ABSTRACT

Using the multiconfiguration Dirac-Hartree-Fock and the relativistic configuration interaction methods, a consistent set of transition energies and radiative transition data for the lowest 546 (623, 701, 745) states of the  $3p^43d$ ,  $3s3p^23d^2$ ,  $3s3p^34p$ ,  $3s3p^4$ ,  $3s^23d^3$ ,  $3s^23p^23d$ ,  $3s^23p^24d$ ,  $3s^23p^24s$ ,  $3p^33d^2$ ,  $3p^5$ ,  $3s3p3d^3$ ,  $3s3p^33d$ ,  $3s3p^34s$ ,  $3s^23p3d^2$ ,  $3s^23p^24p$ ,  $3s^23p^3$  configurations in Mn XI (Fe XII, Co XIII, Ni XIV) is provided. The comparison between calculated excitation energies for the  $n = 4$  states and available experimental values for Fe XII indicate that the calculations are highly accurate, with uncertainties of only a few hundred  $\text{cm}^{-1}$ . Lines from these states are prominent in the soft X-rays. With the present calculations, several recent new identifications are confirmed. Other identifications involving  $3p^24d$  levels in Fe XII that were found questionable are discussed and a few new assignments are recommended. As some  $n = 4$  states of the other ions also show large discrepancies between experimental and calculated energies, we reassess their identification. The present study provides highly accurate atomic data for the  $n = 4$  states of P-like ions of astrophysical interest, for which experimental data are scarce.

*Keywords:* atomic data - atomic processes

1. INTRODUCTION

In the ultraviolet (UV) and extreme ultraviolet (EUV) spectral regions, P-like ions of the iron group elements are used for plasma diagnostics, especially to measure electron densities (see, e.g. the review by [Del Zanna & Mason 2018](#)). Fe XII is especially important for the solar corona. The most prominent lines in the UV/EUV region were observed by SOHO and Skylab, and were recently measured by the Hinode satellite, ([Young et al. 2009](#); [Del Zanna 2012a](#)). In our recent work ([Wang et al. 2018a](#)), using the multiconfiguration Dirac-Hartree-Fock (MCDHF) and the relativistic configuration interaction (RCI) methods ([Froese Fischer et al. 2016](#); [Grant 2007](#)), excitation

energies for the lowest 143 states of the  $n = 3$  ( $3s^23p^3$ ,  $3s3p^4$ ,  $3s^23p^23d$ ,  $3s3p^33d$ ,  $3p^5$ ,  $3s^23p3d^2$ ) configurations from Cr X to Zn XVI were provided. Using these data, we reassessed the previous identifications of the important  $3s^23p^23d$  levels in Fe XII, confirming most of the previous suggestions by [Del Zanna & Mason \(2005a\)](#). On the basis of our calculated energies, the atomic data from [Del Zanna et al. \(2012a\)](#), and Hinode EIS spectra, new identifications of a few  $3s3p^33d$  levels were also suggested, which have been included in the CHIANTI atomic database version 9 ([Dere et al. 2019](#); [Dere et al. 1997](#)).

The  $n = 4 \rightarrow n = 3$  transitions in highly-ionized Fe ions, including Fe XII, are the dominant lines in the soft X-rays (50 Å–150 Å). These transitions have re-

cently been reviewed by [Del Zanna \(2012b\)](#), where a series of large-scale scattering calculations (the first of the kind) for all the ions, provided by [Del Zanna et al.](#) in a series of papers, were used to assess the identifications in this spectral region. Most of the previous identifications of these  $n = 4 \rightarrow n = 3$  transitions were due to [Fawcett et al. \(1972\)](#), although some of the original ones were due to Edlen in his seminal work in the 1930s' (see, e.g. the review in [Del Zanna & Mason \(2018\)](#)). [Del Zanna \(2012b\)](#) pointed out that several of the strongest transitions were never identified, and proposed their identification, on the basis of solar and laboratory spectra (the same used by [Fawcett et al. \(1972\)](#)). A few problems with Fawcett's identifications were also noted, but the accuracy of the theoretical wavelengths did not allow firm identifications.

A significant fraction (about a third) of the spectral lines in the soft X-rays still awaits identification. One purpose of our work is to provide excitation energies and wavelengths involving the  $n = 4$  states for P-like ions from Mn XI to Ni XIV with spectroscopic accuracy, to aid the identification process. Using the MCDHF and RCI method (in the following referred to as MCDHF), excitation energies, wavelengths, lifetimes, and radiative transition data including oscillator strengths, line strengths, and transition rates, are provided for the main  $n = 3, 4$  levels of the  $3p^4 3d$ ,  $3s3p^2 3d^2$ ,  $3s3p^3 4p$ ,  $3s3p^4$ ,  $3s^2 3d^3$ ,  $3s^2 3p^2 3d$ ,  $3s^2 3p^2 4d$ ,  $3s^2 3p^2 4s$ ,  $3p^3 3d^2$ ,  $3p^5$ ,  $3s3p3d^3$ ,  $3s3p^3 3d$ ,  $3s3p^3 4s$ ,  $3s^2 3p3d^2$ ,  $3s^2 3p^2 4p$ ,  $3s^2 3p^3$  configurations. In Section 3, using accurate wavelengths for the  $n = 4 \rightarrow n = 3$  transitions of Fe XII to Ni XIV we will review their identification and suggest some new lines. This provides a stringent accuracy assessment of our calculations.

The other purpose of our work is to provide a consistent accurate set of radiative transition data for P-like ions from Mn XI to Ni XIV for spectral line modeling. This work extends and complements our long-term theoretical efforts ([Wang et al. 2014, 2015, 2016a,b, 2017a,b,c,d, 2018a,b,c,d, 2019, 2020](#); [Chen et al. 2017, 2018](#); [Guo et al. 2015](#); [Guo et al. 2016](#); [Si et al. 2016, 2017, 2018](#); [Zhao et al. 2018](#)) to provide atomic data for L- and M-shells systems with high accuracy. For a review see [Jönsson et al. \(2017\)](#).

## 2. THEORY AND CALCULATIONS

The MCDHF method in the GRASP2K code ([Jönsson et al. 2013](#); [Jönsson et al. 2007](#)) is reviewed by [Froese Fischer et al. \(2016\)](#). This method is also described in our recent papers ([Wang et al. 2018a,b](#)). For this reason, in the sections below, only the computational procedures are described.

In our MCDHF calculations, the multireference (MR) sets for even and odd parities include

even configurations:  $3p^4 3d$ ,  $3s3p^2 3d^2$ ,  $3s3p^3 4p$ ,  $3s3p^4$ ,  $3s^2 3d^3$ ,  $3s^2 3p^2 3d$ ,  $3s^2 3p^2 4d$ ,  $3s^2 3p^2 4s$ ;

odd configurations:  $3p^3 3d^2$ ,  $3p^5$ ,  $3s3p3d^3$ ,  $3s3p^3 3d$ ,  $3s3p^3 4s$ ,  $3s^2 3p3d^2$ ,  $3s^2 3p^2 4f$ ,  $3s^2 3p^2 4p$ ,  $3s^2 3p^3$ .

By allowing single and double substitutions from the  $n = 3, 4$  electrons of the MR sets to orbitals with  $n \leq 8, l \leq 6$ , and allowing single excitations of the  $n = 2$  electrons to orbitals with  $n \leq 6, l \leq 4$ , configuration state function (CSF) expansions are generated. The  $1s$  shell is defined as inactive closed shell in all CSFs of the expansions.

For both energy separations and transition probabilities, the neglected correlations from  $n = 1, 2$  are comparatively unimportant ([Wang et al. 2018a](#)). In the following RCI calculation, the transverse electron interaction in the low-frequency limit and the leading quantum electrodynamic (QED) effects (vacuum polarization and self-energy) corrections are included. In the final CSF expansions for the different  $J$  symmetries, the number of CSFs is, respectively, about 5.9 millions for even parity and 8.1 millions for odd parity.

By using the  $jj$ - $LSJ$  transformation approach ([Gaigalas et al. 2017](#); [Gaigalas et al. 2004](#)), the  $jj$ -coupled CSFs are transformed into  $LSJ$ -coupled CSFs, from which the  $LSJ$  labels used by experimentalists are obtained.

## 3. EVALUATION OF DATA

### 3.1. Energy Levels

In Table 1 excitation energies for the lowest 623 levels of the  $3p^4 3d$ ,  $3s3p^2 3d^2$ ,  $3s3p^3 4p$ ,  $3s3p^4$ ,  $3s^2 3d^3$ ,  $3s^2 3p^2 3d$ ,  $3s^2 3p^2 4d$ ,  $3s^2 3p^2 4s$ ,  $3p^3 3d^2$ ,  $3p^5$ ,  $3s3p3d^3$ ,  $3s3p^3 3d$ ,  $3s3p^3 4s$ ,  $3s^2 3p3d^2$ ,  $3s^2 3p^2 4p$ ,  $3s^2 3p^3$  configurations in Fe XII from the present MCDHF calculations (hereafter referred to as MCDHF1) are displayed. All these states are below the first  $3s^2 3p^2 4f$  level. For comparison, experimental excitation energies compiled in the Atomic Spectra Database (ASD) of the National Institute of Standards and Technology (NIST) ([Kramida et al. 2018](#)), experimental (CHIANTI1) and calculated (CHIANTI2) values from the CHIANTI version 9 ([Dere et al. 2019](#); [Dere et al. 1997](#)) are also included along with excitation energies from our recently MCDHF calculations (MCDHF2) ([Wang et al. 2018a](#)). The previous calculations, such as [Tayal \(2011\)](#); [Storey et al. \(2005\)](#); [Vilkas & Ishikawa \(2004\)](#), were focused on the  $n = 3$  levels, and their comparison with our recently MCDHF results for the  $n = 3$  levels

was shown in our previous work (Wang et al. 2018a). Therefore, their results (Tayal 2011; Storey et al. 2005; Vilkas & Ishikawa 2004) are not included in Table 1.

The differences between the MCDHF1 and MCDHF2 results for the lowest 143 states are listed in Table 1, and are generally within a few hundreds  $\text{cm}^{-1}$ . The average absolute difference with the standard deviation (Wang et al. 2017d) between the two data sets is  $1 \text{ cm}^{-1} \pm 313 \text{ cm}^{-1}$ . When the present MCDHF1 excitation energies for the  $n = 3$  levels are compared with the experimental values from the NIST and CHIANTI database, the agreement is also very good. The differences are generally within a few hundred  $\text{cm}^{-1}$ . There is a misprint for experimental excitation energies of the two levels ( $3s^2 3p^2 (\frac{1}{2}D) ^1D 3d ^2P_{3/2}$  with the key (#37) and #38/ $3s^2 3p^2 (\frac{1}{2}D) ^1D 3d ^2S_{1/2}$ ) in the CHIANTI version 9. The experimental values should be  $577\,680 \text{ cm}^{-1}$  for the #37/ $3s^2 3p^2 (\frac{1}{2}D) ^1D 3d ^2P_{3/2}$  level, and  $579\,630 \text{ cm}^{-1}$  for the #38/ $3s^2 3p^2 (\frac{1}{2}D) ^1D 3d ^2S_{1/2}$  level, respectively (Del Zanna & Mason 2005b). After correcting this misprint, the average absolute differences with our MCDHF1 energy values are  $-164 \pm 313 \text{ cm}^{-1}$  for NIST and  $-113 \pm 313 \text{ cm}^{-1}$  for CHIANTI1, respectively, where the standard deviations are indicated after the values.

Looking at higher-lying levels (above #143) in Fe XII, the present MCDHF1 calculations, as well as the CHIANTI2 theoretical values reported by the AUTOSTRUCTURE calculations by Del Zanna et al. (2012b) provide a complete data set. The AUTOSTRUCTURE calculations were carried out to provide target states wave functions for the scattering calculations. They are therefore not very accurate, providing indeed excitation energies that depart substantially from the present MCDHF1 values. For almost all higher-lying states of Fe XII, experimental values (NIST and CHIANTI1) are scarce. Only some levels of the  $3s^2 3p^2 4s$ ,  $3s^2 3p^2 4p$ ,  $3s^2 3p^2 4d$ , and  $3s 3p^3 4s$  were identified, based on the solar and laboratory spectra of Behring et al. (1972); Fawcett et al. (1972). The differences between our MCDHF1 excitation energies and the experimental values (NIST and CHIANTI1) are generally within a few hundreds of  $\text{cm}^{-1}$ . However, several discrepancies have been noted, as described below.

Our MCDHF excitation energies  $E_{\text{MCDHF}}$  ( $\text{cm}^{-1}$ ), together with MCDHF radiative lifetimes  $\tau_{\text{MCDHF}}^l$  (in s) in the length form and  $\tau_{\text{MCDHF}}^v$  (in s) in the velocity form, are reported in Table 2 for the lowest 546 (623, 701, 745) states of the  $3p^4 3d$ ,  $3s 3p^2 3d^2$ ,  $3s 3p^3 4p$ ,  $3s 3p^4$ ,  $3s^2 3d^3$ ,  $3s^2 3p^2 3d$ ,  $3s^2 3p^2 4d$ ,  $3s^2 3p^2 4s$ ,  $3p^3 3d^2$ ,  $3p^5$ ,  $3s 3p 3d^3$ ,  $3s 3p^3 3d$ ,  $3s 3p^3 4s$ ,  $3s^2 3p 3d^2$ ,  $3s^2 3p^2 4p$ ,  $3s^2 3p^3$  configurations in Mn XI (Fe XII, Co XIII, Ni XIV). Observed val-

ues  $E_{\text{NIST}}$  ( $\text{cm}^{-1}$ ) from the NIST ASD (Kramida et al. 2018), and energy differences  $\Delta E$  ( $\text{cm}^{-1}$ ) between the values of  $E_{\text{MCDHF}}$  and  $E_{\text{NIST}}$  are also listed in this table. As many levels are strongly mixed, their configuration label is not unique. Here, the parity,  $J$  value and energy are used to match the levels to the NIST ASD. For those levels, the NIST values are shown in blue color. The experimental excitation energies  $E_{\text{NIST}}$  agree well with our  $E_{\text{MCDHF}}$  values for a majority of the  $n = 4$  states. However, there are 14 levels, including 4 levels in Mn XI, 4 levels in Fe XII, 4 levels in Co XIII, and 2 levels in Ni XIV, for which differences are over  $2\,000 \text{ cm}^{-1}$ . The  $3s^2 3p^2 (\frac{3}{2}P) ^3P 4d ^2F_{7/2}$  state in Fe XII, where  $E_{\text{NIST}}$  and  $E_{\text{MCDHF}}$  differ by  $3\,616 \text{ cm}^{-1}$ , is discussed below in detail. For the same levels, large difference of about  $3\,700 \text{ cm}^{-1}$  also occur for Mn XI and Co XIII. As an example, the energy differences  $\Delta E$  between  $E_{\text{MCDHF}}$  and  $E_{\text{NIST}}$  as a function of the nuclear charge  $Z$  are displayed in Figure 1 for the  $3s^2 3p^2 (\frac{3}{2}P) ^3P 4d ^2D_{3/2}$ , and  $3s^2 3p^2 (\frac{3}{2}P) ^3P 4d ^2D_{5/2}$  states. Two anomalies appear for the  $3s^2 3p^2 (\frac{3}{2}P) ^3P 4d ^2D_{3/2}$  state in Co XIII and the  $3s^2 3p^2 (\frac{3}{2}P) ^3P 4d ^2D_{5/2}$  state in Ni XIV. Since the same MCDHF computational processes are carried out for all the ions, the accuracy of our MCDHF excitation energies along the sequence should be systematic and consistency is expected. Therefore, the large differences indicate that the identifications involving these levels are questionable or the wavelengths are incorrect.

### 3.2. Fe XII Line Identifications

In this section we review the identifications of the main Fe XII transitions  $n = 4 \rightarrow n = 3$  transitions. Whilst Del Zanna et al. (2012b) only considered the strongest transitions at low plasma density ( $10^8$  electrons  $\text{cm}^{-3}$ ), here we consider the strongest transitions at high plasma density ( $10^{19}$  electrons  $\text{cm}^{-3}$ ), to review Fawcett's identifications based on the laboratory plates. We have also considered one of Fawcett's plates for the evaluation. Table 3 lists the strongest  $n = 4 \rightarrow n = 3$  transitions in Fe XII, calculated with the atomic data described in Del Zanna et al. (2012b). In addition to Fawcett's wavelengths, we list the approximate AUTOSTRUCTURE values and our MCDHF wavelengths, with several comments. Spectral lines that are strongest in low plasma density are noted with an asterisk.

For the strongest lines of the  $3s^2 3p^2 3d - 3s^2 3p^2 4p$  transition array, we find a good agreement (within  $0.05 \text{ \AA}$ ) between Fawcett's wavelengths and our predicted values. There are some important transitions visible at low densities, from the #392/ $3s^2 3p^2 (\frac{3}{2}P) ^3P 4p ^4S_{3/2}^{\circ}$  level. Our values are in excellent agreement ( $0.009 \text{ \AA}$ )

**Figure 1.** The energy differences  $\Delta E$  (in  $\text{cm}^{-1}$ ) between  $E_{\text{MCDHF}}$  and  $E_{\text{NIST}}$  are displayed as a function of the nuclear charge  $Z$  for the  $3s^2 3p^2(^3P)^3P 4d ^2D_{3/2}$  and  $3s^2 3p^2(^3P)^3P 4d ^2D_{5/2}$  states. The corresponding data are available in Table 2. The real differences for the  $3s^2 3p^2(^3P)^3P 4d ^2D_{3/2}$  state in Co XIII ( $Z=27$ ) and  $3s^2 3p^2(^3P)^3P 4d ^2D_{5/2}$  state in Ni XIV ( $Z=28$ ) are reduced by a factor of 100, as marked by the ( $\times 100$ ) label.

with the identifications proposed by Del Zanna (2012b). Generally, we confirm the CHIANTI1 experimental excitation energies for the  $3s^2 3p^2 4p$  levels (#371, #380, #387, #392, #407, #408), proposed by Del Zanna (2012b), as the differences with our MCDHF1 are around a few hundreds  $\text{cm}^{-1}$ . However, for level #387/ $3s^2 3p^2(^3P)^3P 4p ^4D_{7/2}^o$ , the difference is larger ( $-5\,252\text{ cm}^{-1}$ ). The original assignment by Fawcett et al. (1972) of the line at  $108.44\text{ \AA}$  value to the transition  $3s^2 3p^2(^3P)^3P 4p ^4D_{7/2}^o - 3s^2 3p^2(^3P)^3P 3d ^4F_{9/2}$  is most likely correct. Using the CHIANTI1 experimental excitation energy  $443\,121\text{ cm}^{-1}$  for the lower level, this results in an energy of  $1\,365\,290\text{ cm}^{-1}$  for the upper level, in good agreement with our MCDHF1 result ( $1\,365\,552\text{ cm}^{-1}$ ).

Regarding the  $3s^2 3p^3 - 3s^2 3p^2 4s$  transition array, very good agreement with Fawcett's values is observed. The differences of our MCDHF1 excitation energies and experimental values (NIST and CHIANTI1) for the  $3s^2 3p^2 4s$  levels are within  $300\text{ cm}^{-1}$ .

We also confirm the identifications proposed by Del Zanna (2012b) of the decays from the #471/ $3s^2 3p^3(^4S)^5S 4s ^4S_{3/2}^o$  level, which are the strongest Fe XII transitions at low astrophysical densities. In Del Zanna (2012b), the  $83.336\text{ \AA}$  and  $83.631\text{ \AA}$  lines observed by Behring et al. (1972) were tentatively assigned to the decays from level #471/ $3s^2 3p^3(^4S)^5S 4s ^4S_{3/2}^o$  to the lower levels #7/ $3s^2 3p^4(^3P)^4P_{3/2}$  and #8/ $3s^2 3p^4(^3P)^4P_{1/2}$ , respectively. Our MCDHF1 wavelengths ( $83.335\text{ \AA}$  and  $83.636\text{ \AA}$ ) for these two transitions show excellent agreement with the observations. The difference between the MCDHF1 excitation energy ( $1\,484\,211\text{ cm}^{-1}$ ) and the resulting CHIANTI1 experimental energy ( $1\,483\,972\text{ cm}^{-1}$ ) for the upper level is only  $-239\text{ cm}^{-1}$ .

The situation for the experimental energies of the  $3s^2 3p^2 4d$  levels is more complex and Fawcett's identifications of several states are questionable, although we note that none of the transitions are strong in low-density astrophysical plasma. As pointed out by Del Zanna (2012b), the accuracy of previous theo-

retical wavelengths did not allow firm identifications for the  $3s^2 3p^2 4d$  levels. We provide in Table 3 suggestions for several revised identifications. The experimental excitation energies due to Fawcett et al. (1972) for the  $3s^2 3p^2 4d$  levels #498, #507, #552, #581, have large deviations from our MCDHF1 results, with differences between  $-2\,800$  and  $-5\,200\text{ cm}^{-1}$ .

As an example, we consider the transition  $3s^2 3p^2 ({}^3P) {}^3P 4d {}^2F_{7/2} - 3s^2 3p^3 ({}^3D) {}^2D_{5/2}^{\circ}$  between levels #507 and #3. This transition was assigned by Fawcett et al. (1972) to the  $67.702\text{ \AA}$  line, i.e. with a wavelength about  $0.151\text{ \AA}$  greater than our MCDHF1 value ( $67.551\text{ \AA}$ ). We have noted that the observed wavelength is very close to the MCDHF1 value ( $67.706\text{ \AA}$ ) associated with the  $3s^2 3p^2 ({}^3P) {}^3P 4d {}^2F_{5/2} - 3s^2 3p^3 ({}^3D) {}^2D_{3/2}^{\circ}$  transition between levels #498 and #2. The transition rate for this latter (#498–#2) transition is  $1.252 \times 10^{11}\text{ s}^{-1}$ , about two times larger than the rate ( $6.804 \times 10^{10}\text{ s}^{-1}$ ) of the #507–#3 transition, although the two predicted intensities are very similar. Therefore, we suggest to assign the  $67.702\text{ \AA}$  line to the transition #498/ $3s^2 3p^2 ({}^3P) {}^3P 4d {}^2F_{5/2} - \#2/3s^2 3p^3 ({}^3D) {}^2D_{3/2}^{\circ}$ . As a consequence, the NIST (and CHIANTI1) energy for the upper level #498 should be changed to  $1\,518\,627\text{ cm}^{-1}$ , which agrees with our MCDHF1  $1\,518\,836\text{ cm}^{-1}$  to within  $210\text{ cm}^{-1}$ . Similar discrepancies are noted in Table 3.

### 3.3. Transition rates and lifetimes

Wavelengths  $\lambda_{ij}$  and the present MCDHF radiative transition data, which include transition rates  $A_{ji}$ , weighted oscillator strengths  $gf_{ji}$ , line strength  $S_{ji}$ , and branching fractions ( $\text{BF}_{ji} = A_{ji} / \sum_{k=1}^{j-1} A_{jk}$ ) for electric-dipole (E1), magnetic dipole (M1), electric quadrupole (E2), and magnetic quadrupole (M2) transitions among all the levels listed in Table 2 are reported in Table 4. E1 and E2 radiative transition data are given in both length ( $l$ ) and velocity ( $v$ ) forms. Using the uncertainty estimation approach (Kramida 2013, 2014), for E1 and E2 transitions we provide the estimated uncertainties of line strengths  $S$  adopting the NIST ASD (Kramida et al. 2018) terminology (A<sup>+</sup>  $\leq 2\%$ , A  $\leq 3\%$ , B<sup>+</sup>  $\leq 7\%$ , B  $\leq 10\%$ , C<sup>+</sup>  $\leq 18\%$ , C  $\leq 25\%$ , D<sup>+</sup>  $\leq 40\%$ , D  $\leq 50\%$ , and E  $> 50\%$ ) in the last column of this table. The difference  $\delta S$  between line strengths  $S_l$  and  $S_v$  (in length and velocity forms respectively) is defined as  $\delta S = |S_v - S_l| / \max(S_v, S_l)$ . The averaged uncertainties  $\delta S_{av}$  for line strengths  $S$  for E1 transitions Fe XII in various ranges of  $S$  are assessed to  $1\%$  for  $S \geq 10^{-1}$ ;  $1.5\%$  for  $10^{-1} > S \geq 10^{-2}$ ;  $2.7\%$  for  $10^{-2} > S \geq 10^{-3}$ ;  $6\%$  for  $10^{-3} > S \geq 10^{-4}$ ;  $12\%$  for  $10^{-4} > S \geq 10^{-5}$ ,

and  $23\%$  for  $10^{-5} > S \geq 10^{-6}$ . Then, the larger of  $\delta S_{av}$  and  $\delta S_{ji}$  is accepted as the uncertainty of each particular line strength. In Table 4, about  $24\%$  of E1  $S$  values in Fe XII have uncertainties of  $\leq 2\%$  (A<sup>+</sup>),  $27\%$  have uncertainties of  $\leq 3\%$  (A),  $29\%$  have uncertainties of  $\leq 7\%$  (B<sup>+</sup>),  $2.4\%$  have uncertainties of  $\leq 10\%$  (B),  $12\%$  have uncertainties of  $\leq 18\%$  (C<sup>+</sup>),  $3.6\%$  have uncertainties of  $\leq 25\%$  (C), and  $0.9\%$  have uncertainties of  $\leq 40\%$  (D<sup>+</sup>), while only  $0.3\%$  have uncertainties of  $> 40\%$  (D and E).

In the spirit of the uncertainty estimation approach (Kramida 2013, 2014), the estimated uncertainties of line strengths  $S$  for E2 transitions in Fe XII are estimated, as well as those for E1 and E2 transitions in Mn XI, Co XIII, and Ni XIV. The estimated uncertainties for all E1 and E2 transitions with  $\text{BF} \geq 10^{-5}$  in Mn XI, Fe XII, Co XIII, and Ni XIV, are listed in Table 4.

Our MCDHF radiative lifetimes  $\tau_{\text{MCDHF}}^l$  (in s) in the length form and  $\tau_{\text{MCDHF}}^v$  (in s) in the velocity form, for the lowest 546 (623, 701, 745) states of the  $3p^4 3d$ ,  $3s 3p^2 3d^2$ ,  $3s 3p^3 4p$ ,  $3s 3p^4$ ,  $3s^2 3d^3$ ,  $3s^2 3p^2 3d$ ,  $3s^2 3p^2 4d$ ,  $3s^2 3p^2 4s$ ,  $3p^3 3d^2$ ,  $3p^5$ ,  $3s 3p 3d^3$ ,  $3s 3p^3 3d$ ,  $3s 3p^3 4s$ ,  $3s^2 3p 3d^2$ ,  $3s^2 3p^2 4p$ ,  $3s^2 3p^3$  configurations in Mn XI (Fe XII, Co XIII, Ni XIV), which are calculated by considering all possible E1, E2, M1, and M2 transitions, are provided in Table 2. Our MCDHF radiative lifetimes  $\tau_{\text{MCDHF}}^l$  and  $\tau_{\text{MCDHF}}^v$  show good agreement. For example, the average deviation between  $\tau_{\text{MCDHF}}^l$  and  $\tau_{\text{MCDHF}}^v$  for all 623 levels in Fe XII is  $1\%$ .

### 3.4. Summary

Using the MCDHF method combined with the RCI approach, including the transverse electron interaction in the low-frequency limit and the leading QED effects corrections, calculations have been performed for the lowest 546 (623, 701, 745) levels of the  $3p^4 3d$ ,  $3s 3p^2 3d^2$ ,  $3s 3p^3 4p$ ,  $3s 3p^4$ ,  $3s^2 3d^3$ ,  $3s^2 3p^2 3d$ ,  $3s^2 3p^2 4d$ ,  $3s^2 3p^2 4s$ ,  $3p^3 3d^2$ ,  $3p^5$ ,  $3s 3p 3d^3$ ,  $3s 3p^3 3d$ ,  $3s 3p^3 4s$ ,  $3s^2 3p 3d^2$ ,  $3s^2 3p^2 4p$ ,  $3s^2 3p^3$  configurations in Mn XI (Fe XII, Co XIII, Ni XIV). Excitation energies, radiative transition data, and lifetimes are reported.

Our detailed discussion of the excitation energies of the  $n = 4$  levels for Fe XII, highlights that the identifications are questionable for a few  $n = 4$  states. The comparison between experimental and predicted energies clearly shows that the present calculations reach spectroscopic accuracy for these high-lying states. On that basis, several identifications in the other isoelectronic ions are also uncertain. Our calculated excitation energies, as well as radiative transition data, can be used to reliably identify the remaining Fe XII and Ni XIV

levels, and especially to identify all the  $n = 4$  states along the isoelectronic sequence of P-like ions, where very little experimental data are available. The present MCDHF study should therefore stimulate further experimental investigations for those ions. The resulting accurate and consistent MCDHF data set will be useful for astrophysical modeling, line identification work and also for benchmarking other calculations.

#### SCIENTIFIC SOFTWARE PACKAGES

Scientific software packages including

*Software:* GRASP2K (Jönsson et al. 2007; Jönsson et al. 2013) and CHIANTI (Dere et al. 2019; Dere et al. 1997) are used in the present work.

We acknowledge the support from the National Key Research and Development Program of China under Grant No. 2017YFA0403200, the Science Challenge Project of China Academy of Engineering Physics (CAEP) under Grant No. TZ2016005, the National Natural Science Foundation of China (Grant No. 11703004, No. 11674066, No. 11504421, and No. 11734013), the Natural Science Foundation of Hebei Province, China (A2019201300 and A2017201165), and the Natural Science Foundation of Educational Department of Hebei Province, China (BJ2018058). This work is also supported by the Fonds de la Recherche Scientifique - (FNRS) and the Fonds Wetenschappelijk Onderzoek - Vlaanderen (FWO) under EOS Project n° O022818F, and by the Swedish research council under contracts 2015-04842 and 2016-04185. GDZ acknowledges support from STFC (UK) via the consolidated grant to the solar/atomic astrophysics group, DAMTP, University of Cambridge. KW expresses his gratitude to the support from the visiting researcher program at the Fudan University.

**Table 2.** Excitation energies in  $\text{cm}^{-1}$  for the 546 (623, 701, 745) lowest levels of Mn XI (Fe XII, Co XIII, Ni XIV), as well as radiative lifetimes (in s).  $E_{\text{MCDHF}}$  - our MCDHF excitation energies;  $E_{\text{NIST}}$  - observed values compiled in the NIST ASD (Kramida et al. 2018);  $\Delta E$ : energy differences (in  $\text{cm}^{-1}$ ) between the values of  $E_{\text{MCDHF}}$  and  $E_{\text{NIST}}$ .  $\tau_{\text{MCDHF}}^l$  - our MCDHF lifetimes in length form;  $\tau_{\text{MCDHF}}^v$  - our MCDHF lifetimes in velocity form;  $LS$ -composition - the  $LS$  eigenvector compositions. Many levels are strongly mixed, implying ambiguous configuration labels. In these cases, the parity,  $J$ , and energy, are used to match the theoretical levels with the atomic energy levels from NIST ASD. For those levels, the NIST values are shown in the blue color. Energy differences larger than  $2\,000\text{ cm}^{-1}$  are displayed in red color.

Z	Key	Level	$J\pi$	$E_{\text{MCDHF}}$	$E_{\text{NIST}}$	$\Delta E$	$\tau_{\text{MCDHF}}^l$	$\tau_{\text{MCDHF}}^v$	$LS$ -composition

NOTE— Table 2 is published in its entirety in the machine-readable format. The results for the levels, for which the NIST values are available, are shown here for guidance regarding its form and content.

**Table 3.** A list of the strongest lines from  $n = 4$  levels for Fe XII. The relative intensities in column 3  $Int = N_j A_{ji} / N_e$  are normalised (photons) and are calculated at high density ( $10^{19} \text{ cm}^{-3}$ ), using the atomic data in Del Zanna et al. (2012b). Column 4 gives the experimental wavelength  $\lambda_{\text{exp}}$  (Å), as in NIST (due to Fawcett) or due to Del Zanna (2012b) ( $^D$ ). We add a 'No' if we consider the previous identification incorrect. Column 5 gives the AUTOSTRUCTURE (AS) wavelength  $\lambda_{\text{AS}}$ , column 6 our present wavelength  $\lambda_{\text{MCDHF}}$  (with differences with the experimental ones in bracket), while the following column ( $\lambda_{\text{rev}}$ ) reports the new experimental wavelengths that we propose. The last column indicates if a line is strong in low-density astrophysical plasma (\*), if it is blended (sbl), if its identification is questionable (?) or new (N).

$i-j$	Transition	$Int$	$\lambda_{\text{exp}}$	$\lambda_{\text{AS}}$	$\lambda_{\text{MCDHF}}$	$\lambda_{\text{rev}}$	Notes

**Table 4.** Transition wavelengths  $\lambda$  (in Å), transition rates  $A$  (in  $\text{s}^{-1}$ ), weighted oscillator strengths  $gf$ , and line strengths  $S$  (in a.u.) between the states of Mn XI (Fe XII, Co XIII, Ni XIV) listed in Table 2. E1 and E2 transition data in both the length ( $l$ ) and velocity ( $v$ ) forms are provided. Type is the type of the multipole, BF is the branching fraction from the upper level. The last column (Acc.) represents the estimated accuracies of the  $S$  values using the terminologies of the NIST ASD. Only transitions with  $\text{BF} \geq 10^{-5}$  are presented.

$Z$	$i$	$j$	$\lambda$	Type	BF	$A^l$	$gf^l$	$S^l$	$A^v$	$gf^v$	$S^v$	Acc.
