# Investigations on $c$-(almost) perfect nonlinear functions 

Constanza Riera, Pantelimon Stănică ${ }^{\dagger}$

November 20, 2021

#### Abstract

In a prior paper 14, along with P. Ellingsen, P. Felke and A. Tkachenko, we defined a new (output) multiplicative differential, and the corresponding $c$-differential uniformity, which has the potential of extending differential cryptanalysis. Here, we continue the work, by looking at some APN functions through the mentioned concept and show that their $c$-differential uniformity increases significantly, in some cases.

Keywords: Boolean, $p$-ary functions, $c$-differentials, Walsh transform, differential uniformity, perfect and almost perfect $c$-nonlinearity

## 1 Introduction and motivation

In [3], the authors used a new type of differential that is quite useful from a practical perspective for ciphers that utilize modular multiplication as a primitive operation. It is an extension of a type of differential cryptanalysis and it was used to cryptanalyze some existing ciphers (like a variant of the well-known IDEA cipher). The authors argue that one should look (and some authors did) at other types of differentials for a Boolean (vectorial) function $F$, not only the usual $(F(x+a), F(x))$. In [3], the differential used in their attack was $(F(c x), F(x))$. Drawing inspiration from the mentioned

[^0]successful attempt, along with P. Ellingsen, P. Felke and A. Tkachenko (see [14]), we defined a new (output) multiplicative differential, and the corresponding generalized differential uniformity. In this paper, we investigate some known APN functions under this new multiplicative differential, and show that their $c$-differential uniformity drops significantly, in some cases.

The objects of this study are Boolean and $p$-ary functions (where $p$ is an odd prime) and some of their differential properties. We will introduce here only some needed notation, and the reader can consult [4, 5, 6, 11, 21, 23] for more on Boolean and $p$-ary functions.

Let $n$ be a positive integer and $\mathbb{F}_{p^{n}}$ denote the finite field with $p^{n}$ elements, and $\mathbb{F}_{p^{n}}^{*}=\mathbb{F}_{p^{n}} \backslash\{0\}$ is the multiplicative group (for $a \neq 0$, we often write $\frac{1}{a}$ to mean the inverse of $a$ in the multiplicative group). We let $\mathbb{F}_{p}^{n}$ be the $n$-dimensional vector space over $\mathbb{F}_{p}$. We will denote by $\eta(\alpha)$ the quadratic character of $\alpha$ (that is, it is $\eta(\alpha)=0$ if $\alpha=0, \eta(\alpha)=1$ if $0 \neq \alpha$ is a square, $\eta(\alpha)=-1$ if $0 \neq \alpha$ is not a square). $|A|$ will denote the cardinality of a set $A$. We call a function from $\mathbb{F}_{p^{n}}$ to $\mathbb{F}_{p}$ a $p$-ary function on $n$ variables. $\operatorname{Tr}_{n}: \mathbb{F}_{p^{n}} \rightarrow \mathbb{F}_{p}$ is the absolute trace function, given by $\operatorname{Tr}_{n}(x)=\sum_{i=0}^{n-1} x^{p^{i}}$.

Given a $p$-ary function $f$, the derivative of $f$ with respect to $a \in \mathbb{F}_{p^{n}}$ is the $p$-ary function $D_{a} f(x)=f(x+a)-f(x)$, for all $x \in \mathbb{F}_{p^{n}}$.

For positive integers $n$ and $m$, any map $F: \mathbb{F}_{p^{n}} \rightarrow \mathbb{F}_{p^{m}}$ (or, alternatively, $F: \mathbb{F}_{p}^{n} \rightarrow \mathbb{F}_{p}^{m}$, though we will in this paper deal with the former form of the function) is called a vectorial p-ary function, or $(n, m)$-function. When $m=n, F$ can be uniquely represented as a univariate polynomial over $\mathbb{F}_{p^{n}}$ (using some identification, via a basis, of the finite field with the vector space) of the form $F(x)=\sum_{i=0}^{p^{n}-1} a_{i} x^{i}, a_{i} \in \mathbb{F}_{p^{n}}$, whose algebraic degree is then the largest Hamming weight of the exponents $i$ with $a_{i} \neq 0$.

For an $(n, n)$-function $F$, and $a, b \in \mathbb{F}_{p^{n}}$, we let

$$
\Delta_{F}(a, b)=\left|\left\{x \in \mathbb{F}_{p^{n}}: F(x+a)-F(x)=b\right\}\right| .
$$

We call the quantity $\Delta_{F}=\max \left\{\Delta_{F}(a, b): a, b \in \mathbb{F}_{p^{n}}, a \neq 0\right\}$ the differential uniformity of $F$. If $\Delta_{F}=\delta$, then we say that $F$ is differentially $\delta$-uniform. If $\delta=1$, then $F$ is called a perfect nonlinear ( $P N$ ) function, or planar function. If $\delta=2$, then $F$ is called an almost perfect nonlinear ( $A P N$ ) function. It is well known that PN functions do not exist if $p=2$.

Inspired by a practical differential attack developed in [3] (though, via a different differential), we extended the definition of derivative and differential uniformity in [14, in the following way: Given a $p$-ary $(n, m)$-function $F$ : $\mathbb{F}_{p^{n}} \rightarrow \mathbb{F}_{p^{m}}$, and $c \in \mathbb{F}_{p^{m}}$, the (multiplicative) c-derivative of $F$ with respect
to $a \in \mathbb{F}_{p^{n}}$ is the function

$$
{ }_{c} D_{a} F(x)=F(x+a)-c F(x), \text { for all } x \in \mathbb{F}_{p^{n}} .
$$

(Note that, if $c=1$, then we obtain the usual derivative, and, if $c=0$ or $a=0$, then we obtain a shift of the function.)

For an $(n, n)$-function $F$, and $a, b \in \mathbb{F}_{p^{n}}$, we let ${ }_{c} \Delta_{F}(a, b)=$ $\left|\left\{x \in \mathbb{F}_{p^{n}}: F(x+a)-c F(x)=b\right\}\right|$. In the following, we call the quantity ${ }_{c} \Delta_{F}=\max \left\{{ }_{c} \Delta_{F}(a, b): a, b \in \mathbb{F}_{p^{n}}\right.$, and $a \neq 0$ if $\left.c=1\right\}$ the $c$-differential uniformity of $F$. If ${ }_{c} \Delta_{F}=\delta$, then we say that $F$ is differentially $(c, \delta)$ uniform. If $\delta=1$, then $F$ is called a perfect c-nonlinear ( $\operatorname{PcN}$ ) function (certainly, for $c=1$, they only exist for odd characteristic $p$; however, as proven in [14, there exist PcN functions for $p=2$, for all $c \neq 1$ ). If $\delta=2$, then $F$ is called an almost perfect c-nonlinear (APcN) function. When we specify the constant $c$ for which the function is PcN or APcN , then we may use the notation $c$-PN, or $c$-APN. It is easy to see that if $F$ is an $(n, n)$ function, that is, $F: \mathbb{F}_{p^{n}} \rightarrow \mathbb{F}_{p^{n}}$, then $F$ is PcN if and only if ${ }_{c} D_{a} F$ is a permutation polynomial.

NB: Recently, in an independent work, Bartoli and Timpanella [1] gave a generalization of planar functions as follows.

Definition 1. Let $\beta \in \mathbb{F}_{p^{n}} \backslash\{0,1\}$. A function $F: \mathbb{F}_{p^{n}} \rightarrow \mathbb{F}_{p^{n}}$ is a $\beta$-planar function in $\mathbb{F}_{p^{n}}$ if $\forall \gamma \in \mathbb{F}_{p^{n}}, F(x+\gamma)-\beta F(x)$ is a permutation of $\mathbb{F}_{p^{n}}$.

In the particular case, when $\beta=-1$, then $\beta$-planar function is called quasi-planar. In view of the definitions of [14], the $\beta$-planar functions are simply PcN functions and quasi-planar functions are PcN functions with $c=-1$.

In this paper we continue the investigation on the $c$-differential uniformity of the Gold function (resolving some computational observations from [14) and some of the functions from the Helleseth-Rong-Sandberg table and related ones. For example, we showed that $x^{\frac{p^{k}+1}{2}}$ is PcN with respect to $c=-1$ if and only if $\frac{2 n}{\operatorname{gcd}(2 n, k)}$ is odd, as well $x^{\frac{3^{n}+3}{2}}$ is PcN (respectively APcN ) with respect to $c=-1$, if $n$ is odd (respectively, even).
Note added after posting on arxiv: We were made aware that the first part of our Theorems 4 and 7 also appeared concurrently in [24].

## 2 Prior results on $c$-differential uniformity

One of our major theorems from [14] dealt with the known PN functions.

Theorem $2([14])$. Let $F: \mathbb{F}_{p^{n}} \rightarrow \mathbb{F}_{p^{n}}$ be the monomial $F(x)=x^{d}$, and $c \neq 1$ be fixed. The following statements hold:
(i) If $d=2$, then $F$ is APcN, for all $c \neq 1$.
(ii) If $d=p^{k}+1, p>2$, then $F$ is not $P c N$, for all $c \neq 1$. Moreover, when $(1-c)^{p^{k}-1}=1$ and $n / \operatorname{gcd}(n, k)$ is even, the $c$-differential uniformity ${ }_{c} \Delta_{F} \geq p^{g}+1$, where $g=\operatorname{gcd}(n, k)$.
(iii) Let $p=3$. If $d=\frac{3^{k}+1}{2}$, then $F$ is PcN, for $c=-1$ if and only if $\frac{n}{\operatorname{gcd}(n, k)}$ is odd.
(iv) If $p=3$ and $F(x)=x^{10}-u x^{6}-u^{2} x^{2}$, the $c$-differential uniformity of $F$ is ${ }_{c} \Delta_{F} \geq 2$, for $c \neq 1$.

The $c$-differential uniformity of the inverse function has also been investigated [14] and a thorough description was obtained for all values of $c$, both in the even and odd case.

Since it will be used throughout, we state here [14, Lemma 9].
Lemma 3. Let $p, k, n$ be integers greater than or equal to 1 (we take $k \leq n$, though the result can be shown in general). Then

$$
\begin{aligned}
& \operatorname{gcd}\left(2^{k}+1,2^{n}-1\right)=\frac{2^{\operatorname{gcd}(2 k, n)}-1}{2^{\operatorname{gcd}(k, n)}-1}, \text { and if } p>2, \text { then }, \\
& \operatorname{gcd}\left(p^{k}+1, p^{n}-1\right)=2, \text { if } \frac{n}{\operatorname{gcd}(n, k)} \text { is odd, } \\
& \operatorname{gcd}\left(p^{k}+1, p^{n}-1\right)=p^{\operatorname{gcd}(k, n)}+1, \text { if } \frac{n}{\operatorname{gcd}(n, k)} \text { is even. }
\end{aligned}
$$

Consequently, if either $n$ is odd, or $n \equiv 2(\bmod 4)$ and $k$ is even, then $\operatorname{gcd}\left(2^{k}+1,2^{n}-1\right)=1$ and $\operatorname{gcd}\left(p^{k}+1, p^{n}-1\right)=2$, if $p>2$.

## 3 The $c$-differential uniformity of the Gold function

In 14 we found the $c$-differential uniformity of the Gold function $x \mapsto x^{p^{k}+1}$ for odd characteristic $p$. Regarding even characteristic, we observed in the same paper that, if $3 \leq n \leq 8$, the $c$-differential uniformity of the Gold $x \mapsto x^{5}$ and Kasami $x \mapsto x^{13}$ functions is 3 for $n$ odd and 5 for $n$ even. It
was proposed there that it would be interesting to investigate the situation for all values of $n$, especially, since if $c=1$, the result is well-known. It is our goal here to answer the question and surprisingly, reveal that the $c$ differential uniformity of these functions may increase significantly. In this paper we deal with the Gold function and its $c$-differential uniformity.
Theorem 4. Let $2 \leq k<n, n \geq 3$ and $G(x)=x^{2^{k}+1}$ be the Gold function on $\mathbb{F}_{2^{n}}$ and $1 \neq c \in \mathbb{F}_{2^{n}}$. Assume that $n=m d$, where $d=\operatorname{gcd}(n, k)$, and $m \geq 3$, when $n$ is odd, respectively, $m \geq 4$, when $n$ is even. Then, the $c$-differential uniformity of $G$ is ${ }_{c} \Delta_{G}=2^{d}+1$.

Proof. We consider the differential equation at $a$, say $G(x+a)-c G(x)=b$, for some $b \in \mathbb{F}_{2^{n}}$, which is equivalent to

$$
(1-c) x^{2^{k}+1}+x^{2^{k}} a+x a^{2^{k}}+a^{2^{k}+1}-b=0 .
$$

Dividing by $(1-c)$ and taking $x=y-\frac{a}{1-c}$ this last equation transforms into

$$
y^{2^{k}+1}+\frac{a^{2^{k}}}{1-c}\left(1+\frac{1}{\left(1-c 2^{2^{k}-1}\right.}\right) y+\frac{c a^{2^{k}+1}+b(1-c)}{(1-c)^{2}}=0 .
$$

Now, let $y=\alpha z$, where $\alpha=\left(\frac{a^{2^{k}}}{1-c}\left(1+\frac{1}{(1-c)^{2^{k}-1}}\right)\right)^{2^{-k}}$ (the $2^{k}$-root exists since $\operatorname{gcd}\left(2^{k}, 2^{n}-1\right)=1$. The previous equation becomes

$$
\begin{equation*}
z^{2^{k}+1}+z+\beta=0, \tag{1}
\end{equation*}
$$

where $\beta=\frac{c a^{2^{k}+1}+b(1-c)}{\alpha^{2^{k}+1}(1-c)^{2}}$.
We will be using some results of [15] (see also [2] and [12]). We first assume that $\operatorname{gcd}(n, k)=1$. By [15, Theorem 1], we know that Equation (11) has either none, one or three solutions in $\mathbb{F}_{2^{n}}$. In fact, the distribution of these cases for $n$ odd (respectively, $n$ even) is (denoting by $M_{m}$ the amount of equations of type (1) with $m$ solutions)

$$
\begin{aligned}
& M_{0}=\frac{2^{n}+1}{3}\left(\text { respectively }, \frac{2^{n}-1}{3}\right) \\
& M_{1}=2^{n-1}-1\left(\text { respectively }, 2^{n-1}\right) \\
& M_{3}=\frac{2^{n-1}-1}{3}\left(\text { respectively }, \frac{2^{n-1}-2}{3}\right) .
\end{aligned}
$$

Then, for $n \geq 3, c \neq 1$, and $\operatorname{gcd}(n, k)=1$, and since $\beta$ is linear on $b$, this implies that, for any $\beta$ and any $a, c$, we can find $b$ such that $\beta=$ $\frac{c a^{2^{k}+1}+b(1-c)}{\alpha^{2^{k}+1}(1-c)^{2}}$, so the $c$-differential uniformity of the Gold function is 3 .

We now assume that $\operatorname{gcd}(n, k)=d>1$. As in [15], for $v \in \mathbb{F}_{2^{n}} \backslash \mathbb{F}_{2^{d}}$, we denote $v_{i}:=v^{2^{i k}}, i \geq 0$, and we let (for $n=m d$ )

$$
\begin{aligned}
& C_{1}(x)=1 \\
& C_{2}(x)=1 \\
& C_{i+2}(x)=C_{i+1}(x)+x_{i} C_{i}(x) \text { for } 1 \leq i \leq n-1
\end{aligned}
$$

Let $V=\frac{v_{0}^{2 k}+1}{\left(v_{0}+v_{1}\right)^{2 k+1}}$. Then, by [15, Lemma 1]

$$
C_{m}(V)=\frac{\operatorname{Tr}_{d}^{n}\left(v_{0}\right)}{v_{1}+v_{2}} \prod_{j=2}^{m-1}\left(\frac{v_{0}}{v_{0}+v_{1}}\right)^{2^{j k}}
$$

We know by [15, Lemma 1] that if $n$ is odd (respectively, even) there are $\frac{2^{(m-1) d}-1}{2^{2 d}-1}$ (respectively, $\frac{2^{(m-1) d}-2^{d}}{2^{2 d}-1}$ ) distinct zeros of $C_{m}(x)$ in $\mathbb{F}_{2^{n}}$, that are defined by $V$ above with $\operatorname{Tr}_{d}^{n}\left(v_{0}\right)=0$. Further, by [15, Proposition 4], Equation (1) has $2^{d}+1$ zeros in $\mathbb{F}_{2^{n}}$ for as many as $M_{2^{d}+1}=\frac{2^{(m-1) d}-1}{2^{2 d}-1}$, for $n$ odd, respectively, $M_{2^{d}+1}=\frac{2^{(m-1) d}-2^{d}}{2^{2 d}-1}$, for $n$ even, values of $\beta$. To be more precise, those $\beta$ achieving this bound must satisfy $C_{m}(\beta)=0$ (if $d=k$, this is a complete description). For $n$ odd, $M_{2^{d}+1} \geq 1$ is achieved when $m \geq 3$. For $n$ even, $M_{2^{d}+1} \geq 1$ is achieved when $m \geq 4$, and it is not true when $m=3$.

The only thing to argue now is whether for a fixed $c \neq 1$, and given $\beta \in \mathbb{F}_{2^{n}}$, there exist $a, b \in \mathbb{F}_{2^{n}}$ such that $\beta=\frac{c a^{2^{k}+1}+b(1-c)}{\alpha^{2^{k}+1}(1-c)^{2}}$, where $\alpha^{2^{k}}=\frac{a^{2^{k}}}{1-c}\left(1+\frac{1}{(1-c)^{2^{k}-1}}\right)$. However, that is easy to see since the obtained equation is linear in $b$. Therefore, the $c$-differential uniformity of $G$ is $2^{d}+1$.

## 4 Going through some entries in the Helleseth-Rong-Sandberg table and more

We display below some of the known examples of APN power functions in odd characteristic [16, 17].

Theorem 5. Let $F(x)=x^{d}$ be a function over $\mathbb{F}_{p^{n}}$, where $p$ is an odd prime. Then $F$ is an $A P N$ function if:
(1) $d=3, p>3$;
(2) $d=p^{n}-2, p>2$ and $p \equiv 2(\bmod 3)$.
(3) $d=\frac{p^{n}-1}{2}-1, p \equiv 3,7(\bmod 20), p^{n}>7, p^{n} \neq 27$ and $n$ is odd;
(4) $d=\frac{p^{n}+1}{4}+\frac{p^{n}-1}{2}, p^{n} \equiv 3(\bmod 8)$;
(5) $d=\frac{p^{n}+1}{4}, p^{n} \equiv 7(\bmod 8)$;
(6) $d=\frac{2 p^{n}-1}{4}, p^{n} \equiv 2(\bmod 3)$;
(7) $d=p^{n}-3, p=3, n>1$ odd;
(8) $d=p^{m}+2, p^{m} \equiv 1(\bmod 3), n=2 m$;
(9) $d=\frac{5^{k}+1}{2}, p=5$ and $\operatorname{gcd}(2 n, k)=1$.

Dobbertin et al. [13] pushed further the Helleseth-Rong-Sandberg table by explaining some entries (that is, shoving that some of the values $d$ that gave rise to APN functions were members of an infinite family of power functions), and showed that the differential uniformity of $F(x)=x^{d}$ over $\mathbb{F}_{3^{n}}$ is $\Delta_{F} \leq 2$ if

$$
d=\left\{\begin{array}{lll}
\frac{3^{(n+1) / 2}-1}{2} & \text { if } n \equiv 3 & (\bmod 4) \\
\frac{3^{(n+1) / 2}-1}{2}+\frac{3^{n}-1}{2} & \text { if } n \equiv 1 & (\bmod 4)
\end{array}\right.
$$

(if $n=1,3, F$ is PN ), as well as

$$
d=\left\{\begin{array}{lll}
\frac{3^{n+1}-1}{8} & \text { if } n \equiv 3 & (\bmod 4) \\
\frac{3^{n+1}-1}{8}+\frac{3^{n}-1}{2} & \text { if } n \equiv 1 & (\bmod 4)
\end{array}\right.
$$

Later, in [19], Leducq proved that, in fact, for the functions above, $\Delta_{F}=2$, that is, the functions above are APN. The same paper proves that, over $\mathbb{F}_{5^{n}}$, for $l \leq 2$ and $n \equiv-1(\bmod 2)^{l}$, the function $F$ is APN if $d=\frac{1}{2} \frac{5^{n+1}-1}{5^{\frac{n+1}{2^{l}}}+1}+\frac{5^{n}-1}{4}$.

Dobbertin et al. 13 conjectured also that over $\mathbb{F}_{5^{n}}, F$ is APN when $d=\frac{5^{n}-1}{4}+\frac{5^{n+1} / 2-1}{2}$, if $n$ is odd, and this was subsequently shown by Zha and Wang [25].

In this section, we will use Dickson polynomials of the first kind, which are defined as $D_{d}(x, a)=\sum_{i=0}^{\left\lfloor\frac{d}{2}\right\rfloor} \frac{d}{d-i}\binom{d-i}{i}(-a)^{i} x^{d-2 i}$, and have the property $D_{m}\left(u+\frac{a}{u}, a\right)=u^{m}+\left(\frac{a}{u}\right)^{m}$ for $u \in \mathbb{F}_{p^{2 n}}$ [20]; since, in this paper, the second variable is always 1 , in the following, abusing notation, we will write $\left.D_{m}(x)\right)$. We will also use Theorem 9 of [9, which states that, for $p$ odd, and supposing $2^{r} \|\left(p^{2 n}-1\right)$ (where $2^{r} \| t$ means that $2^{r} \mid t$ but $2^{r+1} \nmid t$ ), then, for $x_{0} \in \mathbb{F}_{p^{n}}$,

$$
\left|D_{d}^{-1}\left(D_{d}\left(x_{0}\right)\right)\right|= \begin{cases}m, & \text { if } \eta\left(x_{0}^{2}-4\right)=1, D_{d}\left(x_{0}\right) \neq \pm 2 \\ \bar{\ell}, & \text { if } \eta\left(x_{0}^{2}-4\right)=-1, D_{d}\left(x_{0}\right) \neq \pm 2 \\ \frac{m}{2}, & \text { if } \eta\left(x_{0}^{2}-4\right)=1,2^{t}| | d, 1 \leq t \leq r-2, D_{d}\left(x_{0}\right)=-2 \\ \frac{\ell}{2}, & \text { if } \eta\left(x_{0}^{2}-4\right)=-1,2^{t}| | d, 1 \leq t \leq r-2, D_{d}\left(x_{0}\right)=-2 \\ \frac{m+\bar{\ell}}{2}, & \text { otherwise, }\end{cases}
$$

where $m=\operatorname{gcd}\left(d, p^{n}-1\right), \bar{\ell}=\operatorname{gcd}\left(d, p^{n}+1\right)$, and $\eta(\alpha)$ is the quadratic character of $\alpha$.

In this section, we show that the $c$-differential uniformity of some of these functions will change for some (if not all) $c \neq 1$. We start with item (7) of Theorem 5 (items (1) and (2) were dealt with in our paper [14]).

Theorem 6. Let $p=3, n \geq 2$ and $F(x)=x^{3^{n}-3}$ on $\mathbb{F}_{3^{n}}$. If $c=-1$, the $c$-differential uniformity of $F$ is 6 for $n \equiv 0(\bmod 4)$ and 4 , otherwise. If $c=0$, the $c$-differential uniformity of $F$ over $\mathbb{F}_{3^{n}}$ is 2 . If $c \neq 0, \pm 1$, the $c$-differential uniformity of $F$ is $\leq 5$. Moreover, the $c$-differential uniformity of 4 is attained for some $c$, for all $n \geq 3$, and the $c$-differential uniformity of 5 is attained for all positive $n \equiv 0(\bmod 4)$.

Proof. For $a, b \in \mathbb{F}_{3^{n}}$, we look at the equation $F(x+a)-c F(x)=b$, that is,

$$
\begin{equation*}
(x+a)^{3^{n}-3}-c x^{3^{n}-3}=b . \tag{2}
\end{equation*}
$$

If $c=0$, the equation is then $(x+a)^{3^{n}-3}=b$. If $a=b=0$, then we get the unique solution $x=0$. If $a=0, b \neq 0$, the equation is then $b x^{2}=1$, which has two solutions if $b$ is a square and none, otherwise. If $a \neq 0, b=0$, the solution is $x=-a$. If $a b \neq 0$, the equation is then $b(x+a)^{2}=a$, which has two solutions if $a / b$ is a nonzero perfect square (always realizable). Summarizing, the function is APcN with respect to $c=0$. For the remainder of the proof, we assume that $c \neq 0,1$.

If $a=b=0$, then $x=0$ is the only solution for Equation (2). If $a=0$ and $b \neq 0$, then Equation (2) becomes $(1-c) x^{3^{n}-3}=b$. Surely, $x \neq 0$ and so, the equation becomes $b x^{2}=(1-c)$. Taking $\alpha \neq 0$ a fixed element of $\mathbb{F}_{3^{n}}$ and $b=\frac{1-c}{\alpha^{2}}$, then $x= \pm \alpha$ are solutions for this equation (observe that if $b \neq 0$ and $\frac{1-c}{b}$ is not a square in $\mathbb{F}_{3^{n}}$ there are no solutions for $(1-c) x^{3^{n}-3}=b$; for $c$ fixed, there are $\frac{3^{n}-1}{2}$ nonzero values of $b$ such that $\frac{1-c}{b}$ is a square in $\mathbb{F}_{3^{n}}$.

If $a \neq 0$ and $b=0$, then $0 \neq x \neq-a$, and Equation (2) becomes $(x+a)^{-2}=c x^{-2}$, that is, $\left(\frac{x}{x+a}\right)^{2}=c$, which has two solutions depending on whether $c$ is a nonzero perfect square or not (there are $\frac{3^{n}+1}{2}$ such $c$ 's).

When $a b \neq 0$, we observe that $x=0, x=-a$ are solutions of Equation (21) if and only if $b=a^{-2}$, respectively, $b=-c a^{-2}$. Note that these can happen simultaneously if and only if $c=-1$.

We now assume $a b \neq 0, x \neq 0,-a$. Equation (2) is therefore

$$
\begin{align*}
& (x+a)^{-2}-c x^{-2}=b, \text { that is, } \\
& b(x+a)^{2} x^{2}-x^{2}+c(x+a)^{2}=0, \text { that is, } \\
& b x^{4}-b a x^{3}+b a^{2} x^{2}-x^{2}+c x^{2}-a c x+c a^{2}=0, \\
& x^{4}-a x^{3}+\frac{b a^{2}+c-1}{b} x^{2}-\frac{a c}{b} x+\frac{c a^{2}}{b}=0 \tag{3}
\end{align*}
$$

Using $x=y+a$ in (3), we obtain

$$
\begin{equation*}
y^{4}+\frac{b a^{2}+c-1}{b} y^{2}+\frac{a(c+1)}{b} y+\frac{b a^{4}+(c-1) a^{2}}{b}=0 \tag{4}
\end{equation*}
$$

Now, if $c=-1$ and $b=a^{-2}$, Equation (4) is then

$$
\begin{equation*}
y^{4}-a^{2} y^{2}-a^{4}=0 \tag{5}
\end{equation*}
$$

whose discriminant (of the underlying quadratic) is $2 a^{4}$. Now, we know that the underlying quadratic of Equation (5) has two distinct roots if and only if the above discriminant is a nonzero square. It is surely nonzero for $a \neq 0$, and we know that $2=-1$ is a perfect square, say $-1=\imath^{2}$ in $\mathbb{F}_{3^{n}}$ if and only if $n$ is even. For the quartic to have four distinct roots in $\mathbb{F}_{3^{n}}$, obtained from $y^{2}=a^{2}(1 \pm \imath)$ (these are the roots of the underlying quadratic), one needs $1 \pm \imath$ to be a perfect square, which happens if $n \equiv 0(\bmod 4)$, and we provide the reason next. The minimal polynomial of one of the roots, say $\sqrt{1+\imath}$, is $x^{4}+x^{2}-1$ which has the roots $\left\{\alpha^{2}+2,2 \alpha^{3}+2 \alpha^{2}+2 \alpha, 2 \alpha^{2}+1, \alpha^{3}+\alpha^{2}+\alpha\right\}$ in $\mathbb{F}_{3^{4}}$ (we took the primitive polynomial $x^{4}-x^{3}-1$ with $\alpha$ as one of the
roots), and consequently in all extensions $\mathbb{F}_{3^{n}}$ of $\mathbb{F}_{3^{4}}$ with $n \equiv 0(\bmod 4)$, and no others. Further, if $n \equiv 2(\bmod 4)$ we do not get more roots from Equation (5) under $c=-1, b=a^{-2}$, therefore, in this case we only get the solutions $x=0,-a$.

If $c=-1$ and $b \neq a^{-2}$, we let $b=a$, obtaining the equation $a^{2}+$ $a^{5}+\left(1+a^{3}\right) y^{2}+a y^{4}=0$. The discriminant of the underlying quadratic is $1+a^{3}=(1+a)^{3}$. Thus, if $a=d^{4}-1$ for some random fixed $d \neq 0$ such that $a \neq 0,1$, the previous equation has four solutions and so, the first claim is shown.

If $c \neq \pm 1$, putting together the potential solutions for Equation 4 and $y=0$ or $y=-a$, we see that we cannot have more than 5 solutions.

We now show that the differential uniformity of 4 is attained. For $a=$ $1, b=-1$, the quartic (4) becomes $y^{4}-(1+c) y^{2}-(1+c) y-(1+c)=0$, which is equivalent to $y^{4}-(c+1)\left(y^{2}+y+1\right)=0$, and further, $y^{4}-(c+1)(y-1)^{2}=0$ (observe that $y \neq 0,1$ ). Thus, taking $c=\alpha^{2}-1$, for some $\alpha \neq 0,1$, then $\frac{y^{2}}{y-1}= \pm \alpha$, which is equivalent to

$$
y^{2} \mp \alpha y \pm \alpha=0 .
$$

These pairs of equations will each have two roots if and only if the $\eta\left(\alpha^{2} \pm\right.$ $4 \alpha)=\eta\left(\alpha^{2} \pm \alpha\right)=1(\eta$ is the quadratic character $)$, that is, if $\alpha^{2} \pm \alpha$ are nonzero squares in $\mathbb{F}_{3^{n}}$. However, we do have an argument for the existence of such $\alpha$, in general. We use [20, Theorem 5.48], which states that if $f(x)=a_{2} x^{2}+a_{1} x+a_{0}$ is a polynomial in a finite field $\mathbb{F}_{q}$ of odd characteristic, $a_{2} \neq 0, d=a_{1}^{2}-4 a_{0} a_{2}$, and $\eta$ is the quadratic character on $\mathbb{F}_{q}$, then the Jacobsthal sum

$$
\sum_{x \in \mathbb{F}_{q}} \eta(f(x))= \begin{cases}-\eta\left(a_{2}\right) & \text { if } d \neq 0 \\ (q-1) \eta\left(a_{2}\right) & \text { if } d=0\end{cases}
$$

First, we take $f(x)=x^{2}-x, d=1$, and so, the Jacobsthal sum becomes

$$
\begin{aligned}
& \sum_{x \in \mathbb{F}_{3^{n}}} \eta\left(x^{2}-x\right)=-\eta(1)=-1, \text { so, } \\
& -1=\eta(0)+\eta\left(1^{2}-1\right)+\sum_{x \in \mathbb{F}_{3^{n}}, x \neq 0,1} \eta\left(x^{2}-x\right)=\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0,1}} \eta\left(x^{2}-x\right) .
\end{aligned}
$$

Thus,

$$
\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0,1}} \eta\left(x^{2}-x\right)=-1 .
$$

Similarly,

$$
\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0,-1}} \eta\left(x^{2}+x\right)=-1
$$

Let $N_{1}=\mid\left\{x \mid x \neq 0, \pm 1, \eta\left(x^{2}-x\right)=1\right\}$ and $N_{2}=\mid\left\{x \mid x \neq 0, \pm 1, \eta\left(x^{2}+x\right)=\right.$ 1\}. We compute

$$
\begin{aligned}
-1 & =\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0,1}} \eta\left(x^{2}-x\right) \\
= & \eta\left((-1)^{2}-(-1)\right)+\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(x^{2}-x\right) \\
= & \eta(2)+\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(x^{2}-x\right) \\
= & \eta(-1)+\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(x^{2}-x\right)=\eta(-1)+N_{1}-\left(3^{n}-3-N_{1}\right) \\
-1= & \sum_{x \in \mathbb{F}_{3^{n}, x \neq 0,-1}}^{\eta\left(x^{2}+x\right)} \\
= & \eta\left(1^{2}+1\right)+\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(x^{2}+x\right) \\
= & \eta(-1)+\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(x^{2}+x\right)=\eta(-1)+N_{2}-\left(3^{n}-3-N_{2}\right) .
\end{aligned}
$$

We therefore get

$$
N_{1}=N_{2}=\frac{3^{n}-4-\eta(-1)}{2}
$$

The sets of $x \neq 0, \pm 1$ of cardinality $\frac{3^{n}-4-\eta(-1)}{2}$ (equal to $\frac{3^{n}-3}{2}$ for $n$ odd and $\frac{3^{n}-5}{2}$ for $n$ even) such that $x^{2}-x$, respectively, $x^{2}+x$ are squares, may still be disjoint. If they are not disjoint, we are done. Suppose now that the sets are disjoint; then, we need to consider the Jacobsthal sum (again, using [20, Theorem 5.48])

$$
\begin{aligned}
& \sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(x^{2}-x\right) \eta\left(x^{2}+x\right)=\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(\left(x^{2}-x\right)\left(x^{2}+x\right)\right) \\
= & \sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(x^{2}\left(x^{2}-1\right)\right)=\sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(x^{2}\right) \eta\left(x^{2}-1\right) \\
= & \sum_{x \in \mathbb{F}_{3^{n}, x \neq 0, \pm 1}} \eta\left(x^{2}-1\right)=\sum_{x \in \mathbb{F}_{3^{n}}} \eta\left(x^{2}-1\right)-\eta(-1)=-1+\eta(-1)
\end{aligned}
$$

but that is impossible for $n \geq 3$, if $x^{2}-x$ and $x^{2}+x$ are never squares at the same time (given our prior counts, $N_{1}, N_{2}$ ).

We now take $n$ to be an even integer. We shall show that there are values of $c$ such that the $c$-differential uniformity is 5 . We take $b=a^{-2}$, so that $x=0$ is a solution of Equation (2). The idea is to find, under this condition, $A, B$ such that the quartic in $y$ can be written as $\left(y^{2}+1\right)^{2}+A(y+B)^{2}=0$, where $B$ is a perfect square. We let $a$ such that $a^{6}+a^{2}+2=0$. This equation has the solutions $g+1,2 g+2$ in $\mathbb{F}_{3^{2}}$, where $g$ is the primitive root vanishing $X^{2}-X-1=0$, and consequently, by field embedding, solvable in $\mathbb{F}_{3^{n}}$ for all even $n$. Further, we take $c=d a^{-2}$, where $d=\frac{2+2 a^{6}}{1+2 a^{2}+2 a^{4}}$. Our quartic in $y$ becomes

$$
y^{4}+d y^{2}+\left(a^{3}+a d\right) y+a^{2} d=0
$$

which we will write in the form

$$
\left(y^{2}+1\right)^{2}+(1+d)\left(y-\frac{a^{3}+a d}{1+d}\right)^{2}=0 .
$$

Observe that $\frac{a^{3}+a d}{1+d}=-\frac{a^{4}+1}{a^{3}-a}$, when $d$ has the value we previously chose. Thus, assuming that $-(1+d)=-\frac{1+a^{4}}{2+a^{2}+a^{4}}$ is a perfect square, say $\beta^{2}$ (we will check if that happens later), the four solutions will be given by the equations (we let $\imath$ be the solution to $X^{2}=-1$ in $\mathbb{F}_{3^{2}}$, and any other even extension of $\mathbb{F}_{3^{2}}$ )

$$
y^{2}+1= \pm \beta\left(y+\frac{a^{4}+1}{a^{3}-a}\right)
$$

that is,

$$
y^{2} \mp \beta y \mp \beta \frac{a^{4}+1}{a^{3}-a}+1=0 .
$$

These last equations will have two solutions each if and only if

$$
\beta^{2} \pm \beta \frac{a^{4}+1}{a^{3}-a}-1
$$

is a perfect nonzero square. Using SageMath, we quickly found values of $a$ satisfying the equation $a^{6}+a+2=0$ in $\mathbb{F}_{3^{4}}$ such that $-(1+d)=$ $-\frac{1+a^{4}}{2+a^{2}+a^{4}}$ and the expressions above are perfect squares, as well and, by field embedding, there are values of $a$ for every dimension divisible by 4 where the last displayed expression is a square, as well. The theorem is shown.

Remark 1. Our computations in SageMath revealed that, there are other values of the c-differential uniformity for the function in Theorem 6. In fact, if $c \neq \pm 1$ and $n=2$, then ${ }_{c} \Delta_{F}=2$; when $n=3$, we have ${ }_{c} \Delta_{F} \in\{3,4\}$; for $n=4$, then ${ }_{c} \Delta_{F} \in\{2,4,5\}$; for $n=5$, we have ${ }_{c} \Delta_{F} \in\{4\}$; if $n=6$, then ${ }_{c} \Delta_{F} \in\{4,5\}$.

One might wonder if we can use the results of Bluher [2] to investigate our quartic polynomial. Surely, one can removes the coefficient of $x^{2}$ in our quartic (to match Bluher's polynomial) using the substitution $b=\frac{1-c}{a^{2}}$, and the obtained polynomial is

$$
x^{4}-a x^{3}-\frac{a^{3} c}{1-c} x+\frac{a^{4} c}{1-c}
$$

but this, unfortunately, does not satisfy the needed condition $E A \neq B$ in the polynomial considered by Bluher [2], $X^{q+1}+E X^{q}+A X+B$ ( $q$ is a power of $p ; p=3$ in our case), so we cannot use those methods. Even the more recent paper of Kim et al. [18] cannot be used, because of the same reasons.

We now look at item (9) in Theorem 5, and prove a result for this function, and its generalization to $p$ odd (note that the case $p=3$ was proven in [10, 14]). For $p$ prime and $n, k$ positive integers, we define the following parameter:

$$
\begin{aligned}
\ell=\max \{ & \frac{1}{2} \operatorname{gcd}\left(p^{k}+1, p^{n}-1\right), \frac{1}{2} \operatorname{gcd}\left(p^{k}+1, p^{n}+1\right), \\
& \left.\frac{1}{4}\left(\operatorname{gcd}\left(p^{k}+1, p^{n}-1\right)+\operatorname{gcd}\left(p^{k}+1, p^{n}+1\right)\right)\right\} .
\end{aligned}
$$

Theorem 7. Let $p$ be an odd prime, and let $F(x)=x^{\frac{p^{k}+1}{2}}$ on $\mathbb{F}_{p^{n}}, 1 \leq k<$ $n, n \geq 3$. If $c=-1$, then $F$ is PcN if and only if $\frac{2 n}{\operatorname{gcd}(2 n, k)}$ is odd. Otherwise, $F(x)$ will have the ( -1 )-differential uniformity ${ }_{-1} \Delta_{F}=\frac{p^{\operatorname{gcd}(k, n)}+1}{2}$.

Proof. We take the approach of [10, 14], where it was shown that $x^{\frac{3^{k}+1}{2}}$ is $\operatorname{PcN}$ on $\mathbb{F}_{3^{n}}$, for $c= \pm 1$. Similarly, our function is $P c N$ if and only if the $c$ derivative $(x+a)^{\frac{p^{k}+1}{2}}-c x^{\frac{p^{k}+1}{2}}$ is a permutation polynomial. With a change of variable $z=\frac{-a x}{4}$, we see that this is equivalent to $(z-4)^{\frac{p^{k}+1}{2}}-c z^{\frac{p^{k}+1}{2}}$ being a permutation polynomial. Shifting by 2 , we can see that this happens if and only if $h_{c}(z)=(z-2)^{\frac{p^{k}+1}{2}}-c(z+2)^{\frac{p^{k}+1}{2}}$ is a permutation polynomial.

We can always write $z=y+y^{-1}$, for some $y \in \mathbb{F}_{p^{2 n}}$. Our condition (for general $c \neq 1$ ) becomes

$$
\begin{aligned}
h_{c}(z) & =\left(y+y^{-1}-2\right)^{\frac{p^{k}+1}{2}}-c\left(y+y^{-1}+2\right)^{\frac{p^{k^{k}+1}}{2}} \\
& =\frac{\left(y^{2}-2 y+1\right)^{\frac{p^{k}+1}{2}}-c\left(y^{2}+2 y+1\right)^{\frac{p^{k}+1}{2}}}{y^{\frac{p^{k+1}}{2}}} \\
& =\frac{(y-1)^{p^{k}+1}-c(y+1)^{p^{k}+1}}{y^{\frac{p^{k}+1}{2}}} \\
& =\frac{(1-c) y^{p^{k}+1}-(1+c) y^{p^{k}}-(1+c) y+(1-c)}{y^{\frac{p^{k}+1}{2}}} \\
& =(1-c) y^{\frac{p^{k}+1}{2}}-(1+c) y^{\frac{p^{k}-1}{2}}-(1+c) y^{\frac{-p^{k}+1}{2}}+(1-c) y^{\frac{-p^{k}-1}{2}} \\
& =(1-c) D_{\frac{p^{k}+1}{2}}^{2}(z)-(1+c) D_{\frac{p^{k}-1}{2}}^{2}(z)
\end{aligned}
$$

is a permutation polynomial, where $D_{m}(x)\left(=D_{m}(x, 1)\right)$ is the Dickson polynomial of the first kind, in our notation.

If $c=-1$, we obtain that $D_{\frac{p^{k}+1}{2}}(x)$ must be a permutation polynomial, and this is equivalent (by [22]) to $\operatorname{gcd}\left(\frac{p^{k}+1}{2}, p^{2 n}-1\right)=1$. This last identity can be further simplified to $\operatorname{gcd}\left(p^{k}+1, p^{2 n}-1\right)=2$. By Lemma 3 a necessary and sufficient condition for that to happen is for $\frac{2 n}{\operatorname{gcd}(2 n, k)}$ to be odd (this holds if and only if $k$ is even and, if $n=2^{t} a, 2 \nmid a$, with $t \geq 0$, and $k=2^{\ell} b, 2 \not\langle b$, then $\ell \geq t+1$ ).

In general, if $\ell=\max \left\{\left|D_{\frac{p^{k+1}}{2}}^{-1}(b)\right|: b \in \mathbb{F}_{p^{n}}\right\}$, then ${ }_{-1} \Delta_{F}=\ell$. Here we will use Theorem 9 of [9] stated above. Here $d=\frac{p^{k}+1}{2}$, so $m=$ $\operatorname{gcd}\left(\frac{p^{k}+1}{2}, p^{n}-1\right)=\frac{1}{2} \operatorname{gcd}\left(p^{k}+1, p^{n}-1\right), \bar{\ell}=\operatorname{gcd}\left(\frac{p^{k}+1}{2}, p^{n}+1\right)=\frac{1}{2} \operatorname{gcd}\left(p^{k}+\right.$ $\left.1, p^{n}+1\right)$. Then, in general, we can obtain all cases, and so

$$
\begin{aligned}
\ell & =\max \left\{\frac{1}{2} \operatorname{gcd}\left(p^{k}+1, p^{n}-1\right), \frac{1}{2} \operatorname{gcd}\left(p^{k}+1, p^{n}+1\right),\right. \\
& \left.\frac{1}{4}\left(\operatorname{gcd}\left(p^{k}+1, p^{n}-1\right)+\operatorname{gcd}\left(p^{k}+1, p^{n}+1\right)\right)\right\} \\
& =\max \left\{\frac{1}{2} \operatorname{gcd}\left(p^{k}+1, p^{n}-1\right), \frac{1}{2} \operatorname{gcd}\left(p^{k}+1, p^{n}+1\right)\right\} .
\end{aligned}
$$

Note that, by Lemma 3, $\operatorname{gcd}\left(p^{k}+1, p^{n}-1\right)=2$ if $\frac{n}{\operatorname{gcd}(n, k)}$ is odd and $\operatorname{gcd}\left(p^{k}+1, p^{n}-1\right)=p^{\operatorname{gcd}(k, n)}+1$ if $\frac{n}{\operatorname{gcd}(n, k)}$ is even, while

$$
\begin{aligned}
& \operatorname{gcd}\left(p^{k}+1, p^{n}+1\right)=\operatorname{gcd}\left(p^{k}+1, p^{n}+1-\left(p^{k}+1\right)\right) \\
& =\operatorname{gcd}\left(p^{k}+1, p^{k}\left(p^{n-k}-1\right)\right)=\operatorname{gcd}\left(p^{k}+1, p^{n-k}-1\right) \\
& =\left\{\begin{array}{l}
2 \text { if } \frac{n-k}{\operatorname{gcd}(n-k, k)}=\frac{n-k}{\operatorname{gcc}(n, k)} \text { is odd } \\
p^{\operatorname{gcd}(k, n)}+1 \text { if } \frac{n-k}{\operatorname{gcd}(n-k, k)}=\frac{n-k}{\operatorname{gcd}(n, k)} \text { is even }
\end{array}\right.
\end{aligned}
$$

so, if $n=2^{t} a$, $2 \not \backslash a$, with $t \geq 0$, and $k=2^{\ell} b, 2 \nmid b$, then, if $\ell \geq t+1$, then $m=1=\bar{\ell}$, and so $\ell=1$ and the function is PcN , while, if $\ell=t$, then $m=2, \bar{\ell}=\frac{p_{\operatorname{gcd}(k, n)}+1}{2}=\ell$, while, if $\ell<t$, then $m=\frac{p^{\operatorname{gcd}(k, n)}+1}{2}, \bar{\ell}=2$, and so $\ell=\frac{p^{\operatorname{gcd}(k, n)}+1}{2}$. Summarizing, if $\ell \leq t$, then $\ell=\frac{p^{\operatorname{gcd}(k, n)}+1}{2}$.

The proof of the theorem is complete.
Theorem 8. Let $G(x)=x^{\frac{3^{n}+3}{2}}$ on $\mathbb{F}_{3^{n}}, n \geq 2$. If $c=-1$, then $G$ is $P c N$ if $n$ is odd, APcN if $n$ is even. If $c=1$, then its differential uniformity is ${ }_{1} \Delta_{G}=1$, if $n$ is even and ${ }_{1} \Delta_{G}=4$ if $n$ is odd.

Proof. Now, $G$ is $\operatorname{PcN}$ on $\mathbb{F}_{3^{n}}$, for $c \neq 1$, if and only if (by similar arguments as before) the following is a permutation polynomial (where $z=y+y^{-1}, y \in$ $\mathbb{F}_{3^{2 n}}$,

$$
\begin{aligned}
h_{c}(z) & =\left(y+y^{-1}-2\right)^{\frac{3^{n}+3}{2}}-c\left(y+y^{-1}+2\right)^{\frac{3^{n}+3}{2}} \\
& =\frac{(y-1)^{3^{n}+3}-c(y+1)^{3^{n}+3}}{y^{\frac{3^{n}+3}{2}}} \\
& =\frac{y^{3^{n}+3}-y^{3^{n}}-y^{3}+1-c\left(y^{3^{n}+3}+y^{3^{n}}+y^{3}+1\right)}{y^{\frac{3^{n}+3}{2}}} \\
& =\frac{(1-c)\left(y^{3^{n}+3}+1\right)-(1+c)\left(y^{3^{n}}+y^{3}\right)}{y^{\frac{3^{n}+3}{2}}} \\
& =(1-c) D_{\frac{3^{n}+3}{2}}(z)-(1+c) D_{\frac{3^{n}-3}{2}}(z) .
\end{aligned}
$$

If $c=-1$, then $h_{c}(z)=2 D_{\frac{3^{n}+3}{2}}(z)$, which is known to be a permutation polynomial if and only if $\operatorname{gcd}\left(\frac{3^{n}+3}{2}, 3^{2 n}-1\right)=1$, which is easy to show that it always happens for $n$ odd (for $n$ even, $\operatorname{gcd}\left(\frac{3^{n}+3}{2}, 3^{2 n}-1\right)=2$ ). This can be seen from the following argument:

$$
\operatorname{gcd}\left(\frac{3^{n}+3}{2}, 3^{2 n}-1\right)=\frac{1}{2} \operatorname{gcd}\left(3^{n}+3,3^{2 n}-1\right)
$$

$$
\begin{aligned}
& =\frac{1}{2} \operatorname{gcd}\left(3^{n}+3,3^{2 n}-1-\left(3^{n}+3\right)\left(3^{n}-1\right)\right) \\
& =\frac{1}{2} \operatorname{gcd}\left(3^{n}+3,2-2 \cdot 3^{n}\right) \\
& =\frac{1}{2} \operatorname{gcd}\left(3\left(3^{n-1}+1\right), 2\left(1-3^{n}\right)\right) \\
& =\frac{1}{2} \operatorname{gcd}\left(3^{n-1}+1,3^{n}-1\right) .
\end{aligned}
$$

Now, by Lemma 3, $\operatorname{gcd}\left(3^{n-1}+1,3^{n}-1\right)=2$ if $\frac{n}{\operatorname{gcd}(n-1, n)}=n$ is odd, and $\operatorname{gcd}\left(3^{n-1}+1,3^{n}-1\right)=3^{\operatorname{gcd}(n-1, n)}+1=4$ if $\frac{n}{\operatorname{gcd}(n-1, n)}=n$ is even, which implies our claim.

Thus, for $n$ odd and $c=-1$, the function is $\operatorname{PcN}$. Let $n$ be even: if $\ell=\max \left\{\left|D_{\frac{3^{n}+3}{2}}^{-1}(b)\right|: b \in \mathbb{F}_{p^{n}}\right\}$, then ${ }_{-1} \Delta_{F}=\ell$. By Theorem 9 of [9, supposing $2^{r} \|\left(3^{2 n}-1\right)$, then, for $x_{0} \in \mathbb{F}_{3^{n}}$,

$$
\left|D_{d}^{-1}\left(D_{d}\left(x_{0}\right)\right)\right|= \begin{cases}m, & \text { if } \eta\left(x_{0}^{2}-4\right)=1, D_{d}\left(x_{0}\right) \neq \pm 2 \\ \bar{\ell}, & \text { if } \eta\left(x_{0}^{2}-4\right)=-1, D_{d}\left(x_{0}\right) \neq \pm 2 \\ \frac{m}{2}, & \text { if } \eta\left(x_{0}^{2}-4\right)=1,2^{t}| | d, 1 \leq t \leq r-2, D_{d}\left(x_{0}\right)=-2 \\ \frac{\ell}{2}, & \text { if } \eta\left(x_{0}^{2}-4\right)=-1,2^{t}| | d, 1 \leq t \leq r-2, D_{d}\left(x_{0}\right)=-2 \\ \frac{m+\bar{\ell}}{2}, & \text { otherwise, }\end{cases}
$$

where $m=\operatorname{gcd}\left(\frac{3^{n}+3}{2}, 3^{n}-1\right)=\frac{1}{2} \operatorname{gcd}\left(3^{n}+3,3^{n}-1\right)=\frac{1}{2} \operatorname{gcd}\left(3\left(3^{n-1}+1\right), 3^{n}-\right.$ $1)=2, \bar{\ell}=\operatorname{gcd}\left(\frac{3^{n}+3}{2}, 3^{n}+1\right)=2$, all under $n$ being even. Thus, $\ell=2$.

When $c=1$, we can apply [17, Theorem 3], since $\frac{3^{n}+3}{2}=\frac{3^{n}-1}{2}+2$ and so, ${ }_{1} \Delta_{G}=1$, if $n$ is even and ${ }_{1} \Delta_{G}=4$ if $n$ is odd. We can also show the result easily by a similar argument as above. We need to look at $\frac{D_{\frac{3^{n}-3}{2}}(z) \text { and its }}{}$ value sets. First, observe that (it is easy to show by algebraic manipulations, as in our previous discussion) that

$$
\operatorname{gcd}\left(\frac{3^{n}-3}{2}, 3^{2 n}-1\right)=\left\{\begin{array}{lll}
1 & \text { if } n \equiv 0 & (\bmod 2)  \tag{6}\\
4 & \text { if } n \equiv 3 & (\bmod 4) \\
8 & \text { if } n \equiv 1 & (\bmod 4)
\end{array}\right.
$$

As in the case $c=-1$, we shall be using Theorem 9 of [9]. In this case, $m=\operatorname{gcd}\left(\frac{3^{n}-3}{2}, 3^{n}-1\right)=\operatorname{gcd}\left(\frac{3\left(3^{n-1}-1\right)}{2_{\overline{-}}}, 3^{n}-1\right)=\operatorname{gcd}\left(\frac{3^{n-1}-1}{2}, 3^{n}-1\right)=$ 1,2 , for $n$ even, respectively, odd; $\bar{\ell}=\operatorname{gcd}\left(\frac{3^{n}-3}{2}, 3^{n}+1\right)=1,4,8$, as in Equation (6). Thus, if $n \equiv 0(\bmod 2)$, we get the maximum cardinality of the preimage (4) of our Dickson polynomial to be 1 ; and if $n$ is odd,
the maximum cardinality of the preimage (4) of our Dickson polynomial is $\frac{8}{2}=4$, matching therefore the result from [17, Theorem 3]. The theorem is shown.

## 5 Concluding remarks

In this paper we investigated the $c$-differential uniformity of the Gold function and some of the functions from the Helleseth-Rong-Sandberg table and related ones. For example, we showed that $x^{\frac{p^{k}+1}{2}}$ is PcN with respect to $c=-1$ if and only if $\frac{2 n}{\operatorname{gcd}(2 n, k)}$ is odd, as well $x^{\frac{3^{n}+3}{2}}$ is PcN , respectively, APcN , with respect to $c \stackrel{ }{=}-1$, if $n$ is odd, respectively, even. Surely, it would be interesting to continue with some of the other entries in the Helleseth-Rong-Sandberg table, or the results from Dobbertin et al. [13], or even to find newer PN or APN classes of functions, through the prism of the newly defined $c$-differentials concept we introduced in [14].

Acknowledgments. The authors are grateful to the reviewers for pointing out some initial errors in the proof of Theorem 6, and for the very helpful comments and suggestions which have highly improved the manuscript.
