BOUNDS FOR EXIT TIMES OF BROWNIAN MOTION AND THE FIRST DIRICHLET EIGENVALUE FOR THE LAPLACIAN

RODRIGO BAÑUELOS†, PHANUEL MARIANO⋆, AND JING WANG‡

ABSTRACT. For domains in \( \mathbb{R}^d \), \( d \geq 2 \), we prove universal upper and lower bounds on the product of the lowest eigenvalue for the Laplacian to the power \( p \geq 1 \) and the supremum over all starting points of the \( p \)-moments of the exit time of Brownian motion. It is shown that the lower bound is sharp for integer values of \( p \) and that the upper bound is asymptotically sharp as \( d \to \infty \). These results extend known estimates for \( p = 1 \). We propose a sharp upper bound among the class of doubly symmetric domains in the plane.

1. INTRODUCTION

There is a large class of results often referred to as generalized isoperimetric inequalities that have wide interest in both the mathematics and physics community. At the heart of these inequalities is the classical isoperimetric inequality which states that among all regions of fixed volume, surface area is minimized by balls. In spectral theory among the classical results is the celebrated Rayleigh-Faber-Krahn inequality which states that among all domains \( D \subset \mathbb{R}^d \) having the same volume as a ball \( D^* \),

\[
\lambda_1(D) \geq \lambda_1(D^*),
\]

where $\lambda_1(D)$ denotes the first Dirichlet eigenvalue for the Laplacian in $D$. Further, equality holds if and only if $D$ is a ball. Other such classical isoperimetric-type inequalities involving integrals of green functions and heat kernels can be found in the classical books of Polyá and Szego [61] and Bandle [17].

On the other hand, it has also been known for many years that one can state many of these inequalities in terms of exit time of Brownian motion from the domain $D$. This probabilistic connection provides new insights and raises many interesting questions on their validity for processes other than Brownian motion, such as Lévy processes. To illustrate, let $B_t$ be a $d$–dimensional Brownian motion starting at the point $x \in D$ and let

$$\tau_D = \inf \{ t > 0 \mid B_t \notin D \},$$

be its first exit time from $D$. Using the symmetrization techniques for multiple integrals in [29, 48, 49] it follows that

$$\sup_{x \in D} \mathbb{P}_x (\tau_D > t) \leq \mathbb{P}_0 (\tau_\cdot > t),$$

for all $t > 0$. In particular,

$$\sup_{x \in D} \mathbb{E}_x [\tau_D] \leq \mathbb{E}_0 [\tau_\cdot].$$

Equality holds in these inequalities if and only if $D$ is a ball. Inequality (1.1) follows from inequality (1.2) by taking logs, dividing by time and letting time go to infinity. More precisely, for $D \subset \mathbb{R}^d$ the classical result states that

$$\lim_{t \to \infty} \frac{1}{t} \log \mathbb{P}_x (\tau_D > t) = -\frac{\lambda_1(D)}{2}$$

In a similar way, the classical isoperimetric inequality can be obtained from isoperimetric inequalities for exit times of Brownian motion using small time behavior. These are now classical results with many extensions and applications that can be found in [2, 30, 62, 15] and many other references given in these papers.

There have been other extremal problems for exit times of Brownian motion where instead of fixing the volume one fixes the inradius $R_D$. This quantity is defined to be the supremum over the radii of all balls contained in $D$. In this paper we always assume that $0 < R_D < \infty$ whenever $R_D$ appears. The exit time $\tau_D$ is trivially monotone increasing as a function of $D$ and for a ball $B(0, r) \subset \mathbb{R}^d$ we have

$$\sup_{x \in B(0, r)} \mathbb{E}_x [\tau_{B(0, r)}] = \mathbb{E}_0 [\tau_{B(0, r)}] = \frac{1}{r^2}. $$

It follows that $\frac{1}{r^2} R_D^2 \leq \sup_{x \in D} \mathbb{E}_x [\tau_D]$. On the other hand, since for domains in the plane removing points does not affect the exit time but can decrease the inradius, it follows that the opposite inequality $\sup_{x \in D} \mathbb{E}_x [\tau_D] \leq C_2 R_D^2$ cannot hold with a universal constant $C_2$. It follows from [5] that under a certain capacity condition which in particular holds for all simply connected domains in the plane, we do have $\sup_{x \in D} \mathbb{E}_x [\tau_D] < CR_D^2$. In [9], the authors proved that if we denote the best constant for the planar simply connected case by $D$, then

$$\frac{1}{2} R_D^2 \leq \sup_{x \in D} \mathbb{E}_x [\tau_D] \leq DR_D^2,$$
with $1.584 \leq D \leq 3.228$. This upper bound on $D$ is the best available in the literature while the lower bound was improved in [57] to 1.6707. The question of finding the best constant on the right hand side of (1.4) for all simply connected domains remains wide open, although the existence of an extremal domain was proved in [13].

The problems we will address in this paper concerned yet another extremal problem where the inequalities involve the maximal expected lifetime $\sup_{x \in D} E_x [\tau_D]$ and $\lambda_1(D)$. Since it trivially holds that for domains $D_1, D_2 \subset \mathbb{R}^d$ such that $D_1 \subset D_2$ we have $\lambda_1(D_2) \leq \lambda_1(D_1)$, it follows that $\lambda_1(D) \leq \frac{\lambda_1(B(0,1))}{R_D^2}$, where $\lambda_1(B(0,1))$ is the eigenvalue for the unit ball, which is just a constant depending on $d$. Exactly as the case of an upper bound of the form $C_2 R_D^2$ for the maximal expected time, a lower bound of the form $\frac{C_2}{R_D}$ for the eigenvalue does not hold. Again, removing points in two dimensions does not affect $\lambda_1(D)$ but it can certainly decrease $R_D^2$. On the other hand, exactly as with the $\sup_{x \in D} E_x [\tau_D]$, under the capacity condition the variational formula for $\lambda_1(D)$ and Ancona’s Hardy inequality [3] show that $\lambda_1(D)$ is bounded below by a $\frac{C_2}{R_D}$. Thus for domains with the capacity condition the quantities $\sup_{x \in D} E_x [\tau_D]$, $R_D^2$ and $\frac{1}{\lambda_1(D)}$ are all comparable. Questions of proving sharp comparison theorems for all these quantities are wide open and have been extensively studied. It was proved in [9] that for a simply connected planar domain $D$,

$$
2 \leq \lambda_1(D) \sup_{x \in D} E_x [\tau_D] \leq \frac{7 \zeta(3) j_0^2}{8} \approx 6.08,
$$

where $j_0$ is the first positive root of the first Bessel function. The lower bound had been known for many years. It holds for any domain in $\mathbb{R}^d$ and its proof is quite simple, see the proof of Theorem 2.1 below.

For further discussion on these problems and connections to another long standing open problem concerning the hyperbolic metric (in the case of simply connected planar domains), we refer the reading to [9, pg. 598] and [4].

While the two sided comparabilities of $\sup_{x \in D} E_x [\tau_D]$ with $R_D^2$ and of $\lambda_1(D)$ with $\frac{1}{\lambda_1(D)}$ require assumptions on the domain, the two sided comparability between $\sup_{x \in D} E_x [\tau_D]$ and $\lambda_1(D)$ holds under very general conditions on $D$. More precisely, whenever $\lambda_1(D) > 0$, it holds that

$$
2 \leq \lambda_1(D) \sup_{x \in D} E_x [\tau_D] \leq C_d
$$

for some constant $C_d$ depending only on $d$. It was proved, independently, by van den Berg-Carrol in [23] and Giorgi-Smits [37], that inequality (1.6) holds with

$$
C_d = 2(4 + 3d \log 2),
$$

and that asymptotically the linearity in $d$ is the best possible. In [37], the better bound

$$
d + \frac{4 \cdot 2^{d/4} \Gamma(d/4 + 1)}{\Gamma^{1/2}(d/2 + 1)} \approx c_1 d + c_2.
$$

is obtained. In the recent work [19, 38], the authors independently show that the lower bound of 2 in (1.6) is sharp for all bounded domains. The authors construct a
sequence of non-simply connected domains $D \subset \mathbb{R}^d$ satisfying $\lambda(D) \sup_{x \in D} \mathbb{E}_x[\tau_D] < 2 + \epsilon$ for any small enough $\epsilon > 0$, thus proving that the lower bound 2 is sharp.

The question of proving a sharp upper bound is wide open even when restricted to special classes of domains such as planar simply connected or convex domains. However, there has been some progress in obtaining a better understanding of the behavior of the constant as a function of $d$. In the recent paper [63], the author develops new techniques to improve the upper bound to

$$(1.9) \quad \frac{d}{4} + \frac{\sqrt{d}}{2} \sqrt{5 \left(1 + \frac{1}{4} \log 2\right)} + 2.$$ 

for general domains. This bound is a significant improvement over (1.8). In fact, by comparing with the ball it shows that the leading term $\frac{d}{4}$ is sharp.

In this paper we improve on Vogt’s upper bound and prove versions for higher moments of the exit time. For $0 < p < \infty$, we define the $p$–torsion function $u_p : D \to \mathbb{R}_+$ by,

$$(1.10) \quad u_p(x) = \frac{1}{2p \Gamma(p + 1)} \mathbb{E}_x[\tau_D^p],$$

which is a scaled $p$th moment of the lifetime of Brownian motion in $D$. When $k \in \mathbb{N}$, and $\sup_{x \in D} u_k(x) < \infty$, these functions are solutions to

$$\begin{cases} 
-\Delta u_1 = 1 & u_1 \in H^1_0(D) \\
-\Delta u_k = u_{k-1} & u_k \in H^1_0(D), \, k = 2, 3, \ldots 
\end{cases}$$

When $p = 1$,

$$u_1(x) = \frac{1}{2} \mathbb{E}_x[\tau_D]$$

is the classical torsion function which has been extensively studied in the literature with application in many areas of mathematics and mathematical physics. Here we refer the reader to the classical works [17, 44, 61].

For applications to the study of heat flow and conduction, exit time moments, torsional rigidity, the study of minimal sub-manifolds, and optimal trapping of Brownian motion and gradient estimates, we refer the reader to [28, 27, 40, 43, 46, 47, 53, 26]. In [38], the author obtains a spectral bound for the torsion function of symmetric stable processes that is asymptotically sharp for large dimension. The functions $u_k$ have also been applied to the study of heat flow in [54, 55, 56, 26]. In [33], the authors provide an algorithm that produces uniform approximations of arbitrary continuous functions by exit time moments. In [52] a finite exit time moment condition is used to imply a version of Phragmén-Lindelöf principle. We also point to the work of [41], where the authors use the $L^1$ norms of $u_k$ to give an alternative characterization for $\lambda_1(D)$ on Riemannian manifolds. In the closely related papers [32, 35], the authors give upper bounds on $\lambda_1(D)$ using the $L^1$ norms of exit time moments on manifolds.

For the rest of the paper we will use the notation (as in [9, pg. 598])

$$(1.11) \quad M_{p,d}(\mathcal{E}, \lambda) = \sup_D \left\{ \lambda_1^p(D) \sup_{x \in D} \mathbb{E}_x[\tau_D^p] \right\},$$

$$(1.12) \quad m_{p,d}(\mathcal{E}, \lambda) = \inf_D \left\{ \lambda_1^p(D) \sup_{x \in D} \mathbb{E}_x[\tau_D^p] \right\}.$$
where the supremum and infimum are taken over all domains $D \subset \mathbb{R}^d$ with $\lambda_1(D) > 0$.

The purpose of this paper is to prove sharp upper and lower bounds for $M_{p,d}(E, \lambda)$ and $m_{p,d}(E, \lambda)$, respectively. This is done in Theorems 2.1, 3.1 and 4.1. In Theorem 4.4 we show our upper bound is asymptotically sharp for large $d$ by proving

\[
\lim_{d \to \infty} \frac{M_{p,d}(E, \lambda)}{d^p} = \frac{1}{4^p}.
\]

Our results extends the results in [9, 37, 23, 63] for the case $p = 1$. Our proof combines the probabilistic techniques from [37] and the analytic techniques from [63].

In Section 5, we compare our upper bound estimates for $M_{1,d}(E, \lambda)$ to the previous known estimates and discuss the problems of finding an extremal domains $D$ for this quantity restricted to various subclasses of domains. We conjecture that the square is the maximizer over all open, bounded, planar convex domains that are symmetric with respect to both axis. We refer the reader to the references [18, 39, 50, 20, 21, 22, 24, 25] for further results on improving upper bound estimates and the conjecture that amongst all planar convex domains the equilateral triangle is extremal.

Obviously all the bounds in this paper can be stated in terms of the $p$–torsion function $u_p(x)$ in place of $\sup_{x \in D} E_x [\frac{\tau_D}{d}]$ with the appropriate factor given in (1.10). Since many of the results in the literature are stated in terms of the torsion function, in order to draw clear comparisons to our results, we state those explicitly from time to time. For this reason, we also define similarly to (1.11) and (1.12) their p-torsion versions by

\[
M_{p,d}(T, \lambda) = \sup_D \{ \lambda_1^p(D) \| u_p \|_{\infty} \},
\]

(1.14)

\[
m_{p,d}(T, \lambda) = \inf_D \{ \lambda_1^p(D) \| u_p \|_{\infty} \},
\]

(1.15)

where as above the sup and inf are taking over all domains $D \subset \mathbb{R}^d$ with $\lambda_1(D) > 0$.

2. The Lower Bound for $m_{p,d}(E, \lambda)$

Let $K_D(x,y,t)$ be the Dirichlet heat kernel for $\Delta$ in $D$. The transition density $p_D$ for Brownian motion killed upon leaving $D$ is given by

\[
p_D(x,y,t) = K_D(x,y,t/2),
\]

as $\frac{1}{2} \Delta$ is the generator of Brownian motion. We can then write

\[
E [\tau_D^p] = p \int_0^{\infty} t^{p-1} \mathbb{P}_x (\tau_D > t) \, dt = p \int_0^{\infty} \int_D t^{p-1} p_D(x,y,t) \, dy \, dt
\]

\[= 2^p p \int_0^{\infty} \int_D s^{p-1} K_D(x,y,s) \, dy \, ds.\]

**Theorem 2.1.** Fix $p > 0$. Then

\[
2^p \Gamma (p + 1) \leq m_{p,d}(E, \lambda).
\]

Furthermore, the inequality is an equality when $p$ takes values in $\mathbb{N}$. 5
Proof. We first prove the inequality. Let us assume for the moment that the domain $D$ is bounded (or even just that it has finite volume). In this case we have a discrete spectrum with a complete set of eigenfunctions on $L^2(D)$ and the eigenfunction $\varphi_1$ corresponding to $\lambda_1(D)$ is in $L^\infty(D)$. For this, we refer the reader to [34]. Since

$$e^{-\lambda_1 t/2} \varphi_1(x) = \int_D p_D(x, y, t) \varphi_1(y) dy$$

integrating in time we find that

$$\varphi_1(x) \frac{2p}{\Gamma(p)} = \varphi_1(x) \int_0^\infty p^{p-1} e^{-\lambda_1 t/2} dt$$

$$= p \int_0^\infty \int_D t^{p-1} p_D(x, y, t) \varphi_1(y) dy dt$$

$$\leq \sup_{y \in D} \varphi_1(y) \cdot \left( p \int_0^\infty \int_D t^{p-1} p_D(x, y, t) dy dt \right)$$

$$= \sup_{y \in D} \varphi_1(y) \mathbb{E}_x [\tau_D^p].$$

(2.3)

Since $p\Gamma(p) = \Gamma(p+1)$, this gives the desired lower bound by taking a supremum over all $x \in D$.

To remove the boundedness assumption on $D$, let $r > 0$ and consider the open set $D \cap B(0, r)$ which is nonempty for large enough $r$. Since $D \cap B(0, r) \subset D$, we have $\mathbb{E}_x [\tau_{D \cap B(0, r)}] \leq \mathbb{E}_x [\tau_D^p]$ and it follows that

$$\sup_{x \in D \cap B(0, r)} \mathbb{E}_x [\tau_D^p] \geq \sup_{x \in D \cap B(0, r)} \mathbb{E}_x [\tau_{D \cap B(0, r)}] \geq 2^p \Gamma(p+1) \cdot \left( \lambda_1(D \cap B(0, r)) \right)^{-p}.$$

Taking $r \to \infty$ completes the proof of the lower bound.

It remains to prove the sharpness of (2.1). For any $d \geq 2$, it was shown by van den Berg in [19, Theorem 1] that there exists of a sequence of bounded domains $D_{\epsilon_n} \subset \mathbb{R}^d$ satisfying

$$2 \leq \lambda_1(D_{\epsilon_n}) \sup_{x \in D_{\epsilon_n}} \mathbb{E}_x [\tau_{D_{\epsilon_n}}] < 2 + \epsilon_n,$$

(2.5)

where $\epsilon_n \to 0$, as $n \to \infty$. That is, van den Berg showed that the inequality (2.1) is sharp for $p = 1$. Independently, the same result was shown in [38, Theorem 3.3] using a different proof. As it turns out, van den Berg’s domains also show the sharpness for any integers larger than 1. For this, we need the following well known inequality whose proof we provide here for completeness. (See for example [7, Corollary 1] and [16, Lemma 18.1])

Lemma 2.2. Let $D \subset \mathbb{R}^d$ be a domain satisfying $\sup_{x \in D} \mathbb{E}_x [\tau_D] < \infty$. Then for any $k \in \mathbb{N}$,

$$\mathbb{E}_x [\tau_D^k] \leq k! \left( \sup_{x \in D} \mathbb{E}_x [\tau_D] \right)^k, \quad x \in D.$$
Proof. By the Markov property and Fubini’s theorem we have for any $a \geq 0$,
\[
\int_a^\infty P_x(\tau_D > t) \, dt = \int_0^\infty P_x(\tau_D > t + a) \, dt
\]
\[
= \int_0^\infty E_x[1_{(\tau_D > a)}] P_{X,a}(\tau_D > t) \, dt = E_x[1_{(\tau_D > a)}] E_{X,a}[\tau_D]
\]
(2.6)
\[
\leq \left( \sup_{x \in D} E_x[\tau_D] \right) P_x(\tau_D > a).
\]
Multiplying both sides by $ka^{k-1}$ and integrating on $a$ gives that
\[
\int_0^\infty ka^{k-1} \int_a^\infty P_x(\tau_D > t) \, dt \, da = \int_0^\infty t^k P_x(\tau_D > t) \, dt = \frac{1}{k+1} E_x[\tau_D^{k+1}],
\]
and
\[
\left( \sup_{x \in D} E_x[\tau_D] \right) \int_0^\infty ka^{k-1} P_x(\tau_D > a) \, da = \left( \sup_{x \in D} E_x[\tau_D] \right) E_x[\tau_D^k].
\]
The desired inequality then follows by induction. 

Returning to the sharpness of inequality (2.1), fix $k \in \mathbb{N}$. Let $D_{\epsilon_n}$ be the domains satisfying (2.5). We claim that
\[
\lambda_1 (D_{\epsilon_n})^k \cdot \sup_{x \in D_{\epsilon_n}} E_x[\tau_{D_{\epsilon_n}}^k] \leq 2^k k! + 2k \cdot k! \epsilon_n + o(\epsilon_n)
\]
where $\epsilon_n \to 0$ as $n \to \infty$.

Indeed, from Lemma 2.2 and the estimate (2.5).
\[
\lambda_1 (D_{\epsilon_n})^k \cdot \sup_{x \in D_{\epsilon_n}} E_x[\tau_{D_{\epsilon_n}}^k] \leq \lambda_1 (D_{\epsilon_n})^k \left( \sup_{x \in D_{\epsilon_n}} E_x[\tau_{D_{\epsilon_n}}] \right)^k
\]
\[
= k! \left( \lambda_1 (D_{\epsilon_n}) \cdot \sup_{x \in D_{\epsilon_n}} E_x[\tau_{D_{\epsilon_n}}] \right)^k \leq k! (2 + \epsilon_n)^k
\]
\[
= 2^k k! + 2k \cdot k! \epsilon_n + o(\epsilon_n).
\]
This proves the sharpness of the inequality (2.1) and completes the proof of the Theorem. 

It is reasonable to conjecture that under the same assumptions as in Lemma 2.2, the inequality
(2.7) $E_x[\tau_D^p] \leq \Gamma(p+1) \left( \sup_{x \in D} E_x[\tau_D] \right)^p$
holds for any $p \geq 1$. This leads us to the following conjecture.

**Conjecture 2.3.** The lower bounds (2.1) is sharp for any $p \geq 1$.

For further speculations on the validity of (2.7), see (7.2) and Proposition 7.1.
3. The Upper Bounds for $M_{p,d}(E, \lambda)$

We begin by recalling the classical upper incomplete gamma function

$$\Gamma(s, x) = \int_x^{\infty} u^{s-1} e^{-u} du.$$  

The main result of this section is the following upper bound.

**Theorem 3.1.** For any $p \geq 1$, we have

$$M_{p,d}(T, \lambda) \leq C_1(d, p),$$  

and

$$M_{p,d}(E, \lambda) \leq 2p \Gamma(p + 1) C_1(d, p),$$  

where

$$C_1(d, p) := \inf_{a > 0, 0 < \epsilon < 1} \left\{ \frac{a^p}{2p \Gamma(p + 1)} + \frac{1}{\Gamma(p)} \frac{e^{d/4} \sqrt{2}}{(8d)^{d/4}} \sqrt{\frac{\Gamma(d)}{\Gamma(d/2)}} \left( 1 + \frac{1}{\sqrt{\epsilon}} \right)^{d/2} \frac{\Gamma(p, (1 - \epsilon) a/2)}{(1 - \epsilon)^p} \right\}.$$ 

**Proof.** Note $E_x[\tau_D^p] = \int_0^{\infty} t^{p-1} \mathbb{P}_x(\tau_D > t) dt$. The idea is to split the integral into two parts and to estimate them separately using improvements of the estimates in [63]. Since

$$E_x[\tau_D^p] = \int_0^{a/{\lambda_1}} t^{p-1} \mathbb{P}_x(\tau_D > t) dt + \int_a^{\infty} t^{p-1} \mathbb{P}_x(\tau_D > t) dt$$

$$\leq \frac{a^p}{\lambda_1^p} + p \int_a^{\infty} t^{p-1} \mathbb{P}_x(\tau_D > t) dt$$

$$= \frac{a^p}{\lambda_1^p} + p I,$$

where

$$I = \int_a^{\infty} t^{p-1} \mathbb{P}_x(\tau_D > t) dt.$$ 

The estimate on $I$ is obtained in Lemma 3.2 that is presented below, which in turn yields (3.1) and (3.2). \qed

**Lemma 3.2.** For any $x \in D$, $a > 0$, we have

$$I \leq 2p \frac{e^{d/4} \sqrt{2}}{(8d)^{d/4}} \sqrt{\frac{\Gamma(d)}{\Gamma(d/2)}} \left( 1 + \frac{1}{\sqrt{\epsilon}} \right)^{d/2} \frac{\Gamma(p, (1 - \epsilon) a/2)}{(1 - \epsilon)^p \lambda_1^p}.$$ 

The proof of the above lemma will be given in section 3.1. In section 5 we will show, numerically, that the bound gives improvements to already known bounds in [9, 37, 23, 63], even for the case $p = 1$.

As a direct consequence it gives a sharp bound for $p = 1$, which improves the result in [63].
Corollary 3.3.

\[ M_{1,d}(T, \lambda) \leq \frac{d}{4y_d (1 + \sqrt{y_d})} =: C_3(d, 1) \]

with the same bound multiplied by 2 for \( M_{1,d}(E, \lambda) \). Here, \( y = y_d \in (0, 1) \) is the unique solution to

\[ -d + d\sqrt{y} + (4 \cdot 4A_d) y + (2d) y \log ((1 + 1/\sqrt{y})/2) = 0, \quad y \in (0, 1), \]

where

\[ A_d = \log \left[ \frac{2^{d/2}e^{d/4}\sqrt{2}}{(8d)^{d/4}} \sqrt{\frac{\Gamma(d)}{\Gamma(d/2)}} \right], \]

and

\[ \lim_{d \to \infty} y_d = 1. \]

Proof. From (3.3) we have

\[ C_1(d, 1) := \inf_{x > 0, 0 < y < 1} f(x, y) \]

where \( f : \mathbb{R}_+ \times [0, 1] \to \mathbb{R}_+ \) is defined by

\[ f(x, y) = \frac{x^2}{2} + \frac{e^{d/4}\sqrt{2}}{8d^{d/4}} \frac{\Gamma(d)}{\Gamma(d/2)} \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \frac{1}{1-y} e^{-(1-y)x/2}. \]

We will optimize this function. Note that

\[ f_x(x, y) = \frac{1}{2} - \frac{1}{2} \frac{e^{d/4}\sqrt{2}}{8d^{d/4}} \frac{\Gamma(d)}{\Gamma(d/2)} \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \frac{1}{1-y} e^{-(1-y)x/2}, \]

we obtain the minimizer of \( f(\cdot, y) \)

\[ x_y = \frac{2}{1-y} \log \left[ \frac{e^{d/4}\sqrt{2}}{8d^{d/4}} \frac{\Gamma(d)}{\Gamma(d/2)} \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right]. \]

We are then let to minimize the one variable function

\[ g(y) := f(x_y, y) = \frac{1}{1-y} \log \left[ \frac{e^{d/4}\sqrt{2}}{8d^{d/4}} \frac{\Gamma(d)}{\Gamma(d/2)} \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right] + \frac{1}{1-y} \]

\[ = \frac{d}{4} \log \left( \frac{1+1/y}{2} \right) + 1 + A_d \]

where

\[ A_d = \log \left[ \frac{2^{d/2}e^{d/4}\sqrt{2}}{(8d)^{d/4}} \sqrt{\frac{\Gamma(d)}{\Gamma(d/2)}} \right]. \]

Since

\[ g'(y) = -d (1 - \sqrt{y}) + \left( 2d \log \left( \frac{1+1/\sqrt{y}}{2} \right) + 4 \cdot 4A_d \right) y, \]

if we assume that \( y_d \) is a solution to \( g'(y) = 0 \), then

\[ (1 + A_d) = \frac{d}{4y_d} (1 - \sqrt{y_d}) - \frac{d}{2} \log \left( \frac{1+1/\sqrt{y_d}}{2} \right). \]
Plugging (3.11) back in (3.10) we have that
\[ g(y_d) = \frac{d}{4} \frac{1}{y_d (1 + \sqrt{y_d})}, \]
hence we obtain (3.8). Next we show that (3.9) has a unique solution. Let \( F_d : (0, 1) \to \mathbb{R} \) be
\[ F_d(y) = -\frac{d}{4} + \frac{d\sqrt{y}}{4} + y (1 + A_d) + \frac{d}{2} y \log \left( \frac{1 + 1/\sqrt{y}}{2} \right). \]
We easily find that \( \lim_{y \to 0} F_d(y) = -\frac{d}{4} < 0, \; F_d(1) = 1 + A_d > 0 \) and \( F_d'(y) > 0 \). Therefore the conclusion follows.

**Remark 3.4.** From the above corollary we can easily deduce that \( \lim_{d \to \infty} y_d = 1 \). It can be easily shown that \( y_d \) exists (for instance see (3.3) in [63]). From (3.11) we have
\[ \frac{(4 + 4A_d) y_d}{d} = 1 - \frac{1}{\sqrt{y_d}} - 2y_d \log \left( \frac{1 + 1/\sqrt{y_d}}{2} \right). \]
Taking \( d \to \infty \) on both sides we then obtain \( y_\infty = 1 \). This limit coincides with the conclusion in [63], but the corollary is sharper comparing to [63] by providing almost explicit expression for \( y_d \).

### 3.1. Proof of Lemma 3.2 (Upper bound for \( I \))

In this section we derive an improvement to Vogt’s result in [63] to obtain our upper bound for \( I \).

**Lemma 3.5.** Let \( D \subset \mathbb{R}^d \) be measurable, \( \alpha > 0 \), and let \( L \) be a bounded operator on \( L^2(D) \) satisfying
\[ (3.12) \quad \| e^{-\alpha \rho_w L} e^{\alpha \rho_w} \|_{2 \to \infty} \leq 1, \]
for all \( w \in D \), where \( \rho_w(\cdot) = |\cdot - w|, \; w \in \mathbb{R}^d \). Then
\[ (3.13) \quad \| L \|_{\infty \to \infty} \leq \frac{\sqrt{\pi}^{d/4}}{(2\alpha)^{d/2}} \sqrt{\frac{\Gamma(d)}{\Gamma(d/2)}}. \]

**Proof.** The proof is essentially the same as in [63, Proposition 2.5]. Note that \( \| Lf \|_{\infty} = \sup_{w \in D} \| e^{-\alpha \rho_w L} f \|_{\infty} \). Then we have
\[ \| e^{-\alpha \rho_w L} f \|_{\infty} \leq \| e^{-\alpha \rho_w f} \|_2 \leq \| e^{-\alpha \rho_w} \|_2 \| f \|_\infty. \]
Let \( \sigma_{d-1} \) denote the surface measure of the unit sphere, then the conclusion follows from the estimate below.
\[ \| e^{-\alpha \rho_w} \|_2^2 = \int e^{-2\alpha |w - y|} \chi_D(y) dy \leq \int e^{-2\alpha |y|} dy = \sigma_{d-1} \int_0^\infty e^{-2\alpha r} r^{d-1} dr = \frac{2\pi^{d/2}}{\Gamma(d/2)} \frac{\Gamma(d)}{(2\alpha)^d}. \]

Using Lemma 3.5, we then obtain the following estimates that improve the result in [63, Theorem 2.1].
Proposition 3.6. For all $\epsilon \in (0, 1]$, we have
\[
\|e^{-t(\Delta)}\|_{\infty \to \infty} \leq e^{d/4} \sqrt{\frac{2}{(8d)^{d/4}}} \left( \frac{\Gamma (d)}{\Gamma (d/2)} \right)^{d/4} \left( 1 + \frac{1}{\sqrt{\epsilon}} \right)^{d/2} e^{-(1-\epsilon)\lambda_1 t},
\]
for $t \geq 0$. In particular, for all $x \in D$ and $t \geq 0$,
\[
(3.14) \quad P_x (\tau_D > t) \leq e^{d/4} \sqrt{\frac{2}{(8d)^{d/4}}} \left( \frac{\Gamma (d)}{\Gamma (d/2)} \right)^{d/4} \left( 1 + \frac{1}{\sqrt{\epsilon}} \right)^{d/2} e^{-(1-\epsilon)\lambda_1 t/4}.
\]

Proof. The proof is similar to Theorem 2.1 in [63]. Here we only sketch the key steps. Consider the operator $H = -\Delta_D - \lambda_1$, it is a self-adjoint operator in $L^2 (D)$ with $\lambda (H) = 0$. Clearly the heat kernel of $e^{-tH}$ has the Gaussian upper bound
\[
|K_t (x, y)| \leq e^{\lambda_1 t} \cdot \frac{1}{(4\pi t)^{d/4}} \exp \left( -\frac{|x - y|^2}{4t} \right)
\]
for all $t > 0$ and a.e. $x, y \in D$. It then holds that (see proof of Theorem 2.1, page 43 in [63]) for any $\epsilon \in (0, 1]$
\[
(3.15) \quad \|e^{-\epsilon \alpha \epsilon \cdot e^{-tH} e^{\epsilon \alpha \cdot \cdot}}\|_{\infty \to \infty} \leq (8\pi \epsilon t)^{-d/4} \left( 1 + \frac{1}{\beta} \right)^{d/4} e^{\lambda_1 t e^{(1+\beta)\alpha^2 \epsilon t} + \alpha^2 (1-\epsilon) t}.
\]
Applying Lemma 3.5 to $L = e^{-tH}$ and using (3.15) we have that
\[
\|e^{-tH}\|_{\infty \to \infty} \leq \sqrt{\frac{2\pi^{d/4}}{(2\alpha)^{d/2}}} \sqrt{\frac{\Gamma (d)}{\Gamma (d/2)}} \cdot (8\pi \epsilon t)^{-d/4} \left( 1 + \frac{1}{\beta} \right)^{d/4} e^{\lambda_1 t e^{(1+\beta)\alpha^2 \epsilon t} + \alpha^2 (1-\epsilon) t}.
\]
Taking $\alpha^2 = \frac{d/4}{(1+\beta)\epsilon}$, we obtain
\[
\|e^{-tH}\|_{\infty \to \infty} \leq \sqrt{\frac{2\pi^{d/4}}{(2\alpha)^{d/2}}} \sqrt{\frac{\Gamma (d)}{\Gamma (d/2)}} \cdot (8\pi \epsilon t)^{-d/4} \left( \frac{1+\beta}{\epsilon} \right)^{d/4} e^{\lambda_1 t e^{d/4} \cdot e^{\lambda_1 t d/4}}.
\]
Optimizing the right hand side of the above inequality by taking $\beta = e^{-1/2}$ we have
\[
\|e^{-tH}\|_{\infty \to \infty} \leq e^{d/4} \sqrt{\frac{2}{(8d)^{d/4}}} \sqrt{\frac{\Gamma (d)}{\Gamma (d/2)}} \cdot (1 + \frac{1}{\sqrt{\epsilon}})^{d/2} e^{\lambda_1 t d/4}.
\]
This then completes the proof. \hfill \Box

Proof of Lemma 3.2. By (3.14) we have
\[
I = \int_{\alpha/\lambda_1}^{\infty} t^{p-1} P_x (\tau_D > t) \, dt
\]
\[
(3.16) \quad I \leq e^{d/4} \frac{\sqrt{2}}{(8d)^{d/4}} \sqrt{\frac{\Gamma (d)}{\Gamma (d/2)}} \left( 1 + \frac{1}{\sqrt{\epsilon}} \right)^{d/2} \int_{\alpha/\lambda_1}^{\infty} t^{p-1} e^{-(1-\epsilon)\lambda_1 t/4} \, dt
\]
\[
= 2p e^{d/4} \sqrt{\frac{2}{(8d)^{d/4}}} \sqrt{\frac{\Gamma (d)}{\Gamma (d/2)}} \left( 1 + \frac{1}{\sqrt{\epsilon}} \right)^{d/2} \frac{\Gamma (p, (1-\epsilon) a/2)}{(1-\epsilon)^p \lambda_1^p}.
\]
4. Sharp Asymptotics for $M_{p,d}(E, \lambda)$ and $M_{p,d}(T, \lambda)$.

This section concerns the asymptotic estimates for $M_{p,d}(E, \lambda)$ and $M_{p,d}(T, \lambda)$ in high dimension. First we give an upper bound estimate of $M_{p,d}(E, \lambda)$ by analyzing the variational problem in Theorem 3.1, which provides the correct leading order in $d$ for all $p \geq 1$.

**Theorem 4.1.** For $p \geq 1$,

\[ M_{p,d}(E, \lambda) \leq 2^p \left( \frac{d}{8} + c\sqrt{d} + 1 - \frac{1}{1 - y_d} \right)^p C_2(d, p) \]

and

\[ M_{p,d}(T, \lambda) \leq \frac{1}{\Gamma(p + 1)} \left( \frac{d}{8} + c\sqrt{d} + 1 - \frac{1}{1 - y_d} \right)^p C_2(d, p), \]

where

\[ C_2(d, p) := 1 + p \int_1^\infty u^{p-1} e^{(1-u)[(1-y_d)(\frac{d}{8}+c\sqrt{d}+1)-1]} du, \tag{4.1} \]

\[ c = \frac{1}{4} \left( \frac{5}{1 + \frac{1}{4} \log 2} \right), \quad \text{and} \quad y_d = \frac{1}{\left( 1 + \frac{16c}{5\sqrt{d}} \right)^2}. \]

In the proof of this Theorem we will use the following.

**Lemma 4.2.** With $c$ and $y_d$ as in (4.1) we have

\[ \log \left[ 2^{\frac{1}{2}} \left( 1 + \frac{1}{\sqrt{y_d}} \right)^{d/2} \right] + 1 \leq (1 - y_d) \left( \frac{d}{8} + c\sqrt{d} + 1 \right). \tag{4.2} \]

**Proof.** First note

\[ \text{LHS} = \frac{1}{4} \log 2 + \frac{d}{2} \log \left( \frac{1 + 1/\sqrt{y_d}}{2} \right) + 1. \]

Denote by $\gamma := \frac{5}{16} c$ and set $x = \frac{\gamma}{\sqrt{y_d}}$. We can easily check that $0 < x < 1$. Clearly $1 + 2x = \frac{1}{\sqrt{y_d}}$, and hence

\[ \text{LHS} = \frac{5}{4} \gamma^2 + \frac{d}{2} \log \left( \frac{1 + (1 + 2x)}{2} \right) = \frac{5}{4} \gamma^2 x^2 d + \frac{d}{2} \log (1 + x). \]

On the other hand

\[ \text{RHS} = \left( 1 - \frac{1}{(1 + 2x)^2} \right) \frac{d}{8} \left( 1 + \frac{8c}{\sqrt{d}} + \frac{8}{d} \right) = \frac{x + x^2}{(1 + 2x)^2} \frac{d}{2} \left( 1 + 5x + \frac{8}{\gamma^2} x^2 \right). \]

Thus it suffices to show that for all $x \in (0, 1)$,

\[ \frac{5}{2} x^2 + \log (1 + x) \leq \frac{x + x^2}{(1 + 2x)^2} \left( 1 + 5x + \frac{8}{\gamma^2} x^2 \right). \]

This can be shown by elementary calculus. See details in [63, page 46].

**Proof of Theorem 4.1.** Let

\[ f(x, y) := x^p + 2^p p C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \frac{1}{(1 - y)^p} \Gamma(p, (1 - y)x/2), \]
where \( C_d = \frac{d^{d/4} \sqrt{\pi}}{(8d)^{d/4}} \sqrt{\frac{\Gamma(d)}{\Gamma(d/2)}}. \) Then
\[
2p \Gamma(p + 1) C_1(d, p) = \inf_{x > 0, 0 < y < 1} f(x, y).
\]
First by letting
\[
f_x(x, y) = px^{p-1} \left( 1 - C_d e^{-\frac{1}{2x}} \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right) = 0
\]
we obtain the critical point
\[
x_y = \frac{2}{(1 - y)} \log \left[ C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right].
\]
Hence
\[
f(x, y) = \frac{2p}{(1 - y)^p} \left( \log \left[ C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right] \right)^p + p2^p C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \frac{1}{(1 - y)^p} \Gamma \left( p, \log \left[ C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right] \right).
\]
It is known that (for instance see \[1, 6.1.18]\)
\[
\frac{\Gamma(d)}{\Gamma(d/2)} = \frac{\Gamma(2(d/2))}{\Gamma(2(d/2))} \leq 2^{d-1/2} \left( \frac{d}{2e} \right)^{d/2},
\]
hence we have
\[
(4.4) \quad C_d \leq 2^{-d/2+1/4}.
\]
Combining (4.2) and (4.4) we get
\[
\log \left[ C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right] \leq \log \left[ 2^{\frac{d}{2}} \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right]
\]
\[
\leq (1 - y) \left( \frac{d}{8} + c\sqrt{d} + 1 \right) - 1. \tag{4.5}
\]
Using (4.5) in \( f(x, y) \) we then obtain
\[
(4.6) \quad f(x, y) \leq \frac{2p}{(1 - y)^p} \left( \left( \frac{d}{8} + c\sqrt{d} + 1 \right) - \frac{1}{1 - y} \right)^p + \frac{p2^p}{(1 - y)^p} II,
\]
where \( II = C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \Gamma \left( p, \log \left[ C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right] \right). \) Making the substitution \( x = u \log \left[ C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right] \) and plugging in (4.5) we have
\[
II = C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \left( \log \left[ C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right] \right)^p \int_1^\infty u^{p-1} \left( C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right)^{-u} du
\]
\[
\leq C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \left( 1 - y \right)^p \left( \left( \frac{d}{8} + c\sqrt{d} + 1 \right) - \frac{1}{(1 - y)} \right)^p \int_1^\infty u^{p-1} \left( C_d \left( 1 + \frac{1}{\sqrt{y}} \right)^{d/2} \right)^{-u} du. \tag{4.7}
\]
Moreover, clearly from (4.5) we have
\begin{equation}
(4.8) \quad \left( C_d \left( 1 + \frac{1}{\sqrt{y_d}} \right)^{d/2} \right)^{-u} \leq e^{-u[(1-y_d)(\frac{d}{8}+c\sqrt{d}+1)-1]},
\end{equation}
hence
\begin{equation}
(4.9) \quad II \leq (1 - y_d)^p \left( \left( \frac{d}{8} + c\sqrt{d} + 1 \right) - \frac{1}{1 - y_d} \right)^p \int_1^\infty u^{p-1} e^{(1-u)[(1-y_d)(\frac{d}{8}+c\sqrt{d}+1)-1]} \, du.
\end{equation}
Using (4.9) in (4.6) we arrive at
\begin{equation}
f(x_{y_d}, y_d) \leq 2^p \left( \frac{d}{8} + c\sqrt{d} + 1 - \frac{1}{1 - y_d} \right)^p \left[ 1 + p \int_1^\infty u^{p-1} e^{(1-u)[(1-y_d)(\frac{d}{8}+c\sqrt{d}+1)-1]} \, du \right].
\end{equation}

In the lemma below we show that our result is indeed sharp, by comparing to a unit ball.

**Lemma 4.3.** Let $B(0,1) \subset \mathbb{R}^d$ be the unit ball centered at zero, then
\begin{equation}
\left( \frac{d}{4} \right)^p \leq \lambda_1^p(B(0,1)) \sup_{x \in B(0,1)} \mathbb{E}_x \left[ \tau_{B(0,1)}^p \right].
\end{equation}

**Proof.** It is well known that $\lambda_1(B(0,1)) \geq \frac{d^2}{4}$ (for instance, see [36, Example 5.8]). By a simple calculation we have that $\mathbb{E}_x \left[ \tau_{B(0,1)}^p \right] = \frac{1-|x|^2}{d}$. Hence $\sup_{x \in B(0,1)} \mathbb{E}_x \left[ \tau_{B(0,1)}^p \right] = E_0 \left[ \tau_{B(0,1)}^p \right] = \frac{d}{4}$. By Jensen’s inequality we have
\begin{equation}
\lambda_1^p(B(0,1)) \cdot E_0 \left[ \tau_{B(0,1)}^p \right] \geq \lambda_1^p(B(0,1)) \cdot \left( E_0 \left[ \tau_{B(0,1)}^p \right] \right)^p = \frac{d^p}{4^p}.
\end{equation}

We now have the main result of this section.

**Theorem 4.4.** For $p \geq 1$,
\begin{equation}
(4.10) \quad \lim_{d \to \infty} \frac{M_{p,d}(E, \lambda)}{d^p} = \frac{1}{4^p} \quad \text{and} \quad \lim_{d \to \infty} \frac{M_{p,d}(T, \lambda)}{d^p} = \frac{1}{8^p \Gamma(p+1)}.
\end{equation}

**Proof.** From Theorem 4.1 we have
\begin{equation}
M_{p,d}(E, \lambda) \leq 2^p \left( \frac{d}{8} + c\sqrt{d} + 1 - \frac{1}{1 - y_d} \right)^p C_2(d,p),
\end{equation}
where
\begin{equation}
C_2(d,p) := 1 + p \int_1^\infty u^{p-1} e^{(1-u)(\frac{d}{8}+c\sqrt{d}+1)-1} \, du,
\end{equation}
and
\begin{equation}
y_d = \frac{1}{\left( 1 + \frac{16c}{5\sqrt{d}} \right)^2}, \quad c = \frac{1}{4} \sqrt{5 \left( 1 + \frac{1}{4} \log 2 \right)}.
\end{equation}
First we claim that $\lim_{d \to \infty} C_2(d,p) = 1$. Note that
\begin{equation}
(1 - y_d) \left( \frac{d}{8} + c\sqrt{d} + 1 \right) - 1 \geq 1 + \frac{4c}{5} \sqrt{d} \to \infty
\end{equation}
as \( d \to \infty \). Hence when \( u \geq 1 \) we have
\[
\lim_{d \to \infty} u^{p-1} e^{(1-u)\left(1-y_d\left(\frac{\sqrt{d}}{\pi}+c\sqrt{d}+1\right)-1\right)} = 0,
\]
Moreover, since
\[
\int_{1}^{\infty} u^{p-1} e^{(1-u)\left(1-y_d\left(\frac{\sqrt{d}}{\pi}+c\sqrt{d}+1\right)-1\right)} du \leq \int_{1}^{\infty} u^{p-1} e^{(1-u)} du \leq e\Gamma(p),
\]
by the dominated convergence theorem we obtain that
\[
(4.11) \quad \lim_{d \to \infty} \int_{1}^{\infty} u^{p-1} e^{(1-u)\left(1-y_d\left(\frac{\sqrt{d}}{\pi}+c\sqrt{d}+1\right)-1\right)} du = 0.
\]
It now follows readily that
\[
\limsup_{d \to \infty} \frac{M_{p,d}(E, \lambda)}{d^p} \leq \frac{1}{4^p}.
\]
Together with Lemma 4.3 we then obtain that \( \frac{1}{4^p} \leq \liminf_{d \to \infty} \frac{M_{p,d}(E, \lambda)}{d^p} \), as needed. Using the fact that \( 2^p\Gamma(p+1)M_{p,d}(T, \lambda) = M_{p,d}(E, \lambda) \), we get the conclusion for the \( p \)-torsion function \( u_p \).

5. Some Comparison

We start this section by a comparison of bounds we obtained on \( M_{1,d}(E, \lambda) \) and \( M_{1,d}(T, \lambda) \) with the known upper bounds. We show how the bounds obtained in this paper are not only obtained through a new method, but are indeed improvements to already known bounds.

First we have the bounds for \( M_{1,d}(E, \lambda) \):

\[
\begin{array}{|c|c|c|c|c|c|}
\hline
 & d = 1 & 2 & 3 & 4 & 5 \\
\hline
\lambda_1(B) \sup_{x \in B} \mathbb{E} [\tau_B] & 2.4764 & 2.8916 & 3.2898 & 3.6704 & 4.0382 \\
\text{Banuelos-Carroll, [9]} & 6.0827 & & & & \\
\text{Giorgi-Smits, [37]} & 5.5800 & 8.0898 & 13.2236 & 23.6274 & 45.2082 \\
\text{Vogt, [63]} & 3.461 & 4.2126 & 4.8476 & 5.422 & 5.958 \\
2C_1(d, 1) \leq & 3.33825 & 4.07569 & 4.69866 & 5.26371 & 5.79204 \\
2C_3(d, 1) \leq & 3.33825 & 4.07569 & 4.69866 & 5.26371 & 5.79204 \\
\hline
\end{array}
\]

The bounds for \( M_{1,d}(T, \lambda) \) are obtained by dividing those for \( M_{1,d}(E, \lambda) \) by 2. Given that many papers in the literature are written from the point of view of the torsion function instead of the expected lifetime of Brownian motion, we add the table here for \( M_{1,d}(T, \lambda) \) for the reader’s convenience.
We explain how the estimates of $C_1(d,1)$ and (3.9) are obtained. For example, the bound of

$$C_1(2,1) \leq 2.03785,$$

was found by numerically optimizing the function

$$f_1(a,\epsilon) := \frac{a^p}{2^p \Gamma(p+1)} + \frac{1}{\Gamma(p)} \frac{e^{d/4} \sqrt{2}}{2^d \Gamma(d/2)} \left( 1 + \frac{1}{\sqrt{\epsilon}} \right)^{d/2} \frac{\Gamma(p,(1-\epsilon)a/2)}{(1-\epsilon)^p}.$$

over $a > 0$ and $0 < \epsilon < 1$ for $d = 2$ and $p = 1$ (see Theorem 3.1). Using a computer algebra system, in this case Mathematica, it estimates that the minimum of $f_1(a,\epsilon)$ is obtained at

$$a = 1.65659, \epsilon = 0.173247.$$

Using these values and Theorem 3.1, shows that

$$M_{1,2}(T,\lambda) \leq C_1(2,1) \leq f_1(1.65659,0.173247) \leq 2.03785.$$

This improves the bound of 2.1063 for $\lambda_1(D) \|u_D\|_\infty$ to 2.03785.

Similarly, the bound of

$$C_1(2,1) \leq 2.03785$$

is found by numerically solving the equation

$$(5.1) \quad -d + d\sqrt{y} + (4 + 4A_d) y + (2d) y \log\left((1 + 1/\sqrt{y})/2\right) = 0, \quad y \in (0,1),$$

for $d = 2$, which in this case Mathematica estimates $y_2 \approx 0.173247$. Defining

$$(5.2) \quad f_2(\epsilon) = \frac{d}{4} \frac{1}{y(1 + \sqrt{y})},$$

we have by Corollary 3.3

$$M_{1,2}(T,\lambda) \leq f_2(0.173247) \leq 2.03785.$$

6. Extremal Domains

Given the isoperimetric inequalities (1.1) and (1.3) (as well as other inequalities where balls are extremals), one could speculate about the maximality of the ball $B$ for these extremal problems. It was pointed out in [9, pg. 599] that in fact

$$(6.1) \quad \lambda_1(B) \sup_{x \in B} E_x [\tau_B] < \lambda_1(T) \sup_{x \in T} E_x [\tau_T],$$

where $T$ is the equilateral triangle. This was also later observed in [38, Corollary 3.7]. It was conjectured in [38] that no extremal domain exists over the class of all
domains for the torsion quantity $M_{1,d}(T, \lambda)$ and, of course, this would be the same for $M_{1,d}(\mathbb{E}, \lambda)$. The authors give evidence for their conjecture in their Proposition 3.1. Their techniques involve defining a shape derivative. They show that in the class of bounded open $C^2$ sets, if $\lambda_1(D) \|u_D\|_\infty$ is differentiable at $D$, then $D$ is not a maximizer.

From the above discussion it is reasonable, when looking for extremals, to restrict the class of domains. In [60], Payne showed that

$$m_{1,d}(\mathbb{E}, \lambda) = \frac{\pi^2}{4},$$

where the infimum in (1.12) is now taken over all convex domains. From this it follows trivially that the minimizer domain over convex sets is given by the infinite slab $S_d = \mathbb{R}^{d-1} \times (-1, 1)$. It is proved in [38], that in the class of convex domains there exists maximizers and it is conjectured that when $d = 2$, the equilateral triangle $T$ is an extremal. That is,

**Conjecture 6.1** (Convex Domains, [38]). With the supremum in (1.11) taken over all convex domains,

$$M_{1,2}(\mathbb{E}, \lambda) = \lambda_1(T) \sup_{x \in T} [\tau_T].$$

Though, we believe that if this conjecture is true for $p = 1$, then it most likely is true for all $p > 1$.

There are interesting problems concerning the geometry of the Laplacian in planar convex domains which remain open but for which there has been substantial progress for **doubly symmetric** (symmetric with respect to the both co-ordinate axis) convex domains. As an example, we mention the **hot spots** conjecture for doubly symmetric domains in [8, 14, 59, 42]. For the problem discussed in this paper we have the following conjecture. Let

$$Q_d = \{(x_1, x_2, \ldots, x_d) \in \mathbb{R}^d : |x_i| < 1\}$$

denote the unit cube in $\mathbb{R}^d$.

**Conjecture 6.2** (Doubly Symmetric Convex). With the supremum in (1.11) taken over all doubly symmetric planar convex domains, we have

$$M_{p,2}(\mathbb{E}, \lambda) = \lambda_1^p(Q_2) E_0[\tau_{Q_2}], \quad \text{for all } p \geq 1.$$

It is not hard to see that for the unit disc $B = B(0,1)$, we have

$$\lambda_1(B) \sup_{x \in B} E_x [\tau_B] < \lambda_1(Q_2) \sup_{x \in Q_2} E_x [\tau_{Q_2}].$$

Indeed, note that in both cases $\sup_{x \in B} E_x [\tau_B] = E_{(0,0)}[\tau_B]$ and $\sup_{x \in Q_2} E_x [\tau_{Q_2}] = E_{(0,0)}[\tau_{Q_2}]$. Furthermore,

$$\lambda_1(B) E_{(0,0)}[\tau_B] = \frac{\pi^2}{2} \approx 2.8916,$$

where $j_0$ is the first positive root of the first Bessel function.

On the other hand, $\lambda_1(Q_2) = \frac{\pi^2}{2}$ and by independence,

$$\mathbb{P}_{(0,0)}(\tau_{Q_2} > t) = \mathbb{P}_0(\tau_I > t) \mathbb{P}_0(\tau_I > t).$$
where $I = (-1, 1)$. The eigenfunction expansion for the heat kernel for the interval $I$ (see Proportion 7.1 below or [31, 51]) leads to the formula

$$
E_{(0,0)}[\tau_{Q_2}] = \left[ 1 - \frac{32}{\pi^4} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^3} \text{sech} \left( \left( n + \frac{1}{2} \right) \pi \right) \right].
$$

Thus

$$
\lambda_1(Q_2)E_0[\tau_{Q_2}] = \frac{\pi^2}{2} \left[ 1 - \frac{32}{\pi^3} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^3} \text{sech} \left( \left( n + \frac{1}{2} \right) \pi \right) \right]
\approx 2.90843
$$

which verifies (6.4). Hence, even in the class of doubly symmetric domains the ball fails to be extremal.

Conjecture 6.2 in general seems to be nontrivial. In fact, even the simplest case does not seem obvious. More precisely, let $a = (a_1, a_2, \ldots, a_d)$, where $a_k > 0$ for all $k$. Set $R_a = \{ x = (x_1, x_2, \ldots, x_d) : |x_k| < a_k, k = 1, \ldots, d \}$. Denote the the origin in $\mathbb{R}^d$ by $0$.

Conjecture 6.3 (Hyperrectangular domains).

$$
\lambda_1^p(R_a)E_0[\tau_{R_a}] \leq \lambda_1^p(Q_d)E_0[\tau_{Q_d}]
$$

with equality only when $R_a = Q_d$.

Since the eigenvalues of both $R_a$ and $Q_d$ are explicit and the components of the Brownian motion are independent, the inequality (6.6) can be stated in several different forms. Here is one. Let $I_{a_k} = (-a_k, a_k)$ and recall that $I = (-1, 1)$. Then (6.6) is equivalent to

$$
\left( \sum_{k=1}^{d} \frac{1}{a_k^2} \right)^p \int_0^\infty pt^{p-1} \prod_{k=1}^{d} \mathbb{P}_0(\tau_{I_{a_k}} > t) dt \leq d^p \int_0^\infty pt^{p-1} (\mathbb{P}_0(\tau_I > t))^d dt.
$$

Using the fact that $\mathbb{P}_0(\tau_{I_{a_k}} > t) = \mathbb{P}_0(\tau_I > \frac{t}{a_k})$ we may even assume that $a_1 = 1 < a_2 < \cdots < a_d$. In addition, using the fact that we know the heat kernel for an interval in terms of the eigenfunctions expansion (all which are explicitly given), the inequality has a rather appealing form. Let us look at the case $d = 2$ and $p = 1$. Then (6.7) is equivalent to

$$
(1 + a^2) \left[ 1 - \frac{32}{\pi^4} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^3} \text{sech} \left( \left( n + \frac{1}{2} \right) \pi \right) \right],
$$

$$
\leq 2 \left[ 1 - \frac{32}{\pi^4} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^3} \text{sech} \left( \left( n + \frac{1}{2} \right) \pi \right) \right],
$$

for all $a > 1$.

Unfortunately, despite its simplicity and all its possible formulations, we have not been able to prove Conjecture 6.3 even in the case $d = 2$ and $p = 1$.

We point out that for $p = 1$, Conjecture 6.2 does hold for ellipses. In fact, the following stronger statement holds. Let

$$
E_{a,b} := \left\{ (x, y) \in \mathbb{R}^2 : \frac{x^2}{a^2} + \frac{y^2}{b^2} < 1 \right\}.
$$
Then, with $B$ the unit disc in $\mathbb{R}^2$,

$$\frac{\pi^2}{4} \leq \lambda_1(E_{(0,0)}) \tau_{E_{(0,0)}} \leq \lambda_1(B) \tau_B = \frac{j_0^2}{2},$$

To prove this inequality, it suffices to show that

$$\frac{\pi^2}{4} \left( \frac{a^2 + b^2}{a^2 b^2} \right) \leq \lambda_1(E_{a,b}) \leq \frac{j_0^2}{2} \left( \frac{a^2 + b^2}{a^2 b^2} \right).$$

Assuming for the moment the validity of (6.10), observe that since it is easy to check that

$$E_{(x,y)}[\tau_{E_{a,b}}] = \frac{a^2 b^2 - b^2 x^2 - a^2 y^2}{(a^2 + b^2)},$$

by showing that the right hand side satisfies $\frac{1}{2} \Delta u = -1$ with zero boundary conditions, we have

$$E_{(0,0)}[\tau_{E_{a,b}}] = \frac{a^2 b^2}{a^2 + b^2}.$$ 

Thus the right hand side of (6.10) implies the right hand side of (6.9).

The left hand side of (6.10) is trivial by domain monotonicity. Since $E_{a,b} \subset (-a, a) \times (-b, b)$, it follows immediately that

$$\lambda_1(E_{a,b}) \geq \lambda_1((-a, a) \times (-b, b)) = \frac{\pi^2}{4} \left( \frac{a^2 + b^2}{a^2 b^2} \right).$$

The right hand side inequality in (6.10) is due to Polya and Szegö and can be found in [61, pg. 98]. Here we provide the proof for the convenience of the reader. The proof, as in [61] is based on the idea of conformal transplantation. As in [61] we use a test function $\varphi(x, y)$ with $\varphi|_{\partial E_{a,b}} = 0$ which is an obvious modification of the eigenfunction for the disc and plug it into the Rayleigh quotient.

Let $\varphi(x, y) := J_0 \left( j_0 \sqrt{\frac{x^2}{a^2} + \frac{y^2}{b^2}} \right)$, where $J_0$ is the first Bessel function and $j_0$ is its first positive root. Then

$$\lambda_1(E_{a,b}) \leq \frac{\int_{E_{a,b}} \left| \nabla \varphi(x, y) \right|^2 \, dxdy}{\int_{E_{a,b}} \left| \varphi(x, y) \right|^2 \, dxdy}.$$

Computing we find

$$\frac{\partial \varphi(x, y)}{\partial x} = j_0 \frac{x}{a^2 \sqrt{\frac{x^2}{a^2} + \frac{y^2}{b^2}}} \quad \text{and} \quad \frac{\partial \varphi(x, y)}{\partial y} = j_0 \frac{y}{b^2 \sqrt{\frac{x^2}{a^2} + \frac{y^2}{b^2}}}.$$ 

Thus

$$\int_{E_{a,b}} \left| \nabla \varphi(x, y) \right|^2 \, dxdy = j_0^2 \int_{E_{a,b}} \left( \frac{x^2}{a^2} + \frac{y^2}{b^2} \right) \left| J_0 \left( j_0 \sqrt{\frac{x^2}{a^2} + \frac{y^2}{b^2}} \right) \right|^2 \, dxdy.$$

Using the substitution $x = r a \cos \theta$, $y = r b \sin \theta$ so that $\frac{x^2}{a^2} + \frac{y^2}{b^2} = r^2$, we have
\[ \int_{E_{a,b}} |\nabla \varphi(x,y)|^2 \, dx \, dy = ab j_0^2 \int_0^{2\pi} \int_0^1 \frac{r^2 \cos^2 \theta + r^2 \sin^2 \theta}{r^2} J_0'(j_0 r)^2 r \, dr \, d\theta \]
\[ = ab j_0^2 \int_0^{2\pi} \left( \frac{\cos^2 \theta}{a^2} + \frac{\sin^2 \theta}{b^2} \right) d\theta \int_0^1 |J_0'(j_0 r)|^2 r \, dr \]
(6.11)
\[ = \pi j_0^2 \left( \frac{a^2 + b^2}{ab} \right) \int_0^1 |J_0'(j_0 r)|^2 r \, dr. \]

Recall that \( \varphi^B(x,y) = J_0 \left( j_0 \sqrt{x^2 + y^2} \right) \) is the first eigenfunction for the unit disc \( D = B(0,1) \) with eigenvalue \( j_0^2 \). Thus
\[ \int_D |\nabla \varphi^B(w)|^2 \, dw = j_0^2 \int_D |\varphi^B(w)|^2 \, dw \]
(6.12)
\[ = 2\pi j_0^2 \int_0^1 J_0^2(j_0 r) r \, dr. \]

On the other hand the computation (6.11) for \( E_{a,b} \) with \( a = 1, b = 1 \) gives that
\[ 2\pi j_0^2 \int_0^1 J_0^2(j_0 r) r \, dr = \int_D |\nabla \varphi^B(w)|^2 \, dw = 2\pi j_0^2 \int_0^1 |J_0'(j_0 r)|^2 r \, dr \]
(6.13)
Thus
\[ \int_{E_{a,b}} |\nabla \varphi(x,y)|^2 \, dx \, dy = j_0^2 \pi \left( \frac{a^2 + b^2}{ab} \right) \int_0^1 J_0^2(j_0 r) r \, dr. \]

At last the same change of variables gives
\[ \int_{E_{a,b}} |\varphi(x,y)|^2 \, dx \, dy = 2\pi ab \int_0^1 J_0^2(j_0 r) r \, dr. \]

This shows that
\[ \lambda_1(E_{a,b}) \leq \frac{\int_{E_{a,b}} |\nabla \varphi(x,y)|^2 \, dx \, dy}{\int_{E_{a,b}} |\varphi(x,y)|^2 \, dx \, dy} \leq \frac{j_0^2 \pi \left( \frac{a^2 + b^2}{ab} \right) \int_0^1 J_0^2(j_0 r) r \, dr}{2\pi ab \int_0^1 J_0^2(j_0 r) r \, dr} \]
\[ = \frac{j_0^2}{2} \left( \frac{a^2 + b^2}{a^2 b^2} \right), \]
as claimed.

### 7. Sharp Lower Bound

We end with some remarks concerning the sharp lower bound in Theorem 2.1 for all \( p \geq 1 \).

In [23], the authors show that \( m_{1,d}(E, \lambda) \geq 2e^{-1} \) and in [37] this lower bound was later improved to \( m_{1,d}(E, \lambda) \geq 2 \). In the recent work of [19, 38], it was shown that \( m_{1,d}(E, \lambda) = 2 \), and in Theorem 2.1 we show that \( m_{k,d}(E, \lambda) = 2^k k! \) for \( k \in \mathbb{N} \) and \( m_{p,d}(E, \lambda) \geq 2^p \Gamma(p + 1) \) for any \( p \geq 1 \). In section 2 we conjectured that this lower bound should be attained for any \( p \geq 1 \).

As already observed, what is needed is the inequality
\[ \mathbb{E}_x [\tau_D^p] \leq \Gamma(p + 1) \left( \sup_{x \in D} \mathbb{E}_x [\tau_D] \right)^p, \]
(7.1)
for any $p \geq 1$, which we believe should be true. If we let $p = n + \delta$, for $0 < \delta < 1$, the proof of Lemma 2.2 gives that

$$E_x[\tau^p_D] \leq p(p-1) \cdots (1+\delta) \left( \sup_{x \in D} E_x[\tau_D] \right)^n,$$

$$\leq p(p-1) \cdots (1+\delta) \left( \left( \sup_{x \in D} E_x[\tau_D] \right)^\delta \right)^n,$$

$$= p(p-1) \cdots (1+\delta) \left( \sup_{x \in D} E_x[\tau_D] \right)^p,$$

$$= \Gamma(p+1) \left( \sup_{x \in D} E_x[\tau_D] \right)^p,$$

where we used Jensen’s inequality for the second inequality and the last equality follows from the fact that $\Gamma(x+1) = x\Gamma(x)$.

It is well known that in the interval $[1, 2]$ the function $\Gamma(x)$ has an absolute minimum at $x_m$ with $1 < x_m < 1.46$ for which $\Gamma(x_m) \approx 0.8856031944 \cdot \cdots$. Thus for $0 < \delta < 1$, $0.885 < \Gamma(1+\delta) \leq 1$. This gives the inequality

$$(7.2) \quad E_x[\tau^p_D] \leq (1.129)\Gamma(p+1) \left( \sup_{x \in D} E_x[\tau_D] \right)^p.$$  

If we look at the interval $I_a = (-a, a)$ we can prove inequality (7.1) for all $p > 1.15$. Indeed we have

**Proposition 7.1.** Fix $a > 0$, then for any $p > 0$,

$$\mathbb{P}_0(\tau_{I_a} > t) = \frac{4}{\pi} \sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} \exp \left( -\frac{(2n+1)^2}{8a^2}t \right),$$

and

$$\mathbb{E}_0[\tau_{I_a}^p] = \frac{4 \cdot 8^p \cdot a^{2p} \Gamma(p+1)}{\pi^{2p+1}} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^{2p+1}}.$$

Moreover, for $p > \frac{\log(\pi)}{\log(\pi^2)} \approx 1.15$,

$$\mathbb{E}_0[\tau_{I_a}^p] \leq \Gamma(p+1) (\mathbb{E}_0[\tau_{I_a}])^p.$$  

**Proof.** By scaling we may assume that $a = 1$ and as above $I = (-1, 1)$. Given that the eigenfunctions and eigenvalues for $\Delta$ on $I$ are given by

$$\phi_n(x) = \sin \left( \frac{n\pi}{2} (x+1) \right) \text{ and } \lambda_n = \left( \frac{n\pi}{2} \right)^2,$$

the transition probabilities for the Brownian motion (heat kernel for $\frac{1}{2}\Delta$) are given by

$$p_I(x, y, t) = \sum_{n=1}^{\infty} \exp \left( -\left( \frac{n\pi}{2} \right)^2 \frac{t}{2} \right) \sin \left( \frac{n\pi}{2} (x+1) \right) \sin \left( \frac{n\pi}{2} (y+1) \right),$$
and
\[
\mathbb{P}_0 (\tau_I > t) = \int_{-1}^{1} p_I (0, y, t) dy
= \sum_{n=0}^{\infty} \exp \left( - \frac{(2n+1)^2 \pi^2}{8} t \right) \left( -1 \right)^n \int_{-1}^{1} \sin \left( \frac{(2n+1) \pi}{2} (y+1) \right) dy
= \frac{4}{\pi} \sum_{n=0}^{\infty} \exp \left( - \frac{(2n+1)^2 \pi^2}{8} t \right) \frac{(-1)^n}{2n+1}.
\]

Therefore,
\[
(7.3) \quad \mathbb{E}_0 [\tau_I^p] = p \int_{0}^{\infty} t^{p-1} \mathbb{P}_0 (\tau_I > t) dt
= p \int_{0}^{\infty} t^{p-1} \frac{4}{\pi} \sum_{n=0}^{\infty} \exp \left( - \frac{(2n+1)^2 \pi^2}{8} t \right) \frac{(-1)^n}{2n+1} dt
= \frac{4}{\pi} \sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} \int_{0}^{\infty} t^{p-1} \exp \left( - \frac{(2n+1)^2 \pi^2}{8} t \right) dt
= \frac{4 \Gamma (p+1)}{\pi} \sum_{n=0}^{\infty} \frac{(-1)^n}{2n+1} \left( \frac{8}{(2n+1)^2 \pi^2} \right)^p
= \frac{4 \cdot 8^p \cdot \Gamma (p+1)}{\pi^{2p+1}} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^{2p+1}}.
\]

Using the fact that
\[
\sum_{n=0}^{\infty} \frac{(-1)^n}{(n+r)^s} = \frac{1}{\Gamma (s)} \int_{0}^{\infty} \frac{y^{s-1} e^{-ry}}{1+e^{-y}} dy, \quad r, s > 0,
\]
we can trivially bound
\[
f(p) := \frac{4 \cdot 8^p}{(2\pi)^{2p+1}} \sum_{n=0}^{\infty} \frac{(-1)^n}{\left( n+\frac{1}{2} \right)^{2p+1}} = \frac{4 \cdot 8^p}{(2\pi)^{2p+1}} \Gamma (2p+1) \frac{1}{\Gamma (2p+1)} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)^{2p+1}} \int_{0}^{\infty} \frac{y^{2p} e^{-\frac{y}{2}}}{1+e^{-y}} dy
\]
\[
\leq \frac{4 \cdot 8^p}{(2\pi)^{2p+1}} \frac{1}{\Gamma (2p+1)} \int_{0}^{\infty} \frac{y^{2p} e^{-\frac{y}{2}}}{1+e^{-y}} dy = \frac{4 \cdot 8^p}{(2\pi)^{2p+1}} \frac{2^{2p+1}}{\Gamma (2p+1) \Gamma (2p+1)} \int_{0}^{\infty} x^{2p} e^{-x} dx
\]
\[
= \frac{4 \cdot 8^p}{(2\pi)^{2p+1}} \frac{2^{2p+1}}{\Gamma (2p+1) \Gamma (2p+1)} \Gamma (2p+1) = \frac{4 \cdot 8^p}{\pi^{2p+1}}.
\]

Since
\[
\frac{4 \cdot 8^p}{\pi^{2p+1}} \leq 1 \iff p > \frac{\log \left( \frac{\pi}{4} \right)}{\log \left( \frac{8}{\pi^2} \right)} \approx 1.15,
\]
we see that for \( p > \frac{\log \left( \frac{\pi}{4} \right)}{\log \left( \frac{8}{\pi^2} \right)} \), we have
\[
\mathbb{E}_0 [\tau_I^p] = f(p) \Gamma (p+1) \leq \frac{4 \cdot 8^p}{\pi^{2p+1}} \Gamma (p+1) \leq \Gamma (p+1) = \Gamma (p+1) (\mathbb{E}_0 [\tau_I])^p.
\]
Finally, substituting $p = \frac{1}{2}$ above we have

$$(7.4) \quad E_0 \left[ \tau^1_{I/2} \right] = \frac{8 \sqrt{2} \Gamma(3/2)}{\pi^2} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n + 1)^2}. $$

Thus, in order to have $E_0 \left[ \tau^1_{I/2} \right] \leq \Gamma(\frac{3}{2}) (E_0 [\tau_I])^{1/2} = \Gamma(\frac{3}{2})$, we need to check that

$$(7.5) \quad \frac{8 \sqrt{2}}{\pi^2} \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n + 1)^2} \leq 1. $$

Since

$$\sum_{n=0}^{\infty} \frac{(-1)^n}{(2n + 1)^2} = \beta(2)$$

is the Catalan’s constant with value $0.915965 \cdots$, it follows that the inequality $(7.5)$ is not true. Thus, the inequality $(2.7)$ is false, in general, for $0 < p < 1$.

Acknowledgement. We would like to thank Hugo Panzo for pointing out $(6.4)$ and for helpful discussions.
