Examples of property (T) II$_1$ factors with trivial fundamental group

Ionut Chifan,† Sayan Das and Krishnendu Khan

Abstract

In this short article we provide the first examples of property (T) II$_1$ factors $N$ with trivial fundamental group, $F(N) = 1$. Our examples arise as group factors $N = L(G)$ where $G$ are the property (T) groups introduced in [CDK19] using the Belegradek-Osin Rips construction from [BO06]. In particular, our result provides a continuum of explicit pairwise non-isomorphic property (T) factors.

1 Introduction

Motivated by their continuous dimension theory, Murray and von Neumann introduced the notion of $t$-by-$t$ matrix over a II$_1$ factor $M$, for any positive real number $t > 0$, [MvN43]. This is a II$_1$ factor denoted by $M^t$ and called the $t$-amplification of $M$. When $t \leq 1$ this is the isomorphism class of $pMp$ for a projection $p \in M$ of trace $\tau(p) = t$ and when $1 < t$ it is the isomorphism class of $p(M_n(C) \otimes M)p$ for an integer $n$ with $t/n \leq 1$ and a projection $p \in M_n(C) \otimes M$ of trace $(\text{Tr}_n \otimes \tau)(p) = t/n$. One can see that up to isomorphism the $M^t$ does not depend on $n$ or $p$ but only on the value of $t$.

The fundamental group, $F(M)$, of a II$_1$ factor $M$ is the set of all $t > 0$ such that $M^t \cong M$. Since for any $s, t > 0$ we have $(M^t)^s \cong M^{st}$ then one can see $F(M)$ forms a subgroup of $\mathbb{R}_+$. As the fundamental group is an isomorphism invariant of the factor, its study is of central importance to the theory of von Neumann algebras. In [MvN43] Murray and von Neumann were able to show that the fundamental group of the hyperfinite II$_1$ factor $R$ satisfies $F(R) = \mathbb{R}_+$. This also implies that $F(M) = \mathbb{R}_+$ for all McDuff factors $M$. However, besides this case no other calculations were available for an extended period of time and Murray-von Neumann’s original question whether $F(M)$ could be different from $\mathbb{R}_+$ for some factor $M$ remained wide open (see [MvN43 page 742] and the discussions in [Po20]).

A breakthrough in this direction emerged from Connes’ discovery in [Co80] that the fundamental group of a group factor $F(L(G))$ reflects rigidity aspects of the underlying group $G$, being countable whenever $G$ has property (T) of Kazhdan [Kaz67]. This finding also motivated him to formulate his famous Rigidity Conjecture in [Co82] along with other problems on computing symmetries of property (T) factors—that were highlighted in subsequent articles by other prolific mathematicians [Co94, Problem 2, page 551], [Jo00 Problems 8-9] and [Po13 page 9]. Further explorations of Connes’ idea in [Po86, GN87, GG88, Po95] unveiled new examples of separable factors $M$ with countable $F(M)$, including examples for which $F(M)$ contains prescribed countable sets. However despite these advances concrete calculations of fundamental groups remained elusive for more than two decades.

The situation changed radically with the emergence of Popa’s deformation/rigidity theory in early 2000. Through this novel theory we have witnessed an unprecedented progress towards complete calculations of fundamental groups. The first successes in this direction were achieved by Popa and include a series of striking results: examples of factors with trivial fundamental group [Po01] which

answers a long-standing open problem of Kadison [K67] (see [Ge03, Problem 3]); examples of factors that have any prescribed countable subgroup of $\mathbb{R}_+$ as a fundamental group [Po03]. An array of other powerful results on computations of fundamental groups were obtained subsequently [IPP05, PV06, Io06, Va07, PV08, Ho09, IPV10, BV12]. Remarkably, in [PV08] it was shown that many uncountable proper subgroups of $\mathbb{R}_+$ can be realized as fundamental groups of separable II_1 factors.

However, despite these impressive achievements, significantly less is known about the fundamental groups of property (T) factors as the prior results do not apply to these factors. In fact there is no explicit calculation of the fundamental group of any property (T) factor available in the current literature. In this article we make progress on this problem by providing examples of property (T) icc groups $G$ whose factors $\mathcal{L}(G)$ have trivial fundamental group. In particular the result advances [Co94, Problem 2, page 551] and provides the first group examples satisfying the last conjecture on page 9 in Popa’s list of open problems [Po13].

Our groups $G$ were first introduced in [CDK19] and rely on a Rips construction in geometric group theory developed by Belgradek and Osin in [BO06]. For convenience we briefly recall this construction. Using Dehn filling results from [Os06], it was shown in [BO06] that for every finitely generated group $Q$ one can find a property (T) group $N$ such that $Q$ embeds as a finite index subgroup of $\text{Out}(N)$. This gives rise to an action $\sigma : Q \to \text{Aut}(N)$ such that the corresponding semidirect product group $N \rtimes_\sigma Q$ is hyperbolic relative to $\{Q\}$. When $Q$ is torsion free one can pick $N$ to be torsion free as well and hence both $N$ and $N \rtimes_\sigma Q$ are icc. Moreover, when $Q$ has property (T) then $N \rtimes_\sigma Q$ has property (T). Throughout this article this semidirect product $N \rtimes_\sigma Q$ will be called the Belgradek-Osin Rips construction and denoted by $\text{Rip}(Q)$. Our examples arise as fiber products of these Rips constructions. Specifically, consider any two groups $N_1 \rtimes_{\sigma_1} Q, N_2 \rtimes_{\sigma_2} Q \in \text{Rip}(Q)$ and form the canonical fiber product $G = (N_1 \times N_2) \rtimes_{\sigma} Q$ where $\sigma = (\sigma_1, \sigma_2)$ is the diagonal action. Notice that $G$ has property (T) and the class of all these groups will be denoted by $\mathcal{R}(Q)$.

Developing a new technological interplay between methods in geometric group theory and Popa’s deformation/rigidity theory which continues our prior investigations [CDK19] we will show that the factors associated with groups in class $\mathcal{R}(Q)$ have trivial fundamental group. Specifically, using various technological outgrowths of prior methods [Po03, Oz03, IPP05, Io06, IPV10, Io11, PV12, CIK13, KV15, CD19, CDK19] we are able to show the following more general statement:

**Theorem A.** Assume that $Q_1, Q_2, P_1, P_2$ are icc, torsion free, residually finite, hyperbolic property (T) groups. Let $Q = Q_1 \times Q_2$ and $P = P_1 \times P_2$ and consider any groups $(N_1 \times N_2) \rtimes Q \in \mathcal{R}(Q)$ and $(M_1 \times M_2) \rtimes P \in \mathcal{R}(P)$. Let $p \in \mathcal{R}(\mathcal{L}(M_1 \times M_2) \rtimes P)$ be a projection and let $\Theta : \mathcal{L}((N_1 \times N_2) \rtimes Q) \to p \mathcal{L}(M_1 \times M_2) \rtimes P)$ be a $*$-isomorphism.

Then $p = 1$ and one can find a $*$-isomorphism, $\Theta_i : \mathcal{L}(N_i) \to \mathcal{L}(M_i)$, a group isomorphism $\delta : Q \to P$, a multiplicative character $\eta : Q \to \mathbb{T}$, and a unitary $u \in \mathcal{W}((\mathcal{L}(M_1 \times M_2) \rtimes P))$ such that for all $\gamma \in Q, x_i \in \mathcal{L}(N_i)$ we have that

$$\Theta((x_1 \otimes x_2)u) = \eta(\gamma)u(\Theta_1(x_1) \otimes \Theta_2(x_2)v_{\delta(\gamma)})u^*.$$  

In particular, if we denote by $G = (N_1 \times N_2) \rtimes Q$ then the fundamental group satisfies $\mathcal{F}(\mathcal{L}(G)) = \{1\}$.

Concrete examples of countable families of pairwise non-isomorphic property (T) II_1 factors emerged from the prior fundamental works of Cowling-Hageerup [CH89] and Ozawa-Popa [OP03]. Additional examples were obtained more recently, [CDK19]. Since $\mathcal{F}(\mathcal{M})$ is countable whenever $\mathcal{M}$ is a property (T) factor [Co80, J85], it also follows there exist continuum many pairwise mutually non-isomorphic property (T) factors. But, however, to the best of our knowledge, no explicit constructions of such families exist in the literature till date. Our Theorem 3.6 canonically provides such examples.

**Corollary B.** Let $G$ be a group as in the statement of Theorem 3.6. Then the set $\{ \mathcal{L}(G)^t : t \in (0, \infty) \}$ forms a continuum of pairwise non-isomorphic property (T) factors.
2 Preliminaries

2.1 Notations and Terminology

Throughout this document all von Neumann algebras are denoted by calligraphic letters e.g. $A, B, M, \mathcal{N}$, etc. Given a von Neumann algebra $M$ we will denote by $\mathcal{U}(M)$ its unitary group, by $\mathcal{P}(M)$ the set of all its nonzero projections and by $(M)_1$ its unit ball. Given a unital inclusion $\mathcal{N} \subseteq M$ of von Neumann algebras we denote by $\mathcal{N}' \cap M = \{ x \in M : [x, \mathcal{N}] = 0 \}$. We also denote by $\mathcal{M}_M(\mathcal{N}) = \{ u \in \mathcal{U}(M) : u\mathcal{N}u^* = \mathcal{N} \}$ the normalizing group. We also denote the quasinormalizer of $\mathcal{N}$ in $M$ by $\mathcal{Q}_M(\mathcal{N})$. Recall that $\mathcal{Q}_M(\mathcal{N})$ is the set of all $x \in M$ for which there exist $x_1, x_2, ..., x_n \in M$ such that $N \subseteq \sum_i x_iN$ and $xN \subseteq \sum_i N x_i$ (see [Po99 Definition 4.8]).

All von Neumann algebras $M$ considered in this document will be tracial, i.e. endowed with a unital, faithful, normal linear functional $\tau : M \to \mathbb{C}$ satisfying $\tau(xy) = \tau(yx)$ for all $x, y \in M$. This induces a norm on $M$ by the formula $\|x\| = \tau(x^*x)^{1/2}$ for all $x \in M$. The $\cdot$-completion of $M$ will be denoted by $L^2(M)$. For any von Neumann subalgebra $\mathcal{N} \subseteq M$ we denote by $E_\mathcal{N} : M \to \mathcal{N}$ the $\tau$-preserving condition expectation onto $\mathcal{N}$. We denote the orthogonal projection from $L^2(M) \to L^2(\mathcal{N})$ by $\mathbb{P}_\mathcal{N}$. The Jones’ basic construction [Jo83, Section 3] for $\mathcal{N} \subseteq M$ will be denoted by $(M, \mathbb{P}_\mathcal{N})$.

For any group $G$ we denote by $(u_g)_{g \in G} \subset \mathcal{U}(L^2(G))$ its left regular representation, i.e. $u_g(\delta_h) = \delta_{gh}$ where $\delta_h : G \to \mathbb{C}$ is the Dirac function at $h$. The weak operatorial closure of the linear span of $(u_g : g \in G)$ in $\mathcal{U}(L^2\mathcal{G})$ is called the group von Neumann algebra and will be denoted by $L(G)$; this is a II_1 factor precisely when $G$ has infinite non-trivial conjugacy classes (icc). If $M$ is a tracial von Neumann algebra and $G \curvearrowright M$ is a trace preserving action we denote by $M \rtimes G$ the corresponding cross product von Neumann algebra [MvN57]. For any subset $K \subseteq G$ we denote by $P_MK$ the orthogonal projection from the Hilbert space $L^2(M \rtimes G)$ onto the closed linear span of $\{ xu_g | x \in M, g \in K \}$. When $M$ is trivial we will denote this simply by $P_K$.

All groups considered in this article are countable and will be denoted by capital letters $A, B, G, H, Q, N, M$, etc. Given groups $Q, N$ and an action $Q \curvearrowright N$ by automorphisms we denote by $N \rtimes Q$ the corresponding semidirect product group. For any $n \in N$ we denote by $\text{Stab}_Q(n) = \{ g \in Q : \sigma(n) = n \}$. Given a group inclusion $H \subseteq G$ sometimes we consider the centralizer $C_G(H)$ and the virtual centralizer $\nu C_G(H) = \{ g \in G : |g^H| < \infty \}$. We also denote by $\langle H \rangle$ the normal closure of $H$ in $G$.

2.2 Popa’s Intertwining Techniques

Over more than fifteen years ago, Popa introduced in [Po03] Theorem 2.1 and Corollary 2.3 a powerful analytic criterion for identifying intertwiners between arbitrary subalgebras of tracial von Neumann algebras. Now this is known in the literature as Popa’s intertwining-by-bimodules technique and has played a key role in the classification of von Neumann algebras program via Popa’s deformation/rigidity theory.

**Theorem 2.1.** [Po03] Let $(M, \tau)$ be a separable tracial von Neumann algebra and let $\mathcal{P}, Q \subseteq M$ be (not necessarily unital) von Neumann subalgebras. Then the following are equivalent:

1. There exist $p \in \mathcal{P}(\mathcal{Q}), q \in \mathcal{P}(Q)$, a $*$-homomorphism $\theta : p\mathcal{P}p \to q\mathcal{Q}q$ and a partial isometry $0 \neq v \in qMq$ such that $\theta(x)v = vx$, for all $x \in p\mathcal{P}p$.
2. For any group $\mathcal{G} \subset \mathcal{U}(\mathcal{P})$ such that $\mathcal{G}' = \mathcal{P}$ there is no sequence $(u_n) \subset \mathcal{G}$ satisfying $\|E_\mathcal{Q}(xu_ny)\|_2 \to 0$, for all $x, y \in \mathcal{M}$.
3. There exist finitely many $x_i, y_i \in \mathcal{M}$ and $C > 0$ such that $\sum_i \|E_\mathcal{Q}(x_iu_iy_i)\|_2^2 \geq C$ for all $u \in U(\mathcal{P})$.

If one of the three equivalent conditions from Theorem 2.1 holds then we say that a corner of $\mathcal{P}$ embeds into $Q$ inside $\mathcal{M}$, and write $\mathcal{P} \ll M \mathcal{Q}$. If moreover we have that $\mathcal{P}p' \ll M \mathcal{Q}$, for any projection $0 \neq p' \in \mathcal{P}' \cap 1_pM1_p$ (equivalently, for any projection $0 \neq p' \in \mathcal{U}(\mathcal{P}' \cap 1_pM1_p)$), then we write $\mathcal{P} \ll M \mathcal{Q}$. We
Since \(A\) is amenable relative to \(N\), there exists a positive linear functional \(\phi: p(M, e_Q)p \to \mathbb{C}\) such that \(\phi|_{p(M)p} = \tau\) and \(\phi(xT) = \phi(Tx)\) for all \(T \in Q\) and all \(x \in P\). If \(P\) is amenable relative to \(Q\) inside \(\mathcal{M}\), we write \(P \triangleright_{\mathcal{M}} Q\).

For further use we record the following result which controls the intertwiners in algebras arising from malnormal subgroups. Its proof is essentially contained in [Po03 Theorem 3.1] so it will be left to the reader.

**Lemma 2.2 (Popa [Po03]).** Assume that \(H \leq G\) be an almost malnormal subgroup and let \(G \triangleright\mathcal{N}\) be a trace preserving action on a finite von Neumann algebra \(\mathcal{N}\). Let \(P \in \mathcal{N} \times H\) be a von Neumann algebra such that \(P \triangleright_{\mathcal{N} \times H} N\). Then for every elements \(x, x_1, x_2, \ldots, x_1 \in \mathcal{N} \times G\) satisfying \(Px \in \sum_{i=1}^I x_i P\) we must have that \(x \in \mathcal{N} \times H\).

The following result is a mild generalization of [BY12 Lemma 2.3]. For reader’s convenience we include all the details in our proof.

**Theorem 2.3.** Let \(G\) be a group together \(H \lhd G\) with a normal subgroup and assume that \(G \triangleright (\mathcal{N}, \tau)\) is a trace preserving action on a von Neumann algebra \((\mathcal{N}, \tau)\). Consider \(\mathcal{N} \times H = \mathcal{M}\) the corresponding crossed product von Neumann algebra, assume that \(A \subset \mathcal{N}\) (possibly non-unital) and \(G \in N_{1_{\mathcal{A}, 1_{\mathcal{M}}}A}(A)\) a group of unitaries such that \(A, G'' <_{\mathcal{A}} \mathcal{N} \times H\). Then \((AG)'' <_{\mathcal{A}} \mathcal{N} \times H\).

**Proof.** Let \(G_H \subset G\) be a section for \(G/H\). Also denote by \(P = \mathcal{N} \times H\). Since \(A, G'' <_{\mathcal{A}} \mathcal{P}\), then by [Va10a Lemma 2.5], for all \(\varepsilon_1, \varepsilon_2 > 0\) there exist \(K_{\varepsilon_1}, L_{\varepsilon_2} \subset G_H\) such that for all \(a \in (A)_1\) and \(b \in (G'')_1\) we have 1) \(\|P_{\left(K_{\varepsilon_1} \times H\right)}(a) - a\|_2 \leq \varepsilon_1\) and 2) \(\|P_{\left(L_{\varepsilon_2} \times H\right)}(b) - b\|_2 \leq \varepsilon_2\). Here for every \(S \subset G_H\), the map \(P_S: L^2(\mathcal{M}) \to \text{span} \{Pu_g: g \in S\}\) is the orthogonal projection. Also notice that, for all \(x \in \mathcal{M}\), \(P_S(x) = \sum_{s \in S} E_{\mathcal{P}}(xu_{s-1}) u_s\). In particular, for all \(x \in \mathcal{M}\) we have,

\[
\|P_S(x)\|_\infty \leq |S| \|x\|_\infty \quad \text{and} \quad \|P_S(x)\|_2 \leq \|x\|_2. \quad (2.2.1)
\]

Now for all \(a \in (A)_1, b \in (G'')_1\), we have

\[
\|ab - P_{\left(K_{\varepsilon_1} \times H\right)}(a) P_{\left(L_{\varepsilon_2} \times H\right)}(b)\|_2 \leq \|ab - P_{\left(K_{\varepsilon_1} \times H\right)}(a) b\|_2 + \|P_{\left(K_{\varepsilon_1} \times H\right)}(a)b - P_{\left(K_{\varepsilon_1} \times H\right)}(a) P_{\left(L_{\varepsilon_2} \times H\right)}(b)\|_2
\leq \|a - P_{\left(K_{\varepsilon_1} \times H\right)}(a)\|_2 \|b\|_\infty + \|P_{\left(K_{\varepsilon_1} \times H\right)}(a)\|_\infty \|b - P_{\left(L_{\varepsilon_2} \times H\right)}(b)\|_2 \quad (2.2.2)
\leq \|a - P_{\left(K_{\varepsilon_1} \times H\right)}(a)\|_2 + \|K_{\varepsilon_1}\| \|b - P_{\left(L_{\varepsilon_2} \times H\right)}(b)\|_2
\leq \varepsilon_1 + \|K_{\varepsilon_1}\| \varepsilon_2. \quad (2.2.3)
\]

So letting \(\varepsilon_1 = \varepsilon\) and \(\varepsilon_2 = \frac{\varepsilon}{\|K_{\varepsilon_1}\|}\), we get that there exists \(K_\varepsilon, L_\varepsilon\) finite subsets of the section \(G/H\) such that

\[
\|ab - P_{\left(K_\varepsilon \times H\right)}(a) P_{\left(L_\varepsilon \times H\right)}(b)\|_2 \leq 2\varepsilon. \quad (2.2.4)
\]

Since \(H \lhd G\), then there exist a finite set \(F_\varepsilon \subset G_H\) such that \(|F_\varepsilon| \leq \|K_\varepsilon\| L_\varepsilon\) and \(P_{\left(F_\varepsilon \times H\right)}(P_{\left(K_\varepsilon \times H\right)}(a) P_{\left(L_\varepsilon \times H\right)}(b)) = P_{\left(K_\varepsilon \times H\right)}(a) P_{\left(L_\varepsilon \times H\right)}(b)\) for all \(a \in \mathcal{N}(A), b \in (G'')_1\). Using this fact together with (2.2.4) we get that \(\|P_{\left(F_\varepsilon \times H\right)}(ab) - P_{\left(K_\varepsilon \times H\right)}(a) P_{\left(L_\varepsilon \times H\right)}(b)\|_2 \leq 2\varepsilon\) and combining with (2.2.4) again we get that

\[
\|ab - P_{\left(F_\varepsilon \times H\right)}(ab)\|_2 \leq 2\varepsilon. \quad (2.2.5)
\]

for all \(a \in \mathcal{N}(A), b \in (G'')_1\). Since \((\mathcal{N}(A)G)' = (AG)'\), this already shows that \((AG)'' < \mathcal{P}\). Next we argue that we actually have \((AG)'' <_{\mathcal{A}} \mathcal{P}\). To see this fix \(p \in (AG)' \cap 1_{\mathcal{A}, 1_{\mathcal{M}}}A_1_{\mathcal{A}, 1_{\mathcal{G}''}}\). Then there exists a finite set \(G_\varepsilon \subset G_H\) such that

\[
\|p - P_{\left(G_\varepsilon \times H\right)}(p)\| \leq \frac{\varepsilon}{\|K_\varepsilon\| L_\varepsilon}. \quad (2.2.6)
\]
Combining (2.2.6) and (2.2.5) we get that
\[
|abp - P_{PF}(ab)pP_{PG}(p)| \leq |abp - P_{PF}(ab)pP_{PG}(p)| + |P_{PF}(ab)p - P_{PF}(ab)pP_{PG}(p)|
\leq \|ab - P_{PF}(ab)|2\|p + \|P_{PF}(ab)\|\\|p - P_{PG}(p)\|2
\leq 4\epsilon + \frac{\epsilon}{|K_2||L_2|} < 5\epsilon.
\] (2.2.7)

Again there exists a finite set \(T_\epsilon \subset G\) such that \(P_{PT}(P_{PF}(ab)pP_{PG}(p)) = P_{PF}(ab)pP_{PG}(p)\) and \(|T_\epsilon| \leq |F_\epsilon||G_\epsilon|\).

Using this and (2.2.7) we get that \(|abp - P_{PT}(abp)| < 10\epsilon\) for all \(a \in \mathcal{H}(A)\), \(b \in G\). This shows that \((\mathcal{G})'' \preceq_M^\mathcal{P}, \) as desired. \(\square\)

We end this section by highlighting a straightforward corollary of Theorem 2.3 that we will be very useful in the sequel.

Corollary 1. Let \(H \triangleleft G\) be a normal subgroup of \(G\) and \(G \sim (N, \tau)\) be a trace preserving action on a tracial von Neumann algebra \((N, \tau)\). Let \(M = N \rtimes H\). Assume that \(A, B \subseteq M\) are commuting \(*\)-subalgebras such that \(A \preceq_M^\mathcal{P} N \rtimes H\) and \(B \preceq_M^\mathcal{P} N \rtimes H\). Then \(A \vee B \preceq_M^\mathcal{P} N \rtimes H\).

Proof. Follows from Theorem 2.3 by letting \(\mathcal{G} = \mathcal{H}(B)\). \(\square\)

2.3 Height of elements in group von Neumann algebras

The notion of height of elements in crossed products and group von Neumann algebras was introduced and developed in [Io11] and [IPV10] and was highly instrumental in many of the recent classification results in von Neumann algebras [Io11] [IPV10] [KV15] [Cu18]. Following [IPV10] Section 3 for every \(x \in \mathcal{L}(G)\) we denote by \(h_G(x)\) the largest Fourier coefficient of \(x\), i.e., \(h_G(x) = \max_{\tau \in \mathcal{G}} |\tau(xu^*)|\).

Moreover, for every subset \(\mathcal{G} \subseteq \mathcal{L}(N)\), we denote by \(h_G(\mathcal{G}) = \inf_{\tau \in \mathcal{G}} h_G(x)\), the height of \(\mathcal{G}\) with respect to \(G\). Using the notion of height Ioana, Popa and Vaes proved in their seminal work, [IPV10] Theorem 3.1] that whenever \(G, H\) are icc groups such that \(\mathcal{L}(G) = \mathcal{L}(H)\) and \(h_G(H) > 0\), then \(G\) and \(H\) are isomorphic. The following generalization of this result to embeddings was obtained by Krogager and Vaes [KV15] and will be used in an essential way to derive our main Theorem 3.6 in the last section.

Theorem 2.4 (Theorem 4.1, [KV15]). Let \(G\) be a countable group and denote by \(\mathcal{M} = \mathcal{L}(G)\). Let \(p \in \mathcal{P}(\mathcal{M})\) be a projection and assume that \(\mathcal{G} \subseteq \mathcal{M}(pMp)\) is a subgroup satisfying following properties:

1. The unitary representation \(\{Ad v\}_{v \in \mathcal{G}}\) on \(L^2(pMp \oplus \mathbb{C}p)\) is weakly mixing;
2. For any \(e \neq g \in \mathcal{L}(G)\) we have \(\mathcal{G}'' \preceq_M \mathcal{L}(C_G(g))\);
3. We have \(h_G(\mathcal{G}) > 0\).

Then \(p = 1\) and there exists a unitary \(u \in \mathcal{L}(G)\) such that \(u\mathcal{G}u^* \subseteq TG\).

Next we highlight a new situation when it’s possible to control lower bound for height of unitary elements in the context of crossed product von Neumann algebras arising from group actions by automorphisms with non-trivial stabilizers. Our result and its proof is reminiscent of the prior powerful techniques for Bernoulli actions introduced in [IPV10] Theorem 5.1] (see also [Io11] Theorem 6.1]) and their recent counterparts for the Rips constructions [CDK19] Theorem 5.1]. The precise statement is the following.

Theorem 2.5. Let \(G\) and \(H\) be countable groups and let \(\sigma : G \rightarrow Aut(H)\) be an action by automorphisms for which there exists a scalar \(c > 0\) satisfying \(|\text{Stab}_G(h)| < c\) for all \(h \in H \setminus \{e\}\). Consider \(\mathcal{M} = \mathcal{L}(H \rtimes \sigma, G)\) and let \(A \subseteq \mathcal{M}\) be a diffuse von Neumann subalgebra such that \(A \preceq_M \mathcal{L}(H)\). For any group of unitaries \(\mathcal{G} \subseteq \mathcal{L}(G)\) satisfying \(\mathcal{G} \subseteq \mathcal{M}(A)\) we have that \(h_G(\mathcal{G}) > 0\).

Proof. For ease of exposition denote by \(N = \mathcal{L}(H)\). Next we prove the following property
Claim 1. For every \( x, y \in L(G) \), every finite subsets \( K, S \subseteq G \), every \( a \in \text{span}N'K \) with \( E_{L(G)}(a) = 0 \) and every \( \varepsilon > 0 \) there exists a scalar \( \kappa_{x, K, S, a} > 0 \) such that
\[
|P_{NS}(xay)|_2^2 \leq \kappa_{x, K, S, a} ||y||_2^2 ||a||_2 \|h_G^2(x) + \varepsilon\|_\infty \|y\|_\infty, \tag{2.3.1}
\]
where \( P_{NS} \) denotes the orthogonal projection from \( L^2(M) \) onto \( \text{span}||a||_2^2(N'S) \).

**Proof of Claim [7]** First fix a finite set \( L \subseteq H \setminus \{ e \} \) and let \( b \in \text{span}(LK) \). Observe that using the Fourier decomposition of \( x = \sum x_g u_g \) and \( y = \sum y_g u_g \), where \( x_g = \tau(ux_G) \) and \( y_g = \tau(yu_G) \), basic calculations show that
\[
\|E_N(xby)\|_2^2 = \sum_{g \in G} x_g y_{k-1} \sigma_g(E_N(\langle bu_{k-1} \rangle)) \|	ag{2.3.2}
\]
Furthermore, using the Fourier decomposition \( b = \sum_{l} b_{h} u_{h} \) where \( b_{h} = \tau(\langle bu_{h} \rangle) \) we also see that
\[
\langle \sigma_{g_1}(E_N(\langle bu_{k_1} \rangle)), \sigma_{g_2}(E_N(\langle bu_{k_2} \rangle)) \rangle = \sum_{l_1, l_2 \in L} b_{k_1} l_1 b_{k_2} l_2 \tag{2.3.3}
\]
where for every \( l_1, l_2 \in L \) we denoted by \( S_{l_1, l_2} = \{ g \in G : \sigma_g(l_1) = l_2 \} \).

Thus, combining \((2.3.2)\) and \((2.3.3)\) and using basic inequalities together with \( |S_{l_1, l_2}| \leq c \) we get that
\[
\|E_N(xby)\|_2^2 \leq \sum_{k_1, k_2 \in K, l_1, l_2 \in L, S_{l_1, l_2} \subseteq G} \left| \sum_{g \in G} x_g y_{k_1} \sigma_{g}(E_N(\langle bu_{k_1} \rangle)) \right|^2 \leq \sum_{k_1, k_2 \in K} \sum_{S_{l_1, l_2} \subseteq G} \left| \sum_{g \in G} x_g y_{k_1} \sigma_{g}(E_N(\langle bu_{k_1} \rangle)) \right|^2 \leq c \|K\|^2 \|L\|^2 \|h_G^2(x)\|_2^2 \|y\|_2^2 \leq c \|K\|^2 \|L\|^2 \|h_G^2(x)\|_2^2 \|y\|_2^2 \leq 2 |S| \left( \sum_{g \in S} \|E_N(\langle xbyu_{g-1} \rangle)\|_2^2 \right) + \varepsilon\|x\|_\infty \|y\|_\infty. \tag{2.3.4}
\]

Using these estimates we are now ready to derive the proof of \((2.3.1)\). To this end fix \( \varepsilon > 0 \). Using basic approximations and \( \|E_{L(G)}(a)\| = 0 \) one can find a finite set \( L \subseteq H \setminus \{ e \} \) and \( b \in \text{span}(LK) \) such that
\[
||a - b||_2 \leq \min \left( \frac{\varepsilon}{2}, ||a||_2 \right) \text{ and } ||b||_\infty \leq 2 ||a||_\infty. \tag{2.3.5}
\]
Notice that for all \( z \in M \) we have \( P_{NS}(z) = \sum E_N(zu_{s-1})u_s \) and using this formula together with estimate \((2.3.5)\) and Cauchy-Schwarz inequality we get
\[
|P_{NS}(xay)|_2^2 \leq 2|S| \left( \sum_{g \in S} \|E_N(\langle xbyu_{g-1} \rangle)\|_2^2 \right) + \varepsilon\|x\|_\infty \|y\|_\infty. \tag{2.3.6}
\]
Using \((2.3.4)\) followed by \((2.3.5)\) we further have that the last inequality above is smaller than
\[
\leq 2c|S|\|K\|^2 \|L\|^2 \left( \sum_{g \in S} h_G^2(x) \|y_{u_g-1}\|_2^2 \right) + \varepsilon\|x\|_\infty \|y\|_\infty \leq 4c|S|\|K\|^2 \|L\|^2 \|h_G^2(x)\|_2 \|y\|_2^2 + \varepsilon\|x\|_\infty \|y\|_\infty. \tag{2.3.6}
\]
Combining this with \((2.3.5)\) proves the claim where \( \kappa_{x, K, S, a} = 4c|S|^2\|K|^2 \|L\|^2 \).

In the remaining part we complete the proof of the statement. Towards this first notice that, since \( \mathcal{A} < \mathcal{N} \mathcal{N} \) then by [Val10a, Lemma 2.5] for every \( \varepsilon \) there exists a finite set \( S \subseteq K \) such that for all \( c \in \mathcal{U}(\mathcal{A}) \) we have
\[
||c - P_{NS}(c)||_2 \leq \varepsilon. \tag{2.3.7}
\]
Next we also claim that for every finite set $S \subset G$ and every $\epsilon > 0$ there exists $b \in \mathcal{U}(A)$ such that

$$\|E_{L(G)} \circ P_{NS}(b)\|_2 < \epsilon.$$  \hspace{1cm} \text{(2.3.8)}

Indeed, to see this first notice that $\|E_{L(G)} \circ P_{NS}(b)\|_2^2 = \sum_{s \in S} |\tau(bu_{s^{-1}})|^2$. As $A$ is diffuse and $S$ is finite there exists $b \in \mathcal{U}(A)$ such that $\sum_{s \in S} |\tau(bu_{s^{-1}})|^2 < \epsilon$ and the claim follows.

Now pick $b \in \mathcal{U}(A)$ satisfying (2.3.8). Since $a, gsg^{-1} \in \mathcal{U}(A)$ then using (2.3.7) two times and (2.3.8) we see that

$$1 - \epsilon = \|gag^{-1}\|_2 - \epsilon \leq \|P_{NS}(gag^{-1})\|_2 \leq \|P_{NS}(g(P_{NS}(b))g^{-1})\|_2 + \epsilon$$

$$\leq \|P_{NS}(g(P_{NS}(b) - E_{L(G)}(P_{NS}(b)))g^{-1})\|_2 + |E_{L(G)}(P_{NS}(b))\|_2 + \epsilon$$

$$\leq \|P_{NS}(g(P_{NS}(b) - E_{L(G)}(P_{NS}(b)))g^{-1})\|_2 + 2\epsilon.$$  \hspace{1cm} \text{(2.3.9)}

Thus $\sum_{s \in S,S \neq b} h_G(g) \|P_{NS}(b) - E_{L(G)}(P_{NS}(b))\|_2 + \epsilon^{1/2} > 2\epsilon.$ Since this holds for all $g \in G$, letting $\epsilon > 0$ be sufficiently small we get the desired conclusion.

\section{2.4 A class of groups based on Belegradek-Osin Rips construction}

Using the powerful Dehn filling technology from [Os06], Belegradek and Osin showed in [BO06 Theorem 1.1] that for every finitely generated group $Q$ one can find a property (T) group $N$ such that $Q$ embeds into $\text{Out}(N)$ as a finite index subgroup. This canonically gives rise to an action $Q \acts N$ by automorphisms such that the corresponding semidirect product group $N \rtimes Q$ is hyperbolic relative to $\{Q\}$. Throughout this document the semidirect products $N \rtimes Q$ will be termed Belegradek-Osin’s Rips construction groups. When $Q$ is torsion free then one can pick $N$ to be torsion free as well and hence both $N$ and $N \rtimes Q$ are icc groups. Also when $Q$ has property (T) then $N \rtimes Q$ has property (T). Under all these assumptions we will denote by $\mathcal{Rips}_T(Q)$ the class of these Rips construction groups $N \rtimes Q$.

In [CDK19 Sections 3,5] we introduced a class of property (T) groups based on the Belegradek-Osin Rips construction groups and we have proved several rigidity results for the corresponding von Neumann algebras, [CDK19 Theorem A]. Next we briefly recall this construction also highlighting its main algebraic properties that are relevant in the proofs of our main results in the next section.

\textbf{Class } $\mathcal{S}$. Consider any product group $Q = Q_1 \times Q_2$, where $Q_i$ are any nontrivial, bi-exact, weakly amenable, property (T), residually finite, torsion free, icc groups. Then for every $i = 1, 2$ consider a Rips construction $G_i = N_i \rtimes_{\rho_i} Q \in \mathcal{Rips}_T(Q)$, let $N = N_1 \times N_2$ and denote by $G = N \rtimes_{\sigma} Q$ the canonical semidirect product which arises from the diagonal action $\sigma = \rho_1 \times \rho_2 : Q \rightarrow \text{Aut}(N)$, i.e. $\sigma_g(n_1,n_2) = (\rho_1)_g(n_1), (\rho_2)_g(n_2)$ for all $(n_1, n_2) \in N$. Throughout this article the category of all these semidirect products $G$ will denoted by \textbf{Class } $\mathcal{S}$.

Concrete examples of semidirect product groups in class $\mathcal{S}$ can be obtained if the initial groups $Q_i$ are any uniform lattices in $Sp(n, 1)$ when $n \geq 2$. Indeed one can see that required conditions on $Q_i$'s follow from [Oz03, CH89].

For further reference we record some algebraic properties of groups in class $\mathcal{S}$. For their proofs the reader may consult [CDK19 Sections 3,4,5] and the references within.

\textbf{Theorem 2.6.} For any $G = N \rtimes_{\sigma} Q \in \mathcal{S}$ the following hold

\textbf{a)} $G$ is an icc, torsion free, property (T) group;
b) $Q$ is malnormal subgroup of $G$, i.e. $gQg^{-1} \cap Q = \{e\}$ for every $g \in G \setminus Q$;

c) The stabilizer $\text{Stab}_Q(n) = \{e\}$ for every $n \in N \setminus \{e\}$;

d) The virtual centralizer satisfies $vC_G(N) = 1$;

e) $G$ is the fiber product $G = G_1 \times_Q G_2$; thus embeds into $G_1 \times G_2$ where $Q$ embeds diagonally into $Q \times Q$.

Finally we conclude this section with a folklore lemma related to the calculation of centralizers of elements in products of hyperbolic groups. We include some details for readers’ convenience.

**Lemma 2.7.** Let $Q = Q_1 \times Q_2$, where $Q_i$ are non-elementary torsion free, hyperbolic groups. For any $e \neq g \in Q$ the centralizer $C_Q(g)$ is of one of the following forms: $A$, $A \times Q_2$ or $Q_1 \times A$, where $A$ is an amenable group.

**Proof.** Let $g = (g_1, g_2) \in Q$ where $g_i \in Q_i$ and notice that $C_Q(g) = C_{Q_1}(g_1) \times C_{Q_2}(g_2)$. Therefore to get our conclusion it suffices to show that for every $g_i \in Q_i$ either $C_{Q_i}(g_i) = Q_i$ or $C_{Q_i}(g_i)$ is an elementary group. However this is immediate once we note that for every $g_i \neq e$ the centralizer satisfies $C_{Q_i}(g_i) \leq E_{Q_i}(g_i)$, where $E_{Q_i}(g_i)$ is maximal elementary subgroup containing $g_i$ of the torsion free icc hyperbolic group $Q_i$, see for example [Ol91].

\[ \text{\quad} \]

### 3 Calculation of Fundamental Groups of Property (T) Factors

In this section we prove our main result describing isomorphisms of amplifications of property (T) group factors $\mathcal{L}(G)$ associated with groups $G \in \mathcal{S}$. These factors were first considered in [CDK19], where various rigidity properties were established. For instance, in [CDK19, Theorem A] it was shown that the semidirect product decomposition of the group $G = N \rtimes Q$ is a feature that’s completely recoverable from $\mathcal{L}(G)$. In this section we continue these investigations by showing in particular that these factors also have trivial fundamental group (see Theorem 3.6 and Corollary 2). In order to prepare for the proof of our main theorem we first need to establish several preliminary results on classifying specific subalgebras of $\mathcal{L}(G)$. Some of the theorems will rely on results proved in [CDK19]. We recommend the reader to consult these results beforehand as we will focus mostly on the new aspects of the techniques. Throughout this section we shall use the notations introduced in Section 2.4.

Our first result classifies all diffuse, commuting property (T) subfactors inside these group factors.

**Theorem 3.1.** Let $N \times Q \in \mathcal{S}$. Also let $A_1, A_2 \subseteq \mathcal{L}(N \times Q) = \mathcal{M}$ be two commuting, property (T), type II$_1$ factors. Then for all $k \in \{1, 2\}$ one of the following holds:

1. There exists $i \in \{1, 2\}$ such that $A_i \prec_{\mathcal{M}} \mathcal{L}(N_k)$;

2. $A_1 \vee A_2 \prec_{\mathcal{M}} \mathcal{L}(N_k) \times Q$.

**Proof.** Let $G_k = N_k \times Q$ for $k \in \{1, 2\}$. Notice that by part e) in Theorem 2.5 we have that $N \times Q \leq G_1 \times G_2 = G$ where $Q$ is embedded as diag$(Q) \leq Q \times Q$. Notice that $A_1, A_2 \subseteq \mathcal{L}(N) \times Q \leq \mathcal{L}(G_1 \times G_2) =: \mathcal{M}$. By [CDK19, Theorem 5.3] there exists $i \in \{1, 2\}$ such that

a) $A_i \prec_{\mathcal{M}} \mathcal{L}(G_k)$, or

b) $A_1 \vee A_2 \prec_{\mathcal{M}} \mathcal{L}(G_k \times Q)$.

Assume a). Since $A_1 \vee A_2 \subseteq \mathcal{L}(N) \times Q$, by using [CDK19, Lemma 2.3] we further get that $A_i \prec_{\mathcal{M}} \mathcal{L}(G \cap hG_i h^{-1}) = \mathcal{L}((N_1 \times N_2) \times \text{diag}(Q)) \cap (N_k \times Q)) = \mathcal{L}(N_k)$ and thus we have that $c) A_i \prec_{\mathcal{M}} \mathcal{L}(N_k)$.  

Assume b). Then $A_1 \vee A_2 \prec_{\mathcal{M}} \mathcal{L}(\Gamma \cap h(\Gamma k \times Q) h^{-1}) = \mathcal{L}(h(N_k \times \text{diag}(Q)) h^{-1})$. This implies that

d) $A_1 \vee A_2 \prec_{\mathcal{M}} \mathcal{L}(N_k) \times Q$.

Note that by using [CDK19, Lemma 2.5] case d) already implies that $A_1 \vee A_2 \prec_{\mathcal{M}} \mathcal{L}(N_k) \times Q$ which gives possibility 2. in the statement.
Next we shall prove that $c)$ gives 1. To accomplish this we only need to show that the intertwining actually happens in $M$. By Popa’s intertwining techniques $c)$ implies there exist finitely many $x_i \in M$, and $c > 0$ such that

$$\sum_{i=1}^{n} \|E_{L(N_k)}(ax_i)\|^2_x \geq c \text{ for all } a \in \mathcal{M}(A_i). \quad (3.0.1)$$

Using basic approximations of $x_i$’s and increasing $n \in \mathbb{N}$ and decreasing $c > 0$, if necessary, we can assume that $x_i = u_{g_i}$ where $g_i \in \hat{G}_k \times Q$. Now observe that $E_{L(N_k)}(ax_i) = E_{L(N_k)}(au_{g_i}) = E_{L(N_k)}(E_M(au_{g_i})) = E_{L(N_k)}(aE_M(u_{g_i}))$. Thus equation (3.0.1) becomes

$$\sum_{i=1}^{n} \|E_{L(N_k)}(aE_M(u_{g_i}))\|^2_x \geq c \text{ for all } u \in \mathcal{M}(A_i)$$

and hence $A_i \prec_M L(N_k)$ as desired. □

Next we show that actually the intertwining statements in the previous theorem can be made much more precise.

**Theorem 3.2.** Let $N \times Q \in \mathcal{F}$. Also let $A_1, A_2 \in L(N \times Q) = M$ be two commuting, property (T), type II$_1$ factors. Then for every $k \in \{1, 2\}$ one of the following holds:

1. There exists $i \in \{1, 2\}$ such that $A_i \prec_M L(N_k)$;
2. $A_1 \vee A_2 \prec_M L(Q)$.

**Proof.** Using Theorem 3.1 the statement will follow once we show that $A_1 \vee A_2 \prec_M L(N_k) \times Q$ implies $A_1 \vee A_2 \prec_M L(Q)$, which we do next. Since $A_1 \vee A_2 \prec_M L(N_k) \times Q$, there exists $\psi: p(A_1 \vee A_2)p \to \psi(p(A_1 \vee A_2)p) = R \subseteq q(L(N_k) \times Q)q$ an \*$\$-homomorphism, nonzero partial isometry $v \in qM$ such that

$$\psi(x)v = vx \text{ for all } x \in p(A_1 \vee A_2)p. \quad (3.0.3)$$

Notice that we can pick $v$ such that the support projection satisfies $s(E_{L(N_k) \times Q}^*(vv^*)) = q$. Moreover, since $A_i$’s are factors we can assume that $p = p_1p_2$ for some $p_i \in \mathcal{P}(A_i)$.

Next let $R_i = \psi(p_Ap_i)$. Note that $R_1, R_2$ are commuting property (T) subfactors such that $R_1 \vee R_2 = R \subseteq q(L(N_k) \times Q)q$. Using the Dehn filling technology from [Os06, DG01], we see that there exists a short exact sequence $1 \to \gamma(\gamma_1) \to N_k \times Q \to H \to 1$ where $H$ is a hyperbolic, property (T) group and $Q_0 \subseteq Q$ is a finite index subgroup. Then using [PV12, CIK13] in the same way as in the proof of [CDK19] Theorem 5.2] we have either a) $R_i \prec_{L(N_k) \times Q} L(\gamma(\gamma_1))$, for some $i$, or b) $R = R_1 \vee R_2 \prec_{L(N_k) \times Q} L(\gamma(\gamma_1))$. Since $R_i$’s have property (T) then by [Po01] Proposition 4.6] so does $R$ and hence possibility b) entails $R \prec_{L(N_k) \times Q} L(\gamma(\gamma_1))$. Summarizing, cases a)-b) imply that $R_i \prec_{L(N_k) \times Q} L(\gamma(\gamma_1))$, for some $i$. Then using [IPP05] Theorem 4.3] this further implies $R \prec_{L(N_k) \times Q} L(\gamma(\gamma_1))$ and hence $R_i \prec_{L(N_k) \times Q} L(Q_0) \subseteq L(Q)$. As $Q \subseteq N_k \times Q$ is malnormal, using the same arguments as in the proof of [CDK19] Theorem 5.3] one can show that $R \prec_{L(N_k) \times Q} L(Q)$. Indeed, let $\phi: rR_ir \to \phi(rR_ir) := R \subseteq q_1L(Q)q_1$ be a unital \*$\$-homomorphism, and let $w \in q_1L(N_k \times Q)r$ be a nonzero partial isometry such that

$$\phi(x)w = wx \text{ for all } x \in rR_ir. \quad (3.0.4)$$

9
Note that $ww^* \in \mathcal{L}(Q)$ by Lemma 2.2 and hence $\mathcal{R}w_1^* w_1^* = w_1 w_1^* \in \mathcal{L}(Q)$. For every $u \in \mathcal{R}_{i+1}$ we have

$$
\mathcal{R}w_1^* w_1^* = \mathcal{R}w_1^* w_1^* = w_1 w_1^* w_1 w_1^* = w_1 w_1^* \mathcal{R}w_1^* w_1^* = w_1^* \mathcal{R}w_1^* w_1^* = w_1^* \mathcal{R}w_1^* w_1^* = w_1^* \mathcal{R}w_1^* w_1^* = w_1^* \mathcal{R}w_1^* w_1^*.
$$

Thus Lemma 2.2 again implies that $ww^* \in \mathcal{L}(Q)$. Altogether these show that $\mathcal{R}_{i+1}^* w_1^* \in \mathcal{L}(Q)$. Combining with the above we get $\mathcal{R}w_1^* w_1^* = \mathcal{R}w_1^* w_1^* = w_1 w_1^* \mathcal{R}w_1^* w_1^* = w_1 w_1^* \mathcal{R}w_1^* w_1^* \in \mathcal{L}(Q)$. From relation (3.3.4) we have that $w^* w \in \mathcal{R}$. Also by (3.3.5) we have $\mathcal{R}v = v w_1 \mathcal{R}w_1^* w_1^* = v w_1 \mathcal{R}w_1^* w_1^* = v w_1 \mathcal{R}w_1^* w_1^* = v w_1 \mathcal{R}w_1^* w_1^* = v w_1 \mathcal{R}w_1^* w_1^*$, hence $v w_1 \mathcal{R}w_1^* w_1^* = v w_1 \mathcal{R}w_1^* w_1^* = v w_1 \mathcal{R}w_1^* w_1^* = v w_1 \mathcal{R}w_1^* w_1^*$, which is a contradiction. To this end, combining the previous relations we have $w w_1 \mathcal{R}w_1^* w_1^* = w w_1 \mathcal{R}w_1^* w_1^* = w w_1 \mathcal{R}w_1^* w_1^* = w w_1 \mathcal{R}w_1^* w_1^* = w w_1 \mathcal{R}w_1^* w_1^*$, since the partial isometry $w w_1 \neq 0$ the last relation clearly shows that $A_1 \mathcal{R} w_1^* w_1^* \in \mathcal{M}(\mathcal{L}(Q))$, as desired.

\[\square\]

**Theorem 3.3.** Let $A_1, A_2 \subseteq \mathcal{L}(Q) = \mathcal{M}$ be two commuting, property (T), type II$_1$ factors such that

(a) $A_1 \mathcal{R} w_1^* w_1^* \in \mathcal{M}(\mathcal{L}(Q))$, or

(b) $A_1 \mathcal{R} w_1^* w_1^* \in \mathcal{M}(\mathcal{L}(Q))$.

**Proof.** Fix $k \in \{1, 2\}$. By Theorem 3.2 we get that either

(i) $i_k \in \{1, 2\}$ such that $A_{i_k} \mathcal{L}(N_{i_k})$, or

(ii) $A_1 \mathcal{R} w_1^* w_1^* \in \mathcal{M}(\mathcal{L}(Q))$.

Note that case ii) together with the assumption $(A_1 \mathcal{R} w_1^* w_1^* \in \mathcal{M}(\mathcal{L}(Q))$ already give b). So assume that case i) holds. Hence for all $k \in \{1, 2\}$, there exists $i_k \in \{1, 2\}$ such that $A_{i_k} \mathcal{L}(N_{i_k})$. Using [DHI16, Lemma 2.4], there exists $0 \neq z \in \mathcal{L}(N_{i_k} \mathcal{M}(A_{i_k}^* \mathcal{R} w_1^* w_1^* \mathcal{M} \mathcal{L}(N_{i_k} \mathcal{M}) \mathcal{L}(N_{i_k} \mathcal{M})$ such that $A_{i_k} \mathcal{L}(N_{i_k})$. Since $A_1 \mathcal{R} w_1^* w_1^* \mathcal{M} \mathcal{L}(N_{i_k} \mathcal{M})$, then $N_{i_k} \mathcal{M}(A_{i_k})^* \mathcal{M} \mathcal{L}(N_{i_k} \mathcal{M}) \mathcal{L}(N_{i_k} \mathcal{M})$ and $A_{i_k} \mathcal{L}(N_{i_k} \mathcal{M}) \mathcal{L}(N_{i_k} \mathcal{M})$ such that $A_{i_k} \mathcal{L}(N_{i_k} \mathcal{M}) \mathcal{L}(N_{i_k} \mathcal{M})$.

We now briefly argue that $k \neq l \Rightarrow i_k \neq i_l$. Assume by contradiction that $i_1 = i_2 = i$. Then (3.0.5) implies that $A_i \mathcal{L}(N_{i_k})$ and $A_{i_k} \mathcal{L}(N_{i_k})$. By [DHI16, Lemma 2.6], this implies that $A_i \mathcal{L}(N_{i_k})$ and $A_{i_k} \mathcal{L}(N_{i_k})$. Note that $\mathcal{L}(N_{i_k})$ are regular in $\mathcal{M}$ and hence by [PV11, Proposition 2.7] we get that $A_i \mathcal{L}(N_{i_k}) \mathcal{M}(N_{i_k} \mathcal{M}) \mathcal{L}(N_{i_k}) \mathcal{M}(N_{i_k} \mathcal{M})$ and $A_{i_k} \mathcal{L}(N_{i_k}) \mathcal{M}(N_{i_k} \mathcal{M}) \mathcal{L}(N_{i_k}) \mathcal{M}(N_{i_k} \mathcal{M})$.

Our next result concerns the location of the “core” von Neumann algebra.

**Theorem 3.4.** Let $N \times Q, M \times P \in \mathcal{M}$. Let $p \in \mathcal{L}(M \times P)$ be a projection and assume that $\Theta : \mathcal{L}(N \times Q) \rightarrow \mathcal{L}(M \times P)$ is a $*$-isomorphism. Then there exists a unitary $v \in \mathcal{M}(p \mathcal{L}(M \times P)p)$ such that $\Theta(\mathcal{L}(N)) = v p \mathcal{L}(M)p v^*$. [10, Proposition 2.7]

**Proof.** From assumptions there are $Q_1, Q_2, P_1, P_2$ ecc., residually finite, hyperbolic property (T) groups such that $Q = Q_1 \times Q_2$ and $P = P_1 \times P_2$. We also have that $N = N_1 \times N_2$ and $M = M_1 \times M_2$ where $N_j$’s and $M_j$’s have property (T). Denoting by $\mathcal{M} = \mathcal{L}(M \times P)$, $\mathcal{A} = \mathcal{L}(\mathcal{L}(N))$ and $\mathcal{A}_i = \mathcal{L}(\mathcal{L}(N_i))$, we see that $A_1$ and $A_2$ are commuting property (T) subalgebras of $p \mathcal{M} p$. Using part b) in Theorem 3.3 we have that $\{A_1 \mathcal{R} w_1^* w_1^* \mathcal{L}(N \times Q) \} = C \mathcal{M}(1) = C \mathcal{M}$. Using Theorem 3.3 we get either

a) $A \mathcal{L}(M)$ or,

b) $A \mathcal{L}(M)$ or,

\[\square\]
b) $A \preceq_{\mathcal{M}}^{\star} \mathcal{L}(P)$.

Assume case b) above holds. Then there exists projections $r \in A$, $q \in \mathcal{L}(P)$, a nonzero partial isometry $v \in qM_r$, and a $*$-homomorphism $\psi : rAr \to \psi(rAr) \subseteq q\mathcal{L}(P)q$ such that $\psi(x)v = vx$ for all $x \in rAr$. Arguing exactly as in the proof of [DK19] Theorem 5.5, we can show that $vQN_{r\mathcal{M}(rAr)}'v^* \subseteq q\mathcal{L}(P)q$.

Now, $QN_{r\mathcal{M}(rAr)}'' = rMr$, using [Po03] Lemma 3.5. Thus, $M \preceq_{\mathcal{M}} \mathcal{L}(P)$ and hence $\mathcal{L}(P)$ has finite index in $M$ by [CD18] Theorem 2.3, which is a contradiction. Hence we must a), i.e. $A \preceq_{\mathcal{M}} \mathcal{L}(P)$.

Repeating the above argument verbatim, we get that $p\mathcal{L}(M)p \preceq_{p\mathcal{M}p} A$. Let $N = \mathcal{L}(N \times Q)$ and $B = p\mathcal{L}(M)p$. Note that $\mathcal{A} \subseteq \Theta(N)$ and $B \subseteq p\mathcal{M}p$ are amplifications of genuine crossed product inclusions. Also by part d) in Theorem 2.6, $A$ is regular irreducible subfactor of $\Theta(N) = p\mathcal{M}p$, while $B$ is a quasi-regular irreducible subfactor of $p\mathcal{M}p$ (as $QN_{p\mathcal{M}p}(pBp)' = pQN_{p\mathcal{M}(\mathcal{L}(M))}p$). Thus, we are in the setting of the first part of the proof of [IPP05] Lemma 8.4 and using the same arguments there we conclude one can find $r \in \mathcal{P}(A)$, a unital $*$-isomorphism $\psi : rAr \to \mathcal{R} := \psi(rAr) \subseteq p\mathcal{L}(P)p$, and a partial isometry $v \in p\mathcal{M}p$ satisfying $v^*v = r$, $vrv^* \in \mathcal{R}' \cap p\mathcal{M}p$ and $\psi(x)v = vx$ for all $x \in rAr$. Moreover, we have that $\mathcal{R} \subseteq p\mathcal{L}(M)p$ has finite index, and $\mathcal{R}' \cap p\mathcal{L}(M)p = \mathcal{C}p$. Notice that by [Po02] Lemma 3.1, we have that $[\mathcal{R}' \cap p\mathcal{M}p : (p\mathcal{L}(M)p)' \cap p\mathcal{M}p] \leq [p\mathcal{L}(P)p : \mathcal{R}]$. As $(p\mathcal{L}(M)p)' \cap p\mathcal{M}p = \mathcal{C}$, we conclude that $\mathcal{R}' \cap p\mathcal{M}p$ is finite dimensional.

Let $x \in \mathcal{R}' \cap p\mathcal{M}p$. Since $x = r\sum_{g} x_g u_g \in \mathcal{R}' \cap p\mathcal{M}p$ and $x = \sum_{g} x_g u_g$ is the Fourier decomposition of $x$ in $\mathcal{M} = \mathcal{L}(M) \times \mathcal{P}$. Thus $\sum_{g} r x_g u_g = \sum_{g} x_g v_g = x_g v_g$ and hence $r x_g = x_g v_g(r)$ for all $g$ in $r$. In particular this entails that
\[
\begin{align*}
\sigma_{\mathcal{A}} x_g &= \sum_{g} x_g v_g(r) \\
\langle \sigma_{\mathcal{A}} x_g, \eta \rangle &= \sum_{g} x_g v_g(r) \langle \eta, v_g \rangle \\
\end{align*}
\]
From (3.0.6) we see that $x_g$ is a scalar multiple of a unitary in $p\mathcal{M}p$. Hence by normalization we may assume that each $x_g$ is itself either a unitary or zero.

Let $K$ be the set of all $g \in \mathcal{P}$ for which there exists $x_g \in \mathcal{M}(p\mathcal{M}(M)p)$ such that $x_g u_g \in \mathcal{M}(\mathcal{R}' \cap p\mathcal{M}p)$ and notice that $K$ is a subgroup of $\mathcal{P}$. Note that $\{x_g u_g : g \in K\}$ is a $\tau$-orthogonal family in $\mathcal{R}' \cap p\mathcal{M}p$. As $\mathcal{R}' \cap p\mathcal{M}p$ is finite dimensional, we get that $K$ is a finite subgroup of $\mathcal{P}$. As $\mathcal{P}$ is torsion free (see part a) in Theorem 2.6) then $K = \{e\}$. In particular this shows that $\mathcal{R}' \cap p\mathcal{M}p = \mathcal{R}' \cap p\mathcal{L}(M)p = \mathcal{C}p$ which implies $v^*v = p$ and since $v^*v = r \leq p$ we get $r = p$ and $v \in \mathcal{M}(p\mathcal{M}(M)p)$. Thus $\psi(x)v = vxv^*$ for all $x \in rAr$ and hence $\mathcal{R} = vrArv^* = vrArv^* \subseteq p\mathcal{L}(P)p$. Let $v = \Theta(w_0)$, where $w_0 \in \mathcal{H}(\mathcal{L}(N \times Q))$. Thus, we get that $\mathcal{L}(N) \subseteq w_0^* \Theta^{-1}(p\mathcal{L}(M)p)w_0 \subseteq \mathcal{L}(N) \times \mathcal{Q}$. By [Ch78] (see also [CD19] Corollary 3.8), we deduce that there exists a subgroup $L \subseteq \mathcal{P}$ such that $w_0 \Theta^{-1}(p\mathcal{L}(M)p)w_0 = \mathcal{L}(N) \times L$. As $[w_0^* \Theta^{-1}(p\mathcal{L}(M)p)w_0 : \mathcal{L}(N)]$ is finite, we must have that $L$ is a finite subgroup of the torsion free group $Q$. Thus $L = \{e\}$ which gives that $\Theta(\mathcal{L}(N)) = A = v^*p\mathcal{L}(M)p$.

Next we show that in the previous result we can also identify up to corners the algebras associated with the acting groups. The proof relies heavily on the classification of commuting property (T) subalgebras provided by [3.3] and the malnormality of the acting groups.

**Theorem 3.5.** Let $N \times Q, M \times P \in \mathcal{S}$. Let $p \in \mathcal{L}(M \times P)$ be a projection and assume that $\Theta : (\mathcal{L}(N \times Q) \to \mathcal{L}(M \times P))p$ is a $*$-isomorphism. Then the following hold

1. There exists $v \in \mathcal{M}(p\mathcal{L}(M \times P)p)$ such that $\Theta(\mathcal{L}(N)) = v p \mathcal{L}(M)p v^*$, and
2. There exists $u \in \mathcal{M}(\mathcal{L}(M \times P))$ such that $\Theta(\mathcal{L}(Q)) = pu^* \mathcal{L}(P)up$.

**Proof.** As part 1. follows directly from Theorem 3.4, we only need to show part 2.

Recall that $Q = Q_1 \times Q_2$, $P = P_1 \times P_2$, $N = N_1 \times N_2$ and $M = M_1 \times M_2$ where $Q_i, P_i, N_i$ and $M_i$ are icc, property (T) groups. Denote by $\mathcal{M} = \mathcal{L}(M \times P), \mathcal{A} = \Theta(\mathcal{L}(N)), \mathcal{B} = \Theta(\mathcal{L}(Q))$ and $\mathcal{B}_1 = \Theta(\mathcal{L}(Q_1))$. Then we see that $\mathcal{B}_1 \mathcal{B}_2 \subseteq p\mathcal{M}p$ are commuting property (T) subalgebras such that $\mathcal{B}_1 \mathcal{B}_2 = \mathcal{B}$. Moreover, by part d) in Theorem 2.6, we have that $\{\mathcal{B}_1 \mathcal{B}_2\}' \cap p\mathcal{M}p = \mathcal{B}' \cap \Theta(\mathcal{L}(N \times Q)) = C\theta(1) = C\mathcal{P}$. Hence
by Theorem 2.5 and thus using the conclusion of the same theorem we get the claim. By part 1. we also know that $A \prec_{\mathcal{M}} \mathcal{L}(M)$. Thus, if a) holds, then Theorem 2.3 implies that $p\mathcal{M}p = \Theta(\mathcal{L}(N \times Q)) \prec_{\mathcal{M}} \mathcal{L}(M)$. In turn this implies that $Q$ is finite, a contradiction. Hence b) must hold, i.e. $B \prec_{\mathcal{M}} \mathcal{L}(P)$.

Thus there exist projections $q \in B, r \in \mathcal{L}(P)$, a nonzero partial isometry $v \in M$ and a $*$-homomorphism $\psi : qBq \to \mathcal{R} := \psi(qBq) \subseteq \mathcal{L}(P)r$ such that $\psi(x)v = vx$ for all $x \in qBq$. Note that $\psi v^* \in \mathcal{R} \cap r\mathcal{L}(P)r$. Since $\mathcal{R} \subseteq r\mathcal{L}(P)r$ is diffuse, and $P \leq M \times P$ is a malnormal subgroup (part c) in Theorem 2.6), we have that $\mathcal{L}_{\mathcal{N}_P}(\mathcal{R})'' \subseteq r\mathcal{L}(P)r$. Thus $\psi v^* \in r\mathcal{L}(P)r$ and hence $vqBqv^* = \mathcal{R}v\psi v^* \subseteq r\mathcal{L}(P)r$. Extending $v$ to a unitary $v_0$ in $M$ we have that $v_0qBqv_0^* \subseteq \mathcal{L}(P)$. As $\mathcal{L}(P)$ and $B$ are factors, after perturbing $v_0$ to a new unitary $u$, we may assume that $uBu^* \subseteq \mathcal{L}(P)$. This further implies that $uPu^* \in \mathcal{L}(P)$ and since $\Theta(1) = p$ we also have

$$B = pBp \subseteq uPu^* \mathcal{L}(P)u. \quad (3.0.8)$$

Next we claim that

$$pu^* \mathcal{L}(P)up \prec_{\mathcal{M}} B. \quad (3.0.9)$$

To see this notice that, since $P$ is malnormal in $M \times P$ and $P$ is icc (see parts a) and c) in Theorem 2.6) then $(pu^* \mathcal{L}(P)up)' \cap \Theta(\mathcal{L}(N \times Q)) = (pu^* \mathcal{L}(P)up)' \cap p\mathcal{M}p = u^* \mathcal{L}(P)' \cap \mathcal{M}(M \times P)up = \mathcal{C}p$. Thus using Theorem 3.3 we have either a) $pu^* \mathcal{L}(P)up \prec_{p\mathcal{M}p} A$ or b) $pu^* \mathcal{L}(P)up \prec_{p\mathcal{M}p} B$. Assume a) holds. By part 1. we have $pu^* \mathcal{L}(P)up \prec_{p\mathcal{M}p} A = v\mathcal{M}(M)pv^*$; in particular, this implies that $\mathcal{L}(P) \prec_{\mathcal{M}} \mathcal{L}(M)$ but this contradicts the fact that $\mathcal{L}(M)$ and $\mathcal{L}(P)$ are diffuse algebras that are $\tau$-perpendicular in $M$. Thus b) holds which proves the claim.

Using (3.0.9) together with malnormality of $\Theta(\mathcal{L}(Q))$ inside $\Theta(\mathcal{L}(N \times Q))$ and arguing exactly as in the proof of relation (3.0.8) we conclude that there exists $w \in \mathcal{U}(p\mathcal{M}p)$ such that

$$wpu^* \mathcal{L}(P)upw^* \subseteq B. \quad (3.0.10)$$

Combining (3.0.8) and (3.0.10) we get that $wBw^* \subseteq wpu^* \mathcal{L}(P)upw^* \subseteq B$ and hence $w \in \mathcal{Q}(p\mathcal{M}p)(B)'' = B$. Thus we get

$$pu^* \mathcal{L}(P)up \subseteq w\mathcal{L}(P)w = B. \quad (3.0.11)$$

Combining (3.0.8) and (3.0.11) we get the theorem.

Finally we are now ready to derive the main result of this paper.

**Theorem 3.6.** Let $N \times Q, M \times P \in \mathcal{J}$ with $N = N_1 \times N_2$ and $M = M_1 \times M_2$. Let $p \in \mathcal{L}(M \times P)$ be a projection and assume that $\Theta : \mathcal{L}(N \times Q) \to p\mathcal{L}(M \times P)p$ is a $*$-isomorphism. Then $p = 1$ and one can find $*$-isomorphisms, $\Theta_i : \mathcal{L}(N_i) \to \mathcal{L}(M_i)$, a group isomorphism $\delta : Q \to P$, a multiplicative character $\eta : Q \to \mathbb{T}$, and a unitary $u \in \mathcal{U}(\mathcal{L}(M \times P))$ such that for all $g \in Q, x_i \in N_i$ we have that

$$\Theta((x_1 \otimes x_2)u_g) = \eta(g)u(\Theta_1(x_1) \otimes \Theta_2(x_2)v_{\delta(g)})u^*. \quad (3.0.12)$$

**Proof.** Throughout this proof we will denote by $\mathcal{M} = \mathcal{L}(N \times Q)$. Using Theorem 3.4 and replacing $\Theta$ by $\Theta \circ Ad(v)$ if necessary, we may assume that $\Theta(\mathcal{L}(N)) = p\mathcal{L}(M)p$. By Theorem 3.5 there exists $u \in \mathcal{U}(\mathcal{M})$ such that $\Theta(\mathcal{L}(Q)) \subseteq u^* \mathcal{L}(P)u$, where $\mathcal{M} = \mathcal{L}(M \times P)$. Moreover $\Theta(1) = p, uPu^* \in \mathcal{L}(P)$ and also $\Theta(\mathcal{L}(Q)) = pu^* \mathcal{L}(P)up$. Next we denote by $\Gamma = u^* Pu$ and by $\mathcal{G} = \{\Theta(u_g) : g \in Q\}$. Using these notations we show the following

**Claim 2.** $h_{\Gamma}(\mathcal{G}) > 0$.

**Proof of Claim 2.** Notice that $\mathcal{G} \subseteq \mathcal{L}(\Gamma)$ is a group of unitaries normalizing $\Theta(\mathcal{L}(N))$. Moreover, by Theorem 2.6 we can see that the action $\sigma : P \to Aut(\mathcal{M})$ satisfies all the conditions in the hypothesis of Theorem 2.5 and thus using the conclusion of the same theorem we get the claim. □
Claim 3. Let $e \neq g \in \Gamma$. Then $\mathcal{G}'' \nsupseteq \mathcal{L}(C_\Gamma(g))$.

Proof of Claim 3 Since $\Gamma$ is isomorphic to the product of two biexact groups, say $\Gamma_1 \times \Gamma_2$, by Lemma 2.7 we get that $C_\Gamma(g) = A \times A$, or $A \times A$ for an amenable group $A$. If $C_\Gamma(g) = A$ then since $\mathcal{G}$ is non-amenable we clearly have $\mathcal{G}'' \nsupseteq \mathcal{L}(C_\Gamma(g))$. Next assume $C_\Gamma(g) = A \times A$ and assume by contradiction that $\mathcal{G}'' \subseteq \mathcal{L}(C_\Gamma(g))$. As $Q = Q_1 \times Q_2$ for $Q_i$ property (T) icc group, then $\mathcal{G}'' = \Theta(\mathcal{L}(Q_1)) \otimes \Theta(\mathcal{L}(Q_2))$ is a II$_1$ factor with property (T). Since $\mathcal{G}'' \subsetneq \mathcal{L}(A \times A)$, $\mathcal{L}(A)$ is amenable then it follows that $\mathcal{G}'' \subseteq \mathcal{L}(\Gamma)$. However by [Ozu13] Theorem 1 this is impossible as $\mathcal{L}(\Gamma)$ is solid and $\mathcal{G}''$ is generated by two non-amenable commuting subfactors. The case $C_\Gamma(g) = \Gamma_1 \times A$ follows similarly. 

Claim 4. The unitary representation $\{\text{Ad}(v)\}_{v \in \mathcal{G}}$ on $L^2(p\mathcal{L}(\Gamma)p \oplus \mathbb{C}p)$ is weakly mixing.

Proof of Claim 4 First note we have that $\Theta(\mathcal{L}(Q)) = \mathcal{G}'' = p\mathcal{L}(\Gamma)p$. Also since $Q$ is icc then using [CSU13] Proposition 3.4] the representation $\text{Ad}(Q)$ on $L^2(\mathcal{L}(Q) \oplus \mathbb{C})$ is weak mixing. Combining these two facts, we get that the representation $\mathcal{G}$ on $L^2(p\mathcal{L}(\Gamma)p \oplus \mathbb{C}p)$ is weak mixing, as desired.

Claims 2-4 above together with Theorem 2.4 show that $p = 1$ and moreover there exists unitary $w \in \mathcal{M}(\Gamma \times P)$, a group isomorphism $\delta : Q \to P$ and a multiplicative character $\eta : Q \to \mathbb{T}$ such that $\Theta(\text{ad}(w)) = \eta(g)\omega_{\delta(g)}w^*$ for all $g \in Q$. Since $\Theta(\mathcal{L}(N)) = \mathcal{L}(M)$ then the same argument as in proof of [CD19 Theorem 4.5] (lines 10-27 on page 25) shows that $\mathcal{G}$ and ii) $w^*\mathcal{L}(M)w \subseteq \mathcal{L}(M)$. However re-writing the previous relation as $v_h = \eta(g)w^*\delta(x_{h^{-1}(y)})w$ for all $h \in P$ and applying the same argument as above for the decomposition $M = \Theta(\mathcal{L}(M)) \times \Theta(Q)$ we get that ii) $w\Theta(\mathcal{L}(N))w^* \subseteq \Theta(\mathcal{L}(N))$. Then combining i) and ii) we get that $w^*\mathcal{L}(M)w = \mathcal{L}(M)$. Now from the above relations it follows clearly that the map $\Psi = \text{ad}(\omega^*) \otimes \Theta : \mathcal{L}(N) \to \mathcal{L}(M)$ is a $*$-isomorphism, and $\Theta(\text{ad}(x_{h,g})) = \eta(g)\omega(\Psi(x_{h,g})w^*)$ for all $x \in \mathcal{L}(N)$. Finally, proceeding as in the proof of [CD19 Theorem 5.1] one can further show that the isomorphism $\Psi$ arises from a tensor of $*$-isomorphisms $\Psi_i : \mathcal{L}(N_i) \to \mathcal{L}(M_i)$. We leave these details to the reader.

Corollary 2. For any $G = N \rtimes Q \in \mathcal{F}$ the fundamental group of $\mathcal{L}(G)$ is trivial, i.e. $\mathcal{F}(\mathcal{L}(G)) = 1$.

While it is well known that there exist many families of pairwise non-isomorphic II$_1$ factors with property (T), much less is known about producing concrete such examples. Our Corollary 2 shades new light in this direction.

Corollary 3. For any $G = N \rtimes Q \in \mathcal{F}$ then the set of all amplifications $\{\mathcal{L}(G)^t : t \in (0, \infty)\}$ consists of pairwise non-isomorphic II$_1$ factors with property (T).

Proof. The statement follows trivially from Corollary 2 and the definition of fundamental group.
