

ZETA FUNCTIONS OF PERIODIC CUBICAL LATTICES AND CYCLOTOMIC-LIKE POLYNOMIALS

YASUAKI HIRAOKA, HIROYUKI OCHIAI, AND TOMOYUKI SHIRAI

ABSTRACT. Zeta functions of periodic cubical lattices are explicitly derived by computing all the eigenvalues of the adjacency operators and their characteristic polynomials. We introduce cyclotomic-like polynomials to give factorization of the zeta function in terms of them and count the number of orbits of the Galois action associated with each cyclotomic-like polynomial to obtain its further factorization. We also give a necessary and sufficient condition for such a polynomial to be irreducible and discuss its irreducibility from this point of view.

1. INTRODUCTION

Let K be an abstract simplicial complex over the set $K_0 = \{1, \dots, q\}$ of vertices, where we assume that the empty set \emptyset is an element of K , i.e., $K_{-1} = \{\emptyset\}$. We denote the set of k -simplices and the k -dimensional skeleton of K by K_k and $K^{(k)} (= \sqcup_{i=-1}^k K_i)$. For each simplex $\sigma \in K$, $|\sigma|$ denotes the number of vertices in σ , and similarly, $|S|$ denotes the cardinality of a finite set S .

Let $\mathbf{n} = (n_1, \dots, n_q) \in \mathbb{N}^q$ be a fixed vector of natural numbers with $n_i \geq 2$ for all $i \in K_0$. We write $|\mathbf{n}| = \prod_{i=1}^q n_i$. For each $i \in K_0$, let

$$\mathcal{I}_i^\circ := \{[0, 1], [1, 2], \dots, [n_i - 1, 0]\}, \quad \mathcal{P}_i^\circ := \{[0, 0], [1, 1], \dots, [n_i - 1, n_i - 1]\}$$

be the collections of intervals in $\mathbb{R}/n_i\mathbb{Z}$, where the elements of \mathcal{P}_i° are degenerated intervals. For each simplex $\sigma \in K$, we set a collection of $|\sigma|$ -dimensional elementary cubes by

$$Y_\sigma = \{I_1 \times \dots \times I_q : I_i \in \mathcal{I}_i^\circ \text{ if } i \in \sigma; I_i \in \mathcal{P}_i^\circ \text{ otherwise}\}.$$

Then, we define the d -cubical lattice $Y^{(d)}$ over K by

$$Y^{(d)} = \bigsqcup_{k=0}^d Y_k, \quad Y_k = \bigsqcup_{\sigma \in K_{k-1}} Y_\sigma$$

for $d \leq q$. We also write $Y = Y^{(q)}$. When we need to specify the side lengths \mathbf{n} , we write $Y = Y(\mathbf{n})$. We refer to an element in Y_k as a k -cube. The cubical lattice Y is realized in the q -dimensional torus \mathbb{T}^q . For more explanation about elementary cubes (and also cubical homology), we refer the reader to [4]; in particular, see subsection 2.1.1. for elementary cubes.

A closed path in $Y^{(d)}$ is an alternating sequence $c = (\tau_0, \sigma_0, \tau_1, \sigma_1, \dots, \tau_{n-1}, \sigma_{n-1})$ of $(d-1)$ -cubes $(\tau_i)_{i=0}^{n-1}$ and d -cubes $(\sigma_i)_{i=0}^{n-1}$ such that $\tau_i \neq \tau_{i+1}$ and $\tau_{i+1} \subset \sigma_i \cap \sigma_{i+1}$ for all $i \in \mathbb{Z}_n := \mathbb{Z}/n\mathbb{Z}$. Note that $\tau_0 \subset \sigma_{n-1} \cap \sigma_0$. The length of a closed path c , denoted by $|c|$, is the number of d -cubes (also $(d-1)$ -cubes) in c . We say that a closed path c is a closed geodesic if there is no back-tracking, i.e., $\sigma_i \neq \sigma_{i+1}$ for all $i \in \mathbb{Z}_{|c|}$. We denote by c^m the m -multiple of a closed geodesic c , which is formed by m repetitions of c . If

Key words and phrases. Cubical lattice, zeta function, Laplacian, cyclotomic-like polynomial.

a closed geodesic c is not expressed as an m -multiple of a closed geodesic with $m \geq 2$, then c is said to be prime. Two prime closed geodesics are said to be equivalent if one is obtained from the other through a cyclic permutation. An equivalence class of prime closed geodesics is called a prime cycle. The length of a prime cycle \mathbf{p} is the length of a representative and is denoted by $|\mathbf{p}|$. The (Ihara) zeta function of a finite cubical lattice is defined as follows.

Definition 1.1. For $u \in \mathbb{C}$ with $|u|$ sufficient small, the (Ihara) zeta function of the d -skeleton $Y^{(d)}$ of a cubical lattice Y is defined by

$$\zeta_{Y^{(d)}}(u) = \prod_{\mathbf{p} \in P_d} (1 - u^{|\mathbf{p}|})^{-1},$$

where P_d is the set of prime cycles of $Y^{(d)}$. In particular, we write $\zeta_Y(u)$ for $\zeta_{Y^{(q)}}(u)$.

Although zeta functions can be defined in this manner for any cubical (simplicial) complexes, in the present paper, we only consider zeta functions for the cubical lattice Y with the complete complex K , which includes all the subsets of K_0 .

By symmetry, we have $\zeta_{Y^{(d)}}(u) = \zeta_{Y^{(q-d+1)}}(u)$ for $d = 1, 2, \dots, q$ (see Remark 3.6). For $d = q, q-1$ (and hence, by symmetry, for $d = 1, 2$, respectively), we have explicit factorizations of the zeta functions defined above.

Theorem 1.2. Let Y be the periodic q -cubical lattice with side lengths $\mathbf{n} = (n_1, n_2, \dots, n_q)$. Then, for $d = q$,

$$\zeta_Y(u)^{-1} = (1 - u^2)^{(q-1)|\mathbf{n}|} \prod_{k_1=1}^{n_1} \cdots \prod_{k_q=1}^{n_q} \left\{ 1 - 2u \sum_{i=1}^q \cos \frac{2\pi k_i}{n_i} + (2q-1)u^2 \right\}$$

and for $d = q-1$,

$$\zeta_{Y^{(q-1)}}(u)^{-1} = (1 - u)^{\kappa|\mathbf{n}|} (1 + 3u)^{\gamma|\mathbf{n}|} \times \prod_{k_1=1}^{n_1} \cdots \prod_{k_q=1}^{n_q} F_1^{\text{up}}(u, \mathbf{k}).$$

Here $\mathbf{k} = (k_1, \dots, k_q)$, $\kappa = q(3q-5)/2$, $\gamma = q(q-3)/2$ and

$$F_1^{\text{up}}(u, \mathbf{k}) = \sum_{\ell=0}^q (2-\ell)2^{\ell-1} e_\ell(\mathbf{w}) \left\{ 1 - 2u \sum_{i=1}^q \cos \frac{2\pi k_i}{n_i} + 3(2q-3)u^2 \right\}^{q-\ell} u^\ell,$$

where $e_\ell(\mathbf{t})$ is the ℓ th elementary symmetric polynomial in $\mathbf{t} = (t_1, \dots, t_q)$, and $\mathbf{w} = (2 + 2 \cos \frac{2\pi k_i}{n_i})_{i=1}^q$.

In principle, the expression of $\zeta_{Y^{(d)}}^{-1}$ for arbitrary d can be obtained using Theorem 3.5.

Let $Y = Y(\mathbf{n})$ be the periodic cubical lattice with side lengths $\mathbf{n} = (n_1, \dots, n_q)$. Then, for $|u| < 1$,

$$\begin{aligned} & \lim_{n_1, \dots, n_q \rightarrow \infty} \frac{-1}{|\mathbf{n}|} \log \zeta_Y(u) \\ &= (q-1) \log(1 - u^2) + \int_{[0,1]^q} \log \left(1 - 2u \sum_{i=1}^q \cos 2\pi \theta_i + (2q-1)u^2 \right) d\theta_1 \cdots d\theta_q. \end{aligned}$$

Note that the second term on the right-hand side is the logarithmic Mahler measure of the Laurant polynomial $1 + (2q-1)u^2 - u \sum_{i=1}^q (z_i + z_i^{-1}) \in \mathbb{C}[z_1, z_1^{-1}, \dots, z_q, z_q^{-1}]$ (cf. [2]). It is known that as $u \rightarrow 1$, the second term converges to 0 and $-4G/\pi$ for $q = 1$ and 2, respectively, where G is the Catalan number defined by $G = \sum_{k=0}^{\infty} (-1)^k / (2k+1)^2$.

The zeta function given in Theorem 1.2 can be written as a product of cyclotomic-like polynomials with integer coefficients. Let

$$(1.1) \quad J_1 = J_2 = \{1\}, \quad J_d = \{j \in \mathbb{N} : j < d/2, \gcd(j, d) = 1\} \text{ for } d \geq 3,$$

and then

$$|J_d| = \tilde{\varphi}(d) := \begin{cases} \varphi(d)/2 & \text{for } d \geq 3, \\ 1 & \text{for } d = 1, 2, \end{cases}$$

where φ is the Euler function, i.e., $\varphi(d)$ is the cardinality of $\{j \in \mathbb{N} : j \leq d, \gcd(j, d) = 1\}$. The set J_d can be regarded as a set of representatives of $(\mathbb{Z}/d\mathbb{Z})^\times / \sim$, where \sim is the equivalence relation with respect to the involution $\iota : (\mathbb{Z}/d\mathbb{Z})^\times \rightarrow (\mathbb{Z}/d\mathbb{Z})^\times$ defined by $\iota(k) = d - k \pmod{d}$.

For $\mathbf{d} = (d_1, \dots, d_q) \in \mathbb{N}^q$, we define the following homogeneous polynomial of x and y of degree $\prod_{i=1}^q \tilde{\varphi}(d_i)$:

$$\Psi_{\mathbf{d}}(x, y) := \prod_{j_1 \in J_{d_1}} \cdots \prod_{j_q \in J_{d_q}} \left(x - 2y \sum_{i=1}^q \cos \frac{2\pi j_i}{d_i} \right).$$

Then, it is seen that $\Psi_{\mathbf{d}}(x, y) \in \mathbb{Z}[x, y]$ (Proposition 4.4), and in particular, for $q = 1$, $\Psi_d(x, y)$ is irreducible for any $d \in \mathbb{N}$ (Lemma 4.1) (cf. [7]). Although $\Psi_{\mathbf{d}}(x, y)$ may be reducible for general \mathbf{d} unless $q = 1$, if $\mathbf{d} = (d_1, \dots, d_q)$ are relatively prime, then $\Psi_{\mathbf{d}}$ is irreducible (Corollary 4.5).

Using the polynomials $\Psi_{\mathbf{d}}$, we can factorize the zeta functions as follows.

Corollary 1.3. Let Y be the periodic q -cubical lattice with side lengths $\mathbf{n} = (n_1, n_2, \dots, n_q)$. Then,

$$\zeta_Y(u)^{-1} = (1 - u^2)^{(q-1)|\mathbf{n}|} \prod_{\mathbf{d}|\mathbf{n}} \Psi_{\mathbf{d}}(1 + (2q - 1)u^2, u)^{\epsilon(\mathbf{d})},$$

where $\mathbf{d}|\mathbf{n}$ means $d_i|n_i$ for all $i = 1, 2, \dots, q$ and $\epsilon(\mathbf{d}) = 2^k$ with $k = \#\{1 \leq i \leq q : d_i \geq 3\}$.

For $\mathbf{d} = (d_1, \dots, d_q)$, let $V = V_{\mathbf{d}} = \{j \in \{1, 2, \dots, q\} : d_j \geq 3\}$. We define a graph $\Gamma(V)$ obtained from V by adding an unoriented edge between each pair of distinct i and j satisfying $\gcd(d_i, d_j) \geq 3$. We denote by $\tilde{\beta}_0(\Gamma(V))$ the 0th reduced Betti number, i.e., one less than the number of connected components of $\Gamma(V)$. We understand $\tilde{\beta}_0(\Gamma(\emptyset)) = 0$ when $V = \emptyset$. Then we have the following.

Theorem 1.4. For $\mathbf{d} = (d_1, d_2, \dots, d_q)$, let $N = d_1 \cdots d_q$ and denote the number of $(\mathbb{Z}/N\mathbb{Z})^\times$ -orbits in $J_{d_1} \times \cdots \times J_{d_q}$ by $\text{orb}(\mathbf{d})$, where the $(\mathbb{Z}/N\mathbb{Z})^\times$ acts on $J_{d_1} \times \cdots \times J_{d_q}$ as the component-wise multiplication, i.e., $a \cdot (j_1, \dots, j_q) := (aj_1, \dots, aj_q)$ for $a \in (\mathbb{Z}/N\mathbb{Z})^\times$. Then,

$$\text{orb}(\mathbf{d}) = \frac{\prod_{i=1}^q \tilde{\varphi}(d_i)}{\tilde{\varphi}(\text{lcm}(d_1, d_2, \dots, d_q))} \times 2^{\tilde{\beta}_0(\Gamma(V_{\mathbf{d}}))}.$$

While the above is the general form for the number of orbits, in certain special cases, this is greatly simplified as seen below.

Example 1.5. (i) For $q = 2$, $\text{orb}(d_1, d_2) = \tilde{\varphi}(\gcd(d_1, d_2))$.
(ii) For $d_1 = d_2 = \cdots = d_q = d$, $\text{orb}(\mathbf{d}) = \tilde{\varphi}(d)^{q-1}$.

Next, for the purpose of factorizing $\Psi_{\mathbf{d}}(x)$, we introduce a new polynomial. For a subset $\mathcal{O} \subset J_{d_1} \times \cdots \times J_{d_q}$, we define

$$(1.2) \quad \Psi_{\mathbf{d}}(x; \mathcal{O}) := \prod_{(j_1, \dots, j_q) \in \mathcal{O}} \left(x - 2 \sum_{i=1}^q \cos \frac{2\pi j_i}{d_i} \right).$$

It is obvious that this function has the following multiplicativity for the disjoint union:

$$\Psi_{\mathbf{d}}(x; \mathcal{O}_1 \sqcup \mathcal{O}_2) = \Psi_{\mathbf{d}}(x; \mathcal{O}_1) \Psi_{\mathbf{d}}(x; \mathcal{O}_2).$$

From Theorem 1.4, we obtain the following factorization.

Corollary 1.6. Let $\sqcup_{i=1}^{\text{orb}(\mathbf{d})} \mathcal{O}_i$ be the decomposition of $J_{d_1} \times \cdots \times J_{d_q}$ into $(\mathbb{Z}/N\mathbb{Z})^\times$ -orbits. Then,

$$(1.3) \quad \Psi_{\mathbf{d}}(x) = \prod_{i=1}^{\text{orb}(\mathbf{d})} \Psi_{\mathbf{d}}(x; \mathcal{O}_i).$$

The degree of each $\Psi_{\mathbf{d}}(x; \mathcal{O}_i) \in \mathbb{Z}[x]$ is $\tilde{\varphi}(\text{lcm}(d_1, \dots, d_q)) 2^{-\tilde{\beta}_0(\Gamma(V_{\mathbf{d}}))}$.

The polynomials $\Psi_{\mathbf{d}}(x; \mathcal{O}_i)$ may themselves be reducible. A complete characterization of the irreducibility of $\Psi_{\mathbf{d}}(x; \mathcal{O}_i)$ remains open so far. Further discussion of this point is given in Section 4.

This paper is organized as follows. In Section 2, we compute the eigenvalues of adjacency operators and Laplacians defined on the periodic cubical lattice. In Section 3, we recall the results for zeta functions of hypergraphs, and we present the results for cubical complexes in the cases $d = q, q - 1$. In Section 4, we prove Theorem 1.4 and give a condition for $\Psi_{\mathbf{d}}(x; \mathcal{O})$ to be irreducible (Proposition 4.4). Also, we give further discussion of factorization and present some observations for the case $q = 2$.

2. EIGENVALUES FOR PERIODIC CUBICAL COMPLEXES

2.1. Eigenvalues of adjacency matrices. The set $Y_d = \sqcup_{\sigma \in K_{d-1}} Y_\sigma$ of d -cubes (i.e., $|\sigma| = d$) can be regarded as the set $K_{d-1} \times \mathbb{Z}_{n_1} \times \cdots \times \mathbb{Z}_{n_q}$ if we identify the intervals $I_i = [v_i, v_i + 1] \in \mathcal{I}_i^\circ$ and $I_i = [v_i, v_i] \in \mathcal{P}_i^\circ$ with the points $v_i \in \mathbb{Z}_{n_i}$ as follows:

$$\begin{aligned} Y_d &= \bigsqcup_{\sigma \in K_{d-1}} \{I_1 \times \cdots \times I_q \subset \mathbb{T}^q : I_i \in \mathcal{I}_i^\circ \text{ if } i \in \sigma; I_i \in \mathcal{P}_i^\circ \text{ otherwise}\} \\ &\cong \{(\sigma, v_1, \dots, v_q) : \sigma \in K_{d-1}, v_i \in \mathbb{Z}_{n_i} \text{ for } i \in K_0\}. \end{aligned}$$

Here, note that $|Y_d| = \binom{q}{d} |\mathbf{n}|$.

We write $V := \mathbb{Z}_{n_1} \times \cdots \times \mathbb{Z}_{n_q}$. For $d = 0, 1, \dots, q$, the space $C^d(Y)$ of d -cochains on Y is regarded as $C^d(K_{d-1} \times V)$, the space of functions on $K_{d-1} \times V$, under the identification introduced above. We continue to make this identification below although we use the notation $C^d(Y)$.

Now, we define the incidence operator $M_d : C^d(Y) \rightarrow C^{d+1}(Y)$ by

$$M_d f(\eta, \mathbf{v}) = \sum_{j \in \eta} \{f(\eta_j, \mathbf{v}) + f(\eta_j, S_j \mathbf{v})\} \quad \text{for } \eta \in K_d,$$

where $\eta_j = \eta \setminus \{j\}$, $\mathbf{v} = (v_1, \dots, v_q) \in V$ and $S_j \mathbf{v} = (v_1, \dots, v_j + 1, \dots, v_q)$. Equivalently, we can write M_d as

$$M_d f(\eta, \mathbf{v}) = \sum_{\sigma \in K_{d-1} : \sigma \subset \eta} \{f(\sigma, \mathbf{v}) + f(\sigma, S_{\eta \setminus \sigma} \mathbf{v})\} \quad \text{for } \eta \in K_d.$$

The matrix representation of M_d is nothing but the incidence matrix between Y_d and Y_{d-1} . The dual operator $M_d^* : C^{d+1}(Y) \rightarrow C^d(Y)$ of M_d with respect to the inner product

$$(2.1) \quad \langle f, g \rangle_{C^d(Y)} := |V|^{-1} \sum_{\sigma \in K_{d-1}} \sum_{\mathbf{v} \in V} f(\sigma, \mathbf{v}) \overline{g(\sigma, \mathbf{v})}$$

is given by

$$M_d^* f(\sigma, \mathbf{v}) = \sum_{\eta \in K_d : \eta \supset \sigma} \{f(\eta, \mathbf{v}) + f(\eta, S_{\eta \setminus \sigma}^{-1} \mathbf{v})\} \quad \text{for } \sigma \in K_{d-1}.$$

Let $\hat{\mathbb{Z}}_{n_j}$ be the character group of \mathbb{Z}_{n_j} . An element z_j of $\hat{\mathbb{Z}}_{n_j}$ is expressed as $z_j = \exp(2\pi\sqrt{-1}k_j/n_j)$ for some $k_j \in \mathbb{Z}_{n_j}$. We write $\hat{V} := \hat{\mathbb{Z}}_{n_1} \times \cdots \times \hat{\mathbb{Z}}_{n_q}$. For $\mathbf{z} = (z_1, \dots, z_q) \in \hat{V}$, we consider a subspace $C_{\mathbf{z}}^d$ of $C^d(Y)$ defined by

$$C_{\mathbf{z}}^d := C_{\mathbf{z}}^d(Y) := \{f \in C^d(Y) : S_j f = z_j f \text{ for any } j \in K_0\},$$

where $S_j f(\sigma, \mathbf{v}) := f(\sigma, S_j \mathbf{v})$. It is clear that $\dim C_{\mathbf{z}}^d = |K_{d-1}| = \binom{q}{d}$, and $C_{\mathbf{z}}^d$ and $C_{\mathbf{w}}^d$ are orthogonal unless $\mathbf{z} = \mathbf{w}$. Hence, we have the orthogonal decomposition

$$C^d(Y) = \bigoplus_{\mathbf{z} \in \hat{V}} C_{\mathbf{z}}^d.$$

For $\mathbf{z} = (z_1, \dots, z_q) \in \hat{V}$, we also consider the map $U_{\mathbf{z}} : C^d(K_{d-1}) \rightarrow C_{\mathbf{z}}^d(Y)$ defined by

$$U_{\mathbf{z}} f(\sigma, \mathbf{v}) = f(\sigma) \mathbf{z}^{\mathbf{v}} \quad (\sigma \in K_{d-1}, \mathbf{v} \in V),$$

where $\mathbf{z}^{\mathbf{v}} = \prod_{j=1}^q z_j^{v_j}$. Then, it is easy to see that $\langle U_{\mathbf{z}} f, U_{\mathbf{z}} g \rangle_{C^d(Y)} = \langle f, g \rangle_{C^d(K_{d-1})}$, i.e., $U_{\mathbf{z}}$ is unitary. The inverse map $U_{\mathbf{z}}^{-1} : C_{\mathbf{z}}^d(Y) \rightarrow C^d(K_{d-1})$ is the finite Fourier transform given by

$$(U_{\mathbf{z}}^{-1} f)(\sigma) = \frac{1}{|V|} \sum_{\mathbf{v} \in V} f(\sigma, \mathbf{v}) \mathbf{z}^{-\mathbf{v}} \quad \text{for } \sigma \in K_{d-1}.$$

Since $f(\sigma, \mathbf{v}) \in C_{\mathbf{z}}^d$, we see that $(U_{\mathbf{z}}^{-1} f)(\sigma) = f(\sigma, \mathbf{0})$.

Lemma 2.1. For $d = 0, 1, \dots, q-1$, the operator M_d (also M_d^*) preserves each fiber of \mathbf{z} , i.e., $M_d C_{\mathbf{z}}^d \subset C_{\mathbf{z}}^{d+1}$ (also $M_d^* C_{\mathbf{z}}^{d+1} \subset C_{\mathbf{z}}^d$).

Proof. It is easily verified. □

The restriction M_d on each fiber \mathbf{z} is called the twisted operator of M_d and denoted by $M_d(\mathbf{z})$. Thus, we have the following direct sum decomposition:

$$M_d = \bigoplus_{\mathbf{z} \in \hat{V}} M_d(\mathbf{z}) : \bigoplus_{\mathbf{z} \in \hat{V}} C_{\mathbf{z}}^d \rightarrow \bigoplus_{\mathbf{z} \in \hat{V}} C_{\mathbf{z}}^{d+1}.$$

The situation for $M_d^* : C^{d+1}(Y) \rightarrow C^d(Y)$ is similar.

Lemma 2.2. For $\mathbf{z} \in \hat{V}$,

$$\begin{aligned} (M_d(\mathbf{z})f)(\eta, \mathbf{v}) &= \sum_{\sigma \in K_{d-1} : \sigma \subset \eta} (1 + z_{\eta \setminus \sigma}) f(\sigma, \mathbf{v}), \\ (M_d^*(\mathbf{z})f)(\sigma, \mathbf{v}) &= \sum_{\eta \in K_d : \eta \supset \sigma} (1 + z_{\eta \setminus \sigma}^{-1}) f(\eta, \mathbf{v}). \end{aligned}$$

Proof. By the definition of M_d and $f \in C_{\mathbf{z}}^d$, we see that

$$\begin{aligned} M_d(\mathbf{z})f(\eta, \mathbf{v}) &= \sum_{\sigma \in K_{d-1}: \sigma \subset \eta} \{f(\sigma, \mathbf{v}) + f(\sigma, S_{\eta \setminus \sigma} \mathbf{v})\} \\ &= \sum_{\sigma \in K_{d-1}: \sigma \subset \eta} (1 + z_{\eta \setminus \sigma})f(\sigma, \mathbf{v}). \end{aligned}$$

The proof for $M_d^*(\mathbf{z})$ is similar. \square

The operator $\tilde{M}_d(\mathbf{z}) := U_{\mathbf{z}}^{-1} M_d(\mathbf{z}) U_{\mathbf{z}} : C^d(K_{d-1}) \rightarrow C^{d+1}(K_d)$ is unitarily equivalent to $M_d(\mathbf{z})$ so that we abuse the notation $M_d(\mathbf{z})$ for $\tilde{M}_d(\mathbf{z})$ in what follows.

The matrix representation of $M_d(\mathbf{z})$ is the $|K_d| \times |K_{d-1}|$ -matrix whose (η, σ) -element is given by $(1 + z_{\eta \setminus \sigma})\mathbf{1}(\sigma \subset \eta)$, where $\mathbf{1}(\sigma \subset \eta) = 1$ if $\sigma \subset \eta$; 0 otherwise. Similarly, the matrix representation of $M_d^*(\mathbf{z})$ is the $|K_{d-1}| \times |K_d|$ -matrix whose (σ, η) -element is given by $(1 + z_{\eta \setminus \sigma}^{-1})\mathbf{1}(\sigma \subset \eta)$.

Let $A_d^{\text{up}} = M_d^* M_d$ and $A_d^{\text{down}} = M_{d-1} M_{d-1}^*$, both acting on $C^d(Y)$. They also have the direct sum decompositions

$$A_d^{\text{up}} = \bigoplus_{\mathbf{z} \in \hat{V}} A_d^{\text{up}}(\mathbf{z}), \quad A_d^{\text{down}} = \bigoplus_{\mathbf{z} \in \hat{V}} A_d^{\text{down}}(\mathbf{z}),$$

where $A_d^{\text{up}}(\mathbf{z}) = M_d^*(\mathbf{z}) M_d(\mathbf{z})$ and $A_d^{\text{down}}(\mathbf{z}) = M_{d-1}(\mathbf{z}) M_{d-1}^*(\mathbf{z})$ act on $C_{\mathbf{z}}^d$.

In the following lemma, we use the metric on K_{d-1} defined by $\rho(\sigma, \sigma') := |\sigma \setminus \sigma'| (= |\sigma' \setminus \sigma|)$.

Lemma 2.3. The (σ, σ') -element of the matrix representation of $A_d^{\text{up}}(\mathbf{z})$ is given by

$$a_{\sigma\sigma'}^{\text{up}}(\mathbf{z}) = \begin{cases} \sum_{\eta \in K_d: \eta \supset \sigma} (1 + z_{\eta \setminus \sigma}^{-1})(1 + z_{\eta \setminus \sigma}) & \text{if } \rho(\sigma, \sigma') = 0 \text{ (i.e., } \sigma = \sigma'), \\ (1 + z_{\sigma' \setminus \sigma}^{-1})(1 + z_{\sigma \setminus \sigma'}) & \text{if } \rho(\sigma, \sigma') = 1, \\ 0 & \text{if } \rho(\sigma, \sigma') \geq 2, \end{cases}$$

and the set of eigenvalues of A_d^{up} coincides with the union of the sets of eigenvalues of $A_d^{\text{up}}(\mathbf{z}) = (a_{\sigma\sigma'}^{\text{up}}(\mathbf{z}))_{\sigma, \sigma' \in K_{d-1}}$ for $\mathbf{z} \in \hat{V}$, i.e.,

$$\text{Spec}(A_d^{\text{up}}) = \bigsqcup_{\mathbf{z} \in \hat{V}} \text{Spec}(A_d^{\text{up}}(\mathbf{z})).$$

Similarly, the (σ, σ') -element of the matrix representation of $A_d^{\text{down}}(\mathbf{z})$ is given by

$$a_{\sigma\sigma'}^{\text{down}}(\mathbf{z}) = \begin{cases} \sum_{\tau \in K_{d-2}: \tau \subset \sigma} (1 + z_{\sigma \setminus \tau})(1 + z_{\sigma \setminus \tau}^{-1}) & \text{if } \rho(\sigma, \sigma') = 0, \\ (1 + z_{\sigma \setminus \sigma'})(1 + z_{\sigma' \setminus \sigma}^{-1}) & \text{if } \rho(\sigma, \sigma') = 1, \\ 0 & \text{if } \rho(\sigma, \sigma') \geq 2, \end{cases}$$

and the set of eigenvalues of A_d^{down} coincides with the union of the sets of eigenvalues of $A_d^{\text{down}}(\mathbf{z}) = (a_{\sigma\sigma'}^{\text{down}}(\mathbf{z}))_{\sigma, \sigma' \in K_{d-1}}$ for $\mathbf{z} \in \hat{V}$, i.e.,

$$\text{Spec}(A_d^{\text{down}}) = \bigsqcup_{\mathbf{z} \in \hat{V}} \text{Spec}(A_d^{\text{down}}(\mathbf{z})).$$

Proof. For $\mathbf{z} \in \hat{V}$, we have

$$a_{\sigma\sigma'}^{\text{up}}(\mathbf{z}) = \sum_{\eta \in K_d} (1 + z_{\eta \setminus \sigma}^{-1})(1 + z_{\eta \setminus \sigma'}) \mathbf{1}(\eta \supset \sigma \cup \sigma'),$$

$$a_{\sigma\sigma'}^{\text{down}}(\mathbf{z}) = \sum_{\tau \in K_{d-2}} (1 + z_{\sigma \setminus \tau})(1 + z_{\sigma' \setminus \tau}^{-1}) \mathbf{1}(\tau \subset \sigma \cap \sigma').$$

If $\rho(\sigma, \sigma') \geq 2$, then $\mathbf{1}(\eta \supset \sigma \cup \sigma') = \mathbf{1}(\tau \subset \sigma \cap \sigma') = 0$. If $\rho(\sigma, \sigma') = 1$, then η (resp. τ) must coincide with $\sigma \cup \sigma'$ (resp. $\sigma \cap \sigma'$) when $\eta \supset \sigma \cup \sigma'$ (resp. $\tau \subset \sigma \cap \sigma'$). We thus obtain the desired expressions. \square

Note that when $q \geq 2d - 1$, which is equivalent to $\binom{q}{d} \geq \binom{q}{d-1}$, we have

$$\text{Spec} \left(A_d^{\text{down}}(\mathbf{z}) \right) = \text{Spec} \left(A_{d-1}^{\text{up}}(\mathbf{z}) \right) \cup \{0\},$$

with the multiplicity of 0 being $\binom{q}{d} - \binom{q}{d-1}$, and similarly, when $q \leq 2d - 1$, we have

$$\text{Spec} \left(A_{d-1}^{\text{up}}(\mathbf{z}) \right) = \text{Spec} \left(A_d^{\text{down}}(\mathbf{z}) \right) \cup \{0\},$$

with the multiplicity of 0 being $\binom{q}{d-1} - \binom{q}{d}$.

Corollary 2.4. The eigenvalues of $A_q^{\text{down}} : C^q(Y) \rightarrow C^q(Y)$ on the periodic q -cubical lattice Y are $\{\sum_{j=1}^q 2\{1 + \cos(2\pi k_j/n_j)\} : k_j \in \mathbb{Z}_{n_j}\}$.

Proof. From Lemma 2.3, we know that $A_q^{\text{down}}(\mathbf{z})$ is a scalar and equal to $\sum_{j=1}^q (1 + z_j^{-1})(1 + z_j)$. Therefore, the eigenvalues of A_q^{down} are given by $\{\sum_{j=1}^q (1 + z_j^{-1})(1 + z_j) : z_j \in \hat{\mathbb{Z}}_{n_j}\}$. The assertion follows directly. \square

2.2. Eigenvalues of Laplacians. Techniques similar to those used in the previous section can be applied to eigenvalue problems of Laplacians.

For $\sigma, \tau \in K$ with $\tau \subset \sigma$ and $|\sigma \setminus \tau| = 1$, we write $\text{sgn}(\sigma, \tau) = (-1)^{j-1}$ if $\sigma \setminus \tau$ is in the j th position of σ in lexicographic order. For example, $\text{sgn}(134, 34) = 1$, $\text{sgn}(134, 14) = -1$ and $\text{sgn}(134, 13) = 1$.

For $d = 0, 1, \dots, q - 1$, let $\delta_d : C^d(Y) \rightarrow C^{d+1}(Y)$ be defined by

$$\delta_d f(\eta, \mathbf{v}) = \sum_{\sigma \in K_{d-1} : \sigma \subset \eta} \text{sgn}(\eta, \sigma) \{f(\sigma, S_{\eta \setminus \sigma} \mathbf{v}) - f(\sigma, \mathbf{v})\} \quad \text{for } \eta \in K_d.$$

The dual operator of δ_d , δ_d^* , is defined analogously to M_d^* with respect to the inner product (2.1). As in the previous subsection, because both δ_d and δ_d^* preserve the fiber of \mathbf{z} , the operators δ_d and δ_d^* can be decomposed into the direct sums $\oplus_{\mathbf{z} \in \hat{V}} \delta_d(\mathbf{z})$ and $\oplus_{\mathbf{z} \in \hat{V}} \delta_d^*(\mathbf{z})$, respectively. As in the proof of Lemma 2.2, we easily see that

$$\delta_d(\mathbf{z})f(\eta, \mathbf{v}) = \sum_{\sigma \in K_{d-1} : \sigma \subset \eta} \text{sgn}(\eta, \sigma)(z_{\eta \setminus \sigma} - 1)f(\sigma, \mathbf{v}) \quad \text{for } \eta \in K_d,$$

$$\delta_d^*(\mathbf{z})f(\sigma, \mathbf{v}) = \sum_{\eta \in K_d : \eta \supset \sigma} \text{sgn}(\eta, \sigma)(z_{\eta \setminus \sigma}^{-1} - 1)f(\eta, \mathbf{v}) \quad \text{for } \sigma \in K_{d-1}.$$

Lemma 2.5. For $d = 0, 1, \dots, q - 1$, let $g : K_0 \rightarrow \mathbb{C}$ and define $G_d : C^d(Y) \rightarrow C^{d+1}(Y)$ by

$$G_d f(\eta) = \sum_{\sigma \in K_{d-1} : \sigma \subset \eta} \text{sgn}(\eta, \sigma) g(\eta \setminus \sigma) f(\sigma) \quad (\eta \in K_d).$$

Then, $G_{d+1}G_d = 0$. In particular, $\delta_{d+1}(\mathbf{z})\delta_d(\mathbf{z}) = 0$ for any $\mathbf{z} \in \hat{V}$.

Proof. For $f \in C^d(Y)$,

$$\begin{aligned} (G_{d+1}G_d f)(\tau) &= \sum_{\sigma \in K_d: \sigma \subset \eta} \sum_{\tau \in K_{d-1}: \tau \subset \sigma} \operatorname{sgn}(\eta, \sigma) \operatorname{sgn}(\sigma, \tau) g(\eta \setminus \sigma) g(\sigma \setminus \tau) f(\tau) \\ &= \left(\sum_{1 \leq i < j \leq q} g(i)g(j) \sum_{\{\eta \setminus \sigma, \sigma \setminus \tau\} = \{i, j\}} \operatorname{sgn}(\eta, \sigma) \operatorname{sgn}(\sigma, \tau) \right) f(\tau) \\ &= 0. \end{aligned}$$

The last sum is taken separately for two cases, $(\eta \setminus \sigma, \sigma \setminus \tau) = (i, j)$ and (j, i) , which is equal to 0 as usual. \square

From this lemma, we have the cochain complex

$$\cdots \rightarrow C_{\mathbf{z}}^{d-1} \xrightarrow{\delta_{d-1}(\mathbf{z})} C_{\mathbf{z}}^d \xrightarrow{\delta_d(\mathbf{z})} C_{\mathbf{z}}^{d+1} \rightarrow \cdots,$$

and hence the cohomology group $H_{\mathbf{z}}^d := \ker \delta_d(\mathbf{z}) / \operatorname{Im} \delta_{d-1}(\mathbf{z})$ is defined.

Lemma 2.6. For all $d = 0, 1, \dots, q-1$ and $\mathbf{z} \in \hat{V}$, the cohomology group $H_{\mathbf{z}}^d$ is trivial for $\mathbf{z} \neq \mathbf{1}$ and $H_{\mathbf{1}}^d = C_{\mathbf{1}}^d \simeq \mathbb{C}^{\binom{q}{d}}$.

Proof. First, we note that $H^d(Y) = \bigoplus_{\mathbf{z} \in \hat{V}} H_{\mathbf{z}}^d$ is the d th cohomology of the q -dimensional torus and is given by $H^d(Y) = \mathbb{C}^{\binom{q}{d}}$. For $\mathbf{z} = \mathbf{1}$, since $\delta_d(\mathbf{z}) = 0$, we have $H_{\mathbf{1}}^d = C_{\mathbf{1}}^d \simeq \mathbb{C}^{\binom{q}{d}}$. Hence, $H_{\mathbf{z}}^d = 0$ for $\mathbf{z} \neq \mathbf{1}$. \square

Corollary 2.7. If $\mathbf{z} \neq \mathbf{1}$, then $\dim \ker \delta_d(\mathbf{z}) = \binom{q-1}{d-1}$ and $\dim \ker \delta_{d-1}^*(\mathbf{z}) = \binom{q-1}{d}$ for $d = 0, 1, \dots, q$. Here, $\binom{q-1}{-1} = \binom{q-1}{q} = 0$.

Proof. From the rank-nullity theorem together with Lemma 2.6, we have

$$\binom{q}{d} = \dim \ker \delta_d(\mathbf{z}) + \dim \ker \delta_{d+1}(\mathbf{z}) \quad (d = 0, 1, \dots, q-1).$$

Since $\dim \ker \delta_0(\mathbf{z}) = 0$, taking the alternating sum above yields $\dim \ker \delta_d(\mathbf{z}) = \binom{q-1}{d-1}$. Since $\ker \delta_{d-1}^*(\mathbf{z}) = (\operatorname{Im} \delta_{d-1}(\mathbf{z}))^\perp = (\ker \delta_d(\mathbf{z}))^\perp$, from Lemma 2.6, we have

$$C_{\mathbf{z}}^d = \ker \delta_d(\mathbf{z}) \oplus \ker \delta_{d-1}^*(\mathbf{z}).$$

Therefore, $\dim \ker \delta_{d-1}^*(\mathbf{z}) = \binom{q-1}{d}$. \square

Next, we give the matrix representations for the up/down Laplacians. Let $L_d^{\text{up}} = \delta_d^* \delta_d$ and $L_d^{\text{down}} = \delta_{d-1} \delta_{d-1}^*$. These operators can be decomposed as $L_d^{\text{up}} = \bigoplus_{\mathbf{z} \in \hat{V}} L_d^{\text{up}}(\mathbf{z})$ and $L_d^{\text{down}} = \bigoplus_{\mathbf{z} \in \hat{V}} L_d^{\text{down}}(\mathbf{z})$. As in the case of Lemma 2.3, we have the following.

Lemma 2.8. The (σ, σ') -element of the matrix representation of $L_d^{\text{up}}(\mathbf{z})$ is given by

$$\ell_{\sigma\sigma'}^{\text{up}}(\mathbf{z}) = \sum_{\eta \in K_d: \eta \supset \sigma \cup \sigma'} \operatorname{sgn}(\eta, \sigma) \operatorname{sgn}(\eta, \sigma') (z_{\eta \setminus \sigma}^{-1} - 1)(z_{\eta \setminus \sigma'} - 1)$$

and the (σ, σ') -element of the matrix representation of $L_d^{\text{down}}(\mathbf{z})$ is given by

$$\ell_{\sigma\sigma'}^{\text{down}}(\mathbf{z}) = \sum_{\tau \in K_{d-2}: \tau \subset \sigma \cap \sigma'} \operatorname{sgn}(\sigma, \tau) \operatorname{sgn}(\sigma', \tau) (z_{\sigma \setminus \tau} - 1)(z_{\sigma' \setminus \tau}^{-1} - 1).$$

Corollary 2.9. Suppose K is the complete simplicial complex over $\{1, 2, \dots, q\}$. Then, we have

$$L_d^{\text{up}}(\mathbf{z}) + L_d^{\text{down}}(\mathbf{z}) = \left\{ 2q - \sum_{i=1}^q (z_i + z_i^{-1}) \right\} I.$$

Proof. In Lemma 2.8, we chose $\sigma, \sigma' \in K_{d-1}$. If $\sigma \neq \sigma'$, then $\ell_{\sigma\sigma'}^{\text{up}}(\mathbf{z}) = \ell_{\sigma\sigma'}^{\text{down}}(\mathbf{z}) = 0$ unless $\rho(\sigma, \sigma') = 1$. When $\rho(\sigma, \sigma') = 1$, we see that $\tau = \sigma \cap \sigma'$, $\eta = \sigma \cup \sigma'$, $\sigma \setminus \tau = \eta \setminus \sigma'$ and $\sigma' \setminus \tau = \eta \setminus \sigma$. Using the same argument as in the proof of Lemma 2.5, we obtain

$$\text{sgn}(\sigma \cup \sigma', \sigma) \text{sgn}(\sigma \cup \sigma', \sigma') + \text{sgn}(\sigma, \sigma \cap \sigma') \text{sgn}(\sigma', \sigma \cap \sigma') = 0,$$

and hence $\ell_{\sigma\sigma'}^{\text{up}}(\mathbf{z}) + \ell_{\sigma\sigma'}^{\text{down}}(\mathbf{z}) = 0$. If $\sigma = \sigma'$, then we have

$$\begin{aligned} & \ell_{\sigma\sigma}^{\text{up}}(\mathbf{z}) + \ell_{\sigma\sigma}^{\text{down}}(\mathbf{z}) \\ &= \sum_{\eta \in K_d: \eta \supset \sigma} (z_{\eta \setminus \sigma}^{-1} - 1)(z_{\eta \setminus \sigma} - 1) + \sum_{\tau \in K_{d-2}: \tau \subset \sigma} (z_{\sigma \setminus \tau} - 1)(z_{\sigma \setminus \tau}^{-1} - 1) \\ &= \sum_{i=1}^q (z_i - 1)(z_i^{-1} - 1). \end{aligned}$$

This completes the proof. \square

Lemma 2.10. The eigenvalues of $L_d^{\text{up}}(\mathbf{z})$ (resp. $L_d^{\text{down}}(\mathbf{z})$) on the periodic q -cubical lattice Y are $2q - \sum_{i=1}^q (z_i + z_i^{-1})$ with multiplicity $\binom{q-1}{d}$ (resp. $\binom{q-1}{d-1}$) and 0 with multiplicity $\binom{q-1}{d-1}$ (resp. $\binom{q-1}{d}$).

Proof. By Corollary 2.9, for any $f \in \ker L_d^{\text{down}}(\mathbf{z})$, we have

$$L_d^{\text{up}}(\mathbf{z})f = \left\{ 2q - \sum_{i=1}^q (z_i + z_i^{-1}) \right\} f.$$

Also, for any non-zero $f \in \ker L_d^{\text{up}}(\mathbf{z})$, by definition, $L_d^{\text{up}}(\mathbf{z})f = 0$. Since $\dim \ker L_d^{\text{down}}(\mathbf{z}) = \dim \ker \delta_{d-1}^*(\mathbf{z}) = \binom{q-1}{d}$ and $\dim \ker L_d^{\text{up}}(\mathbf{z}) = \dim \ker \delta_d(\mathbf{z}) = \binom{q-1}{d-1}$ by Corollary 2.7, the space $C_{\mathbf{z}}^d(Y)$ is spanned by those eigenfunctions. \square

Corollary 2.11. The eigenvalues of L_d^{up} are given by

$$(2.2) \quad \text{Spec}(L_d^{\text{up}}) = \left\{ 2q - 2 \sum_{i=1}^q \cos \frac{2\pi k_i}{n_i} : k_i \in \mathbb{Z}_{n_i} \right\} \cup \{0\}.$$

The multiplicity of the eigenvalue $2q - 2 \sum_{i=1}^q \cos \frac{2\pi k_i}{n_i}$ for each $\mathbf{k} = (k_1, \dots, k_q)$ is $\binom{q-1}{d}$, and that of 0 is $\binom{q-1}{d-1} |\mathbf{n}|$.

Note that the eigenvalue for $\mathbf{k} = (0, 0, \dots, 0)$ with multiplicity $\binom{q-1}{d}$ is also 0, but this eigenvalue is represented within the first set of the right-hand side of (2.2), not the second set.

3. ZETA FUNCTIONS OF PERIODIC CUBICAL COMPLEXES

The zeta functions of cubical complexes can be reformulated as those of hypergraphs (see Definition 3.2).

A hypergraph is a pair $H = (V, E)$ of disjoint sets, where V is a non-empty set and the elements of E are non-empty subsets of V . An element of V (resp. E) is called a hypervertex (resp. hyperedge). A hypervertex $v \in V$ is said to be incident to $e \in E$ if v is included in e . The $|V| \times |E|$ -matrix M indexed by the elements of V and E is defined as $M_{v,e} = 1$ if v is incident to e ; 0 otherwise. This is called the incidence matrix for H . The degree, $\deg(v)$, of a hypervertex v is the number of hyperedges that include v , and the degree, $\deg(e)$, of a hyperedge e is the number of hypervertices that are included in

e . A hypergraph $H = (V, E)$ is said to be (a, b) -regular if $\deg(v) = a$ for all $v \in V$ and $\deg(e) = b$ for all $e \in E$.

Example 3.1. (1) When $\deg(e) = 2$ for every $e \in E$, then a hypergraph is nothing but a graph.

(2) A simplicial complex over a set V can be viewed as a hypergraph by regarding all simplices as E .

(3) For a q -dimensional cubical complex, let V be the set of $(d-1)$ -cubes and E the set of d -cubes. Then $H = (V, E)$ forms a hypergraph. In particular, $H = (V, E)$ is a $(2(q-d+1), 2d)$ -regular hypergraph if $V = Y_{d-1}$ and $E = Y_d$ for the periodic q -cubical lattice Y .

A closed path in H is a sequence such that $c = (v_0, e_0, v_1, e_1, \dots, v_{n-1}, e_{n-1})$, where $v_{i+1} \in e_i \cap e_{i+1}$ and $v_i \neq v_{i+1}$ for all $i \in \mathbb{Z}_n$. Note that $v_0 \in e_{n-1} \cap e_0$. The length of c is the number of hyperedges in c , denoted by $|c|$. We say that a closed path c is a closed geodesic if $e_i \neq e_{i+1}$ for all $i \in \mathbb{Z}_{|c|}$. We denote by c^m the m -multiple of a closed geodesic c formed by m repetitions of c . If a closed geodesic c is not expressed as an m -multiple of a closed geodesic with $m \geq 2$, then c is said to be prime. Two prime closed geodesics are said to be equivalent if one is obtained from the other through a cyclic permutation. An equivalence class of prime closed geodesics is called a prime cycle. The length of a prime cycle \mathbf{p} is defined as the length of a representative and is denoted by $|\mathbf{p}|$. The (Ihara) zeta function of a finite hypergraph is defined as follows.

Definition 3.2. For $u \in \mathbb{C}$ with $|u|$ sufficiently small, the (Ihara) zeta function of a finite hypergraph H is defined by

$$\zeta_H(u) = \prod_{\mathbf{p} \in P} (1 - u^{|\mathbf{p}|})^{-1},$$

where P is the set of prime cycles of H .

The factorization theorem for zeta functions of finite graphs was obtained by H. Bass [1] and a conceptually simpler proof employing oriented linegraph structure was given by Kotani-Sunada [5].

One can associate with a hypergraph $H = (V, E)$ a bipartite graph B_H whose vertex partite sets are V and E , and the incidence relation gives edges in B_H , i.e., $V(B_H) = V \sqcup E$ and every edge in $E(B_H)$ connects a vertex in V to one in E ; $v \in V$ and $e \in E$ are joined when $v \in e$. The definition of prime cycles given above fits for the cycle structure of B_H when $\deg(v) \geq 2$ for all $v \in V$ as discussed in [6], and hence the theorem for graphs can be extended to the hypergraph setting as follows:

Theorem 3.3 ([6]). Let $H = (V, E)$ be a finite, connected hypergraph such that $\deg(v) \geq 2$ for all $v \in V$ with adjacency matrix A and diagonal degree matrix D in B_H . Then,

$$\zeta_H(u) = (1 - u)^{\chi(B_H)} \det(I - \sqrt{u}A + uQ)^{-1},$$

where I is the $m \times m$ identity matrix with $m = |V| + |E|$, $Q = D - I$, B_H is the bipartite graph associated with H , and $\chi(B_H) = |V| - |E|$ is the Euler characteristic of B_H .

In the above theorem, although \sqrt{u} appears in the expression, the zeta function is a rational function of u , because the length of the corresponding cycle in B_H of a cycle in H is doubled. The colored, oriented linegraph is constructed from H in the proof given in [6], which is based on an idea presented in [5].

The following theorem can also be regarded as a restatement of Hashimoto's theorem on zeta functions of semi-regular graphs because the bipartite graph B_H is (a, b) -semi-regular

when H is (a, b) -regular. The number of vertices in B_H is $|V| + |E|$ and that of edges in B_H is $a|V| = b|E|$. We can define the dual hypergraph H^* of $H = (V, E)$ by interchanging the roles of partite sets in B_H , i.e., $H^* = (E, E_V)$ with the incidence relation determined by B_H , where $E_V := \{A_v \subset E : v \in V\}$ with $A_v := \{e \in E : e \ni v\}$ for $v \in V$. Clearly, H^* is (b, a) -regular if H is (a, b) -regular. Also, it is clear that $\zeta_H(u) = \zeta_{H^*}(u)$ because the cycle structures in H and H^* are identical since $B_H = B_{H^*}$ as graphs.

Theorem 3.4 ([6]). Let $H = (V, E)$ be a finite connected (a, b) -regular hypergraph with $a, b \geq 2$, and let M be the incidence matrix between V and E . Let $\alpha = a - 1$ and $\beta = b - 1$. Then,

$$\begin{aligned}\zeta_H(u)^{-1} &= (1 - u)^{-\chi(B_H)}(1 + \beta u)^{|E| - |V|} \det((1 + \alpha u)(1 + \beta u)I_V - uMM^*) \\ &= (1 - u)^{-\chi(B_H)}(1 + \alpha u)^{|V| - |E|} \det((1 + \alpha u)(1 + \beta u)I_E - uM^*M),\end{aligned}$$

where $\chi(B_H) = |E| - \alpha|V| = |V| - \beta|E|$, and I_V (resp. I_E) is the $|V| \times |V|$ (resp. $|E| \times |E|$) identity matrix.

Proof. In Theorem 3.3, the adjacency matrix A and the diagonal matrix Q are expressed by $A = \begin{pmatrix} O & M \\ M^* & O \end{pmatrix}$ and $Q = \begin{pmatrix} \alpha I_V & O \\ O & \beta I_E \end{pmatrix}$. Using the determinantal identity

$$(3.1) \quad \det \begin{pmatrix} P_{11} & P_{12} \\ P_{21} & P_{22} \end{pmatrix} = \det P_{11} \cdot \det(P_{22} - P_{21}P_{11}^{-1}P_{12}),$$

we obtain

$$\begin{aligned}\det(I - \sqrt{u}A + uQ) &= (1 + \alpha u)^{|V|} \cdot (1 + \alpha u)^{-|E|} \det((1 + \alpha u)(1 + \beta u)I_E - uM^*M).\end{aligned}$$

The second equality is obtained in the same way by changing the roles of 1 and 2 in (3.1). \square

Theorem 3.4 together with Corollary 2.4 yields the following theorem.

Theorem 3.5. Let Y be a d -dimensional cubical lattice with side length $\mathbf{n} = (n_1, n_2, \dots, n_q)$ and $Y^{(d)}$ its d -skeleton. Let $A_{d-1}^{\text{up}}(\mathbf{z})$ (resp. $A_d^{\text{down}}(\mathbf{z})$) on $C_{\mathbf{z}}^{d-1}$ (resp. $C_{\mathbf{z}}^d$) be the twisted adjacency operator. Then,

$$\begin{aligned}\zeta_{Y^{(d)}}(u)^{-1} &= (1 - u)^{\kappa_d|\mathbf{n}|}(1 + \beta_d u)^{\gamma_d|\mathbf{n}|} \\ &\quad \times \prod_{\mathbf{z} \in \hat{V}} \det((1 + \alpha_d u)(1 + \beta_d u)I_{K_{d-2}} - uA_{d-1}^{\text{up}}(\mathbf{z})) \\ &= (1 - u)^{\kappa_d|\mathbf{n}|}(1 + \alpha_d u)^{-\gamma_d|\mathbf{n}|} \\ &\quad \prod_{\mathbf{z} \in \hat{V}} \det((1 + \alpha_d u)(1 + \beta_d u)I_{K_{d-1}} - uA_d^{\text{down}}(\mathbf{z})),\end{aligned}$$

where $\alpha_d = 2q - 2d + 1$, $\beta_d = 2d - 1$, $\gamma_d = \binom{q}{d} - \binom{q}{d-1}$ and $\kappa_d = (q - d)\binom{q}{d-1} + (d - 1)\binom{q}{d}$.

Proof. We consider the case in which $V = Y_{d-1}$ and $E = Y_d$. Then $H = (V, E)$ is $(2(q - d + 1), 2d)$ -regular as in Example 3.1(3) and $-\chi(B_H) = \kappa_d|\mathbf{n}|$. Since the incidence matrix M in Theorem 3.4 is set to be $\oplus_{\mathbf{z} \in \hat{V}} M_{d-1}(\mathbf{z})$, we have $M_{d-1}(\mathbf{z})M_{d-1}^*(\mathbf{z}) = A_d^{\text{down}}(\mathbf{z})$,

and hence

$$\begin{aligned}\zeta_{Y^{(d)}}(u)^{-1} &= (1-u)^{\kappa_d|\mathbf{n}|}(1+\alpha_d u)^{|Y_{d-1}|-|Y_d|} \\ &\quad \times \prod_{\mathbf{z} \in \hat{V}} \det \left\{ (1+\alpha_d u)(1+\beta_d u)I_{K_{d-1}} - uA_d^{\text{down}}(\mathbf{z}) \right\},\end{aligned}$$

where $\alpha_d = 2(q-d) + 1$, $\beta_d = 2d - 1$. The second equality is obtained similarly. This completes the proof. \square

Remark 3.6. (1) The former expression is useful for $q \geq 2d - 1$, while the latter is useful for $q \leq 2d - 1$ as these two conditions are equivalent to $\gamma_d \geq 0$ and $\gamma_d \leq 0$, respectively. (2) The map $d \mapsto q - d + 1$ leaves α_d, β_d and κ_d invariant, and $\gamma_{q-d+1} = -\gamma_d$. It follows from this invariance that $\zeta_{Y^{(q-d+1)}}(u) = \zeta_{Y^{(d)}}(u)$.

We obtain Theorem 1.2 as a special case of Theorem 3.5.

Proof of Theorem 1.2. We consider the case $d = q$, i.e., $V = Y_{q-1}$ and $E = Y_q$. Then $H = (V, E)$ is $(2, 2q)$ -regular as in Example 3.1(3). In this case, $A_q^{\text{down}}(\mathbf{z}) = M_{q-1}(\mathbf{z})M_{q-1}^*(\mathbf{z})$ is a scalar, and we have $A_q^{\text{down}}(\mathbf{z}) = \sum_{i=1}^q 2(1+\cos\theta_i)$ from Corollary 2.4, where $\theta_i = 2\pi k_i/n_i$. Then, from Theorem 3.5, we have

$$\begin{aligned}\zeta_Y(u)^{-1} &= (1-u)^{\kappa_q|\mathbf{n}|}(1+\alpha_q u)^{\gamma_q|\mathbf{n}|} \\ &\quad \times \prod_{k_1=1}^{n_1} \cdots \prod_{k_q=1}^{n_q} \left\{ (1+\alpha_q u)(1+\beta_q u) - u \sum_{i=1}^q 2(1+\cos\theta_i) \right\},\end{aligned}$$

where $\alpha_q = 1$, $\beta_q = 2q - 1$ and $\kappa_q = \gamma_q = q - 1$. Therefore, we obtain

$$\zeta_Y(u)^{-1} = (1-u^2)^{(q-1)|\mathbf{n}|} \prod_{k_1=1}^{n_1} \cdots \prod_{k_q=1}^{n_q} \left\{ 1 - 2u \sum_{i=1}^q \cos\theta_i + (2q-1)u^2 \right\}.$$

This completes the proof. \square

We denote by $e_k(\mathbf{t})$ the k th elementary symmetric polynomial of $\mathbf{t} = (t_1, \dots, t_q)$ defined by the expansion formula

$$(3.2) \quad \prod_{k=1}^q (\lambda + t_k) = \sum_{k=0}^q e_k(\mathbf{t}) \lambda^{q-k}.$$

Proposition 3.7. Let $w_i = 2 + z_i + z_i^{-1}$. Then,

$$\det(t - uA_1^{\text{up}}(\mathbf{z})) = \sum_{k=0}^q (2-k)2^{k-1}e_k(\mathbf{w})(t - ue_1(\mathbf{w}))^{q-k}u^k.$$

Proof. From Lemma 2.3, we see that the (j, j) -element of the matrix $A_1^{\text{up}}(\mathbf{z}) - e_1(\mathbf{w})I_q$ is given by

$$\sum_{k \neq j} (1 + z_k^{-1})(1 + z_k) - \sum_{k=1}^q (1 + z_k^{-1})(1 + z_k^{-1}) = -(1 + z_j^{-1})(1 + z_j).$$

Thus we have

$$A_1^{\text{up}}(\mathbf{z}) - e_1(\mathbf{w})I_q = D_{\mathbf{1}+\mathbf{z}^{-1}}(J_q - 2I_q)D_{\mathbf{1}+\mathbf{z}},$$

where J_q is the $q \times q$ matrix whose elements are all 1, $D_{\mathbf{1}+\mathbf{z}}$ (resp. $D_{\mathbf{1}+\mathbf{z}^{-1}}$) is the diagonal matrix whose (j, j) -element is $(1 + z_j)$ (resp. $(1 + z_j^{-1})$). Hence, setting $\lambda = t - e_1(\mathbf{w})$, we obtain

$$\begin{aligned}\det(t - A_1^{\text{up}}(\mathbf{z})) &= \det(\lambda - D_{\mathbf{1}+\mathbf{z}^{-1}}(J_q - 2I_q)D_{\mathbf{1}+\mathbf{z}}) \\ &= \det(\lambda - (J_q - 2I_q)D_{\mathbf{w}}) \\ &= \det D_{\mathbf{w}} \det((\lambda D_{\mathbf{w}^{-1}} + 2I_q) - J_q).\end{aligned}$$

It is easy to see that for any $\mathbf{a} = (a_1, \dots, a_q)$ the relation

$$\det(D_{\mathbf{a}} - J_q) = e_q(\mathbf{a}) - e_{q-1}(\mathbf{a})$$

holds. Thus we obtain

$$\det(t - A_1^{\text{up}}(\mathbf{z})) = \left(1 - \frac{q}{2} + \frac{\lambda}{2} \frac{\partial}{\partial \lambda}\right) \prod_{i=1}^q (\lambda + 2w_i) \Big|_{\lambda=t-e_1(\mathbf{w})}.$$

Expanding the right-hand side in λ and using (3.2), we reach the desired relation. \square

Proof of the latter half of Theorem 1.2. A simple calculation shows that

$$\zeta_{Y(2)}(u)^{-1} = (1 - u)^{\kappa_2|\mathbf{n}|} (1 + 3u)^{\gamma_2|\mathbf{n}|} \times \prod_{\mathbf{z} \in \hat{V}} F_1^{\text{up}}(u, \mathbf{z}),$$

where $\kappa_2 = q(3q - 5)/2$, $\gamma_2 = q(q - 3)/2$ and

$$F_1^{\text{up}}(u, \mathbf{z}) = \sum_{k=0}^q (2 - k) 2^{k-1} e_k(\mathbf{w}) \left(1 - u \sum_{i=1}^q (z_i + z_i^{-1}) + 3(2q - 3)u^2\right)^{q-k} u^k.$$

\square

We remark that the right-hand sides of the two expressions in Theorem 1.2 must coincide for $q = 2$ by symmetry. Indeed, when $q = 2$, we see that $\kappa = 1$, $\gamma = -1$ and $F_1^{\text{up}}(u, \mathbf{z}) = (1 + u)(1 + 3u)(1 - u \sum_{i=1}^2 (z_i + z_i^{-1}) + 3u^2)$. Thus, in this case, both of these are equal to $(1 - u^2)^{|\mathbf{n}|} \prod_{k_1=1}^{n_1} \prod_{k_2=1}^{n_2} (1 - 2u \sum_{i=1}^2 \cos 2\pi k_i/n_i + 3u^2)$.

4. CYCLOTOMIC-LIKE POLYNOMIALS

For $\mathbf{d} = (d_1, \dots, d_q) \in \mathbb{N}^q$, we define the following polynomial in x :

$$(4.1) \quad \Psi_{\mathbf{d}}(x) := \prod_{j_1 \in J_{d_1}} \cdots \prod_{j_q \in J_{d_q}} \left(x - 2 \sum_{i=1}^q \cos \frac{2\pi j_i}{d_i}\right),$$

With the notation used in Introduction, this would be written $\Psi_{\mathbf{d}}(x, 1)$, but here, we use the above more concise notation. Since the homogeneous polynomial $\Psi_{\mathbf{d}}(x, y)$ can be recovered from $\Psi_{\mathbf{d}}(x)$, hereafter we focus on $\Psi_{\mathbf{d}}(x)$. We note that $\Psi_{\mathbf{d}} = \Psi_{\mathbf{d}'}$ when \mathbf{d}' is a permutation of \mathbf{d} and that the degree of $\Psi_{\mathbf{d}}$ is equal to $\prod_{i=1}^q \tilde{\varphi}(d_i)$. For $q = 1$, there is a known explicit form of $\Psi_d(x)$ that can be obtained using cyclotomic polynomials.

Lemma 4.1. Suppose $q = 1$. Then $z^{\tilde{\varphi}(d)} \Psi_d(z + z^{-1})$ is the d th cyclotomic polynomial for $d \geq 3$ and the square of that for $d = 1, 2$. Moreover, $\Psi_d(x)$ is irreducible for any $d \in \mathbb{N}$.

Proof. The proof is trivial for $d = 1, 2$. Suppose $d \geq 3$. It is easily seen that $z^{\tilde{\varphi}(d)} \Psi_d(z + z^{-1})$ is a monic polynomial in z of degree $2\tilde{\varphi}(d)$, since the degree of $\Psi_d(x) \in \mathbb{Z}[x]$ is $\tilde{\varphi}(d)$. This polynomial has the following $\varphi(d) = 2|J_d|$ distinct roots

$$\{z = \exp(2\pi\sqrt{-1}j/d) \mid j \in J_d\} \cup \{z = \exp(-2\pi\sqrt{-1}j/d) \mid j \in J_d\}.$$

These properties characterize the cyclotomic polynomial. If $\Psi_d(x)$ is reducible, then so is $\Psi_d(z + z^{-1})$. This contradicts the irreducibility of cyclotomic polynomials. \square

Example 4.2. $\Phi_d(x)$ is the d th cyclotomic polynomial, and $\Psi_d(x)$ is that defined in (4.1) for $q = 1$. We have the following explicit forms:

$$\begin{array}{ll}
\Phi_1(x) = x - 1 & \Psi_1(x) = x - 2 \\
\Phi_2(x) = x + 1 & \Psi_2(x) = x + 2 \\
\Phi_3(x) = x^2 + x + 1 & \Psi_3(x) = x + 1 \\
\Phi_4(x) = x^2 + 1 & \Psi_4(x) = x \\
\Phi_5(x) = x^4 + x^3 + x^2 + x + 1 & \Psi_5(x) = x^2 + x - 1 \\
\Phi_6(x) = x^2 - x + 1 & \Psi_6(x) = x - 1 \\
\Phi_7(x) = x^6 + x^5 + x^4 + x^3 + x^2 + x + 1 & \Psi_7(x) = x^3 + x^2 - 2x - 1 \\
\Phi_8(x) = x^4 + 1 & \Psi_8(x) = x^2 - 2 \\
\Phi_9(x) = x^6 + x^3 + 1 & \Psi_9(x) = x^3 - 3x + 1 \\
\Phi_{10}(x) = x^4 - x^3 + x^2 - x + 1 & \Psi_{10}(x) = x^2 - x - 1
\end{array}$$

Suppose that $d_1 = 1, 2, 3, 4$ or 6 . Then, for $\mathbf{d}' = (d_2, \dots, d_q)$, we have $\Psi_{\mathbf{d}}(x) = \Psi_{\mathbf{d}'}(\Psi_{d_1}(x))$ since $J_{d_1} = \{1\}$. From this observation, one can compute several $\Psi_{\mathbf{d}}$ s by using the above table.

In Theorem 1.2, the polynomial

$$(4.2) \quad F_{\mathbf{n}}(x, y) := \prod_{k_1=1}^{n_1} \cdots \prod_{k_q=1}^{n_q} \left(x - 2y \sum_{i=1}^q \cos \frac{2\pi k_i}{n_i} \right)$$

appears. This polynomial can be decomposed in terms of $\Psi_{\mathbf{d}}(x, y)$ as $x^n - 1$ is decomposed into a product of cyclotomic polynomials $\Phi_d(x)$.

Proof of Theorem 1.3. Let $\tilde{J}_d = \{j \in \{1, 2, \dots, d\} : \gcd(j, d) = 1\}$. We note that

$$\left\{ \frac{k}{n} \mid k \in \{1, 2, \dots, n\} \right\} = \bigsqcup_{d|n} \left\{ \frac{j}{d} \mid j \in \tilde{J}_d \right\}$$

and each set on the right-hand side can be further decomposed as

$$\left\{ \frac{j}{d} \mid j \in \tilde{J}_d \right\} = \begin{cases} \left\{ \frac{j}{d} \mid j \in J_d \right\} \sqcup \left\{ \frac{d-j}{d} \mid j \in J_d \right\} & \text{for } d \geq 3, \\ \left\{ \frac{j}{d} \mid j \in J_d \right\} & \text{for } d = 1, 2. \end{cases}$$

Therefore, we have

$$\begin{aligned}
F_{\mathbf{n}}(x, y) &= \prod_{d_1|n_1} \cdots \prod_{d_q|n_q} \prod_{j_1 \in J_{d_1}} \cdots \prod_{j_q \in J_{d_q}} \left(x - 2y \sum_{i=1}^q \cos \frac{2\pi j_i}{d_i} \right)^{\epsilon(d_1) \times \cdots \times \epsilon(d_q)} \\
&= \prod_{d_1|n_1} \cdots \prod_{d_q|n_q} \Psi_{\mathbf{d}}(x, y)^{\epsilon(\mathbf{d})},
\end{aligned}$$

where $\epsilon(d) = 2$ for $d \geq 3$ and $\epsilon(d) = 1$ for $d = 1, 2$. This completes the proof since $\zeta_Y(u)^{-1} = (1 - u^2)^{(q-1)|\mathbf{n}|} F_{\mathbf{n}}(1 + (2q-1)u^2, u)$. \square

Now, in order to factorize $\Psi_{\mathbf{d}}(x)$ further, we consider the orbit structure for Galois actions.

Suppose $d_i \geq 3$ for $i = 1, \dots, q$. Let $N = d_1 \cdots d_q$. We identify J_d for $d \geq 3$ with the set of representatives of $(\mathbb{Z}/d\mathbb{Z})^\times$ modulo $x \mapsto -x$. We identify $(\mathbb{Z}/N\mathbb{Z})^\times$ with $\{m \in \mathbb{N} \mid m < N, \gcd(m, N) = 1\}$. The group $(\mathbb{Z}/N\mathbb{Z})^\times$ acts on $J_{d_1} \times \cdots \times J_{d_q}$ as component-wise multiplication:

$$(4.3) \quad (j_1, \dots, j_q) \mapsto (aj_1, \dots, aj_q)$$

for $a \in (\mathbb{Z}/N\mathbb{Z})^\times$.

Before proving Theorem 1.4, we give the following lemma.

Lemma 4.3. For (d_1, d_2, \dots, d_q) with $d_i \geq 3$ for all $i = 1, \dots, q$, put $N' := \text{lcm}(d_1, \dots, d_q)$, $G := (\mathbb{Z}/N'\mathbb{Z})^\times$ and

$$H := \{g \in G \mid \exists(\varepsilon_i) \in \{\pm 1\}^q \text{ such that } g \equiv \varepsilon_i \pmod{d_i} (i = 1, \dots, q)\}.$$

Then, the quotient group G/H acts on $J_{d_1} \times \cdots \times J_{d_q}$ freely. In particular, every G/H -orbit on $J_{d_1} \times \cdots \times J_{d_q}$ has $|G/H|$ elements. The cardinality of H is $2^{\beta_0(\Gamma(V))}$, where $V = \{1, 2, \dots, q\}$ and $\beta_0(\Gamma(V))$ is the 0th Betti number, i.e., the number of connected components of $\Gamma(V)$.

Proof. We express the decomposition into connected components as $\{1, \dots, q\} = \sqcup_{k=1}^{\beta_0} A_k$, where β_0 represents $\beta_0(\Gamma(V))$. Note that

$$H = \{g \in G \mid \exists(\varepsilon_k) \in \{\pm 1\}^{\beta_0} \text{ such that } g \equiv \varepsilon_k \pmod{d_i} \text{ for } i \in A_k\}.$$

In fact, we see that $\varepsilon_i \equiv g \equiv \varepsilon_j \pmod{\gcd(d_i, d_j)}$. Thus, if $\gcd(d_i, d_j) \geq 3$, then $\varepsilon_i = \varepsilon_j$. This implies the above identity. Put $N_k := \text{lcm}(d_i \mid i \in A_k)$ for $k = 1, \dots, \beta_0$. Then, we can write

$$H = \{g \in G \mid \exists(\varepsilon_k) \in \{\pm 1\}^{\beta_0} \text{ such that } g \equiv \varepsilon_k \pmod{N_k}\}.$$

Also, it is seen that $\gcd(N_k, N_{k'}) \leq 2$ for $k \neq k'$. It follows that the map

$$H \rightarrow (\varepsilon_k) \in \{\pm 1\}^{\beta_0}$$

is bijective. □

Proof of Theorem 1.4. For simplicity, \mathbf{d} is assumed to be rearranged in such a way that $d_1 \geq \cdots \geq d_{q'} \geq 3 > d_{q'+1} \geq \cdots \geq d_q$, and we write $\mathbf{d}' = (d_1, \dots, d_{q'})$. It is clear that $\text{orb}(\mathbf{d}) = \text{orb}(\mathbf{d}')$ since J_1 and J_2 are singletons, and since $\tilde{\varphi}(1) = \tilde{\varphi}(2) = 1$ and $\tilde{\varphi}(\text{lcm}(m, 2)) = \tilde{\varphi}(m)$ for any $m \in \mathbb{N}$, we have

$$\frac{\prod_{i=1}^q \tilde{\varphi}(d_i)}{\tilde{\varphi}(\text{lcm}(d_1, d_2, \dots, d_q))} = \frac{\prod_{i=1}^{q'} \tilde{\varphi}(d_i)}{\tilde{\varphi}(\text{lcm}(d_1, d_2, \dots, d_{q'}))}.$$

Therefore, it suffices to consider the case $d_i \geq 3$ for all $i = 1, 2, \dots, q$. From Lemma 4.3, it follows that

$$\text{orb}(\mathbf{d}) = \frac{|J_{d_1} \times \cdots \times J_{d_q}|}{|G/H|} = \frac{\prod_{i=1}^q \tilde{\varphi}(d_i)}{\tilde{\varphi}(\text{lcm}(d_1, d_2, \dots, d_q))} 2^{\beta_0(\Gamma(V))-1}.$$

This completes the proof. □

We next give a criterion for the irreducibility of $\Psi_{\mathbf{d}}(x)$, which is later used to obtain a condition for $\Psi_{\mathbf{d}}(x; \mathcal{O})$ defined in (1.2) to factor into the powers of a linear function for $q = 2$.

Proposition 4.4. (1) If $\mathcal{O} \subset J_{d_1} \times \cdots \times J_{d_q}$ is stable under the action of $(\mathbb{Z}/N\mathbb{Z})^\times$, then $\Psi_{\mathbf{d}}(x; \mathcal{O}) \in \mathbb{Z}[x]$.

(2) Let $\mathcal{O} \subset J_{d_1} \times \cdots \times J_{d_q}$ be a $(\mathbb{Z}/N\mathbb{Z})^\times$ -orbit. Then the map

$$(4.4) \quad c : \mathcal{O} \ni (j_1, \dots, j_q) \mapsto 2 \sum_{i=1}^q \cos \frac{2\pi j_i}{d_i} \in \mathbb{R}$$

is injective if and only if $\Psi_{\mathbf{d}}(x; \mathcal{O}) \in \mathbb{Z}[x]$ is irreducible.

Proof. The Galois group $\text{Gal}(\mathbb{Q}(\zeta_N)/\mathbb{Q})$ is identified with $(\mathbb{Z}/N\mathbb{Z})^\times$, where $\zeta_N = \exp(2\pi\sqrt{-1}/N)$ is an N th primitive root of unity. The Galois action of an element $a \in (\mathbb{Z}/N\mathbb{Z})^\times$ to an element $c(j_1, \dots, j_q) \in \mathbb{Q}(\zeta_N)$ is given by the action (4.3). If \mathcal{O} is stable under the action of $(\mathbb{Z}/N\mathbb{Z})^\times$, then $\Psi_{\mathbf{d}}(x; \mathcal{O}) \in \mathbb{Q}[x]$. Since the coefficients of $\Psi_{\mathbf{d}}(x; \mathcal{O})$ are algebraic integers, we obtain the first assertion (1). If the map c is not injective, then $\Psi_{\mathbf{d}}(x; \mathcal{O})$ has a multiple root, and hence it cannot be irreducible. Conversely, if the map c is injective on an orbit \mathcal{O} , then the action of $(\mathbb{Z}/N\mathbb{Z})^\times$ on the roots of $\Psi_{\mathbf{d}}(x; \mathcal{O})$ is transitive, and therefore the polynomial $\Psi_{\mathbf{d}}(x; \mathcal{O})$ is irreducible. \square

We now give an example of Proposition 4.4(2).

Corollary 4.5. Suppose d_1, \dots, d_q are relatively prime and $d_i \geq 3$ for all $i = 1, 2, \dots, q$. Then the action of $(\mathbb{Z}/N\mathbb{Z})^\times$ on $J_{d_1} \times \cdots \times J_{d_q}$ is transitive, the map c in (4.4) is injective, and $\Psi_{\mathbf{d}}(x) \in \mathbb{Z}[x]$ is irreducible.

Proof. For any $(j_1, \dots, j_q) \in J_{d_1} \times \cdots \times J_{d_q}$, there exists $g \in \mathbb{Z}$ such that $j_i \equiv g \pmod{d_i}$ for all $i = 1, \dots, q$ from the Chinese Remainder Theorem. This shows that $(j_1, \dots, j_q) = (g1, \dots, g1)$ belongs to an orbit of $(1, \dots, 1)$, and thus the transitivity follows. The injectivity is proved as follows. First, suppose $c(j_1, \dots, j_q) = c(j'_1, \dots, j'_q)$. Then,

$$-\cos(2\pi j_1/d_1) + \cos(2\pi j'_1/d_1) = \sum_{i=2}^q (\cos(2\pi j_i/d_i) - \cos(2\pi j'_i/d_i))$$

is an element of $\mathbb{Q}(\zeta_{d_1}) \cap \mathbb{Q}(\zeta_{d_2 \cdots d_q}) = \mathbb{Q}$ since d_1 and $d_2 \cdots d_q$ are coprime. There exists a rational number b such that $-\cos(2\pi j_1/d_1) + \cos(2\pi j'_1/d_1) = b$. Taking the Galois conjugates, and summing up over J_{d_1} , we have

$$\tilde{\varphi}(d_1)b = - \sum_{j_1 \in J_{d_1}} \cos \frac{2\pi j_1}{d_1} + \sum_{j'_1 \in J_{d_1}} \cos \frac{2\pi j'_1}{d_1} = 0.$$

This implies $b = 0$ and $j'_1 = j_1$. Then, by induction on q , we have the injectivity. The irreducibility follows from Proposition 4.4(2). \square

The polynomial $\Psi_{\mathbf{d}}(x; \mathcal{O})$ may not be irreducible. The following lemma clarifies the situation in this regard.

Lemma 4.6. Let $\mathcal{O} \subset J_{d_1} \times \cdots \times J_{d_q}$ be a $(\mathbb{Z}/N\mathbb{Z})^\times$ -orbit. Then the fibers of the map c in (4.4) have the same cardinality. In particular, there exist an irreducible polynomial $\Psi_{\mathbf{d}}^{\text{irr}}(x; \mathcal{O}) \in \mathbb{Z}[x]$ and a number $m_{\mathcal{O}} \in \mathbb{N}$ such that $\Psi_{\mathbf{d}}(x; \mathcal{O}) = \Psi_{\mathbf{d}}^{\text{irr}}(x; \mathcal{O})^{m_{\mathcal{O}}}$.

Proof. Take $(j_{10}, \dots, j_{q0}) \in \mathcal{O}$ so that the cardinality of the fiber of the map (4.4) is maximum. Denote $y_0 := c(j_{10}, \dots, j_{q0}) \in \mathbb{R}$. For any $y \in c(\mathcal{O})$, there exists a $g \in$

$(\mathbb{Z}/N\mathbb{Z})^\times$ such that $y = c(gj_{10}, \dots, gj_{q0})$ since \mathcal{O} is an orbit. We see that the map

$$c^{-1}(y_0) \ni (j_1, \dots, j_q) \mapsto (gj_1, \dots, gj_q) \in c^{-1}(y)$$

is a well-defined injective map. By the choice of maximality, this map turns out to be bijective. This proves the first assertion. Letting $m_{\mathcal{O}}$ denote the common cardinality of the fiber and putting

$$\Psi_{\mathbf{d}}^{\text{irr}}(x; \mathcal{O}) = \prod_{y \in c(\mathcal{O})} (x - y),$$

we have the second assertion. \square

Example 4.7. In the case where $q = 2$ and $\mathbf{d} = (5, 5)$, we have two orbits. One is ‘diagonal’ and the other is ‘off-diagonal’:

$$\mathcal{O}_1 = \{(1, 1), (2, 2)\}, \quad \mathcal{O}_2 = \{(1, 2), (2, 1)\}.$$

Note that c in (4.4) maps the orbits as follows:

$$\mathcal{O}_1 \mapsto \{4 \cos \frac{2\pi}{5}, 4 \cos \frac{4\pi}{5}\}, \quad \mathcal{O}_2 \mapsto \{-1, -1\}.$$

The latter is not injective, while the former is. We see that $\Psi_{\mathbf{d}}(x; \mathcal{O}_1) = x^2 + 2x - 4$ is irreducible, and $\Psi_{\mathbf{d}}(x; \mathcal{O}_2) = (x + 1)^2$ is reducible, that is, $\Psi_{\mathbf{d}}^{\text{irr}}(x; \mathcal{O}_2) = x + 1$, $m_{\mathcal{O}_1} = 1$ and $m_{\mathcal{O}_2} = 2$.

In what follows, we focus on the case $q = 2$, in which we know more about the reducibility of $\Psi_{\mathbf{d}}(x; \mathcal{O})$.

Proposition 4.8. Suppose $q = 2$. If the degree of $\Psi_{d_1, d_2}^{\text{irr}}(x; \mathcal{O})$ is one, the possibilities for d_1, d_2 and the orbits \mathcal{O} are as follows:

(d_1, d_2)	\mathcal{O}	$\Psi_{d_1, d_2}^{\text{irr}}(x; \mathcal{O})$	condition
(d_1, d_2)	$\mathcal{O}_{1,1}$	$x - \lambda$	$d_1, d_2 = 1, 2, 3, 4, 6$
(m, m)	$\mathcal{O}_{1, m/2-1}$	x	$4 m$
$(m, 2m)$	$\mathcal{O}_{1, m-2}$	x	$m : \text{odd}$
$(5, 5)$	$\mathcal{O}_{1,2}$	$x + 1$	
$(10, 10)$	$\mathcal{O}_{1,3}$	$x - 1$	

In this table, $\lambda = 2 \cos \frac{2\pi}{d_1} + 2 \cos \frac{2\pi}{d_2} \in \mathbb{Z}$ and $\mathcal{O}_{1,a}$ is the orbit containing $(1, a) \in J_{d_1} \times J_{d_2}$. More explicitly,

$$\begin{aligned} \mathcal{O}_{1,1} &= J_{d_1} \times J_{d_2}, \quad \mathcal{O}_{1, m/2-1} = \{(j, m/2 - j) \mid j \in J_m\}, \\ \mathcal{O}_{1, m-2} &= \{(j, m - 2j) \mid j \in J_m\}, \\ \mathcal{O}_{1,2}, \mathcal{O}_{1,3} &= \{(j_1, j_2) \in J_{d_1} \times J_{d_2} \mid j_1 \neq j_2\}. \end{aligned}$$

By Lemma 4.6, if the degree of $\Psi_{d_1, d_2}^{\text{irr}}(x; \mathcal{O})$ is one, then the image of the map $c : \mathcal{O} \rightarrow \mathbb{Q}$ is a singleton. We now derive some necessary conditions for this to be the case.

Lemma 4.9. Let $g = \gcd(d_1, d_2)$ and define g_i to be the product of all factors of d_i in common with g . Put $m_i := d_i/g_i \in \mathbb{Z}$. If the degree of $\Psi_{d_1, d_2}^{\text{irr}}(x; \mathcal{O})$ is one, or equivalently, if the image of the map $c : \mathcal{O} \rightarrow \mathbb{Q}$ is a singleton, then the following conditions hold:

- (i) $g_i \leq 2$ or $m_i \leq 2$ for $i = 1, 2$.
- (ii) $m_1, m_2 \in \{1, 2, 3, 4, 6\}$.
- (iii) $g_1 = g_2$ or $(g_1, g_2) = (2, 4)$ or $(4, 2)$.

Proof. Let $N' = \text{lcm}(d_1, d_2)$. Suppose there exist $d_1, d_2 \in \mathbb{N}$ and $(j_1, j_2) \in J_{d_1} \times J_{d_2}$ such that

$$2 \cos \frac{2\pi j_1 b}{d_1} + 2 \cos \frac{2\pi j_2 b}{d_2} = \lambda \in \mathbb{Q} \quad \text{for } \forall b \in \mathbb{Z}/N'\mathbb{Z}.$$

We claim that every $b \in \mathbb{Z}$ with $b \equiv 1 \pmod{d_1}$ and $\gcd(b, d_2) = 1$ satisfies $b \equiv \pm 1 \pmod{d_2}$. Indeed, since $\cos \frac{2\pi j_1 b}{d_1} = \cos \frac{2\pi j_1}{d_1}$, we have $\cos \frac{2\pi j_2 b}{d_2} = \cos \frac{2\pi j_2}{d_2}$, which implies that $b \equiv \pm 1 \pmod{d_2}$.

Now we use the claim above for three cases regarding the value of b . Note that $d_i = m_i g_i$, and if $\tilde{g} = \text{lcm}(g_1, g_2)$, then \tilde{g}, m_1 and m_2 are mutually prime.

First, consider $b \in \mathbb{Z}$ with $b \equiv 1 \pmod{m_1 \tilde{g}}$ and $b \equiv -1 \pmod{m_2}$. By the claim, we have $b \equiv \pm 1 \pmod{d_2 = g_2 m_2}$. If $b \equiv 1$, then we have $m_2 \leq 2$, while if $b \equiv -1$, then we have $g_2 \leq 2$. We conclude that either $m_2 \leq 2$ or $g_2 \leq 2$.

Second, consider $b \in \mathbb{Z}$ with $b \equiv 1 \pmod{m_1 \tilde{g}}$ and $\gcd(b, m_2) = 1$. By the claim, we have $b \equiv \pm 1 \pmod{m_2}$. This shows that $\varphi(m_2) \leq 2$, and we conclude that $m_2 = 1, 2, 3, 4$ or 6 .

Third, consider $b \in \mathbb{Z}$ with $b \equiv 1 \pmod{m_1 m_2}$ and $b \equiv 1 + g_1 \pmod{g_2}$. By the claim, we have $b \equiv \pm 1 \pmod{g_2}$. If $b \equiv 1$, then $g_2 | g_1$, while if $b \equiv -1$, then $g_2 | (g_1 + 2)$. Since the conditions on d_1 and d_2 are symmetric, we also have $g_1 | g_2$ or $g_1 | (g_2 + 2)$. We conclude that either $g_1 = g_2$ or $\{g_1, g_2\} = \{2, 4\}$. \square

Now we use Lemma 4.9 (i), (ii) and (iii) to prove Proposition 4.8.

Proof of Proposition 4.8. First, we note that $\Psi_{d_1, d_2}(x) = \Psi_{d_2}(x - \alpha)$ with $\alpha = 2 \cos \frac{2\pi}{d_1} \in \mathbb{Z}$ for $d_1 \in \{1, 2, 3, 4, 6\}$ from the remark in Example 4.2. Since $\Psi_d(x)$ is irreducible for any $d \in \mathbb{N}$ from Lemma 4.1, so is $\Psi_{\mathbf{d}}(x)$ in this case. The degree of $\Psi^{\text{irr}}(x; \mathcal{O})$ is one if and only if that of $\Psi_{d_2}(x)$ is one, which is true if and only if $d_2 \in \{1, 2, 3, 4, 6\}$. This gives the first line in the table. Indeed, in all of the cases above, we have only one orbit $\mathcal{O}_{1,1}$ on $J_{d_1} \times J_{d_2}$.

In what follows, we can assume that $d_1, d_2 \notin \{1, 2, 3, 4, 6\}$, and hence $\tilde{\varphi}(d_1), \tilde{\varphi}(d_2) \geq 2$.

In the case $g = 1$ with $g_1 = g_2 = g$ in (iii), we have $m_i = d_i \in \{1, 2, 3, 4, 6\}$ by (ii). In the case $g_i = 2$ in (iii) for $i = 1$ or 2 , m_i should be odd, and hence choices are only $m_i = 1, 3$ by (ii). This implies $d_i = 2$ or 6 . Both of these cases have already been excluded.

If $g \geq 3$ with $g_1 = g_2 = g$, then $m_i \leq 2$. The only choices in this case are $(m_1, m_2) = (1, 1), (1, 2), (2, 1)$. Furthermore, if $m_i = 2$, then g must be odd. It follows that $(d_1, d_2) = (g, 2g)$ with odd $g \geq 5$ or $(d_1, d_2) = (g, g)$ for arbitrary $g \geq 5$ (with $g = 6$ excluded).

To this point, we have not used the orbit structure. Now we consider the choice of $(j_1, j_2) \in \mathcal{O}$. Taking the sum of all the terms under the Galois action of $(\mathbb{Z}/d_2\mathbb{Z})^\times$, and using the same argument as in the proof of Corollary 4.5, we have

$$\tilde{\varphi}(d_2)\lambda = 2 \sum_{j_1 \in J_{d_1}} \cos \frac{2\pi j_1}{d_1} + 2 \sum_{j_2 \in J_{d_2}} \cos \frac{2\pi j_2}{d_2} = \mu(d_1) + \mu(d_2)$$

for $d_1, d_2 \geq 3$, where μ is the Möbius function. Since λ is an algebraic integer, we see that $\mathbb{Z} \ni \lambda = \frac{\mu(d_1) + \mu(d_2)}{\tilde{\varphi}(d_2)}$. This shows either $\lambda = 0$ or $\tilde{\varphi}(d_2) \leq 2$.

If $\lambda \neq 0$, then $\tilde{\varphi}(d_2) = 2$, i.e., $d_2 \in \{5, 8, 10, 12\}$. In this case, we have $\lambda = \mu(d_1) = \mu(d_2) = \pm 1$, and thus d_2 is not a multiple of 4 and $(d_1, d_2) \neq (g, 2g)$. From this we obtain $d_1 = d_2 \in \{5, 10\}$ and the last two lines in the table.

Now we consider the case $\lambda = 0$. The condition $2 \cos \frac{2\pi j_1}{d_1} + 2 \cos \frac{2\pi j_2}{d_2} = 0$ implies $j_1/d_1 + j_2/d_2 = 1/2$ since $d_1, d_2 \geq 3$. If $d_1 = d_2$, then $j_1 + j_2 = d_1/2$. It follows that d_1 is even, and hence that j_1 and j_2 are odd. This implies that $d_1/2$ is even, and therefore

$4|d_1$. For $j_1 = 1$, we have $j_2 = d_1/2 - 1 \in J_{d_2}$. This gives the second line in the table. If $2d_1 = d_2$, then $2j_1 + j_2 = d_1$. For $j_1 = 1$, we have $j_2 = d_1 - 2 \in J_{d_2}$. This gives the third line in the table. \square

Now we give three examples for $q = 2$: (I) $(d_1, d_2) = (m, 2m)$; (II) $(d_1, d_2) = (m, m)$; (III) $\tilde{\varphi}(d_2) = 2$. From these examples, we obtain three *observations* with the aid of numerical computations.

Before studying each case, we give an elementary remark on the representatives for an orbit decomposition.

Lemma 4.10. Suppose that G acts on X simply transitively. Fix an arbitrary $x_0 \in X$. Then, for any Y (with G action), the set $\{x_0\} \times Y$ consists of complete representatives of the action of G on $X \times Y$.

Proof. For any $(x, y) \in X \times Y$, there exists a $g \in G$ such that $gx = x_0$. Then $g(x, y) = (x_0, gy)$. If (x_0, y) and (x_0, y') belong to the same G -orbit, then $y = y'$, because $g(x_0, y) = (x_0, y')$ implies $g = e$, the identity element of the group G . \square

(I) For $q = 2$, $(d_1, d_2) = (m, 2m)$.

We start with the orbit decomposition.

Lemma 4.11. The number of orbits is $\text{orb}((m, 2m)) = \tilde{\varphi}(m)$, and each orbit has $\tilde{\varphi}(2m)$ elements. The orbit decomposition is given by

$$J_m \times J_{2m} = \begin{cases} \sqcup_{a \in J_m} \mathcal{O}_{1,a} & \text{for even } m, \\ \sqcup_{a \in J_{2m}} \mathcal{O}_{1,a} & \text{for odd } m. \end{cases}$$

Proof. The first part follows from Example 1.5 (i) and the second part follows from Lemma 4.10. If $m \geq 3$ is odd, then $\tilde{\varphi}(2m) = \tilde{\varphi}(m)$ and the natural map induces the group isomorphism $(\mathbb{Z}/2m\mathbb{Z})^\times / \{\pm 1\} \xrightarrow{\sim} (\mathbb{Z}/m\mathbb{Z})^\times / \{\pm 1\}$, so the action of $(\mathbb{Z}/2m\mathbb{Z})^\times / \{\pm 1\}$ on J_m is simply transitive. If m is even, it is easily seen that $(1, i) \in \mathcal{O}$ if and only if $(1, m - i) \in \mathcal{O}$ for $i \in J_{2m}$, from which we have the decomposition. \square

Observation 4.12. (i) $\Psi_{m,2m}(x; \mathcal{O})$ seems to be irreducible except for odd m with $\mathcal{O} = \mathcal{O}_{1,m-2}$ appearing in Proposition 4.8.

(ii) If $\Psi_{m,2m}(x; \mathcal{O}) = \Psi_{m,2m}(x; \mathcal{O}')$, then $\mathcal{O} = \mathcal{O}'$.

(II) For $q = 2$, $(d_1, d_2) = (m, m)$.

We define the involution ι on $J_m \times J_m$ by $\iota(x, y) = (y, x)$. It is obvious from this definition that $\Psi_{m,m}(x; \iota(\mathcal{O})) = \Psi_{m,m}(x; \mathcal{O})$.

Lemma 4.13. (i) The number of orbits is $\text{orb}((m, m)) = \tilde{\varphi}(m)$ and each orbit has $\tilde{\varphi}(m)$ elements. The orbit decomposition is given by

$$J_m \times J_m = \bigsqcup_{a \in J_m} \mathcal{O}_{1,a}.$$

(ii) The diagonal orbit $\mathcal{O}_{1,1} = \{(i, i) : i \in J_m\}$ is invariant under ι . If $\tilde{\varphi}(m)$ is odd, then there is no non-diagonal ι -invariant orbit.

Proof. (i) The first part follows from Example 1.5. The second part follows from Lemma 4.10 by setting $x_0 = 1$ and $Y = J_m$.

(ii) Any non-diagonal ι -invariant orbit has no fixed point under the action of ι . In particular, the cardinality of such an orbit is even. The second assertions follow. \square

If $\tilde{\varphi}(m)$ is even, then the situation is different. Note that if $4|m$ with $m > 4$, then $\tilde{\varphi}(m)$ is even.

Lemma 4.14. (i) Suppose $4|m$. The orbit $\mathcal{O}_{1,m/2-1}$ is ι -invariant and $\Psi_{m,m}(x; \mathcal{O}_{1,m/2-1}) = x^{\tilde{\varphi}(m)}$.

(ii) Suppose $\tilde{\varphi}(m)$ is even. For a non-diagonal ι -invariant orbit \mathcal{O} with $\mathcal{O} \neq \mathcal{O}_{1,m/2-1}$, there exists $\Psi_{m,m}^{(\text{half})}(x; \mathcal{O}) \in \mathbb{Z}[x]$ of degree $\tilde{\varphi}(m)/2$ such that $\Psi_{m,m}(x; \mathcal{O}) = \Psi_{m,m}^{(\text{half})}(x; \mathcal{O})^2$.

Proof. (i) This case is considered in Proposition 4.8.

(ii) This can be shown in the same way as the proof of Lemma 4.13 (ii). \square

We denote by A the number of ι -invariant orbits. As we have seen, $A = 1$ if $\tilde{\varphi}(m)$ is odd. We have the following formula for $A = A(m)$ if $\tilde{\varphi}(m)$ is even:

Lemma 4.15. Suppose $\tilde{\varphi}(m)$ is even. Put

$$f_1 = f_1(m) := \begin{cases} 0 & \text{if } 4 \nmid m, \\ 1 & \text{if } 4 \mid m \text{ and } 8 \nmid m, \\ 2 & \text{if } 8 \mid m. \end{cases}$$

Let f_2 be the number of odd prime factors of m . Let $f_3 = f_3(m) = 1$ if $4 \nmid m$, $f_2(m) \geq 1$, and $p \equiv 1 \pmod{4}$ for every odd prime factor p of m ; otherwise, we put $f_3(m) = 0$. Then we have

$$A = 2^{f_1+f_2+f_3-1}.$$

Proof. We consider the orbits that are invariant under the involution ι . We will solve the equation $x^2 \equiv \pm 1 \pmod{m}$. By the Chinese Remainder Theorem, this equation can be reduced to the equation for each prime factor. If $m = 2^e$, then the number of solutions to the equation $x^2 \equiv 1 \pmod{m}$ is given by $2^{f_1(m)}$. If $m = p^2$, then we have two solutions to $x^2 \equiv 1 \pmod{m}$. This contributes to f_2 . We have a solution to the equation $x^2 \equiv -1 \pmod{m}$ only in the case $f_3(m) = 1$. This solution makes double the number of solution for the equation $x^2 \equiv \pm 1 \pmod{m}$ to the number of solutions to the equation $x^2 \equiv 1 \pmod{m}$. Finally, we parameterize the orbits as $\mathcal{O}_{1,x}$ with $x \in J_m$, so that we will divide by 2. The formula for $A(m)$ given above follows. \square

We now proceed from orbits to polynomials.

Observation 4.16. (i) For an orbit $\mathcal{O} \neq \iota(\mathcal{O})$, $\Psi_{m,m}(x; \mathcal{O})$ seem to be irreducible. In particular, $\Psi_{m,m}(x; \mathcal{O})$ seem to be irreducible if $\tilde{\varphi}(m)$ is odd.

(ii) $\Psi_{m,m}^{(\text{half})}(x; \mathcal{O})$ seems to be irreducible for every ι -invariant orbit $\mathcal{O} \neq \mathcal{O}_{1,m/2-1}$. This happens only if $\tilde{\varphi}(m)$ is even.

(iii) If $\Psi_{m,m}(x; \mathcal{O}) = \Psi_{m,m}(x; \mathcal{O}')$, then $\mathcal{O}' = \mathcal{O}$ or $\mathcal{O}' = \iota(\mathcal{O})$.

(III) For $q = 2$, $\tilde{\varphi}(d_2) = 2$.

In this case, $\tilde{\varphi}(d_2) = 2$ implies $d_2 = 5, 8, 10$ or 12 , for which we set $a = 2, 3, 3$ and 5 , respectively. Then $J_{d_2} = \{1, a\}$.

Lemma 4.17. Suppose $d_2 = 5, 8, 10$ or 12 . If $5|d_1$ for $d_2 = 10$ or $d_2|d_1$ for $d_2 \neq 10$, then we have

$$J_{d_1} \times J_{d_2} = \mathcal{O}_{1,1} \sqcup \mathcal{O}_{1,a}.$$

Otherwise, $J_{d_1} \times J_{d_2}$ forms a single orbit.

Proof. In these cases, we know that $\text{orb}(d_1, d_2) = \tilde{\varphi}(d_2) = 2$ from Example 1.5(i). Therefore, the orbit decomposition must be the one given above. \square

Observation 4.18. If $\tilde{\varphi}(d_2) = 2$, then $\Psi_{d_1, d_2}(x; \mathcal{O})$ seems to be irreducible except in the cases considered in Proposition 4.8.
