 2 \mathbb{E} \left\| \frac{1}{n} - e_i \right\|^2
\]
Moving it to the left side, we finally get

\[
\frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla f(X_k) \right\|^2 + \left( 1 - \frac{2\alpha L}{n} \right) \frac{1}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \nabla F(X_{k-\tau_k}) \right\|^2 \leq \frac{2n(f(0) - f^*)}{\alpha K} + \frac{2L^2}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| (X_k - X_{k-\tau_k}) \mathbb{I}_n \right\|^2 + \left( 2L^2 + \frac{12\alpha L^3}{n} \right) \frac{1}{K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} \mathbb{E} \left\| X_{k-\tau_k} \left( \frac{\mathbb{I}_n}{n} - e_i \right) \right\|^2 + \frac{(\sigma^2 + 6\varsigma^2)\alpha L}{n}
\]

That completes the proof.

**Lemma 21** For all \( k \geq 0 \), we have

\[
\frac{2L^2}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| (X_k - X_{k-\tau_k}) \mathbb{I}_n \right\|^2 \leq \frac{2\alpha^2 T^2(\sigma^2 + 6\varsigma^2)L^2}{n^2} + \frac{24L^4\alpha^2 T^2}{n^2 K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} \mathbb{E} \left\| X_{k-\tau_k} \left( \frac{\mathbb{I}_n}{n} - e_i \right) \right\|^2 + \frac{4\alpha^2 T^2 L^2}{n^2 K} \sum_{k=0}^{K-1} \mathbb{E} \left\| \sum_{i=1}^{n} p_i g_{k-\tau_k,i} \right\|^2
\]

**Proof** From Lemma 20, we know the fact

\[
X_{k+1} = X_k W_k \frac{\mathbb{I}_n}{n} + (Q_k - X_k)(W_k - I) \frac{\mathbb{I}_n}{n} - \alpha \bar{G}_{k-\tau_k} = X_k - \alpha \bar{G}_{k-\tau_k}
\]

As a result

\[
\sum_{k=0}^{K-1} \mathbb{E} \left\| (X_k - X_{k-\tau_k}) \mathbb{I}_n \right\|^2 \\
= \sum_{k=0}^{K-1} \mathbb{E} \left\| \sum_{i=1}^{\tau_k} \alpha \bar{G}_{k-i} \frac{\mathbb{I}_n}{n} \right\|^2 \\
\leq \alpha^2 \sum_{k=0}^{K-1} \tau_k \sum_{i=1}^{\tau_k} \mathbb{E} \left\| \bar{G}_{k-i} \frac{\mathbb{I}_n}{n} \right\|^2 \\
\leq \alpha^2 \sum_{k=0}^{K-1} \tau_k \left( \frac{\sigma^2}{n^2} + \frac{1}{n^2} \sum_{i=1}^{n} p_i \mathbb{E} \| g_{k-t,i} \|^2 \right) \\
\leq \frac{\alpha^2 T^2 \sigma^2 K}{n^2} + \frac{\alpha^2 T^2 \sigma^2 K}{n^2} \sum_{k=0}^{K-1} \tau_k \sum_{t=1}^{n} \mathbb{E} \| g_{k-t,i} \|^2 \\
\leq \frac{\alpha^2 T^2 \sigma^2 K}{n^2} + \frac{\alpha^2 T^2 \sigma^2 K}{n^2} \left( 12L^2 \sum_{i=1}^{n} \mathbb{E} \left\| X_{k-t} \left( \frac{\mathbb{I}_n}{n} - e_i \right) \right\|^2 + 6\varsigma^2 + 2\mathbb{E} \sum_{i=1}^{n} p_i g_{k-t,i} \right)^2
\]

51
That completes the proof.

And we get

\[
\frac{2L^2}{K} \sum_{k=0}^{K-1} \mathbb{E} \left\| (X_k - X_{k-\tau}) \frac{1}{n} \right\|^2 
\leq \frac{2\alpha^2 T^2 (\sigma^2 + 6c^2) L^2}{n^2} + \frac{4 \alpha^2 T^2 L^2}{n^2 K} \sum_{k=0}^{K-1} \sum_{i=1}^{n} p_i \mathbb{E} \left\| X_{k-\tau} \left( \frac{1}{n} - e_i \right) \right\|^2 
\]

That completes the proof.

**Lemma 22** Given non-negative sequences \( \{a_t\}_{t=1}^\infty, \{b_t\}_{t=1}^\infty \) and \( \{\tau_t\}_{t=1}^\infty \) and a positive number \( T \) that satisfying

\[
\sum_{t=1}^{\infty} a_t = \sum_{s=1}^{\infty} \sum_{t=1}^{t-s} \rho^{t-s} b_s 
\]

with \( 0 \leq \rho < 1 \), we have

\[
S_k = \sum_{t=1}^{k} a_t \leq \frac{(2 - \rho) T}{1 - \rho} \sum_{s=1}^{k} b_s 
\]

\[
D_k = \sum_{t=1}^{k} a_t^2 \leq \frac{(2 - \rho) T^2}{(1 - \rho)^2} \sum_{s=1}^{k} b_s^2 
\]

**Proof**

\[
S_k = \sum_{t=1}^{k} a_t = \sum_{t=1}^{k} \sum_{s=1}^{t-s} \rho^{t-s} b_s \leq \sum_{t=1}^{k} \sum_{s=1}^{t} \rho^{t-s} \max \left( \frac{t-s}{t-s} \right) b_s = \sum_{s=1}^{k} \sum_{t=s}^{k} \rho^{t-s} \max \left( \frac{t-s}{t-s} \right) b_s 
\]

\[
= \sum_{s=1}^{k} \sum_{t=1}^{k-s} \rho^{t-s} b_s + \sum_{s=1}^{k} \sum_{t=s}^{k} \rho^{t-s} b_s \leq \sum_{s=1}^{k} \left( \sum_{t=0}^{T-1} \sum_{m=0}^{\infty} \rho^m \right) b_s + \tau_k \sum_{s=1}^{k} b_s \leq \left( T + \frac{T}{1 - \rho} \right) \sum_{s=1}^{k} b_s 
\]

\[
D_k = \sum_{t=1}^{k} a_t^2 = \sum_{t=1}^{k} \sum_{s=1}^{t-s} \rho^{t-s} b_s \sum_{s=1}^{t-s} \rho^{t-s} b_s = \sum_{t=1}^{k} \sum_{s=1}^{t-s} \rho^{t-s} \max \left( \frac{t-s}{t-s} \right) b_s^2 
\]

\[
\leq \sum_{t=1}^{k} \sum_{s=1}^{t-s} \rho^{t-s} \max \left( \frac{t-s}{t-s} \right) \frac{b_s^2}{2} + b_r^2 = \sum_{t=1}^{k} \sum_{s=1}^{t-s} \rho^{t-s} \max \left( \frac{t-s}{t-s} \right) b_s^2 
\]

\[
\leq \sum_{s=1}^{k} \sum_{r=1}^{t-s} \rho^{t-s} \max \left( \frac{t-s}{t-s} \right) \sum_{r=1}^{t-s} \rho^{t-s} \max \left( \frac{t-s}{t-s} \right) b_s^2 
\]

\[
\leq \sum_{s=1}^{k} \sum_{r=1}^{t-s} \rho^{t-s} \max \left( \frac{t-s}{t-s} \right) T-1 \sum_{r=0}^{\infty} \rho^m 
\]

\[
\left( 2 - \rho \right) T^2 \sum_{k=1}^{k} b_s^2 \leq \frac{(2 - \rho) T^2}{(1 - \rho)^2} \sum_{s=1}^{k} b_s^2 
\]

52
Lemma 23 for $\forall i, j$ and $\forall k \geq 0$, we have

$$\|X_k(e_i - e_j)\|_\infty = \theta = 16t_{\text{mix}}aG_\infty$$

**Proof** We use mathematical induction to prove this.

1. First, for $k = 0$, we have

$$\|X_k(e_i - e_j)\|_\infty = 0 < \theta = 16t_{\text{mix}}aG_\infty$$

2. Suppose for $k \geq 0$, we have $\|X_t(e_i - e_j)\|_\infty < \theta$, $\forall t \leq k$, then we have

$$\|X_{k+1}(e_i - e_j)\|_\infty \\
\leq \|X_{k+1}\left(\frac{1}{n} - e_i\right)\|_\infty + \|X_{k+1}\left(\frac{1}{n} - e_j\right)\|_\infty \\
\leq \left\|X_{k+1}\left(I - \frac{1}{n}1_n^T\right)\right\|_1 \|e_i\|_1 + \left\|X_{k+1}\left(I - \frac{1}{n}1_n^T\right)\right\|_1 \|e_j\|_1 \\
= 2 \left\|X_{k+1}\left(I - \frac{1}{n}1_n^T\right)\right\|_1 \\
\leq 2 \left\|X_kW_k - \tilde{\alpha}G_{k-\tau_k} + \Omega_k\left(\frac{1}{n} - e_i\right)\right\|_1 \\
= 2 \sum_{t=0}^{k} \left\|(-\alpha\tilde{G}_{t-\tau_t} + \Omega_t)\left(\prod_{q=t+1}^{k} W_q - \frac{1}{n}1_n^T\right)\right\|_1 \\
\leq 2 \sum_{t=0}^{k} \left\|(-\alpha\tilde{G}_{t-\tau_t} + \Omega_t)\left(\prod_{q=t+1}^{k} W_q - \frac{1}{n}1_n^T\right)\right\|_1 \\
\leq 2 \sum_{t=0}^{k} \left\|(-\alpha\tilde{G}_{t-\tau_t} + \Omega_t)\left(\prod_{q=t+1}^{k} W_q - \frac{1}{n}1_n^T\right)\right\|_1 \\
\leq 4(\alpha G_\infty + 2\delta B_\theta) \sum_{t=0}^{k} 2^{-[(k-t)/t_{\text{mix}}]} \\
< 4(\alpha G_\infty + 2\delta B_\theta) \sum_{t=0}^{t_{\text{mix}}-1} \sum_{r=0}^{\infty} 2^{-r} + 8(\alpha G_\infty + 2\delta B_\theta)t_{\text{mix}} \\
< 8(\alpha G_\infty + 2\delta B_\theta)t_{\text{mix}}$$

Put in $\delta = \frac{1}{64t_{\text{mix}}^2}$, we obtain

$$\|X_{k+1}(e_i - e_j)\|_2 < 8(\alpha G_\infty + 2\delta B_\theta)t_{\text{mix}} = 8t_{\text{mix}}aG_\infty + 8t_{\text{mix}}aG_\infty = 16t_{\text{mix}}aG_\infty$$

Combining I and II and we complete the proof.
