Abstract. We construct a model structure on the category of cubical sets with connections whose cofibrations are the monomorphisms and whose fibrant objects are defined by the right lifting property with respect to inner open boxes, the cubical analogue of inner horns. We show that this model structure is Quillen equivalent to the Joyal model structure on simplicial sets via the triangulation functor. As an application, we show that cubical quasicategories admit a convenient notion of a mapping space, which we use to characterize the weak equivalences between fibrant objects in our model structure as DK-equivalences.

Introduction

The category $sSet$ of simplicial sets carries two canonical model structures: the Kan-Quillen model structure $[Qui67]$, presenting the homotopy theory of $\infty$-groupoids, and the Joyal model structure $[Joy09]$, presenting the homotopy theory of $(\infty,1)$-categories. Both of these model structures have monomorphisms as their cofibrations and their fibrant objects are defined by a more or less restrictive lifting condition, depending on whether the 1-simplices of a fibrant object are invertible.

The category $cSet$ of cubical sets is also known to carry a model structure, called the Grothendieck model structure and constructed by Cisinski $[Cis06, Cis14]$, presenting the theory of $\infty$-groupoids. This model structure is completely analogous to the Kan-Quillen model structure, but with open boxes replacing horns in the definition of fibrant objects. The goal of the present work is provide a cubical analogue of the Joyal model structure, thus filling the bottom right corner in the table:

<table>

Our main theorem (cf. Theorems 4.2, 6.1 and 7.10) states

Theorem. The category $cSet$ of cubical sets carries a model structure in which:

- the cofibrations are the monomorphisms;
- the fibrant objects are defined by having fillers for all inner open boxes;
- the weak equivalences between fibrant objects are the DK-equivalences.

Moreover, this model structure is Quillen equivalent to the Joyal model structure on the category $sSet$ of simplicial sets via the triangulation functor $T: cSet \to sSet$. 
A few comments are in order.

First, there are many different notions of a cubical set, depending on the choice of maps in the indexing category \( \square \), called the box category. Here, we are taking as agnostic a view as possible and most of our theorems apply to a number of different such notions.

Specifically, in addition to the usual box category with face and degeneracy maps, as studied in [Cis06, Jar06], we are also considering the box category with one or both connections. The case of one connection, specifically the negative (a.k.a. maximum) connection, was studied in [Cis14, Mal09, KLMW19], and the case with both connections has been, since the present paper first appeared, investigated in [CKM20]. All of these are EZ-Reedy categories and test categories, and in the case when at least one connection is present in the box category, they are in fact strict test categories, making them convenient to work with. All of the box categories under consideration are displayed in the diagram at the end of Section 1.

All of our results are true for the box category with both connections and the paper can be read with this category in mind. However, the construction of the model structures and characterization of weak equivalences using cubical mapping spaces work for all four box categories mentioned above. The Quillen equivalence with the Joyal model structure on simplicial sets requires at least one connection. Finally, the comparison between cubical and simplicial mapping spaces requires both connections, although weaker comparison results hold for the other three cube categories.

One particularly interesting aspect of our proof of the comparison between cubical and simplicial models of \((\infty, 1)\)-categories is that we do not work with the triangulation functor directly. Instead, we rely on a result of [KLMW19] exhibiting the category of simplicial sets as a co-reflective subcategory of the category of cubical sets with the negative connection via the straightening-over-the-point functor \( Q : sSet \to cSet \), an instance of a more general construction of straightening, studied in [KV18]. While at first glance the straightening-over-the-point functor seems more involved, it ends up being significantly more convenient to work with than the triangulation functor. And so, in order to show that \( T \) is a Quillen equivalence, we first prove that \( Q \) is a Quillen equivalence and establish that the derived functors of \( T \) and \( Q \) are each other’s inverses.

Lastly, the concept of an inner open box appearing in the statement of our main theorem is the cubical analogue of the notion of an inner horn in simplicial sets. Its definition is somewhat subtle, which is the reason behind our taking a slight detour in the construction of the model structure on cubical sets. At this point however, we shall simply note this subtlety here and give a precise definition in Section 4.

In order to establish a model structure on \( cSet \), we consider first a model structure on marked cubical sets. A marked cubical set is a cubical set with a distinguished subset of edges (to be thought of as "equivalences"), containing all degenerate ones. We then use the minimal marking functor, taking a cubical set to a marked cubical set in which the marked edges are precisely the degeneracies, to left-induce (in the sense of [HKRS17]) a model structure on cubical sets.

In order to establish that the triangulation functor is a Quillen equivalence between our model structure on cubical sets and the Joyal model structure on simplicial sets, we introduce a cubical theory of cones, which generalizes the straightening-over-the-point construction. Our cubical cones serve as a convenient way of relating simplicial and cubical shapes, and we believe that these tools will find applications beyond present work.
This paper is organized as follows. In Section 1 we collect the necessary results on model categories, cubical sets, and marked cubical sets. Trying to keep the exposition as self-contained as possible, we include statements of frequently used results and those that may be harder to find in the existing literature.

In Section 2 we construct the model structure on the category of marked cubical sets, using Jeff Smith’s theorem [Bar10]. While this model structure could be constructed using Olschok’s theory [Ols09], we decided to spell out the details of the construction to obtain a better understanding of the resulting classes of maps. Although described here only as means to an end, we believe that this model structure is of independent interest and provides another convenient model for the theory of \((\infty, 1)\)-categories.

Then, in Section 3 we show that this model structure right-induced by a model structure on the category of structurally marked cubical sets, a presheaf category containing marked cubical sets as a reflective subcategory, constructed using the Cisinski theory.

In Section 4 we use the minimal marking functor to construct the desired model structure on the category of cubical sets. We then analyze the resulting classes of maps, characterizing weak equivalences and fibrations between fibrant objects.

In Section 5 we develop the theory of cones and coherent families of composites, which is then used in Section 6 to show that the model structure of Section 4 is Quillen equivalent with the Joyal model structure. This last argument is fairly combinatorial and includes a number of routine computations involving cubical identities. For clarity of exposition, most of these computations are therefore relegated to Appendix A to be verified only by the most masochistic of the readers. Once again, we expect the tools used here to be of independent interest, e.g., in developing category theory in the context of our cubical quasicategories.

We conclude in Section 7 by defining mapping spaces in cubical quasicategories, showing that they are Kan complexes, and characterizing weak equivalences between fibrant objects in our model structure on \(\operatorname{cSet}\) as DK-equivalences, i.e., maps inducing equivalences on homotopy categories and equivalences of mapping spaces. We further establish a relation between these cubical mapping spaces and their simplicial analogs via the triangulation and straightening adjunctions, and give a new proof of the characterization of categorical equivalences in the Joyal model structure as DK-equivalences. While closely related to their simplicial analogs, these mapping spaces appear more convenient to work with, given their inherent symmetry.

Regarding the dependence on choice of the box category:

- the results of Sections 2 to 4 and the main results of Section 7 in particular Theorem 7.10 work for all categories displayed in the diagram at the end of Section 1;
- the results of Sections 5 and 6 require at least one connection;
- the results of Section 7 relating cubical and simplicial mapping spaces require both connections.

**Acknowledgements.** During the work on this paper the first three authors were supported by the Natural Sciences and Engineering Research Council (NSERC) of Canada in a variety of forms, including the Canada Graduate Scholarship awarded to the first-named author and the Discovery Grant awarded to the second-named author. The fourth author was supported by Swedish Research
Council grant 2019-03765. This material is based upon work supported by the National Science Foundation under Grant No. 1440140, while the second-named author was in residence at the Mathematical Sciences Research Institute in Berkeley, California, during Spring 2020.

1. Cubical sets and marked cubical sets

1.1. Model categories. Here we will review various general results from the theory of model categories which we will use throughout subsequent sections. We begin with a result which allows us to construct model structures having specified classes of cofibrations and weak equivalences.

**Theorem 1.1** (Jeff Smith’s Theorem, [Bar10, Prop. 2.2]). Let $\mathcal{C}$ be a locally presentable category. Let $W$ be a class of morphisms forming an accessibly embedded, accessible subcategory of $\mathcal{C}^{\text{op}}$, and $I$ a set of morphisms in $\mathcal{C}^{\text{op}}$. Suppose that the following conditions are satisfied.

- $W$ satisfies the two-out-of-three axiom.
- $W$ contains all maps having the right lifting property with respect to the maps in $I$.
- The intersection of $W$ with the saturation of $I$ is closed under pushouts and transfinite composition.

Then $\mathcal{C}$ admits a cofibrantly generated model structure with weak equivalences $W$ and generating cofibrations $I$.

Next we review some of the machinery of Cisinski theory [Cis06], which allows for the easy construction of model structures on presheaf categories having monomorphisms as cofibrations and weak equivalences defined in terms of homotopy with respect to a cylinder functor.

**Definition 1.2.** Let $\mathcal{C}$ be a small category. A **cylinder functor** on $\mathcal{C}$ consists of an endofunctor $I$ on the presheaf category $\text{Set}^{\mathcal{C}^{\text{op}}}$, together with natural transformations $\partial^0, \partial^1 : \text{id} \rightarrow I$, $\sigma : I \rightarrow \text{id}$, such that:

- $\partial^0$ and $\partial^1$ are sections of $\sigma$;
- For all $X : \mathcal{C}^{\text{op}} \rightarrow \text{Set}$, the map $(\partial^0_X, \partial^1_X) : X \sqcup X \rightarrow IX$ is a monomorphism;
- $I$ preserves small colimits and monomorphisms;
For all monomorphisms \( j: X \to Y \) in \( \text{Set}^{\text{op}} \) and all \( \varepsilon \in \{0, 1\} \), the following square is a pullback:

\[
\begin{array}{ccc}
X & \xrightarrow{j} & Y \\
\downarrow^{\partial^\varepsilon} & & \downarrow^{\partial^\varepsilon} \\
IX & \xrightarrow{Ij} & IY \\
\end{array}
\]

In what follows, let \( C \) be a small category equipped with a cylinder functor \( I: \text{Set}^{\text{op}} \to \text{Set}^{\text{op}} \).

**Definition 1.3.** Let \( f, g: X \to Y \) be maps of presheaves on \( C \). An **elementary homotopy** from \( f \) to \( g \) is a map \( H: IX \to Y \) such that \( H\partial^0 = f, H\partial^1 = g \). A **homotopy** is a zig-zag of elementary homotopies. The set of maps from \( X \) to \( Y \) modulo the relation of homotopy is denoted \( [X,Y] \).

It is easy to see that pre- and post-composition by a fixed map preserve the relation of homotopy; thus a map \( X \to Y \) induces maps \([Z,X] \to [Z,Y]\) and \([Y,Z] \to [X,Z]\) for any \( Z \).

**Definition 1.4.** A **cellular model** for \( \text{Set}^{\text{op}} \) is a set \( M \) of monomorphisms in \( \text{Set}^{\text{op}} \) whose saturation is precisely the class of monomorphisms of \( \text{Set}^{\text{op}} \).

Let \( M \) be a cellular model for \( \text{Set}^{\text{op}} \), and \( S \) a set of monomorphisms in \( \text{Set}^{\text{op}} \). The set of morphisms \( \Lambda(S) \) is defined by the following inductive construction. For a monomorphism \( X \to Y \) in \( \text{Set}^{\text{op}} \) and \( \varepsilon \in \{0, 1\} \), let \( IX \cup \varepsilon Y \) and \( IX \cup (Y \sqcup Y) \) be defined by the following pushout squares:

\[
\begin{array}{ccc}
X & \xrightarrow{j} & Y \\
\downarrow^{\partial^\varepsilon} & & \downarrow^{\partial^\varepsilon} \\
IX & \xrightarrow{Ij} & IY \\
\end{array}
\]

We now define a set of monomorphisms \( \Lambda(S) \) by an inductive construction. We begin by setting:

\[
\Lambda^0(S) = S \cup \{ IX \cup \varepsilon Y \to IY | X \to Y \in M, \varepsilon \in \{0, 1\} \}
\]

Now, given \( \Lambda^n(S) \), we define:

\[
\Lambda^{n+1}(S) = \{ IX \cup (Y \sqcup Y) \to IY | X \to Y \in \Lambda^n(S) \}
\]

Finally, we let \( \Lambda(S) = \bigcup_{n \geq 0} \Lambda^n(S) \). We now define several distinguished classes of maps and objects in \( \text{Set}^{\text{op}} \).

- A **cofibration** is a monomorphism; a **trivial fibration** is a map having the right lifting property with respect to the cofibrations.
- An **anodyne map** is a map in the saturation of \( \Lambda(S) \); a **naive fibration** is a map having the right lifting property with respect to the anodyne maps.
- A **fibrant object** is a presheaf \( X \) such that the map from \( X \) to the terminal presheaf is a naive fibration.
• A **weak equivalence** is a map \( X \to Y \) such that the induced map \([Y,Z] \to [X,Z]\) is a bijection for any fibrant \( Z \).

• A **trivial cofibration** is a map which is both a cofibration and a weak equivalence; a **fibration** is a map having the right lifting property with respect to the trivial cofibrations.

**Theorem 1.5.** The classes above define a cofibrantly generated model structure on \( \mathbf{Set}^{\mathbf{C}^{\text{op}}} \), in which a map between fibrant objects is a fibration if and only if it is a naive fibration.

**Proof.** The existence of the model structure is \([\text{Cis06} \text{ Thm. 1.3.22}]\); the characterization of fibrant objects is \([\text{Cis06} \text{ Thm. 1.3.36}]\). \(\square\)

**Corollary 1.6.** The homotopy category of \( \mathbf{Set}^{\mathbf{C}^{\text{op}}} \) with the model structure of Theorem 1.5 can be described as follows:

- its objects are the fibrant presheaves;
- the maps from \( X \) to \( Y \) are given by \([X,Y]\). \(\square\)

**Example 1.7.** Let \( J \) denote the simplicial set depicted below:

```
1 \rightarrow \rightarrow 0
\downarrow \quad \quad \downarrow
1 \rightarrow \rightarrow 0
```

Taking the product with \( J \) defines a cylinder functor on \( \mathbf{sSet} \), with the natural transformations \( \partial^0, \partial^1 \) given by taking the product with the endpoint inclusions \( \{0\} \hookrightarrow J, \{1\} \hookrightarrow J \). Applying Theorem 1.5 with this cylinder functor, the cellular model \( M = \{ \partial \Delta^n \rightarrow \Delta^n | n \geq 0 \} \), and \( S = \{ \Lambda^n_i | n \geq 2, 1 < i < n \} \) (the set of inner horn inclusions), we obtain the **Joyal model structure** on \( \mathbf{sSet} \), characterized as follows:

- Cofibrations are monomorphisms;
- Fibrant objects are **quasicategories**, simplicial sets having fillers for all inner horns;
- Fibrations between fibrant objects are characterized by the right lifting property with respect to the inner horn inclusions and the endpoint inclusions \( \{ \varepsilon \} \hookrightarrow J, \varepsilon \in \{0,1\} \);
- Weak equivalences are **weak categorical equivalences**, maps \( X \to Y \) inducing bijections \([Y,Z] \to [X,Z]\) for all quasicategories \( Z \).

Homotopy equivalences between quasicategories are referred to as **categorical equivalences**. For more on the Joyal model structure, see \([\text{Joy09}]\); for the details of its construction as a Cisinski model structure, see \([\text{Cis19} \text{ Sec. 3.3}]\).

Next we review a theorem which allows us to induce one model structure from another using an adjunction between their respective categories.

**Definition 1.8.** Let \( F : \mathbf{C} \Rightarrow \mathbf{D} : U \) be an adjunction between model categories. The model structure on \( \mathbf{C} \) is **left induced** by \( F \) if \( F \) preserves and reflects cofibrations and weak equivalences.
Likewise, the model structure on $D$ is right induced by $U$ if $U$ preserves and reflects weak equivalences and fibrations.

**Remark 1.9.** Note that for a given adjunction $C \rightleftarrows D$ and a given model structure on $D$, the left-induced model structure is unique, if one exists, since the definition determines the cofibrations and weak equivalences of $C$. Likewise, for a given model structure on $C$, the right-induced model structure is unique, if one exists.

**Theorem 1.10** ([HKRS17, Thm. 2.2.1]). Let $F : C \rightleftarrows D : U$ be an adjunction between locally presentable categories such that $D$ carries a cofibrantly generated model structure with all objects cofibrant. If, for every object $X \in C$, the co-diagonal map admits a factorization $X \sqcup X \xrightarrow{i_X} I X \xrightarrow{p_X} X$, such that $Fi_X$ is a cofibration and $Fp_X$ is a weak equivalence, then $C$ admits a model structure left-induced by $F$ from that of $D$. □

Finally, we review some results which allow us to easily recognize Quillen adjunctions and Quillen equivalences.

**Proposition 1.11** ([JT07, Prop. 7.15]). Let $F : C \rightleftarrows D : U$ be an adjunction between model categories. If $F$ preserves cofibrations and $U$ preserves fibrations between fibrant objects, then the adjunction is Quillen. □

This statement has an immediate corollary, which we will apply in practice:

**Corollary 1.12.** Let $F : C \rightarrow D$ be a left adjoint between model categories and suppose that fibrations between fibrant objects in $C$ are characterized by right lifting against a class $S$. If $F$ preserves cofibrations and sends $S$ to trivial cofibrations, then $F$ is a left Quillen functor. □

**Proposition 1.13** ([Hov99, Cor. 1.3.16]). Let $F : C \rightleftarrows D : U$ be a Quillen adjunction between model categories. Then the following are equivalent.

(i) $F \dashv U$ is a Quillen equivalence.

(ii) $F$ reflects weak equivalences between cofibrant objects and, for every fibrant $Y$, the derived counit $FUY \rightarrow Y$ is a weak equivalence.

(iii) $U$ reflects weak equivalences between fibrant objects and, for every cofibrant $X$, the derived unit $X \rightarrow U(FX)'$ is a weak equivalence.

Again, in practice we will often apply the following corollary:

**Corollary 1.14.** Let $F : C \rightleftarrows D : U$ be a Quillen adjunction between model categories.

(i) If $U$ preserves and reflects weak equivalences, then the adjunction is a Quillen equivalence if and only if, for all cofibrant $X \in C$, the unit $X \rightarrow UFX$ is a weak equivalence.

(ii) If $F$ preserves and reflects weak equivalences, then the adjunction is a Quillen equivalence if and only if, for all fibrant $Y \in D$, the counit $FUY \rightarrow Y$ is a weak equivalence. □

We will also have some use for the following consequence of this result, which concerns involutions of model categories. Recall that any involution of a category is self-adjoint, with the identity natural transformation as both unit and counit.
Corollary 1.15. Let $\mathcal{C}$ be a model category, and $F : \mathcal{C} \to \mathcal{C}$ an involution. If the adjunction $F \dashv F$ is Quillen, then it is a Quillen equivalence.

Proof. If $F \dashv F$ is Quillen, then $F$ preserves trivial cofibrations and trivial fibrations, hence all weak equivalences. The fact that $F$ is an involution thus implies that it reflects weak equivalences as well. Both the unit and counit of the adjunction are the identity natural transformation on $\mathcal{C}$, thus we may apply either statement of Corollary 1.14 to conclude that the adjunction is a Quillen equivalence. \hfill \Box

1.2. The box category and cubical sets. We begin by defining the box category $\square$. The objects of $\square$ are posets of the form $[1]^n$ and the maps are generated (inside the category of posets) under composition by the following four special classes:

- **faces** $\partial_i^\varepsilon : [1]^{n-1} \to [1]^n$ for $i = 1, \ldots, n$ and $\varepsilon = 0, 1$ given by:
  $$\partial_i^\varepsilon(x_1, x_2, \ldots, x_{n-1}) = (x_1, x_2, \ldots, x_{i-1}, \varepsilon, x_{i+1}, \ldots, x_{n-1}).$$

- **degeneracies** $\sigma_i^n : [1]^n \to [1]^{n-1}$ for $i = 1, 2, \ldots, n$ given by:
  $$\sigma_i^n(x_1, x_2, \ldots, x_n) = (x_1, x_2, \ldots, x_{i-1}, x_{i+1}, \ldots, x_n).$$

- **negative connections** $\gamma_{i,0}^n : [1]^n \to [1]^{n-1}$ for $i = 1, 2, \ldots, n - 1$ given by:
  $$\gamma_{i,0}^n(x_1, x_2, \ldots, x_n) = (x_1, x_2, \ldots, x_{i-1}, \min\{x_i, x_{i+1}\}, x_{i+2}, \ldots, x_n).$$

- **positive connections** $\gamma_{i,1}^n : [1]^n \to [1]^{n-1}$ for $i = 1, 2, \ldots, n - 1$ given by:
  $$\gamma_{i,1}^n(x_1, x_2, \ldots, x_n) = (x_1, x_2, \ldots, x_{i-1}, \max\{x_i, x_{i+1}\}, x_{i+2}, \ldots, x_n).$$

These maps obey the following cubical identities:

- $\partial_j^{\varepsilon} \partial_{i, \varepsilon} = \partial_{i+1, \varepsilon} \partial_j^{\varepsilon}$ for $j \leq i$;
- $\sigma_i \sigma_j = \sigma_j \sigma_{i+1}$ for $j \leq i$;
- $\sigma_j \partial_{i, \varepsilon} = \begin{cases} \partial_{i, \varepsilon} \sigma_j & \text{for } j < i, \\ \text{id} & \text{for } j = i, \\ \partial_{j, \varepsilon} \sigma_{j-1} & \text{for } j > i; \end{cases}$
- $\gamma_j^{\varepsilon} \gamma_{i, \varepsilon} = \begin{cases} \gamma_{i, \varepsilon} \gamma_{j+1, \varepsilon} & \text{for } j > i, \\ \gamma_{i, \varepsilon} \gamma_{i+1, \varepsilon} & \text{for } j = i, \varepsilon' = \varepsilon; \end{cases}$
- $\sigma_j \gamma_{i, \varepsilon} = \begin{cases} \gamma_{i-1, \varepsilon} \sigma_j & \text{for } j < i, \\ \sigma_i \sigma_j & \text{for } j = i, \\ \gamma_{i, \varepsilon} \sigma_{j+1} & \text{for } j > i. \end{cases}$

Theorem 1.16 ([GM03, Thm. 5.1]). Every map in the category $\square$ can be factored uniquely as a composite

$$\partial_{c_1, \varepsilon_1} \cdots \partial_{c_r, \varepsilon_r} (\gamma_{b_1, \varepsilon_1} \cdots \gamma_{b_q, \varepsilon_q} (\sigma_{a_1} \cdots \sigma_{a_p})), $$

where $1 \leq a_1 < \ldots < a_p$, $1 \leq b_1 \leq \ldots \leq b_q$, $b_i < b_{i+1}$ if $\varepsilon_i = \varepsilon_{i+1}$, and $c_1 > \ldots > c_r \geq 1$. \hfill \Box

Corollary 1.17. $\square$ admits the structure of an EZ-Reedy category, in which:

- $\deg([1]^n) = n$;
- $\square_+$ is generated under composition by the face maps;
• □− is generated under composition by the degeneracy and connection maps.

The category of cubical sets, i.e., contravariant functors □op → Set will be denoted by cSet. We will write □n for the representable cubical set, represented by [1]n. We adopt the convention of writing the action of cubical operators on the right. For instance, the (1, 0)-face of an n-cube x: □n → X will be denoted x∂1,0.

We write ∂□n → □n for the maximal proper subobject of □n, i.e., the union of all of its faces. We will refer to these as the n-cube and the boundary of the n-cube, respectively. The subobject of □n given by the union of all faces except ∂i,ε will be denoted ⊓n i,ε and referred to as an (i, ε)-open box.

From Theorem 1.16, we obtain the following:

**Proposition 1.18.** Given a cubical set X, for any cube x: □n → X there exist unique (possibly empty) sequences a1 < ... < ap, b1 ≤ ... ≤ bq, ε1, ..., εq ∈ {0, 1}, where bi < bi+1 if εi = εi+1, and a unique non-degenerate cube y: □n−p−q → X such that x = yγb1,ε1...γbq,εqσa1...σap.

This factorization is called the standard form of x.

**Corollary 1.19.** A map X → Y in cSet is determined by its action on the non-degenerate cubes of X.

**Corollary 1.20.** A map X → Y in cSet is a monomorphism if and only if it maps non-degenerate cubes of X to non-degenerate cubes of Y, and does so injectively.

For brevity, we will often say that the standard form of a cube x is zf, or “ends with f”, where f is some map in □; this is understood to mean that f is the rightmost map in the standard form of x. For instance, if the standard form of x is zσap, then z = yγb1,ε1...γbq,εqσa1...σap−1 in the notation of Proposition 1.18.

**Definition 1.21.** The critical edge of □n with respect to a face ∂i,ε is the unique edge of □n which is adjacent to ∂i,ε and which, together with ∂i,ε, contains both of the vertices (0,...,0) and (1,...,1).

More explicitly, the critical edge with respect to ∂i,ε corresponds to the map f: [1] → [1]n given by f1 = id11, fj = const i−ε for j ≠ i.

The assignment ([1]m, [1]n) ↦ [1]m+n defines a functor □ × □ → □. Postcomposing it with the Yoneda embedding and left Kan extending, we obtain the geometric product functor

\[
\begin{array}{ccc}
\Box × \Box & \rightarrow & \text{cSet} \\
\downarrow & & \\
\text{cSet} × \text{cSet} & \rightarrow & \Box
\end{array}
\]

The standard formula for left Kan extensions gives us the following formula for the geometric product:

\[
X ⊗ Y = \colim_{x: □n → X} □^{m+n}
\]
In particular, for any \( X, Y \) degeneracies and connections of these cones are computed as described in the statement.

**Proposition 1.22.** The geometric product \( \otimes \) defines a monoidal structure on the category of cubical sets, with the unit given by \( \square^0 \).

This monoidal structure is however not symmetric. Indeed, the existence of a symmetry natural transformation would in particular imply that there is a non-identity bijection

\[
\hom_X \rightarrow \text{transformation would in particular imply that there is a non-identity bijection}
\]

Given a cubical set \( X \), we form two non-isomorphic functors \( c\Set \rightarrow c\Set \): the left tensor \( - \otimes X \) and the right tensor \( X \otimes - \). As they are both co-continuous, they admit right adjoints and we write \( \hom_l(X, -) \) for the right adjoint of the left tensor and \( \hom_R(X, -) \) for the right adjoint of the right tensor. Explicitly, these functors are given by \( \hom_l(X,Y)_n = c\Set(\square^n \otimes X, Y) \), \( \hom_R(X,Y)_n = c\Set(X \otimes \square^n, Y) \). Thus the monoidal structure on \( c\Set \) given by the geometric product is closed, but non-symmetric.

The standard construction of an arbitrary small colimit as a coequalizer of coproducts gives us the following lemma about colimits in presheaf categories.

**Lemma 1.23.** Let \( C \) be a category and \( D \) a small diagram in \( \Set^{C^{op}} \). Then any map \( C(-, c) \rightarrow \text{colim } D \) factors through some map in the colimit cone.

This lemma allows us to describe the geometric product of cubical sets explicitly.

**Proposition 1.24.** For \( X, Y \in c\Set \), the geometric product \( X \otimes Y \) admits the following description.

- For \( k \geq 0 \), the \( k \)-cubes of \( X \otimes Y \) consist of all pairs \( (x: \square^m \rightarrow X, y: \square^n \rightarrow Y) \) such that \( m + n = k \), subject to the identification \( (x\sigma_{m+1}, y) = (x, y_1) \).

- For \( x: \square^m \rightarrow X, y: \square^n \rightarrow Y \), the faces, degeneracies, and connections of the \((m + n)\)-cube \((x, y)\) are computed as follows:

\[
- (x, y)\partial_{i, e} = \begin{cases} (x\partial_{i, e}, y) & 1 \leq i \leq m \\ (x, y\partial_{i-m, e}) & m + 1 \leq i \leq m + n \end{cases}
\]

\[
- (x, y)\sigma_i = \begin{cases} (x\sigma_i, y) & 1 \leq i \leq n_1 + 1 \\ (x, y\sigma_{i-m}) & m + 1 \leq i \leq m + n + 1 \end{cases}
\]

\[
- (x, y)\gamma_{i, e} = \begin{cases} (x\gamma_{i, e}, y) & 1 \leq i \leq m \\ (x, y\gamma_{i-m, e}) & m + 1 \leq i \leq m + n \end{cases}
\]

**Proof.** We begin by noting that for every pair \( (x: \square^m \rightarrow X, y: \square^n \rightarrow Y) \) there is a corresponding \((m + n)\)-cube \((x, y): \square^{m+n} \rightarrow X \otimes Y \) given by the colimit cone. Next we will show that faces, degeneracies and connections of these cones are computed as described in the statement.
For such an $(m + n)$-cube $(x, y)$, consider a face $(x, y)\partial_{i,ε}$ for $1 \leq i \leq m$. We can express the face map $\partial_{i,ε}^{m+n}$ as $\partial_{i,ε}^m \otimes □^n$; thus $(x, y)\partial_{i,ε} = (x\partial_{i,ε}, y)$ by the naturality of the colimit cone.

\[
\begin{array}{cc}
\square^{m-1} \otimes □^n & □^m \otimes □^n \\
\downarrow & \downarrow \\
(x\partial_{i,ε}, y) & (x, y)
\end{array}
\]

Likewise, for $m + 1 \leq i \leq m + n$ we have $\partial_{i,ε}^{m+n} = □^m \otimes \partial_{i-m-ε}^n$, implying $(x, y)\partial_{i,ε} = (x, y\partial_{i-m,ε})$. Similar proofs hold for degeneracies and connections. In particular, this implies that for any $(x, y)$ we have $(xσ_{m+1}, y) = (x, yσ_1)$, as both are equal to $(x, y)σ_{m+1}$.

To see that all cubes in $X \otimes Y$ are of this form, note that by Lemma 1.23 every cube of $X \otimes Y$ is equal to $(x, y)ψ$ for some such pair $(x, y)$ and some map $ψ$ in □. We have shown that the set of cubes arising from pairs is closed under faces, degeneracies and connections; since these classes generate all maps in □, this proves our claim.

Finally, we must show that the cubes of $X \otimes Y$ are not subject to any additional identifications, beyond the identification $(xσ_{m+1}, y) = (x, yσ_1)$ mentioned above. In other words, we must show that for each $k \geq 0$, $(X \otimes Y)_k$ is the quotient of the set $\{(x: □^m \rightarrow X, y: □^n \rightarrow Y)| m + n = k\}$ under the smallest equivalence relation $\sim$ such that $(x′σ_{m+1}, y′) \sim (x′, y′σ_1)$ for all $x′: □^{m′} \rightarrow X, y′: □^{n′} \rightarrow Y$ such that $m′ + n′ = k − 1$.

To that end, let $x: □^m \rightarrow X, y: □^n \rightarrow Y, x′: □^{m′} \rightarrow X, y′: □^{n′} \rightarrow Y$, such that $m + n = m′ + n′$ and $(x, y) = (x′, y′)$ in $(X \otimes Y)$. Without loss of generality, assume $m \geq m′$. We compute the image of this cube under the map $π_X: X \otimes Y \rightarrow X$.

\[
π_X(x, y) = π_X(x′, y′)
\]

\[
\therefore xσ_{m+1}σ_{m+2}…σ_{m+n} = x′σ_{m′+1}…σ_{m′+n′}
\]

(If $n$ or $n′$ is equal to 0, we interpret the corresponding string of degeneracies to be empty.) We can apply face maps to both sides of this equation to reduce the left-hand side to $x$. If $m = m′$ then this gives the equation $x = x′$, and a similar calculation shows $y = y′$. Otherwise, we have $x = x′σ_{m′+1}…σ_m$. In this case, a similar calculation shows $y′ = yσ_1…σ_1$, where $σ_1$ is applied $m′ - m$ times on the right-hand side of the equation. From this we can see that $(x, y) \sim (x′, y′)$. Thus we see that quotienting the set of pairs $(x, y)$ of appropriate dimensions by $\sim$ does indeed suffice to obtain $(X \otimes Y)_k$.

**Corollary 1.25.** For cubical sets $X$ and $Y$, we have $(X \otimes Y)_1 \cong (X_1 \times Y_0) ∪ (X_0 \times Y_1)$. □

The following lemma, which can be verified by simple computation, allows us to express boundary inclusions and open box inclusions as pushout products with respect to this monoidal structure.

**Lemma 1.26.**

(i) For $m, n \geq 0$, we have

\[ (\partial □^m \rightarrow □^m) \otimes (\partial □^n \rightarrow □^n) = (\partial □^{m+n} \rightarrow □^{m+n}). \]
By left Kan extension, we obtain functors \((-)^\co\), \((-)^\co\): \(\square \to \square\) as follows:

- Both \((-)^\co\) and \((-)^\co\) act as the identity on objects;
- \((-)^\co\) acts on generating morphisms as follows:
  - \(\partial_{n,i,\varepsilon}^\co = \partial_{n-i+1,\varepsilon}^n\);
  - \(\sigma_i^\co = \sigma_{n-i+1}^n\);
  - \(\gamma_{i,\varepsilon}^\co = \gamma_{n-1-i,1,\varepsilon}^{n-1}\);
- \((-)^\co\) acts on generating morphisms as follows:
  - \(\partial_{n,i,\varepsilon}^{\co\op} = \partial_{i-1,1-\varepsilon}^n\);
  - \(\sigma_i^{\co\op} = \sigma_i^n\);
  - \(\gamma_{i,\varepsilon}^{\co\op} = \gamma_{i,1-\varepsilon}^n\).

From the definition we can see that the endofunctors \((-)^\co\) and \((-)^{\co\op}\) commute; we denote their composite by \((-)^\op\).

By left Kan extension, we obtain functors \((-)^\co\), \((-)^{\co\op}\): \(\mathsf{cSet} \to \mathsf{cSet}\).

Some simple computations show:

**Lemma 1.27.** The functors \((-)^\co\), \((-)^{\co\op}\), \((-)^\op\) are involutions of \(\mathsf{cSet}\). □

In particular, for \(X \in \mathsf{cSet}\), the cubes of \(X\) are in bijection with those of \(X^\co\), \(X^{\co\op}\), and \(X^\op\); given \(x: \square \to X\) we have corresponding cubes \(x^\co: \square^n \to \square^n X^\co\), \(x^{\co\op}: \square^n \to \square^n X^{\co\op}\), \(x^\op: \square^n \to \square^n X^\op\).

Let \(\square_0\) denote the subcategory of \(\square\) generated by the face, degeneracy, and negative connection maps, and let \(\mathsf{cSet}_0\) denote the presheaf category \(\mathsf{Set}^{\square_0\op}\). This is the category of cubical sets studied in [KLW19].

By pre-composition, the inclusion \(i: \square_0 \to \square\) defines a functor \(i^*: \mathsf{cSet} \to \mathsf{cSet}_0\). Left and right Kan extension define left and right adjoints of this functor, respectively denoted \(i_l, i_r: \mathsf{cSet}_0 \to \mathsf{cSet}\).

We may characterize the functors \(i^*, i_l, i_r\) as follows:

- For \(X \in \mathsf{cSet}\), \(n \geq 0\) we have \((i^* X)_n = X_n\), with structure maps computed as in \(X\). However, certain degenerate cubes of \(X\) become non-degenerate in \(i^* X\), namely those which cannot be expressed as degeneracies or negative connections of any other cube.
• For $X \in \mathbf{cSet}_0$, we have $(i_*X)_n = \mathbf{cSet}_0(i^*\Box^n, X)$.

• For $X \in \mathbf{cSet}_0$, $i^*X$ is obtained by freely adding positive connections to $X$. Given a map $f : X \to Y$ in $\mathbf{cSet}_0$, $i^*f$ agrees with $f$ on the non-degenerate cubes of $i^*X$; by Corollary 1.19 this is enough to determine $i^*f$.

**Lemma 1.28.** Given a map $f : i^*X \to Y$ in $\mathbf{cSet}$, $f$ and the adjunct map $\overline{f} : X \to i^*Y$ agree on non-degenerate cubes.

Similarly, we let $\Box_1$ denote the subcategory of $\Box$ generated by the face, degeneracy, and positive connection maps, and let $\mathbf{cSet}_1$ denote the presheaf category $\mathbf{Set}^{\Box_1^{op}}$. Likewise, we let $\Box_\partial$ denote the subcategory of $\Box$ generated by the face and degeneracy maps, and let $\mathbf{cSet}_\partial$ denote the presheaf category $\mathbf{Set}^{\Box_\partial^{op}}$. Most of our arguments will not require fixing a specific choice of box category, so that our main results will be valid in all of these categories of cubical sets. For concreteness, we will work with the category $\mathbf{cSet}$ of cubical sets having both positive and negative connections; at the beginning of each section we will note the extent to which that section’s results apply to the other three categories of cubical sets.

The restriction of the nerve functor defines a functor $\Box \to \mathbf{sSet}$; taking the left Kan extension of this functor along the Yoneda embedding, we obtain the triangulation functor $T : \mathbf{cSet} \to \mathbf{sSet}$.

The triangulation functor has a right adjoint $U : \mathbf{sSet} \to \mathbf{cSet}$ given by $(UX)_n = \mathbf{sSet}(\Delta^n, X)$. Intuitively, we think of triangulation as creating a simplicial set $TX$ from a cubical set $X$ by subdividing the cubes of $X$ into simplices.

We now record two basic facts about triangulation. In the given references, these results are proven using a different definition of the category $\Box$, lacking connection maps, but the proofs apply equally well to the cubical sets under consideration here.

**Proposition 1.29** ([Cis06, Ex. 8.4.24]). The triangulation functor sends geometric products to cartesian products; that is, for cubical sets $X$ and $Y$, there is a natural isomorphism $T(X \otimes Y) \cong TX \times TY$.

**Corollary 1.30.** Triangulation preserves pushout products; that is, for maps $f, g$ in $\mathbf{cSet}$ there is a natural isomorphism $T(f \circ g) \cong Tf \circ Tg$.

**Proof.** Immediate by Proposition 1.29 and the fact that $T$ preserves colimits as a left adjoint.

**Proposition 1.31** ([Cis06, Lem. 8.4.29]). The triangulation functor preserves monomorphisms.

### 1.3. Homotopy theory of cubical sets.

**Lemma 1.32.** The boundary inclusions $\partial \Box^n \to \Box^n$ form a cellular model for $\mathbf{cSet}$.

**Proof.** This follows from Corollary 1.17.
Definition 1.33. A map of cubical sets is a Kan fibration if it has the right lifting property with respect to all open box fillings. A cubical set $X$ is a cubical Kan complex if the map $X \to \square^0$ is a Kan fibration.

The functor $\square^1 \otimes - : \text{cSet} \to \text{cSet}$, together with the natural transformations $\partial_{1,0}^1 \otimes - , \partial_{1,1}^1 \otimes - : \text{id} \to \square^1 \otimes -$, and $\pi : \square^1 \otimes - \to \text{id}$, defines a cylinder functor on $\text{cSet}$ in the sense of Definition 1.2. Thus, for any $X,Y \in \text{cSet}$ we have a set $[X,Y]$ of homotopy classes of maps from $X$ to $Y$ defined by this cylinder functor.

Theorem 1.34 (Cisinski). The category $\text{cSet}$ carries a cofibrantly generated model structure, referred to as the Grothendieck model structure, in which

- cofibrations are the monomorphisms;
- weak equivalences are maps $X \to Y$ inducing bijections $[Y,Z] \to [X,Z]$ for all cubical Kan complexes $Z$;
- fibrations are the Kan fibrations.

Proof. The existence of the model structure and characterization of the cofibrations, weak equivalences, and fibrant objects follows from applying Theorem 1.5 with the cylinder functor $I = \square^1 \otimes -$, cellular model $M = \{ \partial \square^n \to \square^n \mid n \geq 0 \}$, and $S = \emptyset$. The characterization of the fibrations is given in [Cis14, Thm. 1.7]. (This proof is for cubical sets with only negative connections, but the proof for cubical sets with both kinds of connections is identical.)

Proposition 1.35. The category $\square$ is a strict test category, and the test category model structure on $\text{cSet}$ is the Grothendieck model structure.

Proof. For the proof that $\square$ is a strict test category, see [Mal09 Thm. 4.3] and [BM17 Thm. 3]. That the test category model structure is the Grothendieck model structure follows from [Cis14 Thm. 1.7].

The canonical inclusion $\square \to \text{Cat}$ induces the adjoint pair $\tau_1 : \text{cSet} \rightleftarrows \text{Cat} : N_{\square}$ via hom-out and the left Kan extension. In particular, $N_{\square}(C)_n = \text{Cat}([1]^n, C)$. The functor $\tau_1$ takes a cubical set $X$ to its fundamental category, which is obtained as the quotient of the free category on the graph $X_1 \rightrightarrows X_0$ modulo the relations: $\sigma_1 x = \text{id}_x$ and $gf = qp$ for every 2-cube.

1.4. Marked cubical sets. To define marked cubical sets, we need to introduce a new category $\square_\sharp$, a slight enlargement of $\square$. The category $\square_\sharp$ consists of objects of the form $[1]^n$ for $n = 0, 1, \ldots$ and an object $[1]_e$. The maps of $\square_\sharp$ are generated by the usual generating maps of $\square$ along with $\varphi : [1] \to [1]_e$ and $\zeta : [1]_e \to [1]^0$ subject to an additional identity $\zeta \varphi = \sigma_1^0$.

Proposition 1.36. The category $\square_\sharp$ is an EZ-Reedy category with the Reedy structure defined as follows:
CUBICAL MODELS OF ($\infty, 1$)-CATEGORIES

- $\deg([1]^0) = 0$, $\deg([1] = 1$, $\deg([1]_e) = 2$, and $\deg([1]^n) = n + 1$ for $n \geq 2$;
- $([\square^1]_+)$ is generated by face maps and $\varphi$ under composition;
- $([\square^1]_-)$ is generated by degeneracy maps, connections, and $\zeta$ under composition.

A \textit{structurally marked cubical set} is a contravariant functor $X : \square^\text{op} \to \text{Set}$ and a morphism of structurally marked cubical sets is a natural transformation of such functors. We will write $\text{cSet}''$ for the category of structurally marked cubical sets. When working with the category of structurally marked cubical sets, we will write $X_n$ for the value of $X$ at $[1]^n$ and $X_e$ for the value of $X$ at $[1]_e$.

Structurally marked cubical sets should be thought of as cubical sets with (possibly multiple) labels on their edges such that for each vertex $x$, the degenerate edge $x\sigma_1$ has, in particular, a distinguished label $x\zeta$.

A \textit{marked cubical set} is a structurally marked cubical set for which the map $X_e : X_1 \to X_1$ is a monomorphism. We write $\text{cSet}'$ for the category of marked cubical sets. Alternatively, we may view a marked cubical set as a pair $(X, W_X)$ consisting of a cubical set $X$ together with a subset $W_X \subseteq X_1$ of edges that includes all degenerate edges and a morphism of marked cubical sets is a map of cubical sets that preserves marked edges.

The functor taking a (structurally) marked cubical set to its underlying cubical set admits both a left and a right adjoint, given by the minimal and maximal marking respectively. The minimal marking on a cubical set $X$, denoted $X^\flat$, marks exactly the degenerate edges, whereas the maximal marking, denoted $X^\sharp$, marks all edges of $X$. If considered as structurally marked cubical sets, the marked edges of $X^\flat$ and $X^\sharp$ are marked exactly once. Altogether we obtain the following adjunctions

\[
\begin{array}{c}
\text{cSet}'
\end{array} \xrightarrow{(-)^\flat} \text{cSet} \xleftarrow{(-)^\sharp} \text{cSet}''
\]

The notation $\text{cSet}'(\cdot)$ above indicates that the same constructions can be applied to both marked and structurally marked cubical sets. In the context of (structurally) marked cubical sets, we regard a cubical set with its minimal marking by default, writing $X$ for $X^\flat$.

There is moreover an inclusion $\text{cSet}' \to \text{cSet}''$. This inclusion admits a left adjoint taking $X \in \text{cSet}''$ to $\text{Im}X$ given by $(\text{Im}X)_n = X_n$ and $(\text{Im}X)_e = \varphi^*(X_e)$, i.e., the image of $X_e$ under $\varphi^* = X(\varphi)$. The inclusion is easily seen to not have a right adjoint, since it fails to preserve the pushout of $\square^1 \to ([\square^1])^\sharp$ against itself.

Altogether we obtain the following diagram:

\[
\begin{array}{c}
\text{cSet}'' \xrightarrow{(-)^\sharp} \text{cSet}' \xleftarrow{(-)^\flat} \text{cSet}
\end{array}
\]

(*)
A geometric product entirely analogous to that of Section 1.2 exists for structurally marked cubical sets. We extend $\Box \times \Box \to \text{cSet}$ to $\Box e \times \Box e \to \text{cSet}''$ by taking $[1]e \otimes [n]$ to have $\Box^{n+1}$ as the underlying cubical set with edges of the form $(0, x_2, \ldots, x_{n+1}) < (1, x_2, \ldots, x_{n+1})$ uniquely marked. Similarly, let $[n] \otimes [1]e$ have $\Box^{n+1}$ as its underlying cubical set, and marked edges those of the form $(x_1, \ldots, x_n, 0) < (x_1, \ldots, x_n, 1)$. Finally, let $[1]e \otimes [1]e := (\Box_2)^{\Box}$. The left Kan extension yields $\otimes : \text{cSet}'' \times \text{cSet}'' \to \text{cSet}''$.

This geometric product admits a concrete description analogous to that of Proposition 1.24.

**Proposition 1.37.** For $X, Y \in \text{cSet}''$, the geometric product $X \otimes Y$ admits the following description.

- The underlying cubical set of $X \otimes Y$ is the geometric product of the underlying cubical sets of $X$ and $Y$.

- $(X \otimes Y)_e$ is the set of all pairs of the form $(\varphi : (\Box^{1})^{\Box} \to X, y : \Box^{0} \to Y)$ or $(x : \Box^{0} \to X, \psi : (\Box^{1})^{\Box} \to Y)$, subject to the identification $(x, y) = (x, y\zeta)$ for $x : \Box^{0} \to X, y : \Box^{0} \to Y$.

- Structure maps not arising from those of the underlying cubical set are computed as follows:

  - $(x, y)\zeta = (x, y)$;
  - $(\varphi, y)\varphi = (\varphi y, y)$;
  - $(x, \psi)\varphi = (x, \psi x)\varphi$.

**Proof.** To compute the underlying cubical set of $X \otimes Y$, we analyze maps $\Box^{k} \to X \otimes Y$ exactly as in the proof of Proposition 1.24.

Now we consider maps $(\Box^{1})^{\Box} \to X \otimes Y$. First observe that for every pair of maps $\varphi : (\Box^{1})^{\Box} \to X, y : \Box^{0} \to Y$ we have a map $(x, y) : (\Box^{1})^{\Box} \otimes \Box^{0} \to X \otimes Y$ in the colimit cone, and the same holds for $x : \Box^{0} \to X, \psi : (\Box^{1})^{\Box} \to Y$. Once again, the stated computations of structure maps follow from the naturality of the colimit cone.

Now we will show that every map $p : (\Box^{1})^{\Box} \to X \otimes Y$ has the form described above. By Lemma 1.23 for every such map we have a commuting diagram

$$
\begin{array}{ccc}
(\Box^{1})^{\Box} & \xrightarrow{\psi} & \Box^{m} \otimes \Box^{n} \\
p & & \downarrow \\
X \otimes Y & & \\
\end{array}
$$

where $\Box^{m}_e, \Box^{n}_e$ denote representable presheaves, and the map $\Box^{m}_e \otimes \Box^{n}_e \to X \otimes Y$ is part of the colimit cone. We proceed by case analysis on $\Box^{m}_e$ and $\Box^{n}_e$.

First note that if $\psi$ factors through $\zeta$, then $p = (x, y)\zeta$ for some $x : \Box^{0} \to X, y : \Box^{0} \to Y$. This takes care of the case $\Box^{n}_e = \Box^{m}, \Box^{m}_e = \Box^{n}$, since any map from $(\Box^{1})^{\Box}$ into these objects factors through $\zeta$.

Now assume $\psi$ does not factor through $\zeta$, implying that at least one of $\Box^{m}_e, \Box^{n}_e$ is $(\Box^{1})^{\Box}$; then $\Box^{m} \otimes \Box^{n}$ is either $\Box^{m} \otimes (\Box^{1})^{\Box}$, $(\Box^{1})^{\Box} \otimes \Box^{n}$, or $(\Box^{2})^{\Box}$. Since every map $(\Box^{1})^{\Box} \to (\Box^{2})^{\Box}$ factors through either $\Box^{1} \otimes (\Box^{1})^{\Box}$ or $(\Box^{1})^{\Box} \otimes \Box^{1}$, we need only consider the first two cases. If $\Box^{m}_e \otimes \Box^{n}_e = \Box^{m} \otimes (\Box^{1})^{\Box}$,
then $\psi$ picks out the unique marking on an edge of the form $(x_1, \ldots, x_m, 0) < (x_1, \ldots, x_m, 1)$. In other words, $\psi$ factors through the map $(x_1, \ldots, x_m) \otimes (1) \otimes (1)^2 : \square^0 \otimes (1)^2 \rightarrow \square^m \otimes (1)^2$.

Thus we have reduced the problem to the case that $p \psi_{hom, y}$ admits right adjoints and we write

Proposition 1.39. 

$(\mathcal{T})$ To show that the elements of $(\mathcal{T})$ are identified under the projections $\pi$ shows that for $x$, $y \in \text{cSet}''$, the set of markings on the edge $(x, y)$ in $\text{X}$ is simply the set of markings on $x$ in $X$, that the analogous result holds for $x : \square^0 \rightarrow X, y : \square^0 \rightarrow Y$, and that for a pair of vertices $x$ and $y$ the distinguished marking $(x, y)_\zeta$ is identified with both $(x, y)$ and $(y, x)_\zeta$.

Corollary 1.38. For $X, Y \in \text{cSet}'$, $(X \otimes Y)_e \cong (X_e \times Y_0) \cup (X_0 \times Y_e)$.

What Proposition 1.37 shows is that for $x : \square^1 \rightarrow X, y : \square^0 \rightarrow Y$, the set of markings on the edge $(x, y)$ in $(X \otimes Y)_e$ is subject to no further identifications, consider two pairs $(x, y), (x', y')$ which are identified in $(X \otimes Y)_e$. Considering the image of the cube corresponding to these pairs under the projections $\pi_X, \pi_Y$, we see that $\overrightarrow{\pi} = \overrightarrow{x}, y = \overrightarrow{y}$. A similar proof holds for identified pairs of the form $(x, \overrightarrow{y}), (x', \overrightarrow{y'})$. Finally, if $(\overrightarrow{x}, y) = (x, \overrightarrow{y})$, then applying the projections shows $\overrightarrow{x} = x_\zeta, \overrightarrow{y} = y_\zeta$.

Corollary 1.39. The geometric product on $\text{cSet}''$ restricts to a monoidal product on $\text{cSet}'$.  

As in the case of cubical sets, given a marked cubical set $A$, we form two non-isomorphic functors $\text{cSet}'(\cdot) \rightarrow \text{cSet}'(\cdot)$: the left tensor $- \otimes A$ and the right tensor $A \otimes -$. As they are both co-continuous, they admit right adjoints and we write $\text{hom}_L(A, -)$ for the right adjoint of the left tensor $- \otimes A$ and $\text{hom}_R(A, -)$ for the right adjoint of the right tensor $A \otimes -$.

Observe that we may extend the functors $(-)^c, (-)^{co-op}, (-)^{op} : \square \rightarrow \square$ of Section 1.2 to obtain involutions $(-)^c, (-)^{co-op}, (-)^{op} : \square_\phi \rightarrow \square_\phi$, by having these functors act as the identity on the object $[1]_e$ and the maps $\phi$ and $\zeta$. By left Kan extension we obtain involutions $(-)^c, (-)^{co-op}, (-)^{op} : \text{cSet}'' \rightarrow \text{cSet}''$, which restrict to involutions of $\text{cSet}'$. Given $X' \in \text{cSet}'$ with underlying cubical set $X$, the underlying cubical set of $(X')^c$ is $X'^c$, with an edge $x^c : \square^1 \rightarrow (X')^c$ marked if and only if $x$ is marked in $X'$, and similarly for $(X')^{co-op}$.

Proposition 1.41 ([CKM20 Prop. 1.17]). The endofunctors $(-)^c, (-)^{co-op}, (-)^{op}$ on $\text{cSet}, \text{cSet}'$, and $\text{cSet}''$ interact with the geometric product as follows:

- The functor $(-)^c$ is strong anti-monoidal, i.e. $(X \otimes Y)^c \cong Y^c \otimes X^c$;
- The functor $(-)^{co-op}$ is strong monoidal, i.e. $(X \otimes Y)^{co-op} \cong X^{co-op} \otimes Y^{co-op}$;
- The functor $(-)^{op}$ is strong anti-monoidal, i.e. $(X \otimes Y)^{op} \cong Y^{op} \otimes X^{op}$.

Using Proposition 1.41 and the adjunctions $(-)^c \dashv (-)^{co-op} \dashv (-)^{op}$, we obtain:

Corollary 1.42. For $X, Y$ in $\text{cSet}, \text{cSet}'$, or $\text{cSet}''$, we have isomorphisms, natural in $X$ and $Y$:

- $\text{hom}_L(X, Y)^c \cong \text{hom}_R(X^{co}, Y^c), \text{hom}_R(X, Y)^c \cong \text{hom}_L(X^{co}, Y^c)$;
- $\text{hom}_L(X, Y)^{co-op} \cong \text{hom}_L(X^{co-op}, Y^{co-op}), \text{hom}_R(X, Y)^{co-op} \cong \text{hom}_R(X^{co-op}, Y^{co-op})$;
Finally, we relate the adjunction $T \dashv U$ to the involutions $(-)^{co}$, $(-)^{co-op}$, and $(-)^{op}$ of $cSet$ and the involution $(-)^{op}$ of $sSet$.

**Proposition 1.43.** We have the following natural isomorphisms in $sSet$ and $cSet$:

1. $T \circ (-)^{co} \cong T$;
2. $T \circ (-)^{co-op} \cong (-)^{op} \circ T$;
3. $T \circ (-)^{op} \cong (-)^{op} \circ T$;
4. $(-)^{co} \circ U \cong U$;
5. $(-)^{co-op} \circ U \cong U \circ (-)^{op}$;
6. $(-)^{op} \circ U \cong U \circ (-)^{op}$.

**Proof.** It suffices to prove (i) and (ii). As $T$ and the involutions preserve colimits, it suffices to establish the desired natural isomorphisms on the objects $\Box^n$. For this, observe that the maps between these objects are generated, under composition and the geometric product, by the maps $\partial_1, \varepsilon: [0] \to [1]$, $\sigma_1: [1] \to [0]$, and $\gamma_{1,1}: [1]^2 \to [1]$. By Propositions 1.29 and 1.41 it thus suffices to show that $T \circ (-)^{co}$ and $T$ (resp. $T \circ (-)^{co-op}$ and $(-)^{op} \circ T$) agree on these maps; this can easily be verified. 

For reference, the following diagrams show the inclusions of the four cube categories under consideration, and the functors between the corresponding categories of cubical sets induced by pre-composition.

**2. Model structure on marked cubical sets**

The goal of this section is to construct a combinatorial model category structure on the category $cSet'$ of marked cubical sets. One would like to do this by applying Cisinski theory, as described in Section 1, but unfortunately $cSet'$ is not a presheaf category. Although there exists a generalization of Cisinski theory to a non-topos case (due to Olschok [Ols09]), we choose to construct the model structure directly, using Jeff Smith’s Theorem 1.1 to obtain a better understanding of it as a result. It is also worth pointing out that our language (e.g., cellular model, cylinder functor) follows the conventions of Cisinski to make the analogy with the Cisinski machinery clear.

None of the arguments in this section rely on the existence of connections, thus they are valid in all of the categories of cubical sets shown in the diagram [†] at the end of Section 1.
2.1. Classes of maps. To begin, we lay out the definitions of the classes of maps that will comprise the model structure.

The cofibrations are the monomorphisms. The trivial fibrations are the maps with the right lifting property with respect to the cofibrations.

Using Lemma 1.32 one obtains:

Lemma 2.1. The cofibrations are the saturation of the set consisting of the boundary inclusions \( \partial \square^n \to \square^n \) for \( n \geq 0 \) and the inclusion \( \square^1 \to (\square^1)^\# \).

By Lemma 2.1 we have a cofibrantly generated weak factorization system (cofibrations, trivial fibrations).

Definition 2.2. We introduce three classes of maps in \( \text{cSet}' \).

(i) Let the marked open box inclusions \( i_{n,\epsilon} \) be the marked cubical set maps whose underlying cubical set maps are the open box inclusions \( \square^n \to \square^n \), with the critical edge marked in each (except for the domain of \( i_{1,\epsilon} \), i.e. \( \square^0 \), in which the critical edge is not present).

(ii) Let \( K \) be the cubical set depicted as:

\[
\begin{array}{c}
\bullet \\
\downarrow \\
\bullet \\
\end{array}
\]

Let \( K' \) be the marked cubical set that has the middle edge in the above marked. Define the saturation map to be the inclusion \( K \subseteq K' \).

(iii) For each of the four faces of the square, let the 3-out-of-4 map associated to that face be the inclusion of \( \square^2 \) with all but that face marked into \( (\square^2)^\# \).

The anodyne maps are defined as the saturation of the set of maps consisting of the marked open box inclusions, the saturation map, and the 3-out-of-4 maps. The naive fibrations are those maps that have the right lifting property against anodyne maps. Call an object \( X \) of \( \text{cSet}' \) a marked cubical quasicategory if the map \( X \to \square^0 \) is a naive fibration.

Remark 2.3. Viewing marked cubical quasicategories as \((\infty, 1)\)-categories, the marked edges represent equivalences. The generating anodyne maps have the following \((\infty, 1)\)-categorical meanings.

- The \( n \)-dimensional marked open box fillings for \( n \geq 2 \) correspond to composition of maps and homotopies, analogous to filling inner and special horns in quasicategories. They also ensure that every morphism presented by a marked edge has a left and right inverse, i.e., is an equivalence.
- The 1-dimensional marked open box fillings, \( i_{1,\epsilon} : \square^0 \to (\square^1)^\# \), are the inclusions of endpoints into the marked interval; thus marked edges may be lifted along naive fibrations, analogous to the lifting of isomorphisms along isofibrations in 1-category theory.
- The saturation map ensures that equivalences, maps having both left and right inverses, are marked.
The 3-out-of-4 maps represent the principle that if three maps in a commuting square are equivalences, then so is the fourth. They encode a condition analogous to the two-out-of-three property.

**Remark 2.4.** For $n \geq 1$, the representable marked cubical set $\Box^n$ is not a marked cubical quasi-category, as it lacks fillers for certain marked open boxes. This stands in contrast to the case of simplicial sets, in which the representables $\Delta^n$ are quasicategories.

**Lemma 2.5.** Let $X$ be a marked cubical quasicategory, and $x: \Box^1 \to X$ an edge of $X$. Then $x$ is marked if and only if it factors through the inclusion of the middle edge $\Box^1 \to K$.

**Proof.** The inclusions $K \to K'$ and $(\Box^1)^\sharp \to K'$ are both anodyne (the latter as a composite of marked open box fillings). The stated result thus follows from the fact that $X \to \Box^0$ has the right lifting property with respect to both of these maps. \hfill \square

**Lemma 2.6.** For a marked cubical set $X$ to be a marked cubical quasicategory, it suffices for the map $X \to \Box^0$ to have the right lifting property with respect to marked open box fillings and the saturation map.

**Proof.** Assume that $X$ has the right lifting property with respect to marked open box inclusions and the saturation map. The proof of Lemma 2.5 only requires lifting with respect to these maps, so the marked edges of $X$ are precisely those which factor through $K$.

To show that $X \to \Box^0$ lifts against the 3-out-of-4 maps, we must show that, if three sides of a 2-cube in $X$ are marked, then so is the fourth. Using the fact that the three marked sides factor through $K$, we can show that the fourth does as well by a simple exercise in filling three-dimensional marked open boxes. Hence the fourth edge is also marked. \hfill \square

**Remark 2.7.** In view of Lemma 2.6 it is natural to wonder whether omitting the 3-out-of-4 maps as generators would change the class of anodyne maps. To see that it would, observe that, using the small object argument, we can factor any three-out-of-four map as a composite of a map in the saturation of the marked open box fillings and two-out-of-six map, followed by a map having the right lifting property with respect to these maps. Examining the details of this construction, we can see that the second of these maps will not have the right lifting property with respect to the 3-out-of-4 maps. Thus the 3-out-of-4 maps are not in the saturation of the other two classes of generating anodynes.

One may further note that, without the 3-out-of-4 maps as generators, anodyne maps would not be closed under pushout product with cofibrations. This makes them crucial for our development.

**Definition 2.8.** Given a map $f: X \to Y$ of marked cubical sets, a naive fibrant replacement of $f$ consists of a diagram as depicted below, with $\overline{X}$ and $\overline{Y}$ marked cubical quasicategories, $i_X$ and $i_Y$ anodyne, and $\overline{f}$ a naive fibration.
We have a cofibrantly generated weak factorization system (anodyne maps, naive fibrations). This induces a functorial factorization of any map \( X \rightarrow Y \) as

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow_{\eta_f} & \searrow \& \downarrow_{\eta_Y} \\
Mf & \rightarrow & Qf \\
\end{array}
\]

where \( Q \) is an endofunctor on \((\text{cSet}')^\rightarrow\) sending objects to naive fibrations and \( \eta: \text{Id} \rightarrow Q \) is pointwise anodyne. Where \( f \) is the unique map \( X \rightarrow \square^0 \), we write \( \eta_X \) for \( \eta_f \).

Given \( f: X \rightarrow Y \), we can use this factorization to obtain a canonical naive fibrant replacement of \( f \):

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow_{\eta_{\text{pr} f}} & \searrow \& \downarrow_{\eta_Y} \\
X & \rightarrow & Q(\eta_f) \\
\end{array}
\]

We declare \( f \) to be a weak equivalence if \( Q(\eta_Y f) \) is a trivial fibration. A trivial cofibration is a map that is a cofibration and weak equivalence, and a fibration is a map that has the right lifting property against trivial cofibrations.

We now want to show that if \( Y \) is a marked cubical quasicategory, so is \( \text{hom}_L(X, Y) \). The following lemma on pushout-products helps with the proof of this fact.

**Lemma 2.9.** The pushout product of two cofibrations is a cofibration. Furthermore, the pushout product of an anodyne map and a cofibration is anodyne.

**Proof.** Since \( \otimes \) preserves colimits in each variable and anodynes are stable under pushouts and transfinite compositions, we can use induction on skeleta to show that if \( S \rightarrow T \) is one of the generating cofibrations (resp. anodynes), then \((S \rightarrow T) \otimes (\partial \square^n \rightarrow \square^n)\) and \((S \rightarrow T) \otimes (\square^1 \rightarrow (\square^1)^\triangleright)\) are cofibrations (resp. anodyne). This will show that if \( i \) and \( j \) are cofibrations, and \( i \) is anodyne, then \( i \otimes j \) is anodyne; the proof for the case where \( j \) is anodyne is entirely analogous.

Several cases can be taken care of by the following fact: If \( f: A \rightarrow B \) is an inclusion which is a bijection on vertices and \( p: X \rightarrow Y \) is an isomorphism of underlying cubical sets, then \( f \otimes p \) is an isomorphism. To see this, first observe that because the pushout product is an isomorphism of underlying cubical sets, we need only consider which edges are marked. That the sets of marked edges in \((A \otimes Y) \cup_{A \otimes X} (B \otimes X)\) and \( B \otimes Y \) coincide follows from Corollary \( \text{Lem} \) together with the fact that \( f \) is a bijection on vertices.

This claim, along with the fact that taking the pushout product with \( \varnothing \rightarrow \square^0 \) is the identity, handles all but the following pushout products:

- \((\partial \square^m \rightarrow \square^m) \otimes (\partial \square^n \rightarrow \square^n)\): this is the map \( \partial \square^{m+n} \rightarrow \square^{m+n} \). This completes the proof of the first statement, concerning the pushout product of two cofibrations; the remaining cases complete the second statement, concerning the pushout product of a cofibration and an anodyne map.

- \( s^m_{i,\varepsilon} \otimes (\partial \square^n \rightarrow \square^n)\): the underlying cubical set map is the open box inclusion \( i^{m+n} \rightarrow \square^{m+n} \), with edges in the codomain being marked if and only if they are present and marked in the
domain. The critical edge is marked, so this is anodyne as a pushout of a marked open box inclusion.

- \( \iota_{1,\varepsilon}^1 \otimes (\emptyset \Box^1 \to (\Box^1)^2) \): this is the 3-out-of-4 map associated to the face \((1,1-\varepsilon)\).

\[ \square \]

**Corollary 2.10.** If \( f: A \to B \) is a cofibration and \( g: X \to Y \) is a naive fibration, then the pullback exponential \( f \triangleright g: \text{hom}(A,Y) \to \text{hom}(A,X) \times_{\text{hom}(A,Y)} \text{hom}(B,Y) \) (where \( \text{hom} \) may designate either \( \text{hom}_L \) or \( \text{hom}_R \)) is a naive fibration. Furthermore, if \( f \) is anodyne or \( g \) is a trivial fibration, then \( f \triangleright g \) is a trivial fibration.

In particular, if \( Y \) is a marked cubical quasicategory, then for any \( X \), \( \text{hom}(X,Y) \) is a marked cubical quasicategory.

**Proof.** Let \( i: C \to D \) be anodyne; we wish to show that \( f \triangleright g \) has the right lifting property with respect to \( i \). By a standard duality, it suffices to show that \( g \) has the right lifting property with respect to \( \iota \circ f \). This map is anodyne by Lemma 2.9, so the first statement holds.

For the second statement, we can apply the same result with \( i \) an arbitrary cofibration. Then \( g \) has the right lifting property with respect to \( \iota \circ f \), either because \( f \), and hence also \( \iota \circ f \), are anodyne, or because \( \iota \circ f \) is a cofibration and \( g \) is a trivial fibration.

The third statement follows from the first by the fact that \( \text{hom}(X,Y) \to \Box^0 \) is the pullback exponential of the cofibration \( \emptyset \to X \) with the naive fibration \( \Box^0 \). \[ \square \]

### 2.2. Homotopies

Next we define the closely-related concepts of connected components in a marked cubical set, and homotopies of maps between cubical sets.

**Definition 2.11.** For a marked cubical set \( X \), let \( \sim_0 \) denote the relation on \( X_0 \), the set of vertices of \( X \), given by \( x \sim_0 y \) if there is a marked edge from \( x \) to \( y \) in \( X \). Let \( \sim \) denote the smallest equivalence relation on \( X_0 \) containing \( \sim_0 \).

**Remark 2.12.** For \( x,y \in X_0 \), one can easily see that \( x \sim y \) if and only if \( x \) and \( y \) are connected by a zigzag of marked edges.

**Definition 2.13.** For a marked cubical set \( X \), the set of connected components \( \pi_0(X) \) is \( X_0/\sim \).

We may observe that the construction of \( \pi_0(X) \) is functorial, since maps of marked cubical sets preserve marked edges, and hence preserve the equivalence relation \( \sim \).

**Definition 2.14.** An **elementary left homotopy** \( h: f \sim g \) between maps \( f,g: A \to B \) is a map \( h: (\Box^1)^2 \otimes A \to B \) such that \( h|_{\{0\} \otimes A} = f \) and \( h|_{\{1\} \otimes A} = g \). Note that the elementary left homotopy \( h \) corresponds to an edge \( (\Box^1)^2 \to \text{hom}_L(A,B) \) between the vertices corresponding to \( f \) and \( g \). A **left homotopy** between \( f \) and \( g \) is a zig-zag of elementary left homotopies.

A left homotopy from \( f \) to \( g \) corresponds to a zig-zag of marked edges in \( \text{hom}_L(A,B) \) and so maps from \( A \) to \( B \) are left homotopic exactly if \( \pi_0(f) = \pi_0(g) \), where the set of connected components is taken in \( \text{hom}_L(A,B) \). We write \([A,B]\) for the set of left homotopy classes of maps \( A \to B \).

These induce notions of **elementary left homotopy equivalence** and **left homotopy equivalence**. Each of these notions has a “right” variant using \( A \otimes (\Box^1)^2 \) and \( \text{hom}_R(A,B) \). Unless the potential for confusion arises or a statement depends on the choice, we will drop the use of “left” and “right”.
Lemma 2.15. In a marked cubical quasicategory $X$, the relations $\sim_0$ and $\sim$ conicide.

Proof. Using 2-dimensional open box fillers with certain edges degenerate, and the 3-out-of-4 property, we can reduce any zigzag of marked edges connecting $x$ and $y$ in $X$ to a single marked edge from $x$ to $y$. \hfill \Box

By adjointness, we obtain the following corollary.

Corollary 2.16. If $f, g : A \to B$ are homotopic and $B$ a marked cubical quasicategory, then $f$ and $g$ are elementarily homotopic. Hence, between marked cubical quasicategories homotopy equivalences coincide with elementary homotopy equivalences.

Proof. By Corollary 2.10, $\hom(A, B)$ is a marked cubical quasicategory, and so $\sim_0$ is an equivalence relation on $\hom(A, B)_0$ by Lemma 2.15. Translating what this means for homotopies gives the result. \hfill \Box

Lemma 2.17. If $f, g : X \to Y$ are left homotopic, then for any $Z$, then the induced maps $\hom_L(Y, Z) \to \hom_L(X, Z)$ are right homotopic.

Proof. We consider the case of elementary homotopies; the general result follows from this. An elementary left homotopy $f \sim g$ is given by a map $H : (\square^1)^f \otimes X \to Y$. Pre-composition with $H$ induces a map $\hom_L(Y, Z) \to \hom_L((\square^1)^f \otimes X, Z)$. Under the adjunction defining $\hom_L$, this corresponds to a map $\hom_L(Y, Z) \otimes (\square^1)^f \otimes X \to Z$, which in turn corresponds to a map $\hom_L(Y, Z) \otimes (\square^1)^f \to \hom_L(X, Z)$. It is easy to see that this map defines an elementary right homotopy between the pre-composition maps induced by $f$ and $g$. \hfill \Box

2.3. Category theory in a marked cubical quasicategory. Let $X$ be a marked cubical quasicategory and $x, y \in X_0$. We will write $X_1(x, y)$ for the subset of $X_1$ consisting of 1-cubes $f$ with $f\partial_1,0 = x$ and $f\partial_1,1 = y$. Define an equivalence relation relation $\sim_X$ on the set $X_1(x, y)$ of edges from $x$ to $y$ as follows: $f \sim_X g$ if and only if there is a 2-cube in $X$ of the form

\[
\begin{array}{ccc}
x & \overset{f}{\to} & y \\
\downarrow & & \downarrow \\
x & \overset{g}{\to} & y
\end{array}
\]

It is straightforward to verify that this is indeed an equivalence relation: reflexivity follows from degeneracies, whereas symmetry and transitivity are given by filling 3-dimensional open boxes.

We now define three increasingly strong refinements of the concept of a homotopy equivalence.

Definition 2.18. Let $f : X \to Y$ be a map in $\cSet$. Then:

- $f$ is a semi-adjoint equivalence if there exist $g : Y \to X$ and homotopies $H : gf \sim \id_X$, $K : fg \sim \id_Y$ such that $fH \sim Kf$ as edges of $\hom(X, Y)$;
- $f$ is a strong homotopy equivalence if there exist $g, H, K$ as above with $fH = Kf$;
- a map $g : Y \to X$ is a strong deformation section of $f$ if $fg = \id_Y$ and there exists a homotopy $H : gf \sim \id_X$ such that $fH = \id_f$. 
Our next goal will be two show the following:

**Lemma 2.19.** Let \( f : X \to Y \) be a map of marked cubical quasicategories. The following are equivalent:

(i) \( f \) is a homotopy equivalence;

(ii) \( f \) is a semi-adjoint equivalence.

Furthermore, if \( f \) is a naive fibration, then these are equivalent to:

(iii) \( f \) is a strong homotopy equivalence.

We will prove this by means of a 2-categorical argument.

We define the *homotopy category* \( \Ho X \) of a marked cubical quasicategory \( X \) as follows:

- the objects of \( \Ho X \) are the 0-cubes of \( X \);
- the morphisms from \( x \) to \( y \) in \( \Ho X \) are the equivalence classes of edges \( X_1(x, y)/\sim_X \);
- the identity map on \( x \in X_0 \) is given by \( x\sigma_1 \);
- the composition of \( f : x \to y \) and \( g : y \to z \) is given by filling the open box

\[
\begin{array}{c}
\xymatrix{ x \ar[r]^{gf} & y \\
\downarrow^f & \downarrow^g \\
x \ar[r]^g & z }
\end{array}
\]

Using standard arguments about open box fillings, one verifies the following lemma.

**Lemma 2.20.** The above data define a category. \( \square \)

**Lemma 2.21.** Let \( X \) be a marked cubical quasicategory. There is a 2-cube of the form

\[
\begin{array}{c}
\xymatrix{ x \ar[r]^f & y \\
p \ar[ur]^f & g \\
z \ar[r]^g & w }
\end{array}
\]

if and only if \( gf = qp \) in \( \Ho X \).

**Proof.** Consider the following 3-cube:
The equality $gf = qp$ in $\text{Ho} X$ is equivalent to the existence of a filler for the back face of this cube, using the fact that composition in $\text{Ho} X$ is well-defined. Thus we want to show that there is a filler for the top face if and only if there is a filler for the left face. If we assume that either of these 2-cubes exists, then together with the remaining faces of the cube depicted above, it forms a marked open box in $X$, with critical edge $w\sigma_1$. Thus we can fill this open box to obtain a filler for the missing face. □

Remark 2.22. The above argument makes use of positive connections, as two of the faces of the 3-cube used in its proof are positive connections of 1-cubes. However, it can still be adapted to the categories $\text{cSet}_0$ and $\text{cSet}_1$. A simple argument involving filling of 3-dimensional open boxes shows that 1-cubes of cubical quasicategories in these categories admit positive connections, in the sense that for any 1-cube $x$ in such a cubical set, there exists a 2-cube $x_{\gamma_1,0}$ having the faces specified by the cubical identities, though in general this cube will be non-degenerate.

Lemma 2.23. Let $X$ be the underlying cubical set of a marked cubical quasicategory $X'$. The categories $\text{Ho} X'$ and $\tau_1 X$ are equivalent.

Proof. There is a natural inclusion $\text{Ho} X' \to \tau_1 X$, which is the identity on objects and takes a 1-cube $f$ to a string of length 1 consisting of $f$. This is clearly faithful and essentially surjective. To see that it is full, we simply fill in 2-dimensional open boxes with one degenerate edge to reduce a sequence of arbitrary length to a sequence of length 1. □

The assignment $X \mapsto \text{Ho} X$ extends in a straightforward manner to a functor taking a marked cubical quasicategory to its homotopy category. Postcomposing this functor with $\text{core} : \text{Cat} \to \text{Gpd}$, we obtain a groupoid $\text{Ho}^2 X$.

Lemma 2.24. The groupoid $\text{Ho}^2 X$ can be constructed directly as follows:

- Objects are 0-cubes of $X$;
- Morphisms from $x$ to $y$ are equivalence classes of marked edges from $x$ to $y$;
- Composition and identities are defined as in $\text{Ho} X$. 
Proof. Let $X$ be a marked cubical quasicategory. It is easy to see that an edge $f : \Box^1 \to X$ is invertible in $\text{Ho}X$ if and only if it factors through the map $\Box^1 \to K$ which picks out the middle edge. Since the inclusions $(\Box^1)^2 \to K'$ and $K \to K'$ are anodyne, this holds if and only if $f$ is marked. □

Definition 2.25. Define a strict 2-category $\text{Ho}_2\text{cSet}'$ whose objects are the marked cubical quasi-categories and whose mapping category from $X$ to $Y$ is

$$\text{Ho}_2\text{cSet}'(X,Y) := \text{Ho}\text{hom}_L(X,Y).$$

This means the 1-morphisms are the usual 1-morphisms $X \to Y$, and the 2-morphisms are maps $X \otimes \Box^1 \to Y$, modulo an equivalence relation. Denote the (vertical) composition in $\text{Ho}\text{hom}_L(X,Y)$ with $\circ$. The (horizontal) composition $\text{Ho}\text{hom}_L(Y,Z) \times \text{Ho}\text{hom}_L(X,Y) \to \text{Ho}\text{hom}_L(X,Z)$ (which will be written by concatenation) is defined on objects by the usual composition. If $H : Y \otimes \Box^1 \to Z$ and $K : X \otimes \Box^1 \to Y$ are morphisms $K : g \to g'$ and $H : f \to f'$, respectively, define the morphism $KH : gf \to g'f'$ by choosing a fill for the open box of $\text{hom}_L(X,Z)$ depicted by

$$\begin{array}{c}
gf \xrightarrow{KF} g'f' \\
gf \xrightarrow{KH} g'H \\
g'H \xrightarrow{g'f'}
\end{array}$$

where the top edge is induced by the composite $X \otimes \Box^1 \to Y \otimes \Box^1 \to Z$ and the right edge by $X \otimes \Box^1 \to Y \to Z$. The fact that the $\text{hom}_L(X,Y)$ are marked cubical quasicategories ensures this defines a well-defined, associative, unital, and functorial operation. For functoriality, note that the morphism $X \otimes \Box^1 \otimes \Box^1 H \otimes \Box^1 Y \otimes \Box^1 K \to Z$ yields a 2-cube $\Box^2 \to \text{hom}_L(X,Z)$ which can be depicted as

$$\begin{array}{c}
gf \xrightarrow{KF} g'f' \\
g'H \xrightarrow{g'f'}
\end{array}$$

and so by Lemma 2.21 we have $(g'H) \circ (KF) = (KF') \circ (gH)$, which implies the interchange law.

Definition 2.26. Let $\text{Ho}_2^{\Box}\text{Set}'$ denote the maximal $(2,1)$-category contained in $\text{Ho}_2\text{cSet}'$, i.e. the 2-category whose objects are marked cubical sets, with $\text{Ho}_2^{\Box}\text{Set}'(X,Y) = \text{Ho}^{\Box}\text{hom}_L(X,Y)$, and the 2-categorical operations induced by those of $\text{Ho}_2\text{cSet}'$.

The $\text{Ho}^\Box$ construction, together with the following general results about $(2,1)$-categories, give us the desired result about compatibility of homotopies.

Lemma 2.27 (Undergraduate Lemma). Let $X$ be an object in a $(2,1)$-category $C$, and let $H : p \sim id_X$ be a morphism in $C(X,X)$. Then $pH = Hp$.

Proof. By the interchange law,

$$H \circ (pH) = (Hid_X) \circ (pH) = (id_XH) \circ (Hp) = H \circ (Hp).$$
Since \( \mathcal{C}(X, X) \) is a groupoid, we can cancel \( H \). 

**Lemma 2.28** (Graduate Lemma). Let \( X, Y \) be objects in a \((2,1)\)-category \( \mathcal{C} \), \( f : X \Rightarrow Y : g \) two morphisms between them, and \( H : gf \Rightarrow id_Y \) and \( K : fg \Rightarrow id_X \) two cells. Then there is a 2-cell \( K' : fg \Rightarrow id_Y \) for which \( K'f = fH \).

**Proof.** Define \( K' := K \circ (fHg) \circ (Kfg)^{-1} \). Now, we compute:

\[
K'f = Kf \circ (fHgf) \circ (Kfg)^{-1} = fH (by \text{ Lemma } 2.27)
\]

(by naturality/interchange)

\( \square \)

**Proof of Lemma 2.19.** The implications \((iii) \Rightarrow (ii) \Rightarrow (i)\) are clear. The implication \((i) \Rightarrow (ii)\) follows from applying Lemma 2.28 to the \((2,1)\)-category \( \text{Ho}^\sharp_{\text{cSet}} \).

Now let \( f \) be a naive fibration and a semi-adjoint equivalence. By Corollary 2.10 the map \( \text{hom}(X, X) \rightarrow \text{hom}(X, Y) \) is a naive fibration. A simple exercise in 2-dimensional marked open box filling, using this fact and the definition of a semi-adjoint equivalence, shows that there exists a homotopy \( H' : gf \Rightarrow id_X \) such that \( fH' = Kf \). \( \square \)

### 2.4. Fibration category of marked cubical quasicategories.

**Lemma 2.29.** Every anodyne map between marked cubical quasicategories is a homotopy equivalence.

**Proof.** Now let \( f : X \rightarrow Y \) be anodyne, with \( X \) and \( Y \) marked cubical quasicategories. We can obtain a retraction \( r : Y \rightarrow X \) as a lift in the following diagram:

\[
\begin{array}{ccc}
X & \xrightarrow{f} & X \\
\downarrow & & \downarrow \\
Y & \xrightarrow{\delta} & \Box^0
\end{array}
\]

We can then obtain a left homotopy \( fr \Rightarrow id_Y \) as a lift in the following diagram:

\[
\begin{array}{ccc}
(\partial \Box^1 \otimes Y) & \cup & (\Box^1)^{\sharp} \otimes X \\
\downarrow & \Rightarrow & \downarrow \\
(\Box^1)^{\sharp} \otimes Y & \xrightarrow{[fr, id_Y, f_{=1}]} & Y \\
\end{array}
\]

The lift exists since the left-hand map is anodyne by Lemma 2.9.

An analogous proof shows that \( f \) is a right homotopy equivalence. \( \square \)

**Lemma 2.30.** Let \( f : X \rightarrow Y \) be a naive fibration. The following are equivalent:

(i) \( f \) is a trivial fibration;
(ii) \( f \) has a strong deformation section;
(iii) \( f \) is a strong homotopy equivalence.

Proof. If \( f : X \to Y \) is a trivial fibration, then we can obtain a section \( g : Y \to X \) as a lift of the following diagram:

\[
\begin{array}{ccc}
\emptyset & \longrightarrow & X \\
| & & | \\
Y & \longrightarrow & Y \\
\end{array}
\]

We can then obtain a left homotopy \( H : gf \sim \text{id}_X \) satisfying \( fH = \text{id}_f \) as a lift in the following diagram:

\[
\begin{array}{ccc}
X \sqcup X & \longrightarrow & X \\
\downarrow & & \downarrow f \\
(\square^1)^\sharp \otimes X & \longrightarrow & Y \\
\end{array}
\]

This shows \((i) \Rightarrow (ii)\) and the implication \((ii) \Rightarrow (iii)\) is trivial. To show that \((iii) \Rightarrow (i)\) we first show that \((iii)\) implies the following condition:

\((iii)'\) the canonical map \( i_{1,0} \circ f \to f \) in \((\text{cSet'})^\rightarrow\) admits a section.

To see \((iii) \Rightarrow (iii)'\), suppose \( f \) is a strong homotopy equivalence with homotopy inverse \( g : Y \to X \) and homotopies \( H : gf \sim \text{id}_X, K : fg \sim \text{id}_Y \) satisfying \( fH = Kf \). Then we have the following commuting diagram in \( \text{cSet}' \):

\[
\begin{array}{ccc}
X & \longrightarrow & \text{hom}(\square^1)^\sharp, X \\
\downarrow f & & \downarrow f \\
Y & \longrightarrow & X \times_Y \text{hom}(\square^1)^\sharp, Y \\
\end{array}
\]

The top-left map is the adjunct of \( H \), while the bottom-left map is induced by \( g \) and the adjunct of \( K \); the right-hand square is as in the statement of \((iii)'\). It is easy to see that the composite square is simply the identity square on \( f \).

Finally, note that \( i_{1,1} \circ f \) is a trivial fibration by Corollary 2.10. Therefore, if the square given in the statement of \((iii)'\) has a section, then \( f \) is a trivial fibration as a retract of a trivial fibration. Thus \((iii)' \Rightarrow (i)\).

Corollary 2.31. A map \( f : X \to Y \) between marked cubical quasicategories is a trivial fibration exactly if it is a homotopy equivalence and a naive fibration.

Proof. This follows from Lemmas 2.19 and 2.30 together with the fact that every trivial fibration is a naive fibration since all anodyne maps are cofibrations.

Proposition 2.32. The category of marked cubical quasicategories forms a fibration category, with naive fibrations as the fibrations and homotopy equivalences as the weak equivalences.
Proof. The class of homotopy equivalences is closed under 2-out-of-3. Corollary 2.31 shows that the maps between marked cubical quasicategories which are naive fibrations and homotopy equivalences are exactly the trivial fibrations; both fibrations and trivial fibrations are defined via a right lifting property, and hence they are stable under pullback. By Lemma 2.29 each anodyne map between marked cubical quasicategories is a homotopy equivalence, and so the (anodyne, naive fibration)-factorization gives the factorization axiom. □

Lemma 2.33. Let \( f : X \to Y \) be a map between marked cubical quasicategories. Then the following conditions are equivalent:

- (i) \( f \) is a weak equivalence;
- (ii) \( f \) is a left homotopy equivalence;
- (iii) \( f \) is a right homotopy equivalence.

Proof. Consider the canonical naive fibrant replacement of \( f \) used in the definition of the weak equivalences:

\[
\begin{array}{ccc}
X & \xrightarrow{f} & Y \\
\downarrow{\iota_X} & & \downarrow{\iota_Y} \\
X & \xrightarrow{\mathcal{F}} & Y
\end{array}
\]

(here \( \iota_Y = \eta_Y, \mathcal{F} = Q(\eta_Y f), \iota_X = \eta_Y f \)).

By Lemma 2.29 \( \iota_X \) and \( \iota_Y \) are left homotopy equivalences. It is easy to show that left homotopy equivalences satisfy the two-out-of-three property, so \( f \) is a left homotopy equivalence if and only if \( \mathcal{F} \) is one. By Corollary 2.31 \( \mathcal{F} \) is a left homotopy equivalence if and only if it is a trivial fibration, i.e. if and only if \( f \) is a weak equivalence. So \( (i) \Leftrightarrow (ii) \) an analogous argument shows \( (i) \Leftrightarrow (iii) \). □

2.5. Cofibration category of marked cubical sets. Our next result shows that the definition of the weak equivalences is not sensitive to the choice of naive fibrant replacement.

Lemma 2.34. Let \( f : X \to Y \) be a map of marked cubical sets. The following are equivalent:

- (i) \( f \) is a weak equivalence.
- (ii) there exists a naive fibrant replacement of \( f \) by a trivial fibration;
- (iii) any naive fibrant replacement of \( f \) is a trivial fibration.

Proof. The implications \( (i) \Rightarrow (ii) \) and \( (iii) \Rightarrow (i) \) are immediate from the definition of the weak equivalences. To prove \( (ii) \Rightarrow (iii) \) consider a map \( f : X \to Y \) having a naive fibrant replacement by a trivial fibration \( \mathcal{F} : X' \to Y' \), and an arbitrary naive fibrant replacement \( \mathcal{F}' : X' \to Y' \) of \( f \). As depicted below, let \( \mathcal{F}' : X' \to Y' \) be a naive fibrant replacement of the induced map between the pushouts \( X \cup_X X' \to Y \cup_Y Y' \).
The maps $\overline{X} \to \overline{X}'$, $\overline{Y} \to \overline{Y}'$, $\overline{X}' \to \overline{X}''$, $\overline{Y}' \to \overline{Y}''$ are anodyne, as anodyne maps are closed under pushout and composition. Furthermore, $\overline{f}$ is a trivial fibration by assumption. Thus all of these maps are homotopy equivalences by Lemma 2.29 and Corollary 2.31. So we can apply the two-out-of-three property to see that $\overline{f}'$ is a homotopy equivalence; applying it again, we see that $\overline{f}$ is a homotopy equivalence. Thus $\overline{f}$ is a trivial fibration by Corollary 2.31. Since $\overline{f}$ was arbitrary, we have shown that $f$ satisfies (iii). □

**Corollary 2.35.** Every anodyne map is a weak equivalence.

**Proof.** Let $f : X \to Y$ be anodyne. The following diagram gives a naive fibrant replacement of $f$:

$$
\begin{array}{c}
X \\
\downarrow f \\
Y \\
\end{array}
\quad
\begin{array}{c}
\eta_Y f \\
\eta_Y Y \\
\end{array}
$$

Since $\text{id}_{\overline{Y}}$ is a trivial fibration, $f$ is a weak equivalence by Lemma 2.34. □

**Proposition 2.36.** The following are equivalent for a marked cubical map $A \to B$:

(i) $A \to B$ is a weak equivalence;

(ii) for any marked cubical quasicategory $X$, the induced map $\text{hom}(B, X) \to \text{hom}(A, X)$ is a homotopy equivalence;

(iii) for any marked cubical quasicategory $X$, the induced map $\pi_0(\text{hom}(B, X)) \to \pi_0(\text{hom}(A, X))$ is a bijection.

**Proof.** First, suppose that $A \to B$ is a weak equivalence. Thus, there is a square

$$
\begin{array}{c}
A \\
\downarrow \quad \downarrow \\
\overline{A} \\
\end{array}
\quad
\begin{array}{c}
B \\
\end{array}
$$

with $A \to \overline{A}$ and $B \to \overline{B}$ anodyne, and $\overline{A} \to \overline{B}$ a trivial fibration. By Corollary 2.31 $\overline{A} \to \overline{B}$ is a left homotopy equivalence.
Applying $\text{hom}_L(-, X)$ to the diagram above, we obtain a diagram in which all objects are marked cubical quasicategories by Corollary 2.10:

$$\text{hom}_L(A, X) \leftarrow \text{hom}_L(B, X) \leftarrow \text{hom}_L(A, X) \leftarrow \text{hom}_L(B, X)$$

The vertical maps are trivial fibrations by Corollary 2.10 hence homotopy equivalences by Corollary 2.31. By Lemma 2.17 the bottom horizontal map is a right homotopy equivalence, since $\overline{A} \to \overline{B}$ is a left homotopy equivalence. Hence so is the upper horizontal map by 2-out-of-3. Thus we have proven $(i) \Rightarrow (ii)$.

The implication $(ii) \Rightarrow (iii)$ is clear, so it remains to show $(iii) \Rightarrow (i)$. For that, we first observe that it suffices to consider $A$ and $B$ marked cubical quasicategories. To see this, consider the canonical naive fibrant replacement $f: \overline{A} \to \overline{B}$ of a map $f: A \to B$. By definition, $f$ is a weak equivalence if and only if $\overline{f}$ is a trivial fibration; by Corollary 2.31 and Lemma 2.33 this holds if and only if $\overline{f}$ is a weak equivalence. Furthermore, the anodyne maps $\iota_X, \iota_Y$ are weak equivalences by Corollary 2.35 and therefore satisfy $(iii)$ hence $f$ satisfies $(iii)$ if and only if $\overline{f}$ does, by the 2-out-of-3 property for bijections.

Hence we can assume $A$ and $B$ are marked cubical quasicategories. Now take $X := A$ and set $g := (\pi_0 f^*)^{-1}[\text{id}_A]$. The verification that a representative of the class $g \in \pi_0 \text{hom}_L(B, A)$ defines a homotopy inverse of $f$ is straightforward; thus $f$ is a weak equivalence by Lemma 2.33. □

Corollary 2.37. The weak equivalences satisfy the 2-out-of-6 property (and hence the 2-out-of-3 property).

Proof. This is immediate from condition $(iii)$ of Proposition 2.36. □

Corollary 2.38. The endpoint inclusions $\square^0 \to K$ are trivial cofibrations.

Proof. The maps in question are clearly cofibrations. To see that they are weak equivalences, consider the following commuting diagram:

$$\square^0 \longrightarrow K \quad \downarrow \quad \square^0$$

The left, right, and bottom maps are anodyne, hence weak equivalences by Corollary 2.35. Thus the top map is a weak equivalence by Corollary 2.37. □

Lemma 2.39. Trivial fibrations are weak equivalences.

Proof. If $A \to B$ is a trivial fibration, then it is a homotopy equivalence by Corollary 2.31. Hence $\text{hom}(B, X) \to \text{hom}(A, X)$ is a homotopy equivalence for all marked cubical quasicategories $X$ by Lemma 2.17 and hence $A \to B$ a weak equivalence by Proposition 2.36. □

Proposition 2.40. The category of marked cubical sets forms a cofibration category with the above classes of weak equivalences and cofibrations.
Proof. The class of weak equivalences is closed under 2-out-of-3 by Corollary 2.37. The category clearly has an initial object and pushouts. Cofibrations are the left class in a weak factorization system, hence stable under pushout. Using the characterization of weak equivalences given by item (ii) of Proposition 2.36, stability of cofibrations that are weak equivalences under pushout reduces to stability of trivial fibrations under pullback. By Lemma 2.39, trivial fibrations are weak equivalences, so the (cofibration, trivial fibration)-factorization gives the factorization axiom. □

2.6. Model structure for marked cubical quasicategories.

Definition 2.41. A marked cubical set is finite (resp. countable) if it has only finitely (resp. countably) many non-degenerate cubes. The cardinality of a finite marked cubical set is its total number of non-degenerate cubes, in all dimensions.

Lemma 2.42. The trivial fibrations form an $\omega_1$-accessible, $\omega_1$-accessibly embedded subcategory of $(cSet') \rightarrow$.

Proof. It suffices to show two things: that filtered colimits (and hence in particular $\omega_1$-filtered colimits) in $cSet'$ preserve trivial fibrations, and that any trivial fibration can be expressed as an $\omega_1$-filtered colimit of trivial fibrations between countable marked cubical sets. The first statement follows from the fact that the domains and codomains of the generating cofibrations are finite.

For the second statement, consider a trivial fibration $f: X \rightarrow Y$. Let $P$ denote the poset of countable subcomplexes of $X$; note that we consider edges of subcomplexes of $X$ to be marked if and only if they are marked in $X$. This category is $\omega_1$-filtered since any countable union of countable subcomplexes is countable.

Let $i$ denote the inclusion $P \hookrightarrow cSet'$; the colimit of this diagram is $X$. The images under $f$ of the countable subcomplexes of $X$, with the natural inclusions, also define a diagram $f_i: P \rightarrow cSet'$. One can easily show that trivial fibrations are surjective on underlying cubical sets; thus every cube of $Y$ appears in $fS$ for some countable subcomplex $S \subseteq X$. So $f_i$ is a filtered diagram of subcomplexes of $Y$, in which the maps are inclusions and each cube of $Y$ is contained in some object of the diagram, with every marked edge of $Y$ being marked in some subcomplex in the diagram. From this, one can show that the colimit of $f_i$ is $Y$. The map $f$ induces a natural transformation from $i$ to $f_i$, whose induced map on the colimits is $f$ itself.

However, it may not be the case that for every component of this natural transformation is a trivial fibration. Thus we will replace $i$ by a different diagram, still having colimit $X$, with a natural transformation to $f_i$ which does satisfy this property. For each countable subcomplex $S \subseteq X$, we will define a new countable subcomplex $\overline{S} \subseteq X$, such that $f\overline{S} = fS$, $f|_{\overline{S}}: \overline{S} \rightarrow f\overline{S}$ is a trivial fibration, and for $S' \subseteq S$, we have $\overline{S'} \subseteq \overline{S}$.

We first define $\overline{S}$ for finite $S$, proceeding by induction on cardinality. For $S = \emptyset$, we can simply set $\overline{S} = \emptyset$. Now assume that we have defined $\overline{S}$ for $|S| \leq m$, and consider a subcomplex $S$ of cardinality $m + 1$. We will inductively define a family of subcomplexes $\overline{S^i}$ for $i \geq 0$, each countable and satisfying $f\overline{S^i} = fS$. Begin by setting $\overline{S^0} = S \cup \bigcup_{S' \subseteq S} \overline{S'}$. Then $\overline{S^0}$ is countable, $f\overline{S^0} = fS$, and for $S' \subseteq S$ we have $\overline{S'} \subseteq \overline{S^0}$.
Now assume that we have defined $S_i$ for some $i \geq 0$, and let $D$ be the set of all diagrams $D$ of the form:

$$
\begin{array}{c}
\partial \Box^n \rightarrow \Box^n \\
\downarrow \\
\Box^n \rightarrow fS
\end{array}
$$

Because $S^i$ and $fS$ are countable, while $\partial \Box^n$ and $\Box^n$ are finite for any given $n$, there are countably many such diagrams. Because $f$ is a trivial fibration, for each such diagram we may choose a filler in $X$, i.e. an $n$-cube $x_D: \Box^n \rightarrow X$ whose boundary is $\partial x_D$, such that $fx_D = y_D$. Let $S^i+1 = S^i \cup \bigcup_{D \in D} \{x_D\}$. Then $S^i+1$ is still countable, since we have added at most countably many cubes to $S^i$, and its image under $f$ is still $fS$, since each $x_D$ was chosen to map to a specific $y_D \in fS$.

Now let $S = \bigcup_{i \geq 0} S^i$. This is countable, its image is $fS$, and for any $S' \subseteq S$ we have $\overline{S'} \subseteq \overline{S}$. Now consider a diagram:

$$
\begin{array}{c}
\partial \Box^n \rightarrow \Box^n \\
\downarrow \\
\Box^n \rightarrow fS
\end{array}
$$

Because $\Box^n$ is finite, the image of $\partial x$ is contained in some finite subcomplex of $\overline{S}$, hence in some $\overline{S^i}$, so it has a filler in $\overline{S}^i+1$ which maps to $y$. Furthermore, $f|_{\overline{S}}$ has the right lifting property with respect to the map $\Box^1 \rightarrow (\Box^1)^\sharp$, i.e. an edge $x: \Box^1 \rightarrow \overline{S}$ is marked if and only if $fx$ is marked, since this is true of edges in $X$. Thus $f|_{\overline{S}}: \overline{S} \rightarrow fS$ is a trivial fibration.

For a countably infinite $S \subseteq X$ we let $\overline{S} = \bigcup \overline{S^i}$, where the union is taken over all finite subcomplexes $S' \subseteq S$. Then $f|_{\overline{S}}$ is the filtered colimit of the trivial fibrations $f|_{\overline{S'}}$, hence it is a trivial fibration.

The subcomplexes $\overline{S}$ with the natural inclusions define a diagram $\overline{t}: P \rightarrow \text{cSet}',$ and $f$ induces a natural trivial fibration $\overline{t} \Rightarrow fi$. Observe that $\overline{t}$ is a filtered diagram of subcomplexes of $X$, in which the maps are inclusions and edges in the objects are marked if and only if they are marked in $X$; furthermore, every cube of $X$ is contained in some finite subcomplex $S$, and hence in $\overline{S}$. From this we can deduce that the colimit of $\overline{t}$ is $X$, by the same argument we used to show that the colimit of $fi$ is $Y$. The induced map between colimits is $f$; thus we have expressed $f$ as an $\omega_1$-filtered colimit of trivial fibrations between countable marked cubical sets.

**Lemma 2.43.** The weak equivalences form an $\omega_1$-accessible, $\omega_1$-accessibly embedded subcategory of $(\text{cSet}')^\rightarrow$.

**Proof.** The (anodyne, naive fibration) factorization gives us a naive fibrant replacement functor $F: (\text{cSet}')^\rightarrow \rightarrow (\text{cSet}')^\rightarrow$. By [Joy09, Prop. D.2.10], this functor is $\omega_1$-accessible, since the domains and codomains of the generating anodyne maps are all countable. By definition, the category of weak equivalences $\mathcal{E}$ is given by the following pullback in $\text{Cat}$:
By Lemma 2.42, \( \text{tfib} \) is an \( \omega_1 \)-accessible category, and its embedding into \( \text{(cSet')} \) is an \( \omega_1 \)-accessible functor. By [MP89, Thm. 5.1.6], the category of \( \omega_1 \)-accessible categories and \( \omega_1 \)-accessible functors has finite limits, and these are computed in \( \text{Cat} \). Thus we is \( \omega_1 \)-accessible, and its embedding into \( \text{(cSet')} \) is an \( \omega_1 \)-accessible functor. □

**Theorem 2.44** (Analogue of model structure on marked simplicial sets). The above classes of weak equivalences, cofibrations, and fibrations define a model structure on \( \text{cSet}' \).

**Proof.** We verify the assumptions of Theorem 1.1.

The category of marked cubical sets is locally finitely presentable. Weak equivalences are an \( \omega_1 \)-accessibly embedded, \( \omega_1 \)-accessible subcategory of \( \text{(cSet')} \) by Lemma 2.43. Cofibrations have a small set of generators by Lemma 2.1.

Weak equivalences are closed under \( 2 \)-out-of-3 and weak equivalences that are cofibrations are closed under pushout by Proposition 2.40. Weak equivalences are closed under transfinite composition by Lemma 2.43, implying that the same holds for trivial cofibrations. Every map lifting against cofibrations is a weak equivalence by Lemma 2.39. □

We refer to the model structure constructed above as the **cubical marked model structure**. We will now analyze this model structure, beginning with a strengthening of Lemma 2.9 and Corollary 2.10.

**Lemma 2.45.** If \( X \to Y \) is a weak equivalence, then so is \( A \otimes X \to A \otimes Y \) for any \( A \in \text{cSet}' \).

**Proof.** By the adjunction \( A \otimes - \dashv \text{hom}_R(A, -) \), for \( Z \in \text{cSet}' \) we have a natural isomorphism \( \text{hom}_R(A \otimes X, Z) \cong \text{hom}_R(X, \text{hom}_R(A, Z)) \). Let \( Z \) be a marked cubical quasicategory; then we have a commuting diagram

\[
\begin{array}{ccc}
\text{hom}_R(A \otimes Y, Z) & \xrightarrow{\cong} & \text{hom}_R(A \otimes X, Z) \\
\downarrow & & \downarrow \\
\text{hom}_R(Y, \text{hom}_R(A, Z)) & \xrightarrow{\cong} & \text{hom}_R(X, \text{hom}_R(A, Z))
\end{array}
\]

By Corollary 2.10, \( \text{hom}_R(A, Z) \) is a marked cubical quasicategory, so the bottom map is a homotopy equivalence by Proposition 2.36. Hence the top map is a homotopy equivalence; thus we see that \( A \otimes X \to A \otimes Y \) is a weak equivalence by Proposition 2.36. □

**Lemma 2.46.** The pushout product of a cofibration and a weak equivalence is a weak equivalence.

**Proof.** Let \( i: A \to B \) be a cofibration and \( f: X \to Y \) a weak equivalence; we will show that \( i \otimes f \) is a weak equivalence (the case of \( f \otimes i \) is similar). Consider the diagram which defines \( i \otimes f \):
The maps $A \otimes X \to A \otimes Y$ and $B \otimes X \to B \otimes Y$ are weak equivalences by Lemma 2.45. The map $A \otimes X \to B \otimes X$ is a cofibration by Lemma 2.9. The model structure is left proper, since all objects are cofibrant; thus the map from $B \otimes X$ into the pushout is a weak equivalence. Hence $i \hat{\otimes} f$ is a weak equivalence by 2-out-of-3.

**Corollary 2.47.** Let $i: A \to B, j: A' \to B'$ be cofibrations. If either $i$ or $j$ is trivial, then so is the pushout product $i \hat{\otimes} j$.

*Proof. This is immediate from Lemmas 2.9 and 2.10.*

**Corollary 2.48.** If $i$ is a cofibration and $f$ is a fibration, then the pullback exponential $i \triangleright f$ is a fibration, which is trivial if $i$ or $f$ is trivial.

**Corollary 2.49.** The category $cSet'$, equipped with the cubical marked model structure and the geometric product, is a monoidal model category.

Next we will characterize the fibrant objects, and fibrations between fibrant objects, of this model structure.

**Proposition 2.50.** A map between marked cubical quasicategories is a fibration if and only if it is a naive fibration. In particular, the fibrant objects of the cubical marked model structure are precisely the marked cubical quasicategories.

*Proof. It is clear that every fibration is a naive fibration. Now let $f: X \to Y$ be a naive fibration between marked cubical quasicategories, and $i: A \to B$ a trivial cofibration. We wish to show that $f$ has the right lifting property with respect to $i$; for this it suffices to show that $i \triangleright f$ has the right lifting property with respect to the map $\emptyset \to \Box^0$. For this, in turn, it suffices to show that $i \triangleright f$ is a trivial fibration.

First, note that $i \triangleright f$ is a naive fibration between marked cubical quasicategories by Corollary 2.10. Therefore, by Corollary 2.31 it is a trivial fibration if and only if it is a homotopy equivalence. Now consider the diagram which defines $i \triangleright f$: \[ \begin{array}{c}
\text{hom}(B, X) \\
\downarrow \text{hom}(A, X) \times_{\text{hom}(A, Y)} \text{hom}(B, Y) \\
\downarrow \\
\text{hom}(B, Y) \\
\end{array} \]
The maps \( \text{hom}(B, X) \to \text{hom}(A, X) \) and \( \text{hom}(B, Y) \to \text{hom}(A, Y) \) are trivial fibrations by Corollary 2.48, the map from the pullback to \( \text{hom}(A, X) \) is a trivial fibration as a pullback of a trivial fibration. Thus \( i \triangleright f \) is a weak equivalence by 2-out-of-3, hence a homotopy equivalence by Lemma 2.33.

**Proposition 2.51.** The adjunctions \((-)\text{co} \dashv (-)\text{co} \), \((-)\text{co-op} \dashv (-)\text{co-op} \) are Quillen self-equivalences of \( \text{cSet}' \).

**Proof.** By Corollary 1.15 it suffices to show that the adjunctions are Quillen. To do this, we apply Corollary 1.12. It is clear that both \((-)\text{co} \) and \((-)\text{co-op} \) preserve cofibrations. Now we consider the images of the generating anodyne maps under these functors. It is easy to see that both functors preserve marked open box inclusions and three-out-of-four maps; thus it remains to consider only the saturation map.

The image of the saturation map under \((-)\text{co-op} \) is isomorphic to the saturation map itself, and is therefore a trivial cofibration. Now consider the map \( K^{\text{co}} \to (K')^{\text{co}} \). To show that this is a trivial cofibration, it suffices to show that it has the left lifting property with respect to fibrations between marked cubical quasicategories. If \( X \) is a marked cubical quasicategory, then \( K^{\text{co}} \to (K')^{\text{co}} \) has the left lifting property against \( X \to \square^0 \) by the fact that the marked edges in \( X \) are precisely those which are invertible in \( \text{HoX} \). Since \( K^{\text{co}} \to (K')^{\text{co}} \) is an epimorphism, it therefore has the left lifting property against all maps between marked cubical quasicategories.

\[ \square \]

3. Model structure on structurally marked cubical sets

The model structure on marked cubical sets described in the previous section resembles the Cisinski model structure on a presheaf category. In this section, we show that the category \( \text{cSet}'' \) of structurally marked cubical sets (see Section 1.4) admits a Cisinski model structure which right induces the model structure on marked cubical sets from the previous section via the embedding \( \text{cSet}' \hookrightarrow \text{cSet}'' \), and that the two are Quillen equivalent.

None of the arguments in this section make use of connections, thus they are valid in all of the categories of cubical sets shown in the diagram (†) at the end of Section 1.

Since \( \text{cSet}'' \) is a presheaf category, we may apply Theorem 1.3 in order to construct a model structure on this category. To do that, we first find a cellular model for \( \text{cSet}'' \), i.e., a generating set of monomorphisms, using the Reedy category structure of \( \square \), established in Proposition 1.36.

**Lemma 3.1.** The monomorphisms of \( \text{cSet}'' \) are the saturation of the set consisting of the boundary inclusions \( \partial \square^n \to \square^n \) and the inclusion \( \square^1 \hookrightarrow (\square^1)^\sharp \). \[ \square \]

The functor \((\square^1)^\sharp \otimes - : \text{cSet}'' \to \text{cSet}''\), together with the natural transformations \( \partial^1_{0,0} \otimes -, \partial^1_{1,0} \otimes -, \text{id} \to (\square^1)^\sharp \otimes - \), and \( \pi : (\square^1)^\sharp \otimes - \to \text{id} \), defines a cylinder functor on \( \text{cSet}'' \) in the sense of Definition 1.2.

Thus we have a notion of homotopy defined in terms of this cylinder functor: an elementary homotopy \( f \sim g : X \to Y \) is a map \( H : (\square^1)^\sharp \otimes X \to Y \) with \( H|_{\square^0} \otimes X = f, H|_{\square^1} \otimes X = g \), and a homotopy is a zigzag of elementary homotopies. In keeping with the notation of Section 1.1 we will write \([X,Y]\) for the set of homotopy classes of maps from \( X \) to \( Y \).
Lemma 3.2.

(i) The cylinder functors in $cSet'$ and $cSet''$ agree, i.e., the latter is the image of the former under the embedding $cSet' \to cSet''$.

(ii) For marked cubical sets $X$ and $Y$, the embedding $cSet' \to cSet''$ induces a bijection $[X, Y]_{cSet'} \to [X, Y]_{cSet''}$, where the subscript indicates which category the homotopy classes are taken in.

Proof. Both of these statements follow easily from the fact that the embedding $cSet' \to cSet''$ is monoidal, established in Corollary 1.40.

Let $S$ be the set of maps in $cSet''$ consisting of the following maps:
- the marked open box inclusions,
- the saturation map, and
- the 3-out-of-4 maps.

Definition 3.3. A map of structurally marked cubical sets is anodyne if it is in the saturation of $S$.

Note that the anodyne generators in $cSet''$ are precisely those of $cSet'$, embedded via $cSet' \to cSet''$.

Remark 3.4. It might seem natural to include the map $(\square^1)^1 \to (\square^1)^2$, the inclusion of the marked interval into the interval with two distinct markings, in $S$, so that adding a marking to an already-marked edge of a structurally marked cubical set would not change its homotopy type. In fact, however, this map is already anodyne, as it is a pushout of a 3-out-of-4 map.

The following lemma shows that this definition of anodyne maps is consistent with that of Subsection 1.1.

Lemma 3.5. The set $\Lambda(S)$ is contained in the saturation of $S$.

Proof. The proof of Lemma 2.9 applies equally well in this context, showing that a pushout product of a monomorphism with a map in the saturation of $S$ is again in the saturation of $S$. This implies that $\Lambda^0(S)$ is contained in the saturation of $S$; applying the same lemma inductively, we see that each set $\Lambda^n(S)$ is contained in the saturation of $S$.

Theorem 3.6. The category $cSet''$ of structurally marked cubical sets carries a cofibrantly generated model structure in which:
- the cofibrations are the monomorphisms;
- the fibrant objects, and fibrations between fibrant objects, are defined by the right lifting property with respect to the set of generating anodyne maps $S$;
- the weak equivalences are maps $X \to Y$ inducing bijections $[Y, Z] \to [X, Z]$ for all fibrant objects $Z$. 

Proof. The existence of the model structure follows from Theorem 1.5. Lemma 3.5 shows that the set of generating anodyne maps is exactly $S$. □

The remainder of this section will be devoted to analyzing this model structure and its relationship with the model structure on marked cubical sets of Theorem 2.44. More precisely, we will prove:

**Theorem 3.7.**

(i) The adjunction $cSet'' \rightleftarrows cSet'$ is a Quillen equivalence.

(ii) The cubical marked model structure is right induced from the model structure of Theorem 3.6 by the embedding $cSet' \rightarrow cSet''$.

Before proving this theorem, we establish a number of intermediate results.

**Proposition 3.8.** The adjunction $cSet'' \rightleftarrows cSet'$ is a Quillen adjunction between the model structure of Theorem 3.6 to the cubical marked model structure.

*Proof.* By Corollary 1.12, it suffices to show that $\text{Im}$ preserves monomorphisms and takes generating anodynes to anodynes. Both of these statements are immediate. □

**Lemma 3.9.** A map of structurally marked cubical sets $f: X \rightarrow Y$ is a trivial fibration if and only if the underlying map of cubical sets is a trivial fibration in model structure of Theorem 1.34 (i.e., has the right lifting property with respect to monomorphisms) and, for each edge $x$ of $X$, the map from the set of markings of $x$ to that of $fx$ is surjective.

*Proof.* By Lemma 3.1, $f$ is a trivial fibration if and only if it has the right lifting property with respect to all boundary inclusions and the inclusion of the interval into the marked interval. Having the right lifting property with respect to all boundary inclusions is equivalent to being a trivial fibration on underlying cubical sets; having the right lifting property with respect to the inclusion of the interval into the marked interval is equivalent to each map of marking sets being surjective. □

**Corollary 3.10.** For all structurally marked cubical sets $X$, the adjunction unit $X \rightarrow \text{Im}X$ is a trivial fibration.

**Lemma 3.11.** The functor $\text{Im}: cSet'' \rightarrow cSet'$ preserves fibrations and trivial fibrations.

*Proof.* We will show that if $p: X \rightarrow Y$ is a fibration between structurally marked cubical sets, then $\text{Im}p: \text{Im}X \rightarrow \text{Im}Y$ is also a fibration. Given a trivial cofibration of marked cubical sets $i: A \hookrightarrow B$ with maps $\alpha: A \rightarrow \text{Im}X$ and $\beta: B \rightarrow \text{Im}Y$ making the square commute, apply Corollary 3.10 to $\varnothing \rightarrow A \rightarrow \text{Im}X$ to get $\alpha': A \rightarrow X$ with $\alpha = u_X\alpha'$ and then again to the square

$$
\begin{array}{ccc}
A & \xrightarrow{p\alpha'} & Y \\
\downarrow^i & & \downarrow^{u_Y} \\
B & \xrightarrow{\beta} & \text{Im}Y
\end{array}
$$

□
to get $\beta': B \to Y$ that fits into a square

$$
\begin{array}{ccc}
A & \xrightarrow{\alpha'} & X \\
\downarrow & & \downarrow \\
B & \xrightarrow{\beta'} & Y
\end{array}
$$

whose lift $L: B \to X$ yields $u_X L: B \to \text{Im}X$ which satisfies the equations

$$(\text{Imp}) u_X L = u_Y p L = u_Y \beta' = \beta \quad \text{and} \quad u_x L i = u_x \alpha' = \alpha$$

and so provides the lift. Thus Imp is a fibration.

The proof for trivial fibrations is analogous.

□

Lemma 3.12. Let $X$ be a structurally marked cubical set. Then $X$ is fibrant if and only if $\text{Im}X$ is fibrant (in the model structure of Theorem 3.6).

Proof. If $\text{Im}X$ is fibrant, then $X$ is fibrant by Corollary 3.10. Conversely, if $X$ is fibrant, then $\text{Im}X$ is fibrant in $\text{cSet}'$ by Lemma 3.11 hence also in $\text{cSet}''$ by Proposition 3.8. □

Proof of Theorem 3.7. First, let us show that the right derived functor of the embedding $\text{cSet}' \to \text{cSet}''$ is an equivalence. Since $[X,Y]_{\text{cSet}'} \to [X,Y]_{\text{cSet}''}$ is bijective by Lemma 3.2, it is full and faithful. For essential surjectivity, by Corollary 1.6, given fibrant $X \in \text{cSet}''$, we need fibrant $Y \in \text{cSet}'$ weakly equivalent to $X$ in $\text{cSet}''$. This is given by Lemmas 3.11 and 3.12.

Now, let us show that cubical marked model structure is right induced. Since $\text{Im}$ is a left Quillen equivalence and all objects are cofibrant, it preserves and reflects weak equivalences by Proposition 1.13, hence so does the embedding. Since $\text{Im}$ preserves fibrations, the embedding reflects them. That the embedding preserves fibrations is part of Proposition 3.8. □

4. Joyal model structure on cubical sets

Recall the adjunction $\text{cSet} \rightleftarrows \text{cSet}'$ of Section 1.4, in which the left adjoint is the minimal marking functor and the right adjoint is the forgetful functor. In this section we will use this adjunction to induce a model structure on $\text{cSet}$ from the model structure on $\text{cSet}'$ of Theorem 2.44.

None of the arguments in this section rely on the existence of connections, thus they are valid in all of the categories of cubical sets shown in the diagram (†) at the end of Section 1.

Lemma 4.1. For $X \in \text{cSet}$, the image of the factorizations $X \sqcup X \to K \otimes X \to X$ and $X \sqcup X \to X \otimes K \to X$ under the minimal marking functor define cylinder objects for $X^*$ in $\text{cSet}'$.

Proof. That the minimal marking functor sends the first map in each of these factorizations to a cofibration, i.e. a monomorphism, is clear; that it sends the second to a weak equivalence follows from Corollaries 2.38 and 2.47. □

Theorem 4.2 (Analogue of Joyal model structure). The category $\text{cSet}$ of cubical sets carries a model structure in which:
the cofibrations are the monomorphisms,

• the weak equivalences are created by the minimal marking functor,

• the fibrations are right orthogonal to trivial cofibrations.

Proof. Apply Theorem 1.10 to the adjunction \( \textbf{cSet} \rightleftarrows \textbf{cSet}' \) and the cubical marked model structure, with the factorization \( X \sqcup X \to K \otimes X \to X \). Lemma 4.1 shows that this factorization satisfies the hypotheses of Theorem 1.10. \( \square \)

We refer to the model structure constructed above as the cubical Joyal model structure. Its weak equivalences will be referred to as weak categorical equivalences, respectively.

**Proposition 4.3.** The adjunction \( \textbf{cSet} \rightleftarrows \textbf{cSet}' \) is a Quillen equivalence.

Proof. The minimal marking functor preserves and reflects weak equivalences by definition, thus we may apply Corollary 1.14 (ii). Let \( X \) be a marked cubical quasicategory; abusing notation slightly, let \( X^\flat \) denote the minimal marking of the underlying cubical set of \( X \). We must show that the inclusion \( X^\flat \to X \) is a weak equivalence.

The marked edges of \( X^\flat \) are precisely the degenerate edges; by Lemma 2.5, the marked edges of \( X \) are precisely those edges \( \square^1 \to X \) which factor through \( K \). Thus \( X^\flat \to X \) is a pushout of a coproduct of saturation maps, hence a trivial cofibration. \( \square \)

We define some terminology which will be used in the analysis of this model structure.

• For \( n \geq 2, 1 \leq i \leq \epsilon \in \{0, 1\} \), the \((i, \epsilon)\)-inner open box, denoted \( \hat{\sqcup}^n_{i, \epsilon} \), is the quotient of an open box with the critical edge quotiented to a point. The \((i, \epsilon)\)-inner cube, denoted \( \mathcal{I}^n_{i, \epsilon} \), is defined similarly.

• The class of anodyne maps is the saturation of the set of inner open box inclusions.

• An inner fibration is a map having the right lifting property with respect to the inner open box inclusions.

• An isofibration is a map having the right lifting property with respect to the endpoint inclusions \( \square^0 \to K \).

• A cubical quasicategory is a cubical set \( X \) such that the map \( X \to \square^0 \) is an inner fibration.

• An equivalence in a cubical set \( X \) is an edge \( \square^1 \to X \) which factors through the inclusion of the middle edge \( \square^1 \to K \).

• For \( n \geq 2, 1 \leq i \leq n, \epsilon \in \{0, 1\} \), a special open box in a cubical set \( X \) is a map \( \mathcal{I}^n_{i, \epsilon} \to X \) which sends the critical edge to an equivalence.

The concept of homotopy developed in Section 2 adapts naturally to this setting, using equivalences in place of marked edges.

**Definition 4.4.** For a cubical set \( X \), let \( \sim_0 \) denote the relation on \( X_0 \), the set of vertices of \( X \), given by \( x \sim_0 y \) if there is an equivalence from \( x \) to \( y \) in \( X \). Let \( \sim \) denote the smallest equivalence relation on \( X_0 \) containing \( \sim_0 \).
Remark 4.5. For \( x, y \in X_0 \), one can easily see that \( x \sim y \) if and only if \( x \) and \( y \) are connected by a zigzag of equivalences.

Definition 4.6. For a cubical set \( X \), the set of connected components \( \pi_0(X) \) is \( X_0/\sim \).

Definition 4.7. An elementary left homotopy \( h : f \sim g \) between maps \( f, g : A \to B \) is a map \( h : K \otimes A \to B \) such that \( h|_{\{0\}} \otimes A = f \) and \( h|_{\{1\}} \otimes A = g \). Note that the elementary left homotopy \( h \) corresponds to an edge \( K \to \text{hom}_L(A, B) \) between the vertices corresponding to \( f \) and \( g \). A left homotopy between \( f \) and \( g \) is a zig-zag of elementary left homotopies.

A left homotopy from \( f \) to \( g \) corresponds to a zig-zag of equivalences in \( \text{hom}_L(A, B) \) and so maps from \( A \) to \( B \) are left homotopic exactly if \( \pi_0(f) = \pi_0(g) \), where the set of connected components is taken in \( \text{hom}_L(A, B) \).

These induce notions of elementary left homotopy equivalence and left homotopy equivalence. Each of these notions has a “right” variant using \( A \otimes K \) and \( \text{hom}_R(A, B) \). As in Section 2, unless the potential for confusion arises or a statement depends on the choice, we will drop the use of “left” and “right”. Homotopy equivalences between cubical quasicategories will be referred to as categorical equivalences.

Definition 4.8. Let \( X \) be a cubical set. The natural marking on \( X \) is a marked cubical set \( X^\natural \) whose underlying cubical set is \( X \), with edges marked if and only if they are equivalences.

It is easy to see that this defines a functor \((-)^\natural : \text{cSet} \to \text{cSet}'\), as maps of cubical sets preserve equivalences.

Many results about the cubical Joyal model structure follow easily from the corresponding results about the cubical marked model structure.

Lemma 4.9. If \( i, j \) are cofibrations in \( \text{cSet} \), then the pushout product \( i \hat{\otimes} j \) is a cofibration. Moreover, if either \( i \) or \( j \) is trivial then so is \( i \hat{\otimes} j \).

Proof. This is immediate from Corollaries 1.40 and 2.47 and Lemma 2.9. \( \square \)

Corollary 4.10. Let \( i, f \) be maps in \( \text{cSet} \). If \( i \) is a cofibration and \( f \) is a fibration, then the pullback exponential \( i \triangleright f \) is a fibration. \( \square \)

Corollary 4.11. The category \( \text{cSet} \), equipped with the cubical Joyal model structure and the geometric product, is a monoidal model category. \( \square \)

Next we will characterize the fibrant objects, and fibrations between fibrant objects, in the cubical Joyal model structure.

Lemma 4.12. The inner open box inclusions \( \hat{\bigotimes}_{i,\varepsilon}^n \to \bigotimes_{i,\varepsilon}^n \), and the endpoint inclusions \( \Box^0 \to K \), are trivial cofibrations.

Proof. The minimal marking of an inner open box inclusion is a pushout of a marked open box inclusion in \( \text{cSet}' \). The minimal marking of \( \Box^0 \to K \) is a trivial cofibration by Corollary 2.38. \( \square \)

Lemma 4.13. Cubical quasicategories have fillers for special open boxes.
Proof. We only consider positive filling problems; the negative case is dual. We argue by induction on the dimension of the filling problem. For a special open box of dimension 2, it is a simple exercise to explicitly construct a filler by extending the given open box to an inner open box of dimension 3.

Now let $X$ be a cubical quasicategory, and suppose that $X$ has fillers for all special open boxes of dimension less than $n$. Consider a filling problem in $X$ of dimension $n$:

\[
\begin{array}{c}
\partial \square^a \otimes \square^1 \otimes \square^b \cup (\square^a \otimes \{0\} \otimes \square^b) \cup (\square^a \otimes \square^1 \otimes \partial \square^b) \\
\rightarrow \square^a \otimes \square^1 \otimes \square^b
\end{array}
\]

We regard the codomain of the left map as a negative face of a larger cube via the map

\[
\square^a \otimes \square^1 \otimes \square^b \rightarrow \square^a \otimes \square^1 \otimes \{0\} \otimes \square^b
\]

and the domain as the corresponding subobject. The original filling problem then becomes a filling problem in $X$ of the form

\[
\begin{array}{c}
(\partial \square^a \otimes \square^1 \otimes \{0\} \otimes \square^b) \\
\cup (\square^a \otimes \{0\} \otimes \square^b) \\
\cup (\square^a \otimes \square^1 \otimes \{0\} \otimes \partial \square^b) \\
\rightarrow \square^a \otimes \square^1 \otimes \{0\} \otimes \square^b
\end{array}
\]

where the critical edge is

\[
0^a000^b \rightarrow 0^a100^b.
\]

We will solve this problem by extending the given partial data to the whole of

\[
\square^a \otimes \square^1 \otimes \square^1 \otimes \square^b.
\]

For $n \geq 0$, let $\Gamma^n \subseteq \square^n$ denote the union of the positive faces. We use degeneracies in the new direction to fill

\[
\begin{align*}
(\Gamma^n \otimes \square^1 \otimes \{0\} \otimes \square^b) & \quad (\Gamma^n \otimes \square^1 \otimes \square^1 \otimes \square^b) \\
\cup (\square^a \otimes \{0\} \otimes \square^b) & \quad \cup (\square^a \otimes \square^1 \otimes \square^b) \\
\cup (\square^a \otimes \square^1 \otimes \{0\} \otimes \Gamma^b) & \quad \cup (\square^a \otimes \square^1 \otimes \square^1 \otimes \Gamma^b).
\end{align*}
\]

Since the critical edge is an equivalence, we can fill the square

\[
\begin{array}{c}
0^a000^b \\
\rightarrow 0^a011^b \\
0^a100^b \\
\rightarrow 0^a110^b
\end{array}
\]

where the dotted edge is again an equivalence.

In the following, we will indicate the filling direction of (generalized) open boxes by underlining the appropriate factor in the pushout monoidal product. What this means is that we can factor the
given generalized open box inclusion as a series of open box fillings in different dimensions, each of which fills in the specified direction. We now fill the generalized open box

\[ \{0^a\} \otimes (\{0\} \to □^1) \otimes (\{0\} \to □^1) \otimes (\{0\} \to □^b) \]

if \(a, b \geq 1\). Here, the critical edges are of the form \(uv0w \to uv1w\) where \(u, v, w\) are certain vertices of □\(^a\), □\(^1\), □\(^b\), respectively. All of these edges are degenerate except for the bottom edge in (4.1), which is an equivalence. Moreover, this edge only appears as a critical edge in filling problems of lower dimension. So we may indeed fill this generalized open box using fibrancy of \(X\) and the induction hypothesis. Dually, we fill the generalized open box

\[ (\{0^a\} \to □^a) \otimes (\{0\} \to □^1) \otimes (\{0\} \to □^1) \otimes \{0^b\} \]

if \(a, b \geq 1\).

We now fill the generalized open box

\[ (\{0^a\} \cup Γ^a \to \partial □^a) \otimes (\{0\} \to □^1) \otimes (\{0\} \to □^1) \otimes (\partial □^b \to □^b) \]

if \(a \geq 1\). Again, the critical edges are of the form as above and we may argue as before. Dually, we fill the generalized open box

\[ (\partial □^a \to □^a) \otimes (\{0\} \to □^1) \otimes (\{0\} \to □^1) \otimes (\{0^b\} \cup Γ^b \to \partial □^b) \]

if \(b \geq 1\).

At this stage, we have defined the cube on

\[ (\partial □^a \otimes □^1 \otimes □^1 \otimes □^b) \]

\[ \cup (□^a \otimes \{0\} \otimes □^1 \otimes □^b) \]

\[ \cup (□^a \otimes □^1 \otimes □^1 \otimes \partial □^b). \]

We now fill the open box

\[ (\partial □^a \to □^a) \otimes (\{0\} \to □^1) \otimes (\{0\} \to □^1) \otimes (\partial □^b \to □^b), \]

noting that the critical edge \(0^a000^b \to 0^a100^b\) is degenerate. We then fill the open box

\[ (\partial □^a \to □^a) \otimes (\{0\} \to □^1) \otimes (\{0\} \to □^1) \otimes (\partial □^b \to □^b), \]

noting that the critical edge \(0^a000^b \to 0^a010^b\) is degenerate. We finally fill the open box

\[ (\partial □^a \to □^a) \otimes (\partial □^1 \to □^1) \otimes (\{0\} \to □^1) \otimes (\partial □^b \to □^b), \]

noting that the critical edge \(0^a000^b \to 0^a010^b\) is degenerate. This defines the entire cube. □

**Lemma 4.14.** Let \(X \to Y\) be an inner fibration between cubical quasicategories. Then a lift exists for any diagram of the form

\[
\begin{array}{ccc}
\cap_{\varepsilon}^{n} & \longrightarrow & X \\
\downarrow & & \downarrow \\
□^a & \longrightarrow & Y
\end{array}
\]

in which \(\cap_{\varepsilon}^{n}\) is a special open box in \(X\).
Proof. Again we only consider positive filling problems; the negative case is dual. Again we argue by induction on the dimension of the filling problem, with the case for dimension 2 being a simple exercise in filling three-dimensional open boxes, entirely analogous to the base case of the previous proof. Consider a lifting problem

\[ (\partial a \otimes \partial 1 \otimes \partial b) \cup (\partial a \otimes \{0\} \otimes \partial b) \cup (\partial a \otimes \{0\} \otimes \partial 1 \otimes \partial b) \rightarrow X \]

where the right map is an inner fibration between cubical quasicategories. As before, we regard the codomain of the left map as a negative face of a larger cube via the map

\[ a \otimes 1 \otimes b \rightarrow a \otimes 1 \otimes \{0\} \otimes b \]

and the domain as the corresponding subobject \( H \). The critical edge is once again \( 0^a000^b \rightarrow 0^a100^b \). Let \( H' \) be the union of \( H \) with the subobjects

\[ \Gamma^a \otimes \{0\} \otimes \{0\} \otimes b \]

\[ (\partial a \otimes \{0\} \otimes 1 \otimes \partial b) \]

and \( H'' \) be the union of \( H' \) with the square

\[ \{0^a\} \otimes 1 \otimes 1 \otimes \{0^b\} \]

We use degeneracies in the new direction to extend the map to \( X \) from \( H \) to \( H' \):

\[ H \rightarrow X, \]

Since the critical edge is an equivalence in \( X \), we extend the map to \( X \) from \( H' \) to \( H'' \) by filling the square

\[ \begin{array}{ccc}
0^a000^b & \rightarrow & 0^a010^b \\
\downarrow & & \downarrow \\
0^a100^b & \rightarrow & 0^a110^b
\end{array} \]

where the dotted edge is again an equivalence in \( X \). Note that the map \( X \rightarrow Y \) preserves equivalences.

We construct the dotted arrow in the diagram
by solving a filling problem

$$\begin{array}{c}
\square^a \otimes \square^1 \otimes \{0\} \otimes \square^b \\
\downarrow
\square^a \otimes \square^1 \otimes \square^1 \otimes \square^b
\end{array} \cup H'' \rightarrow Y$$

as follows: the left map factors as a finite composite of open box inclusions of the form

$$(\partial \square^a' \rightarrow \square^a') \otimes (\{0\} \rightarrow \square^1) \otimes (\{\square^1\} \rightarrow \square^1) \otimes (\partial \square^b' \rightarrow \square^b')$$

where $\square^a'$ and $\square^b'$ are faces of $\square^a$ and $\square^b$, respectively. All critical edges are of the form $uv0w \rightarrow uv1w$ where $u, v, w$ are certain points of $\square^a, \square^1, \square^b$, respectively. All of these edges are degenerate in $Y$ except for the bottom edge in (4.1), which is an equivalence. We can thus fill these open boxes using fibrancy of $Y$ and Lemma 4.13.

It remains to construct a lift

$$\begin{array}{c}
H'' \rightarrow X \\
\downarrow
\square^a \otimes \square^1 \otimes \square^1 \otimes \square^b \\
\downarrow
Y
\end{array}$$

which is done exactly as in the proof of Lemma 4.13 using that $X \rightarrow Y$ is a fibration.

Lemma 4.15. If $X$ is a cubical quasicategory, then $X^3$ is a marked cubical quasicategory.

Proof. Given a cubical quasicategory $X$, we have fillers for special open boxes in $X$ by Lemma 4.13. This implies that $X^3$ has fillers for marked open boxes. Furthermore, the definition of the natural marking implies that $X^3$ has the right lifting property with respect to the saturation map for any cubical set $X$. By Lemma 2.6, this suffices to show that $X^3$ is a marked cubical quasicategory.

Theorem 4.16. The fibrant objects of the cubical Joyal model structure are given by cubical quasi-categories. The fibrations between fibrant objects are characterized by lifting against inner open box inclusions and endpoint inclusions $\square^0 \rightarrow K$.

Proof. By Lemma 4.12, every fibrant object is a cubical quasicategory and every fibration is an inner isofibration.

If $X$ is a cubical quasicategory, then $X^3$ is a marked cubical quasicategory by Lemma 4.15. The forgetful functor $cSet' \rightarrow cSet$ preserves fibrant objects as a right Quillen adjoint, and the underlying cubical set of $X^3$ is $X$, thus $X$ is fibrant.

The case of fibrations between fibrant objects proceeds in an analogous way. Let $f: X \rightarrow Y$ be an inner isofibration between cubical quasicategories; we will show that $f^3$ is a fibration in $cSet'$. Lifting against one-dimensional marked open box inclusions follows from the isofibration property; lifting against higher-dimensional marked open box inclusions follows from Lemma 4.14. To see that $f^3$ has the right lifting property with respect to the saturation and 3-out-of-4 maps, observe that any marked cubical quasicategory has the right lifting property with respect to these maps, hence so does any map between marked cubical quasicategories since the maps in question are epimorphisms. Since $X^3$ and $Y^3$ are marked cubical quasicategories, this implies that $f^3$ is a fibration by Proposition 2.50.

□
Corollary 4.17. Let \( f : X \to Y \) be a map between cubical quasicategories. Then \( f \) is a weak categorical equivalence if and only if it is a categorical equivalence.

Proof. This follows from Lemma 4.1 and Theorem 4.16.

Corollary 4.18. Let \( X, Y \in \mathbf{cSet} \), with \( Y \) a cubical quasicategory. Then \( \text{hom}(X,Y) \) is a cubical quasicategory.

Proof. This follows from Corollary 4.10 and Theorem 4.16.

Using Theorem 4.16, we can see that this model structure can also be constructed using the Cisinski theory of Section 1.1.

Proposition 4.19. Let \( \mathbf{cSet}_K \) denote the model structure given by applying Theorem 1.5 to \( \mathbf{cSet} \) with the following data:

- \( I = - \otimes K \), with natural transformations \( \partial_e \) and \( \sigma \) induced by the endpoint inclusions and the map \( K \to \square^0 \);
- \( M = \{ \partial_\square^n \to \square^n | n \geq 0 \} \);
- \( S = \{ \hat{\square}_i^{n+1} \to \hat{\square}_i^n | n \geq 2, 1 \leq i \leq n, \varepsilon = 0, 1 \} \).

Then \( \mathbf{cSet}_K \) coincides with the cubical Joyal model structure.

Proof. The cofibrations in both model structures are the monomorphisms. Therefore, to show that the model structures coincide, it suffices to show that they have the same fibrant objects, i.e. that the objects having the right lifting property with respect to all maps in \( \Lambda(S) \) are precisely the cubical quasicategories. For this, observe that all fibrant objects of \( \mathbf{cSet}_K \) are cubical quasicategories, since \( S \subseteq \Lambda(S) \) is precisely the set of inner open box inclusions. Furthermore, an inductive argument involving Lemma 4.9 shows that all maps in \( \Lambda(S) \) are trivial cofibrations in the cubical Joyal model structure, so all cubical quasicategories are fibrant in \( \mathbf{cSet}_K \).

Our next goal will be to characterize the weak categorical equivalences in a manner similar to Proposition 2.36.

Lemma 4.20. The following triangle of functors commutes:

\[
\begin{array}{ccc}
\mathbf{cSet} & \xrightarrow{(-)\natural} & \mathbf{cSet}' \\
\pi_0 \downarrow & & \downarrow \pi_0 \\
\mathbf{Set} & & \mathbf{Set}
\end{array}
\]

Proof. For \( X \in \mathbf{cSet} \), \( X \) and \( X\natural \) have the same set of vertices, and the equivalence relations defining \( \pi_0 X \) and \( \pi_0 X\natural \) coincide.

Lemma 4.21. Let \( X, Y \in \mathbf{cSet} \), and let \( Y' \) be a marked cubical set whose underlying cubical set is \( Y \). The underlying cubical set of \( \text{hom}(X^\natural, Y') \) is isomorphic to \( \text{hom}(X,Y) \), and this isomorphism is natural in both \( X \) and \( Y \).
**Proof.** We will prove the statement for \( \text{hom}_R \); the proof for \( \text{hom}_L \) is similar. The \( n \)-cubes in the underlying cubical set of \( \text{hom}_R(\mathcal{X}^\flat, \mathcal{Y}) \) are maps \( X^\flat \times \boxtimes^n \cong (X \times \boxtimes^n)^\flat \to \mathcal{Y}' \) (the isomorphism follows from Corollary 1.40). Under the adjunction \( \text{cSet} \rightleftarrows \text{cSet}' \), these correspond to maps \( X \times \boxtimes^n \to \mathcal{Y} \).

**Proposition 4.22.** The following are equivalent for a cubical map \( A \to B \):

(i) \( A \to B \) is a weak categorical equivalence;

(ii) for any cubical quasicategory \( \mathcal{X} \), the induced map \( \text{hom}(B, \mathcal{X}) \to \text{hom}(A, \mathcal{X}) \) is a categorical equivalence;

(iii) for any cubical quasicategory \( \mathcal{X} \), the induced map \( \pi_0(\text{hom}(B, \mathcal{X})) \to \pi_0(\text{hom}(A, \mathcal{X})) \) is a bijection.

**Proof.** To see that \( (i) \Rightarrow (ii) \), let \( A \to B \) be a weak categorical equivalence in \( \text{cSet} \), and \( \mathcal{X} \) a cubical quasicategory. Then \( \mathcal{X}^\flat \) is a marked cubical quasicategory by Lemma 4.15, so \( \text{hom}(B^\flat, \mathcal{X}^\flat) \to \text{hom}(A^\flat, \mathcal{X}^\flat) \) is a homotopy equivalence by Proposition 2.36. The underlying cubical set functor preserves weak equivalences between fibrant objects by Ken Brown’s lemma, so \( \text{hom}(B, \mathcal{X}) \to \text{hom}(A, \mathcal{X}) \) is a weak categorical equivalence by Lemma 4.21. Hence it is a categorical equivalence by Corollaries 4.17 and 4.18.

The implication \( (ii) \Rightarrow (iii) \) is clear, so now we consider \( (iii) \Rightarrow (i) \). For this, let \( \mathcal{X} \) be the underlying cubical set of a marked cubical quasicategory \( \mathcal{X}' \), and note that by Lemmas 4.20 and 4.21, we have the following commuting diagram in \( \text{Set} \):

\[
\begin{array}{ccc}
\pi_0\text{hom}(B, \mathcal{X}) & \longrightarrow & \pi_0\text{hom}(A, \mathcal{X}) \\
\approx & & \approx \\
\pi_0\text{hom}(B^\flat, \mathcal{X}') & \longrightarrow & \pi_0\text{hom}(A^\flat, \mathcal{X}')
\end{array}
\]

Since the underlying cubical set functor preserves fibrant objects, \( \mathcal{X} \) is a cubical quasicategory. So if \( (iii) \) holds then the top map is an isomorphism, hence so is the bottom map. Thus \( A^\flat \to B^\flat \) is a weak equivalence in \( \text{cSet}' \) by Proposition 2.36, meaning that \( A \to B \) is a weak categorical equivalence.

We now state two straightforward properties of the cubical Joyal model structure.

**Proposition 4.23.**

(i) The Grothendieck model structure on \( \text{cSet} \) of Theorem 1.34 is a localization of the cubical Joyal model structure.

(ii) The adjunction \( \tau_1 : \text{cSet} \rightleftarrows \text{Cat} : \mathbb{N} \) is a Quillen adjunction between the canonical model structure on \( \text{Cat} \) and the cubical Joyal model structure.

The cubical Joyal model structure is clearly left proper, since all objects are cofibrant. However, it is not right proper. The proof of this fact is similar to the standard proof of the corresponding result for the Joyal model structure on \( \text{sSet} \), but requires an additional step due to the fact that inner cubes, unlike representable simplicial sets, are generally not fibrant.
Proposition 4.24. The cubical Joyal model structure is not right proper.

Proof. We will exhibit a fibration $X \to Z$ and a weak equivalence $Y \to Z$ such that the pullback map $X \times_Z Y \to X$ is not a weak equivalence.

First consider the map $[1] \to [2]$ in $\mathbf{Cat}$ which picks out the morphism $0 \to 2$. This is an isofibration, hence its image under $N_{\square}$ is a fibration by Proposition 4.23 (ii).

We have a map $\hat{\square}^2 \to N_{\square}[2]$ given by the following 2-cube in $N_{\square}[2]$:

Now consider the following commuting diagram in $\mathbf{cSet}$:

$$
\begin{array}{ccc}
\partial\square^1 & \to & \hat{\square}^2 \\
\downarrow & & \downarrow \\
\square^1 & \to & \hat{\square}^2 \\
\downarrow & & \downarrow \\
N_{\square}[1] & \to & N_{\square}[2]
\end{array}
$$

Pullbacks of two monomorphisms in $\mathbf{cSet}$ are given by intersections; this is immediate from the corresponding result in $\mathbf{Set}$. From this, it follows that both of the squares in the diagram above are pullbacks.

The middle horizontal map is a fibration, as a pullback of a fibration. So the inclusion $\partial\square^1 \to \square^1$ is the pullback of the trivial cofibration $\hat{\square}^2 \to \hat{\square}^2$, along a fibration. However, it is not a weak equivalence by Proposition 4.23 (ii), since its image under $\tau$ is not an equivalence of categories. □

Next we will study the interactions of the functors $(-)^{co}$ and $(-)^{co\text{-}op}$ of Section 1.2 with the cubical Joyal model structure.

Proposition 4.25. The adjunctions $(-)^{co} \dashv (-)^{co}$ and $(-)^{co\text{-}op} \dashv (-)^{co\text{-}op}$ are Quillen self-equivalences of the cubical Joyal model structure.

Proof. By Corollary 1.15 it suffices to show that the adjunctions are Quillen. We will prove the statement for $(-)^{co}$; the proof for $(-)^{co\text{-}op}$ is identical.

To show that the adjunction $(-)^{co} \dashv (-)^{co}$ is Quillen, we must show that $(-)^{co}$ preserves cofibrations and trivial cofibrations. Unwinding the definitions, we must show that, given a map $f$ in $\mathbf{cSet}$, if $f^\flat$ is a (trivial) cofibration in $\mathbf{cSet}'$ then so is $(f^{co})^\flat$. We have the following commuting diagram:

$$
\begin{array}{ccc}
\mathbf{cSet} & \xrightarrow{(-)^{co}} & \mathbf{cSet} \\
(-)^\flat & \downarrow & (-)^\flat \\
\mathbf{cSet}' & \xrightarrow{(-)^{co}} & \mathbf{cSet}'
\end{array}
$$
The result thus follows from the fact that the map \((-)^{co}: \text{cSet'} \to \text{cSet'}\) preserves (trivial) cofibrations by Proposition 2.51. \(\square\)

**Remark 4.26.** The statement of Proposition 4.25 of \((-)^{co-op}\) is not immediately adaptable to \(\text{cSet}_0\) and \(\text{cSet}_1\), as \((-)^{co-op}\) does not define an automorphism of either of these categories, but rather an isomorphism between them. Thus the corresponding result for cubical sets with only one connection states that for \(\varepsilon \in \{0,1\}\), the adjunction \((-)^{co-op}: \text{cSet}_\varepsilon \rightleftarrows \text{cSet}_{1-\varepsilon}: (-)^{co-op}\) is a Quillen equivalence.

We conclude this section with a proof of the following result, relating the cubical Joyal model structure to the Joyal model structure on simplicial sets via the triangulation functor.

**Proposition 4.27.** The adjunction \(T: \text{cSet} \rightleftarrows \text{sSet} : U\) is a Quillen adjunction between the cubical Joyal model structure and the Joyal model structure on \(\text{sSet}\).

Conceptually, this adjunction might be best understood at the level of marked simplicial and marked cubical sets. However, in order to avoid the burden of relying on the model structure on marked simplicial sets, we will compare the model structures on \(\text{cSet}\) and \(\text{sSet}\) directly.

**Lemma 4.28.** \(T\) sends the endpoint inclusions \(\Box^0 \to K\) to trivial cofibrations in the Joyal model structure.

**Proof.** We will construct a weak categorical equivalence from \(TK\) to the simplicial set \(J\) of Example 1.7. It is easy to see that \(TK\) is the simplicial set depicted below:

![Diagram](attachment:image.png)

Let \(Z\) denote the simplicial set defined by the following pushout:

\[
\begin{array}{ccc}
\Lambda^1_2 & \to & \Delta^0 \\
\downarrow & & \downarrow \\
\Delta^2 & \to & Z
\end{array}
\]

The map \(\Delta^0 \to Z\) is a trivial cofibration, as a pushout of an inner horn inclusion; thus \(Z\) is contractible. We have a pair of cofibrations \(Z \to TK\), picking out the bottom-left and top-right simplices in the illustration above; the induced map \(Z \sqcup Z \to TK\) is a cofibration since these two simplices have no faces in common. We obtain \(J\) as a quotient of \(TK\) by contracting each of these two simplices to a point; in other words, we have the following pushout diagram:

\[
\begin{array}{ccc}
Z \sqcup Z & \to & TK \\
\downarrow & & \downarrow \\
\Delta^0 \sqcup \Delta^0 & \to & J
\end{array}
\]

The left map is a weak equivalence since coproducts preserve weak equivalences in the Joyal model structure. Thus \(TK \to J\) is a weak equivalence as a pushout of a weak equivalence along a
cofibration. The composite of \( \Delta^0 \to TK \) with this quotient map is an endpoint inclusion \( \Delta^0 \to J \), hence a weak equivalence; thus \( \Delta^0 \to TK \) is a weak equivalence by 2-out-of-3. \( \square \)

**Lemma 4.29.** \( T \) sends inner open box inclusions to trivial cofibrations.

**Proof.** By Lemma 1.26, Corollary 1.30, and the symmetry of the cartesian product in \( sSet \), the triangulation of an open box inclusion \( \sqcup^n_{i,\varepsilon} \xrightarrow{\sim} \sqcup^m \) is the pushout product \( (T\partial \sqcup^m \hookrightarrow (\Delta^1)^m) \times (\{\varepsilon\} \hookrightarrow \Delta^1) \). Therefore, since \( T \) preserves colimits, the triangulation of \( \sqcup^n_{i,\varepsilon} \xrightarrow{\sim} \hat{\sqcup}^m \) is the inclusion of the quotients of these simplicial sets in which the edge corresponding to the critical edge of \( \sqcup^n_{i,\varepsilon} \) is collapsed to a vertex.

Since \( T\partial \hat{\sqcup}^m \hookrightarrow (\Delta^1)^m \) is a monomorphism of simplicial sets, it can be written as a composite of boundary fillings. Since pushout products commute with composition, we can thus rewrite \( T\sqcup^n_{i,\varepsilon} \hookrightarrow (\Delta^1)^m \) as a composite of pushouts of maps of the form \( \partial \Delta^n \to \Delta^n \times (\{\varepsilon\} \hookrightarrow \Delta^1) \), i.e. open prism fillings. We can obtain \( T\hat{\sqcup}^n \) from \( T\sqcup^n_{i,\varepsilon} \), therefore, by filling the corresponding open prisms in \( T\sqcup^n_{i,\varepsilon} \).

Each open prism filling can be explicitly written as a composite of horn fillings. Each of these horn fillings but one will be inner, and hence a trivial cofibration. However, the critical edge of the unique outer horn, i.e. the unique non-degenerate edge containing either the initial or the terminal vertices of both the horn and its missing face, corresponds to the critical edge of \( \sqcup^n_{i,\varepsilon} \), hence it is degenerate. Thus this horn-filling is also a trivial cofibration by [Joy02, Thm. 2.2]. \( \square \)

**Proof of Proposition 4.27.** This follows from Corollary 1.12, together with Proposition 1.31 and Lemmas 4.28 and 4.29. \( \square \)

**Corollary 4.30.** The triangulation functor preserves weak equivalences.

**Proof.** Since all cubical sets are cofibrant, this is immediate from Proposition 4.27 and Ken Brown’s lemma. \( \square \)

### 5. Cones in cubical sets

In this section we introduce the concept of a cone in a cubical set, which will be a useful tool in our study of the cubical Joyal model structure. We will prove many technical lemmas about these cones, which will play important roles in the proofs of our main results.

To define the constructions of this section, only one kind of connection is necessary; thus our arguments apply not only in \( cSet \), but also in \( cSet_0 \) and \( cSet_1 \), as displayed in the diagram at the end of Section 4 after making suitable changes to the definitions.

**Definition 5.1.** The cone functor \( C : cSet \to cSet \) is defined by the following pushout diagram in \( \text{End } cSet \):

\[
\begin{array}{c}
\text{id} \\
\downarrow \\
\sqcup^1 \otimes - \\
\downarrow \\
C
\end{array}
\]

\[
\begin{array}{c}
\sqcup^0 \otimes - \\
\downarrow \\
\text{id}
\end{array}
\]
For \( m, n \geq 0 \), the \textit{standard} \((m, n)\)-cone is the object \( C^{m,n} = C^n \square^m \). In particular, for all \( m \), \( C^{m,0} = \square^m \). We refer to the natural map \( \square^0 \Rightarrow C \) appearing in this diagram as the \textit{cone point}.

A simple computation shows:

\textbf{Lemma 5.2.} For all \( n \geq 1 \), \( C^n \square \cong C^{0,n-1} \) and \( C^{0,n} \cong C^{1,n-1} \).

To develop our understanding of the cone construction, we consider certain examples of cones \( CX \) for \( X \in \text{cSet} \). In all of our illustrations, we will denote the cone point of \( CX \) by \( c \). For our simplest example, we may observe that \( C \square^0 \cong \square^1 \):

\[
\begin{array}{c}
0 \rightarrow c
\end{array}
\]

\( C \square^1 \) is the quotient of \( \square^2 \) depicted below:

\[
\begin{array}{c}
0 & \rightarrow & c \\
\bigg\downarrow & & \bigg\downarrow \\
1 & \rightarrow & c
\end{array}
\]

For our final example, let \( X \) denote the cubical set \( 0 \rightarrow 1 \rightarrow 2 \). Then \( CX \) is the cubical set depicted below:

\[
\begin{array}{c}
0 & \rightarrow & c \\
\bigg\downarrow & & \bigg\downarrow \\
1 & \rightarrow & c \\
\bigg\downarrow & & \bigg\downarrow \\
2 & \rightarrow & c
\end{array}
\]

We define the natural transformation \( \eta \): \( \text{id} \Rightarrow C \) to be the composite of \( \partial_{1,0} \otimes - : \text{id} \rightarrow \square^1 \otimes - \) with the quotient map \( \square^1 \otimes - \Rightarrow C \). We also define a natural transformation \( \mu : C^2 \Rightarrow C \) as follows. By the universal property of the pushout, such a natural transformation corresponds to a diagram of the form depicted below:

\[
\begin{array}{c}
C \rightarrow \square^0 \\
\partial_{1,1} \otimes C \\
\square^1 \otimes C \rightarrow C
\end{array}
\]

The only natural transformation \( \square^0 \rightarrow C \) is the cone point. Now note that \( \square^1 \otimes - \) preserves pushouts as a left adjoint. Thus we may define the map \( \square^1 \otimes C \rightarrow C \) as the map between pushouts induced by the following map between diagrams:

\[
\begin{array}{c}
\square^1 \otimes \square^1 \otimes - \rightarrow \partial_{1,1} \otimes - : \square^1 \otimes - \rightarrow \square^0 \\
\gamma_{1,0} \otimes - \\
\square^1 \otimes - \\
\partial_{1,1} \otimes - \\
\square^1 \otimes - \rightarrow \text{id} \rightarrow \square^0
\end{array}
\]

The commutativity of the left-hand square follows from the cubical identities.
We can also view the natural transformation $\mu$ more concretely, using Proposition \[\text{1.24}\] For $X \in \text{cSet}$, $k \geq 0$, a $k$-cube of $\square^1 \otimes X$ consists of a pair $(f: \square^a \to \square^1, x: \square^b \to X)$ such that $a + b = k$. The quotient $CX$ is then obtained by identifying cubes $(f, x)$ and $(f', x')$ if $f = f' = \text{const}_1$. Similarly, cubes of $C^2_{L,1}X$ consist of pairs $(f_1, f_2, x)$, with $(f_1, f_2, x)$ and $(f'_1, f'_2, x')$ identified if $f_1 = f'_1 = \text{const}_1$ or $f_1 = f'_1$ and $f_2 = f'_2 = \text{const}_1$. It is clear that $\gamma_{1,0} \otimes X$ respects these identifications, thus it descends to a map $\mu: C^2 X \to CX$.

**Proposition 5.3.** The triple $(C, \eta, \mu)$ defines a monad on $\text{cSet}$.

**Proof.** The monad laws follow from a straightforward calculation using the cubical identities. \[\square\]

Given a cubical set $X$, the natural way to form a cone on $X$ is to take its geometric product with the interval $\square^1$, and quotient one end of the cylinder to a vertex, as was done in Definition \[\text{5.1}\] This definition, however, involved certain choices: we chose to tensor on the left rather than on the right, and to quotient the subcomplex $\{1\} \otimes X$ rather than $\{0\} \otimes X$. Considering the alternative choices, we obtain four distinct cone functors. In general, we will work with the functor $C$ of Definition \[\text{5.1}\] when the potential for ambiguity arises, we will refer to this functor as $C_{L,1}$.

**Definition 5.4.** We define the left negative, left positive, right negative, and right positive cone functors, denoted $C_{L,0}, C_{L,1}, C_{R,0}, C_{R,1}: \text{cSet} \to \text{cSet}$, respectively, by the following pushout diagrams in End $\text{cSet}$:

$$
\begin{array}{ccc}
\square^1 \otimes - & \xrightarrow{id} & \square^1 \\
\downarrow & & \downarrow \\
C_{L,0} & & C_{L,1}
\end{array}
\quad
\begin{array}{ccc}
\square^1 \otimes - & \xrightarrow{- \otimes \gamma_{1,0}} & \square^1 \\
\downarrow & & \downarrow \\
C_{R,0} & & C_{R,1}
\end{array}
$$

To understand the differences between these definitions, we illustrate the cubical sets $C_{W,e} \square^1$ for $W \in \{L, R\}, e \in \{0, 1\}$. These are the four quotients which can be obtained from $\square^2$ by collapsing one of its faces to a vertex.

$$
\begin{array}{ccc}
\begin{array}{ccc}
c & 0 & c \\
c & 1 & c
\end{array} & \quad & \\
\begin{array}{ccc}
0 & c & 1 \\
c & 0 & 1
\end{array} & \quad & \\
\begin{array}{ccc}
c & 0 & 1 \\
c & c & c
\end{array}
\end{array}
$$

Applying the involutions $(-)^{co}, (-)^{co-op}, (-)^{op}$ to the pushout diagrams of Definition \[\text{5.4}\] and using Proposition \[\text{1.41}\] we obtain the following result, which shows that any one of these cone concepts suffices to describe all the others.

**Lemma 5.5.** The functors $C_{W,e}$ for $W \in \{L, R\}, e \in \{0, 1\}$ are related by the following formulas:

- $C_{L,0} = (-)^{co-op} \circ C_{L,1} \circ (-)^{co-op}$;
- $C_{R,0} = (-)^{op} \circ C_{L,1} \circ (-)^{op}$;
- $C_{R,1} = (-)^{co} \circ C_{L,1} \circ (-)^{co}$.

\[\square\]
Proposition 5.6. For $W \in \{L, R\}, \varepsilon \in \{0, 1\}$, the functor $C_{W, \varepsilon}: \mathbf{cSet} \to \mathbf{cSet}$ admits the structure of a monad, with the unit $\eta$ and multiplication $\mu$ induced by natural transformations $\text{id} \Rightarrow I_W$ and $I^2_W \Rightarrow I_W$, as follows:

<table>
<thead>
<tr>
<th>endofunctor</th>
<th>unit</th>
<th>multiplication</th>
</tr>
</thead>
<tbody>
<tr>
<td>$C_{L,0}$</td>
<td>$\partial_{1,1} \otimes -$</td>
<td>$\gamma_{1,1} \otimes -$</td>
</tr>
<tr>
<td>$C_{L,1}$</td>
<td>$\partial_{1,0} \otimes -$</td>
<td>$\gamma_{1,0} \otimes -$</td>
</tr>
<tr>
<td>$C_{R,0}$</td>
<td>$- \otimes \partial_{1,1}$</td>
<td>$- \otimes \gamma_{1,1}$</td>
</tr>
<tr>
<td>$C_{R,1}$</td>
<td>$- \otimes \partial_{1,0}$</td>
<td>$- \otimes \gamma_{1,0}$</td>
</tr>
</tbody>
</table>

Proof. This follows from Proposition [5.3] and Lemma [5.5]. □

For the remainder of this section, we will work exclusively with left positive cones, with the understanding that our results may be adapted to any of the other three varieties of cones using the formulas of Lemma [5.5].

Definition 5.7. For $m, n \geq 0$, an $(m, n)$-cone in a cubical set $X$ is a map $C^{m,n} \to X$.

Observe that each cone $C^{m,n} \to X$ corresponds to a unique $(m+n)$-cube of $X$ by pre-composition with the quotient map $\Box^{m+n} \to C^{m,n}$. Thus we will also use the term “$(m, n)$-cone” to refer to a map $\Box^{m+n} \to X$ which factors through this quotient map. In particular, when we refer to the $(i, \varepsilon)$-face of a cone $x$, this means the $(i, \varepsilon)$-face of the corresponding cube: $\Box^{m+n-1} \xrightarrow{\partial_i, \varepsilon} \Box^{m+n} \to C^{m,n} \xrightarrow{x} X$.

For $m, n, k \geq 0$, recall that $\Box^k$ is the set of maps $[1]^k \to [1]^m$ in the box category $\Box$; thus we may write such a $k$-cube $f, g$ if there exists $j$ with $1 \leq j \leq n$ such that $f_i = g_i$ for $i \leq j$ and $f_j = g_j = \text{const}_1$ (the constant map $[1]^k \to [1]$ with value 1).

Lemma 5.8. For all $m, n \geq 0$, $C^{m,n}$ is the quotient of $\Box^{m+n}$ obtained by identifying two $k$-cubes $f, g$ if there exists $j$ with $1 \leq j \leq n$ such that $f_i = g_i$ for $i \leq j$ and $f_j = g_j = \text{const}_1$ (the constant map $[1]^k \to [1]$ with value 1).

Proof. We fix $m$ and proceed by induction on $n$. For the base case $n = 0$, there cannot exist any $j$ satisfying the given criteria, thus no identifications are to be made; and indeed we have $C^{m,0} = \Box^m$ by definition.

Now suppose that the given description holds for $C^{m,n}$, and let $q$ denote the quotient map $\Box^{m+n} \to C^{m,n}$. Then because the functor $\Box^1 \otimes -$ preserves colimits, $\Box^1 \otimes C^{m,n}$ is a quotient of $\Box^{1+m+n}$ with quotient map $\Box^1 \otimes q$. From this description we see that $\Box^1 \otimes C^{m,n}$ is obtained from $\Box^{1+m+n}$ by identifying two $k$-cubes $f, g$ whenever $f_1 = g_1$ and the cubes $(f_2, ..., f_{n+1})$ and $(g_2, ..., g_{n+1})$ are identified in $C^{m,n}$. In other words, we obtain $\Box^1 \otimes C^{m,n}$ from $\Box^{1+m+n}$ by identifying $f$ and $g$ if there exists $j$ with $2 \leq j \leq n+1$ such that $f_i = g_i$ for all $i \leq j$ and $f_j = g_j = \text{const}_1$. Taking the pushout of the inclusion $\partial_{1,1} \otimes C^{m,n}: C^{m,n} \to \Box^1 \otimes C^{m,n}$ along the unique map $C^{m,n} \to \Box^0$, we then see that $C^{m,n+1}$ is the quotient of $\Box^1 \otimes C^{m,n}$ obtained by identifying cubes $f, g$ whenever $f_1 = g_1 = \text{const}_1$. Thus the description holds for $C^{m,n+1}$. □
Lemma 5.10. For \( i \leq n \), the image of the composite map \( \square^{m+n-1} \xrightarrow{\partial_i} \square^{m+n} \rightarrow C^{m,n} \) is isomorphic to \( C^{m,n-1} \). For \( i \geq n+1, \varepsilon \in \{0,1\} \), the image of the composite map \( \square^{m+n-1} \xrightarrow{\partial_i,\varepsilon} \square^{m+n} \rightarrow C^{m,n} \) is isomorphic to \( C^{m-1,n} \).

Proof. First consider the composite map \( \square^{m+n-1} \xrightarrow{\partial_i,\varepsilon} \square^{m+n} \rightarrow C^{m,n} \). Let \( f = (f_1, \ldots, f_{m+n-1}) \) denote a \( k \)-cube of \( \square^{m+n-1} \), as in the proof of Lemma 5.8. We denote the image of this cube under \( \partial_i,\varepsilon \) by \( f' = (f'_1, \ldots, f'_{m+n-1}) \), where \( f'_j = f_j \) for \( j < i \), \( f'_i = \text{const}_0 \), and \( f'_j = f_{j-1} \) for \( j > i \). By Lemma 5.8, given two \( k \)-cubes \( f \) and \( g \) in \( \square^{m+n-1} \), their images under \( \partial_i,\varepsilon \) will be identified in the quotient \( C^{m,n} \) if and only if there exists \( j \leq n \) such that \( f'_j = g'_j \) for \( l \leq j \) and \( f'_j = g'_j = \text{const}_1 \) in other words, if there exists \( j \leq n-1 \) such that \( f_i = g_i \) for \( l \leq j \) and \( f_j = g_j = \text{const}_1 \). The desired isomorphism thus follows from Lemma 5.8.

The analysis of \( \partial_i,\varepsilon \) where \( i \geq n+1, \varepsilon \in \{0,1\} \) is similar, except that in that case we have \( f'_j = f_j \) for all \( j \leq i \). Thus we conclude that the images of \( f \) and \( g \) in the quotient \( C^{m,n} \) are equal if and only if there exists \( j \leq n \) such that \( f_i = g_i \) for \( l \leq j \) and \( f_j = g_j = \text{const}_1 \).

Using Lemma 5.10 and further computations, we can analyze the effect of cubical structure maps on cones.

Lemma 5.11. Let \( x \) be an \( (m,n) \)-cone in a cubical set \( X \). Then:

(i) for \( 1 \leq i \leq n \), \( x\partial_{i,0} \) is an \( (m,n-1) \)-cone;
(ii) for \( n+1 \leq i \leq m+n \), \( x\partial_{i,0} \) is an \( (m-1,n) \)-cone;
(iii) if \( m \geq 1 \), then for all \( i \), \( x\partial_{i,1} \) is an \( (m-1,n) \)-cone;
(iv) for \( n+1 \leq i \leq m+n+1 \), \( x\sigma_i \) is an \( (m+1,n) \)-cone;
(v) for \( 1 \leq i \leq n \), \( x\gamma_{i,0} \) is an \( (m,n+1) \)-cone;
(vi) for \( n+1 \leq i \leq m+n \), \( x\gamma_{i,\varepsilon} \) is an \( (m+1,n) \)-cone.

Proof. First consider item (i). By Lemma 5.10 we have a commuting diagram as shown below:

\[
\begin{array}{ccc}
\square^{m+n-1} & \xrightarrow{\partial_i} & \square^{m+n} \\
\downarrow & & \downarrow \\
C^{m,n-1} & \xrightarrow{\partial_i} & C^{m,n}
\end{array}
\]

Now, for an \( (m+n) \)-cube \( x \in X_{m+n} \) to be an \( (m,n) \)-cone means precisely that the corresponding map \( x: \square^{m+n} \rightarrow X \) factors through \( C^{m,n} \). So the face \( x\partial_{i,0} \) can be written as \( \square^{m+n-1} \xrightarrow{\partial_i,0} \).
\[ \square^{m+n} \to C^{m,n} \xrightarrow{\partial_{i,1}} X; \] by the diagram above we can rewrite this as \[ \square^{m+n-1} \to C^{m,n-1} \to C^{m,n} \xrightarrow{\partial_{i,1}} X. \] So \( x\partial_{i,0} \) factors through \( C^{m,n-1} \), meaning that it is an \((m,n-1)\)-cone.

Similar commuting diagrams can be used to prove the remaining statements. For item \( \text{(ii)} \) we may again apply Lemma \( \ref{lem:cone} \). The other statements require new computations. We will show these computations for item \( \text{(iii)} \); the others are similar.

Let \( m \geq 1, i \leq n \) and consider the composite \( \square^{m+n-1} \xrightarrow{\partial_{i,1}} \square^{m+n} \to C^{m,n} \). As in the proof of Lemma \( \ref{lem:cone} \), we let \( f \) denote an arbitrary \( k \)-cube of \( \square^{m+n-1} \) and let \( f' \) denote its image under \( \partial_{i,1} \); then once again we have \( f'_j = f_j \) for \( j \leq i - 1 \), but now \( f'_i = \text{const}_1 \). So let \( f \) and \( g \) be two \( k \)-cubes of \( \square^{m+n-1} \), and suppose that there exists \( j \leq n \) such that \( f_l = g_l \) for \( l \leq j \) and \( f_j = g_j = \text{const}_1 \). Then there exists \( j' \leq n \) such that \( f'_l = g'_l \) for \( l \leq j' \) and \( f'_{j'} = g'_{j'} = \text{const}_1 \); if \( j < i \) then \( j' = j \), while if \( j \geq i \) then \( j' = i \). So \( f' \) and \( g' \) are identified in \( C^{m,n} \). Thus the composite map factors through \( C^{m-1,n} \), i.e. we have a commuting diagram:

\[
\begin{array}{ccc}
\square^{m+n-1} & \xrightarrow{\partial_{i,1}} & \square^{m+n} \\
\downarrow & & \downarrow \\
C^{m-1,n} & \to & C^{m,n}
\end{array}
\]

So for any \((m,n)\)-cone \( x \), \( x\partial_{i,1} \) is an \((m-1,n)\)-cone.

**Corollary 5.12.** For \( n \geq 1 \), every face of a \((0,n)\)-cone is a \((0,n-1)\)-cone. \( \square \)

**Proof.** Let \( x: \square^n \to X \) be a \((0,n)\)-cone, and consider a face \( x\partial_{i,\varepsilon} \). If \( i \leq n, \varepsilon = 0 \), then \( x\partial_{i,\varepsilon} \) is a \((0,n-1)\)-cone by Lemma \( \ref{lem:cone} \). Otherwise, we may note that \( x \) is a \((1,n-1)\)-cone by Corollary \( \ref{cor:cone} \) and therefore \( x\partial_{i,\varepsilon} \) is a \((0,n-1)\)-cone by Lemma \( \ref{lem:cone} \) or \( \text{(iii)} \). \( \square \)

**Corollary 5.13.** For \( m \geq 1, n \geq 0 \), let \( x \) be an \((m+n-1)\)-cube in a cubical set \( X \). If \( x\gamma_{n,0} \) is an \((m,n)\)-cone, then it is also an \((m-1,n+1)\)-cone.

**Proof.** By Lemma \( \ref{lem:cone} \) \( \text{(ii)} \), \( x\gamma_{n,0} \partial_{n+1,0} = x \) is an \((m-1,n)\)-cone. Therefore, \( x\gamma_{n,0} \) is an \((m-1,n+1)\)-cone by Lemma \( \ref{lem:cone} \) \( \text{(v)} \). \( \square \)

In some cases it will be more convenient to characterize cones in a cubical set by a set of conditions on their faces. By a direct analysis of the cubes of \( C^{m,n} \), or by an inductive argument similar to that used in the proof of Lemma \( \ref{lem:cone} \), we have the following characterization of \((m,n)\)-cones in \( X \).

**Lemma 5.14.** For \( m, n \) with \( n \geq 1 \), and \( X \in cSet \), a cube \( x: \square^{m+n} \to X \) is an \((m,n)\)-cone if and only if for all \( i \) such that \( 1 \leq i \leq n \) we have

\[
x\partial_{i,1} = x\partial_{m+n,0}\partial_{m+n-1,0}...\partial_{i+1,0}\partial_{i,1}\sigma_i\sigma_{i+1}...\sigma_{m+n-2}\sigma_{m+n-1}
\]

(\emph{In the case} \( m = 0, i = n \) \emph{we interpret this statement as the tautology} \( x\partial_{n,1} = x\partial_{n,1} \)). \( \square \)

This formula is admittedly somewhat ad hoc; various other choices of face maps would give equivalent conditions. The intuition behind it is that for \( 1 \leq i \leq n \), the \((i,1)\)-face of an \((m,n)\)-cone is degenerate in dimensions \( i + 1 \) to \( m + n \).
We will also use for the following result, which shows that the standard cones contain many inner open boxes.

**Lemma 5.15.** For \( n \geq 1, 2 \leq i \leq m+n \), the quotient map \( \Box^{m+n} \to C^{m,n} \) sends the critical edge with respect to the face \( \partial_i,0 \) to a degenerate edge.

**Proof.** The critical edge in question corresponds to the function \( f: [1] \to [1]^{m+n} \) with \( f_i = \text{id}([1]) \), \( f_j = \text{const}_1 \) for \( j \neq i \). In particular, \( f_1 = \text{const}_1 \), so \( f \) is equivalent, under the equivalence relation of Lemma 5.8, to the map \([1] \to [1]^{m+n}\) which is constant at \((1,...,1)\). \( \square \)

We now prove a lemma regarding the standard forms of cones.

**Lemma 5.16.** Let \( m \geq 1 \), and let \( x: C^{m,n} \to X \) be a degenerate \((m,n)\)-cone.

1. If the standard form of \( x \) is \( z\sigma_{ap} \), then \( a_p \geq n+1 \).
2. If the standard form of \( x \) is \( z\gamma_{b_q,1} \), then \( b_q \geq n+1 \).

**Proof.** For \( n = 0 \) these statements are trivial, so assume \( n \geq 1 \). We will prove item (i); the proof for item (ii) is similar.

Towards a contradiction, suppose that \( a_p \leq n \), and let \( z = y_{b_1,ε_1,1}...γ_{b_q,ε_q,1}σ_{a_1}...σ_{a_p,1} \), so that \( z\sigma_{ap} = x \). Taking the \((a_p,1)\)-faces of both sides of this equation, and applying Lemma 5.14, we see that:

\[
\begin{align*}
z &= x\partial_{m+n,0}...\partial_{a_p+1,0}\partial_{a_p,1}\sigma_{a_p}...\sigma_{m+n-1} \\
\therefore z\sigma_{ap} &= x\partial_{m+n,0}...\partial_{a_p+1,0}\partial_{a_p,1}\sigma_{a_p}...\sigma_{m+n-1}\sigma_{ap} \\
\therefore x &= x\partial_{m+n,0}...\partial_{a_p+1,0}\partial_{a_p,1}\sigma_{a_p}...\sigma_{m+n}
\end{align*}
\]

In the last step, we have repeatedly used the identity \( σ_jσ_i = σ_is_{j+1} \) for \( i \leq j \) to rearrange the string \( σ_{a_p}...σ_{m+n-1,1}\sigma_{ap} \) into one whose indices are in strictly increasing order. (We can do this because, by our assumption on \( m, m+n-1 \geq n \geq a_p \).) Now let \( y'_{b'_q,ε'_q,1}...γ_{b'_j,ε'_j,1}σ_{a'_1}...σ_{a'_p,1} \) be the standard form of \( x\partial_{m+n,0}...\partial_{a_p+1,0}\partial_{a_p,1} \); then we have:

\[
x = y'_{b'_q,ε'_q,1}...γ_{b'_j,ε'_j,1}σ_{a'_1}...σ_{a'_p,1}\sigma_{a_p}...\sigma_{m+n}
\]

We can apply further identities to re-order the maps on the right-hand side of this equation, obtaining a standard form for \( x \) in which the rightmost degeneracy map has index greater than or equal to \( m+n \). But as the standard form of \( x \) is unique, this contradicts our assumption that \( a_p \leq n \). \( \square \)

**Corollary 5.17.** Let \( x: \Box^n \to X \). If \( x \) is a \((0,n)\)-cone, then the standard form of \( x \) contains no positive connection maps.
Proof. Let \( x = y^{\gamma_{b_1,e_1}} \cdots y^{\gamma_{b_l,e_l}} a_{a_1} \cdots a_{a_n} \) in standard form. Towards a contradiction, suppose that there exists \( 1 \leq i \leq q \) such that \( \varepsilon_i = 1 \). By repeatedly applying face maps and using Corollary 5.12 we see that \( y^{\gamma_{b_1,e_1}} \cdots y^{\gamma_{b_l,e_l}} \) is a \((0, n - p - q + i)\)-cone. Lemma 5.16(ii) thus implies that \( b_i \geq n - p - q + i + 1 \). But \( \gamma_{b_1,1} \) is a map \([1]^{n - p - q + i} \rightarrow [1]^{n - p - q + i - 1} \), implying \( b_i \leq n - p - q + i - 1 \). □

We will also require some lemmas concerning subcomplexes of \( C_{m,n} \) consisting of specified faces.

Definition 5.18. For \( m, n \geq 0, k \leq n \), \( B_{m,n,k} \) is the subcomplex of \( C_{m,n} \) consisting of the images of the faces \( \partial_{1,0} \) through \( \partial_{k,0} \), as well as all faces \( \partial_{i,1} \), under the quotient map \( \Box^{m+n} \rightarrow C_{m,n} \).

In order to characterize maps out of \( B_{m,n,k} \), we will need to prove a couple of lemmas concerning the faces of \( C_{m,n} \).

Lemma 5.19. For \( m, n \geq 0, 1 \leq i_1 < i_2 \leq m + n, \varepsilon_1, \varepsilon_2 \in \{0, 1\} \), where \( i_j \geq n + 1 \) if \( \varepsilon_j = 1 \), the intersection of the images of the faces \( \partial_{i_1,\varepsilon_1} \) and \( \partial_{i_2,\varepsilon_2} \) of \( \Box^{m+n} \) under the quotient map \( \Box^{m+n} \rightarrow C_{m,n} \) is exactly the image of the face \( \partial_{i_1,\varepsilon_1} \partial_{i_2,\varepsilon_2} \partial_{1,\varepsilon_1} = \partial_{1,\varepsilon_1} \partial_{i_2-1,\varepsilon_2} \).

Proof. That the intersection of the images of \( \partial_{i_1,\varepsilon_1} \) and \( \partial_{i_2,\varepsilon_2} \) contains the image of \( \partial_{i_1,\varepsilon_1} \partial_{i_2,\varepsilon_2} \partial_{1,\varepsilon_1} \) is clear, as this face is the intersection of \( \partial_{i_1,\varepsilon_1} \) and \( \partial_{i_2,\varepsilon_2} \) in \( \Box^{m+n} \). Now we will verify the opposite containment, using description of \( C_{m,n} \) from Lemma 5.8.

To this end, consider a map \( f: [1]^k \rightarrow [1]^{m+n} \) such that the equivalence class \([f] \in C_{m,n}^{m,n}\) is contained in the images of faces \((i_1, \varepsilon_1)\) and \((i_2, \varepsilon_2)\). We will construct \( f': [1]^k \rightarrow [1]^{m+n} \) such that \( f \sim f' \) and \( f' \) is contained in the intersection of faces \((i_1, \varepsilon_1)\) and \((i_2, \varepsilon_2)\), thereby showing that \([f] = [f']\) is contained in the image of this intersection under the quotient map.

Since \( f \) is in the image of face \((i_1, \varepsilon_1)\), \( f \sim g \) for some \( g: [1]^k \rightarrow [1]^{m+n} \) such that \( g_{i_1} = \text{const}_{\varepsilon_1} \). Therefore, at least one of the following holds:

(i) \( f_{i_1} = \text{const}_{\varepsilon_1} \);

(ii) \( f_j = g_j = \text{const}_1 \) for some \( j \leq \min(i_1 - 1, n) \).

If (ii) holds, then \( f \) is equivalent to any \( f' \) such that \( f '_l = f_l \) for \( l \leq j \); in particular, we can choose such an \( f' \) satisfying \( f'_{i_1} = \text{const}_{\varepsilon_1} \), \( f'_{i_2} = \text{const}_{\varepsilon_2} \).

Now suppose that (i) holds, but (ii) does not. Then because \( f \) is in the image of face \((i_2, \varepsilon_2)\), \( f \sim h \) for some \( h: [1]^k \rightarrow [1]^{m+n} \) such that \( h_{i_2} = \text{const}_{\varepsilon_2} \). Therefore, at least one of the following holds:

(i) \( f_{i_2} = \text{const}_{\varepsilon_2} \);

(ii) \( f_j = h_j = \text{const}_1 \) for some \( i_1 + 1 \leq j \leq \min(i_2 - 1, n) \).

In case (i), we have \( f_{i_1} = \text{const}_{\varepsilon_1} \), \( f_{i_2} = \text{const}_{\varepsilon_2} \), so we can simply choose \( f' = f \). In case (ii), \( f \) is equivalent to any \( f' \) such that \( f'_l = f_l \) for \( l \leq j \) (which implies \( f'_{i_1} = \text{const}_{\varepsilon_1} \)); in particular, we can choose such an \( f' \) satisfying \( f'_{i_2} = \text{const}_{\varepsilon_2} \). □

Lemma 5.20. For \( i \leq n \), the image of the face \( \partial_{i,1} \) under the quotient map \( \Box^{m+n} \rightarrow C_{m,n} \) is contained in the image of \( \partial_{m+n,1} \).

Proof. Let \( f: [1]^k \rightarrow [1]^{m+n} \) be a \( k \)-cube of \( \Box^{m+n} \) which factors through \( \partial_{i,1} \). Then \( f_i = \text{const}_1 \). Thus \( f \) is equivalent to any \( f': [1]^k \rightarrow [1]^{m+n} \) such that \( f'_j = f_j \) for all \( j \leq i \); in particular, we may
choose such an $f'$ with $f'_{m+n} = \text{const}_1$. So $f'$ factors through $\partial_{m+n,1}$; thus $[f] = [f']$ is contained in the image of $\partial_{m+n,1}$ under the quotient map.

Note that Lemma 5.20 can also be seen as a consequence of Lemma 5.14.

**Lemma 5.21.** For a cubical set $X$, a map $x : B^{m,n,k} \to X$ is determined by a set of $(m,n-1)$-cones $x_{i,0} : C^{m,n-1} \to X$ for $1 \leq i \leq n$ and a set of $(m-1,n)$-cones $x_{i,1}$ for $n + 1 \leq i \leq m + n$ such that for all $i_1 < i_2, \varepsilon_1, \varepsilon_2 \in \{0,1\}, x_{i_2,\varepsilon_2} \partial_{i_1,\varepsilon_1} = x_{i_1,\varepsilon_1} \partial_{i_2-1,\varepsilon_2}$, with $x_{i,\varepsilon}$ being the image of $\partial_{i,\varepsilon} x$ under $x$.

**Proof.** To define a map $x : B^{m,n,k} \to X$, it suffices to assign the values of $x$ on the faces $[\partial_{i,\varepsilon}]$ of $C^{m,n}$ for which $i \leq k$ or $\varepsilon = 1$, provided that these choices are consistent on the intersections of faces. By Lemma 5.20 it suffices to consider only those faces for which $i \leq k, \varepsilon = 0$ or $i \geq n + 1, \varepsilon = 1$. These faces are isomorphic to $C^{m,n-1}$ or $C^{m-1,n}$, respectively, by Lemma 5.10. By Lemma 5.19 to show that these choices are consistent on the intersections of faces, it suffices to show that they satisfy the cubical identity for composites of face maps.

**Proposition 5.22.** For all $m, n \geq 1, n \leq k \leq m + n - 1$, the inclusion $B^{m,n,k} \hookrightarrow C^{m,n}$ is a trivial cofibration.

**Proof.** We proceed by induction on $m$. In the base case $m = 1$, the only relevant value of $k$ is $k = n$. The only face of $C^{1,n}$ which is missing from $B^{1,n,n}$ is $[\partial_{n+1,0}]$, so the inclusion $B^{1,n,n} \hookrightarrow C^{1,n}$ is an $(n + 1, 0)$-open box filling. By Lemma 5.14 the critical edge for this open box filling is degenerate, so the inclusion is a trivial cofibration.

Now let $m \geq 2$, and suppose the statement holds for $m - 1$. For $n \leq k \leq m + n - 2$, consider the intersection of the $(k + 1, 0)$-face of $C^{m,n}$, $[\partial_{k,0}]$, with the subcomplex $B^{m,n,k}$. By Lemma 5.19 and Lemma 5.20 this intersection consists of faces $(1, 0)$ through $(k, 0)$ and $(1, 1)$ through $(m + n - 1, 1)$ of $[\partial_{k+1,0}]$. By Lemma 5.10 it is thus isomorphic to $B^{m-1,n,k}$.

Thus we can express $B^{m,n,k+1}$ as the following pushout:

\[
\begin{array}{ccc}
B^{m-1,n,k} & \longrightarrow & B^{m,n,k} \\
\downarrow & & \downarrow \\
C^{m-1,n} & \longrightarrow & B^{m,n,k+1}
\end{array}
\]

By the induction hypothesis, $B^{m,n,k} \hookrightarrow C^{m-1,n}$ is a trivial cofibration, since $n \leq k$ implies $m + n - 2$. Thus $B^{m,n,k} \hookrightarrow B^{m,n,k+1}$ is a trivial cofibration, as a pushout of a trivial cofibration. From this we can see that for any $n \leq k \leq m + n - 2$, the composite inclusion $B^{m,n,k} \hookrightarrow B^{m,n,k+1} \hookrightarrow \ldots \hookrightarrow B^{m,n,m+n-1}$ is a trivial cofibration.

Thus it suffices to prove that $B^{m,n,m+n-1} \hookrightarrow C^{m,n}$ is a trivial cofibration. Here, as in the base case, the subcomplex $B^{m,n,m+n-1}$ is only missing the face $[\partial_{m+n,0}]$, so the inclusion is an $(m+n,0)$-open box filling. The critical edge of this open box is degenerate by Lemma 5.13, so the inclusion is indeed a trivial cofibration.

Thus we see that the inclusion $B^{m,n,k} \hookrightarrow C^{m,n}$ is a trivial cofibration for any $m, n, k$ satisfying the constraints given in the statement.
Definition 5.23. A coherent family of composites $\theta$ in a cubical quasicategory $X$ consists of a family of functions $\theta^{m,n} : cSet(C^{m,n}, X) \to cSet(C^{m,n+1}, X)$ satisfying the following identities:

$(\Theta 1)$ for $x : C^{m,n} \to X$ and $i \leq n$, $\theta^{m,n}(x)\partial_{i,0} = \theta^{m,n-1}(x\partial_{i,0})$

$(\Theta 2)$ for $x : C^{m,n} \to X$, $\theta^{m,n}(x)\partial_{n+1,0} = x$

$(\Theta 3)$ for $x : C^{m,n} \to X$ and $i \geq n + 2$, $\theta^{m,n}(x)\partial_{i,1} = \theta^{m-1,n}(x\partial_{i-1,1})$

$(\Theta 4)$ for $x : C^{m-1,n} \to X$ and $i \geq n + 1$, $\theta^{m,n}(x\sigma_i) = \theta^{m-1,n}(x)\sigma_{i+1}$

$(\Theta 5)$ for $x : C^{m,n-1} \to X$ and $i \leq n - 1$, $\theta^{m,n}(x\gamma_{i,0}) = \theta^{m,n-1}(x)\gamma_{i,0}$

$(\Theta 6)$ for $x : C^{m-1,n} \to X$ $i \geq n + 1$, then $\theta^{m,n}(x\gamma_{i,e}) = \theta^{m-1,n}(x)\gamma_{i+1,e}$

$(\Theta 7)$ for $x : C^{m,n-1} \to X$, $\theta^{m,n}(\theta^{m,n}(x)) = \theta^{m,n-1}(x)\gamma_{n,0}$

$(\Theta 8)$ for $x : C^{m-1,n+1} \to X$, $\theta^{m,n}(x) = x\gamma_{n+1,0}$

The rough intuition behind Definition 5.23 is this: thinking of cubes in a cubical quasicategory $X$ as representing diagrams commuting up to homotopy, constructing a coherent family of composites on $X$ amounts to coherently choosing a specific composite edge for each $x : \square^n \to X$. For instance, consider a 2-cube $x$ as depicted below, witnessing $gf \sim qp$:

\begin{center}
\begin{tikzpicture}
\draw[->, thick] (0,0) -- (1,0) node[midway, above] {$f$};
\draw[->, thick] (0,0) -- (0,1) node[midway, right] {$g$};
\draw[->, thick] (0,1) -- (1,1) node[midway, above] {$b$};
\draw[->, thick] (1,0) -- (1,1) node[midway, right] {$d$};
\draw[->, thick] (0,0) -- (0,1) node[midway, left] {$c$};
\draw[->, thick] (0,0) -- (1,0) node[midway, below] {$a$};
\end{tikzpicture}
\end{center}

Then the identities $(\Theta 1)$ through $(\Theta 8)$ imply that $\theta^{2,0}(x)$ is a 3-cube of the form depicted below:

\begin{center}
\begin{tikzpicture}
\draw[->, thick] (0,0) -- (1,0) node[midway, above] {$f$};
\draw[->, thick] (0,0) -- (0,1) node[midway, right] {$g$};
\draw[->, thick] (0,1) -- (1,1) node[midway, above] {$b$};
\draw[->, thick] (1,0) -- (1,1) node[midway, right] {$d$};
\draw[->, thick] (0,0) -- (0,1) node[midway, left] {$c$};
\draw[->, thick] (0,0) -- (1,0) node[midway, below] {$a$};
\draw[->, thick] (0,1) -- (1,1) node[midway, below] {$d$};
\draw[->, thick] (0,0) -- (0,1) node[midway, right] {$q$};
\draw[->, thick] (1,0) -- (0,1) node[midway, left] {$p$};
\draw[->, thick] (1,0) -- (1,1) node[midway, right] {$q$};
\draw[->, thick] (0,1) -- (1,0) node[midway, above] {$f$};
\end{tikzpicture}
\end{center}

The edge $s$ from $a$ to $d$ is homotopic to both composites $gf$ and $qp$.

Theorem 5.24. Every cubical quasicategory admits a coherent family of composites.

To prove this, we will construct the family of functions $\theta^{m,n}$ by induction on $m$ and $n$. 
Definition 5.25 (Base case). For a cubical quasicategory $X$ and $x: C^{0,n} \to X$, let $\theta^{0,n}(x) = x\sigma_{n+1}$. For $x: C^{1,n} \to X$, let $\theta^{1,n}(x) = x\gamma_{n+1,0}$. These define $(0, n + 1)$-cones and $(1, n + 1)$-cones, respectively, by Lemma 5.11.

Remark 5.26. While it may appear that these definitions of $\theta^{0,n}$ and $\theta^{1,n}$ were chosen arbitrarily, in fact they are implied by the identities of Definition 5.23. Specifically, the given definition of $\theta^{1,n}$ is implied by $(\Theta 8)$ and Lemma 5.2. This, together with $(\Theta 3)$ and Lemma 5.11(iv), then implies the given definition of $\theta^{0,n}$.

Lemma 5.27. For a cubical quasicategory $X$, the families of functions $\theta^{0,n}$ and $\theta^{1,n}$ satisfy the identities of Definition 5.23.

Proof. We first verify the identities for $\theta^{0,n}$. The hypotheses of $(\Theta 3)$, $(\Theta 4)$ and $(\Theta 6)$ are vacuous here, as there are no cubical structure maps satisfying the given constraints on their indices; $(\Theta 8)$ similarly does not apply in this case. The remaining identities follow easily from the cubical identities:

- For $(\Theta 1)$ let $i \leq n$. Then $\theta^{0,n}(x)\partial_{i,0} = x\sigma_{n+1}\partial_{i,0} = x\partial_{i,0}\sigma_{n} = \theta^{0,n-1}(x)\sigma_{n}$.
- For $(\Theta 2)$ we have $\theta^{0,n}(x)\partial_{n+1,0} = x\gamma_{n+1,0}\partial_{n+1,0} = x$.
- For $(\Theta 5)$ let $1 \leq i \leq n - 1$. Then $\theta^{0,n}(x\gamma_{i,0}) = x\gamma_{i,0}\sigma_{n+1} = x\sigma_{n}\gamma_{i,0} = \theta^{0,n-1}(x)\gamma_{i,0}$.
- For $(\Theta 7)$ we have $\theta^{0,n+1}(\theta^{0,n}(x)) = x\sigma_{n+1}\sigma_{n+2} = x\sigma_{n+1}\gamma_{n+1,0} = \theta^{0,n}(x)\gamma_{n+1,0}$.

Next we will verify the identities for $\theta^{1,n}$. Here $(\Theta 8)$ holds by definition, while the hypothesis of $(\Theta 6)$ is still vacuous, as there are no connection maps $\gamma_{i,0}: [1]^{n} \to [1]^{n-1}$ with $i \geq n + 1$. Once again, we can verify the remaining identities using the cubical identities:

- For $(\Theta 1)$ let $i \leq n$. Then $\theta^{1,n}(x)\partial_{i,0} = x\gamma_{n+1,0}\partial_{i,0} = x\partial_{i,0}\gamma_{n,0} = \theta^{1,n-1}(x)\partial_{i,0}$.
- For $(\Theta 2)$ we have $\theta^{1,n}(x)\partial_{n+1,0} = x\gamma_{n+1,0}\partial_{n+1,0} = x$.
- For $(\Theta 3)$ we need only consider the case $m' = 1, i = n + 2$. For this case we have $\theta^{1,n}(x)\partial_{n+2,1} = x\gamma_{n+1,0}\partial_{n+2,1} = x\partial_{n+1,1}\sigma_{n+1} = \theta^{0,n}(x)\partial_{n+1,1}$.
- For $(\Theta 4)$ the only relevant degeneracy is $\sigma_{n+1}$, and we have $\theta^{1,n}(x\sigma_{n+1}) = x\sigma_{n+1}\gamma_{n+1,0} = x\sigma_{n+1}\partial_{n+2} = \theta^{0,n}(x)\sigma_{n+2}$.
- For $(\Theta 5)$ let $1 \leq i \leq n - 1$. Then $\theta^{1,n}(x\gamma_{i,0}) = x\gamma_{i,0}\gamma_{n+1,0} = x\gamma_{n,0}\gamma_{i,0} = \theta^{1,n-1}(x)\gamma_{i,0}$.
- For $(\Theta 7)$ we have $\theta^{1,n+1}(\theta^{1,n}(x)) = x\gamma_{n+1,0}\gamma_{n+2,0} = x\gamma_{n+1,0}\gamma_{n+1,0} = \theta^{1,n}(x)\gamma_{n+1,0}$.

The following lemma will be used in defining $\theta^{m,n}$ in the inductive case.

Lemma 5.28. Let $m \geq 2, n \geq 0$, and let $X$ be a cubical quasicategory equipped with functions $\theta^{m,n}$ satisfying the identities of Definition 5.23 for all pairs $(m', n')$ such that $m' \leq m$, $n' \leq n$, and at least one of these two inequalities is strict. Then for any $x: C^{m,n} \to X$, there exists an $(m, n + 1)$-cone $\theta^{m,n}(x): C^{m,n+1} \to X$ satisfying $(\Theta 1)$, $(\Theta 2)$, and $(\Theta 3)$.

Proof. For each $i \leq n$, the face $x\partial_{i,0}$ is an $(m, n - 1)$-cone by Lemma 5.11(iii), thus $X$ contains an $(m, n)$-cone $\theta^{m,n-1}(x\partial_{i,0})$. Similarly, for each $i \geq n + 2$, the face $x\partial_{i-1,1}$ is an $(m - 1, n)$-cone,
and so $X$ contains an $(m - 1, n + 1)$-cone $\theta^{m-1,n}(x \partial_{-1,1})$, and these cones satisfy the identities of Definition 5.23. Using Lemma 5.21 we will define a map $y: B^{m,n+1,n+1} \to X$ with $y_{i,0} = \theta^{m-1,n}(x \partial_{i,0})$ for $1 \leq i \leq n$, $y_{n+1,0} = x$, and $y_{i,1} = \theta^{m-1,n}(x \partial_{-1,1})$ for $i \geq n + 2$.

To show that we can define such a map, we must verify that our choices of $y_{i,\varepsilon}$ satisfy the cubical identity for composing face maps.

For $i_1 < i_2 \leq n$, $\varepsilon_1 = \varepsilon_2 = 0$, we have:

$$y_{i_2,0} \partial_{i_1,0} = \theta^{m,n-1}(x \partial_{i_2,0}) \partial_{i_1,0}$$
$$= \theta^{m,n-2}(x \partial_{i_2,0} \partial_{i_1,0})$$
$$= \theta^{m,n-2}(x \partial_{i_1,0} \partial_{i_2-1,0})$$
$$= \theta^{m,n-1}(x \partial_{i_1,0}) \partial_{i_2-1,0}$$
$$= y_{i_1,0} \partial_{i_2-1,0}$$

For $i_1 < i_2 = n + 1$, we have:

$$y_{n+1,0} \partial_{i_1,0} = x \partial_{i_1,0}$$
$$= \theta^{m,n-1}(x \partial_{i_1,0}) \partial_{n,0}$$
$$= y_{i_1,0} \partial_{n,0}$$

For $n + 1 = i_1 < i_2$ we have:

$$y_{i_2,1} \partial_{n+1,0} = \theta^{m-1,n}(x \partial_{i_2-1,1}) \partial_{n+1,0}$$
$$= x \partial_{i_2-1,1}$$
$$= y_{n+1,0} \partial_{i_2-1,1}$$

Finally, for $n + 2 \leq i_1 < i_2$, we have:

$$y_{i_2,1} \partial_{i_1,1} = \theta^{m-1,n}(x \partial_{i_2-1,1}) \partial_{i_1,1}$$
$$= \theta^{m-2,n}(x \partial_{i_2-1,1} \partial_{i_1-1,1})$$
$$= \theta^{m-2,n}(x \partial_{i_1-1,1} \partial_{i_2-2,1})$$
$$= \theta^{m-1,n}(x \partial_{i_1-1,1}) \partial_{i_2-1,1}$$
$$= y_{i_1,1} \partial_{i_2-1,1}$$
Thus the \((n + 1)\)-tuple \(y\) does indeed define a map \(B^{m,n+1,n+1} \to X\). Now consider the following commuting diagram:

\[
\begin{array}{ccc}
B^{m,n+1,n+1} & \xrightarrow{y} & X \\
\sim & \downarrow & \\
C^{m,n+1} & \to & \square^0
\end{array}
\]

The left-hand map is a trivial cofibration by Proposition \[5.22\] while the right-hand map is a fibration by assumption. Thus there exists a lift of this diagram, i.e. an \((m, n+1)\)-cone \(\tilde{\theta}^{m,n}(x): C^{m,n+1} \to X\) such that for \(i \leq n\), \(\tilde{\theta}^{m,n}(x)\partial_{i,0} = \theta^{m,n-1}(x\partial_{i,0})\), \(\tilde{\theta}^{m,n}(x)\partial_{n+1,0} = x\), and for \(i \geq n+2\), \(\tilde{\theta}^{m,n}(x)\partial_{i,1} = \theta^{m-1,n}(x\partial_{i-1,1})\).

Although Lemma \[5.28\] applies for an arbitrary \((m, n)\)-cone \(x\) with \(m \geq 2\), we will not use it to construct \(\theta^{m,n}\) for all such cones, as the arbitrary lift used in its proof may not satisfy \((4)\) through \((8)\). Instead, we define \(\theta^{m,n}\) for \(m \geq 2\), \(n \geq 0\) by the following case analysis.

**Definition 5.29** (Inductive case). Let \(m \geq 2\), \(n \geq 0\), and let \(X\) be a cubical quasicategory equipped with functions \(\theta^{m,n}\) satisfying the identities of Definition \[5.23\] for all pairs \((m', n')\) such that \(m' \leq m\), \(n' \leq n\), and at least one of these two inequalities is strict. Let \(x: C^{m,n} \to X\) be an \((m, n)\)-cone. Then \(\theta^{m,n}(x): \square^{m+n+1} \to X^{m,n}\) is defined as follows:

1. If the standard form of \(x\) is \(z\sigma_{a_p}\) for some \(a_p \geq n + 1\), then \(\theta^{m,n}(x) = \theta^{m-1,n}(z)\sigma_{a_p+1};\)
2. If the standard form of \(x\) is \(z\gamma_{b_q,0}\) for some \(b_q \leq n - 1\), then \(\theta^{m,n}(x) = \theta^{m,n-1}(z)\gamma_{b_q,0};\)
3. If the standard form of \(x\) is \(z\gamma_{b_q,\varepsilon}\) for some \(b_q \geq n + 1\), then \(\theta^{m,n}(x) = \theta^{m-1,n}(z)\gamma_{b_q+1,\varepsilon};\)
4. If \(x\) is an \((m-1, n+1)\)-cone not covered under any of cases (1) through (3), then \(\theta^{m,n}(x) = x\gamma_{n+1,0};\)
5. If \(x = \theta^{m,n-1}(x')\) for some \(x': C^{m,n-1} \to X\) and \(x\) is not covered under any of cases (1) through (4) then \(\theta^{m,n}(x) = x\gamma_{n,0};\)
6. If \(x\) is not covered under any of cases (1) through (5), then \(\theta^{m,n}(x)\) is the cone \(\tilde{\theta}^{m,n}(x)\) constructed in Lemma \[5.28\].

That each of the constructions of Definition \[5.29\] produces an \((m, n + 1)\)-cone can be seen from Corollary \[5.9\] and Lemmas \[5.11\] and \[5.28\].

Before proving that this definition satisfies the identities of Definition \[5.23\] we prove some simple lemmas about its cases.

**Lemma 5.30.** Every degenerate cone in a cubical quasicategory \(X\) falls under one of cases (1) to (4) of Definition \[5.29\].

**Proof.** This follows from Corollary \[5.13\] and Lemma \[5.16\].

**Corollary 5.31.** Case (6) of Definition \[5.29\] consists precisely of those \((m, n)\)-cones of \(X\) which are:

- Non-degenerate;
• Not \((m - 1, n + 1)\)-cones;
• Not equal to \(\theta^{m,n-1}(x)\) for any \(x\): \(C^{m,n-1} \to X\).

\[\square\]

**Lemma 5.32.** Let \(X\) be a cubical quasicategory, and let \(m, n \geq 0\) for which we have defined \(\theta^{m,n}\) satisfying the identities of Definition \ref{def-theta}. Then \(x: C^{m,n} \to X\) is covered under case (6) of Definition \ref{def-theta} i.e.:

- \(x\) is non-degenerate;
- \(x\) is not an \((m - 1, n + 1)\)-cone;
- \(x\) is not equal to \(\theta^{m,n-1}(x')\) for any \(x': C^{m,n-1} \to X\);

if and only if \(\theta^{m,n}(x)\) is covered under case (5), i.e. it is non-degenerate and is not an \((m - 1, n + 2)\)-cone.

**Proof.** First suppose \(x\) is covered under case (6). The cubical identities show that if a degenerate cube \(y\) has a non-degenerate face \(z\), then \(z\) appears as at least two distinct faces of \(y\). We have \(\theta^{m,n}(x)\partial_{n+1,0} = x\), and \(x\) is non-degenerate by assumption, so if \(\theta^{m,n}(x)\) is degenerate, then \(x\) must appear as at least one other face of \(\theta^{m,n}(x)\). However, for \(i \leq n\) we have \(\theta^{m,n}(x)\partial_{i,0} = \theta^{m,n-1}(x\partial_{i,0})\), while for \(i \geq n + 2\) or \(\varepsilon = 1\), \(\theta^{m,n}(x)\partial_{i,\varepsilon}\) is an \((m - 1, n + 1)\)-cone by Lemma \ref{lem-theta}. Thus none of these faces are equal to \(x\), showing that \(\theta^{m,n}(x)\) is non-degenerate. Furthermore, \(\theta^{m,n}(x)\) is not an \((m - 1, n + 2)\)-cone, as this would imply that \(\theta^{m,n}(x)\partial_{n+1,0} = x\) was an \((m - 1, n + 1)\)-cone by Lemma \ref{lem-theta}.

On the other hand, if \(x\) is not covered under case (6), then \(\theta^{m,n}(x)\) is degenerate, hence covered under one of cases (1) to (4) by Lemma \ref{lem-theta}.

\[\square\]

The proof that the construction \(\theta\) of Definition \ref{def-theta} satisfies all of the identities of Definition \ref{def-theta} involves many elaborate case analyses; for brevity, these calculations have been relegated to Appendix \ref{app-identities}.

**Proof of Theorem \ref{thm-cubical}.** The functions \(\theta^{m,n}\) are defined inductively by Definitions \ref{def-theta} and \ref{def-theta}. That this definition satisfies all the given identities is proven in Propositions \ref{prop-theta} to \ref{prop-theta}.

\[\square\]

The following lemma will be useful in various proofs involving coherent families of composites.

**Lemma 5.33.** Let \(X\) be a cubical quasicategory equipped with a coherent family of composites \(\theta\). For \(m \geq 0\) and \(x: \Box^m \to X\), the critical edge of \(\theta^{m,0}(x): \Box^{m+1} \to X\) with respect to its \((1,0)\)-face is degenerate.

**Proof.** We proceed by induction on \(m\). For \(m = 0\), we have \(\theta^{0,0}(x) = x\sigma_1\); so \(\theta^{0,0}(x)\) is degenerate of a vertex, thus its unique edge is degenerate.

Now let \(m \geq 1\), and suppose that the statement holds for \(m - 1\). The edge in question may be written as \(\theta^{m,0}(x)\partial_{m+1,1}...\partial_{3,1}\partial_{2,1}\). By \([\Theta3]\) this is equal to \(\theta^{m-1,0}(x\partial_{m,1})\partial_{m,1}...\partial_{2,1}\), which is degenerate by the induction hypothesis.

\[\square\]
6. Comparison with the Joyal model structure

In this section we use the theory of cones developed in Section 5 to compare the cubical Joyal model structure with the Joyal model structure on $sSet$, showing that the model structures constructed in Sections 2 to 4 present the theory of $(\infty,1)$-categories. As in Section 5, our results can be adapted to $cSet_0$ and $cSet_1$ by replacing the constructions of Section 5 with their analogues in the appropriate settings.

Our main goal is to prove the following:

**Theorem 6.1.** The adjunction $T : cSet \rightleftarrows sSet : U$ is a Quillen equivalence between the cubical Joyal model structure on $cSet$ and the Joyal model structure on $sSet$.

Throughout this section, $sSet$ and $cSet$ will be equipped with the Joyal and cubical Joyal model structures, respectively, unless otherwise noted.

Due to the difficulty of working directly with the triangulation functor, we first establish a second Quillen adjunction $Q : sSet \rightleftarrows cSet : \int$; this adjunction was previously studied in [KLW19] for cubical sets having only negative connections, but here we will construct it using the theory of cones developed in Section 5. We will prove that $Q \dashv \int$ is a Quillen equivalence, and that the left derived functor of $Q$ is an inverse to that of $T$. In order to define $Q$, we first recall a folklore result about constructing cosimplicial objects out of monads.

**Proposition 6.2.** Let $M$ be a monad on a category $C$. Then $M$ induces an augmented cosimplicial object $\Delta_{aug} \to \text{End} C$, defined as follows:

- For $n \geq -1$, $[n] \mapsto M^{n+1}$;
- $(\partial_i : [n-1] \to [n]) \mapsto M^{n-i} \eta_M$;
- $(\sigma_i : [n] \to [n-1]) \mapsto M^{n-i-1} \mu_M$.

In particular, for any $c \in C$ there is an augmented cosimplicial object $\Delta_{aug} \to C$ given by instantiating this construction at $c$.

**Proof.** This follows from the characterization of $\Delta_{aug}$ as the universal monoidal category equipped with a monoid, together with the characterization of monads on a category $C$ as monoids in $\text{End} C$. □

For $n \geq 0$, let $Q^n$ denote the cubical set $C^{n+1} \varnothing = C^{0,n}$. Likewise, for $W \in \{L,R\}, \varepsilon \in \{0,1\}$, let $Q^n_W = C^{n+1}_W \varnothing$.

**Proposition 6.3.** The assignment $[n] \mapsto Q^n$ extends to a cosimplicial object $Q : \Delta \to cSet$, with simplicial structure maps defined as follows:

<table>
<thead>
<tr>
<th>a map $Q^{n-1} \to Q^n$</th>
<th>$0^{th}$ face</th>
<th>$1^{st}$ face</th>
<th>$2^{nd}$ face</th>
<th>$\cdots$</th>
<th>$j^{th}$ face</th>
<th>$\cdots$</th>
<th>$n^{th}$ face</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
</tbody>
</table>
Proof. This follows from applying Proposition 6.2 to the monad of Proposition 5.6 and the object $\emptyset \in cSet$. For a direct construction, see [KV19] Prop. 2.3.

Taking the left Kan extension of this cosimplicial object along the Yoneda embedding, we obtain a functor $Q : sSet \to cSet$.

This functor has a right adjoint $f : cSet \to sSet$, given by $(fX)_n = cSet(Q^n, X)$.

**Remark 6.4.** Viewing $sSet$ as the slice category $sSet \downarrow \Delta^0$ and $cSet$ as the functor category $cSet^{[0]}$, the adjunction $Q \dashv f$ coincides with the cubical straightening-unstraightening adjunction developed in [KV18].

The alternative cone monads described in Proposition 5.6 admit similar constructions.

**Proposition 6.5.** For $W \in \{L, R\}$, $\varepsilon \in \{0, 1\}$, the assignment $[n] \mapsto Q^n_{W, \varepsilon}$ extends to a cosimplicial object $Q_W : \Delta \to cSet$. For $(W, \varepsilon) \neq (L, 1)$ the simplicial structure maps are defined as follows:

| a map $Q^n_{L,0} \to Q^n_{L,0}$ | is induced by a map $\square^n \to \square^n$ | $0^{th}$ face | $1^{st}$ face | $2^{nd}$ face | $\cdots$ | $j^{th}$ face | $\cdots$ | $n^{th}$ face |
|----------------------------------|-----------------------------------------------|--------------|--------------|--------------|.........|--------------|.........|--------------|
| $\partial_{n,0}$ | $\partial_{n,1}$ | $\partial_{n-1,1}$ | $\cdots$ | $\partial_{n-j+1,1}$ | $\cdots$ | $\partial_{1,1}$ |

| a map $Q^n_{L,0} \to Q^n_{R,0}$ | is induced by a map $\square^n \to \square^n$ | $0^{th}$ face | $1^{st}$ face | $2^{nd}$ face | $\cdots$ | $j^{th}$ face | $\cdots$ | $n^{th}$ face |
|----------------------------------|-----------------------------------------------|--------------|--------------|--------------|.........|--------------|.........|--------------|
| $\sigma_n$ | $\gamma_{n-1,1}$ | $\gamma_{n-2,1}$ | $\cdots$ | $\gamma_{n-j,1}$ | $\cdots$ | $\gamma_{1,1}$ |

| a map $Q^n_{R,0} \to Q^n_{R,0}$ | is induced by a map $\square^n \to \square^n$ | $0^{th}$ face | $1^{st}$ face | $2^{nd}$ face | $\cdots$ | $j^{th}$ face | $\cdots$ | $n^{th}$ face |
|----------------------------------|-----------------------------------------------|--------------|--------------|--------------|.........|--------------|.........|--------------|
| $\sigma_1$ | $\gamma_{1,1}$ | $\gamma_{2,1}$ | $\cdots$ | $\gamma_{j,1}$ | $\cdots$ | $\gamma_{n-1,1}$ |

**Proof.** This follows from applying Proposition 6.2 to the monads of Proposition 5.6.
Remark 6.6. We could instead have chosen to define the cosimplicial object of Proposition 6.2 by \(\partial_i \mapsto M^i \eta_{M^{n-1}}, \sigma_i \mapsto M^i \mu_{M^{n-1}}\); this amounts to pre-composing the cosimplicial object as we have defined it with the involution \((-)^{\text{op}}: \text{sSet} \to \text{sSet}\). If we had made this choice, we would have obtained a different set of cosimplicial objects \(Q_{W,\varepsilon}\).

As with the cosimplicial object constructed using left positive cones, each of these Kan extends to a functor \(Q_{W,\varepsilon}: \text{sSet} \to \text{cSet}\) having a right adjoint \(\int_{W,\varepsilon}: \text{cSet} \to \text{sSet}\).

Lemma 6.7. The functors \(Q_{W,\varepsilon}\) and \(\int_{W,\varepsilon}\), for \(W \in \{L, R\}, \varepsilon \in \{0, 1\}\), are related by the following formulas:

\[
\begin{align*}
Q_{L,0} &= (-)^{\text{co-op}} \circ Q_{L,1}; \\
Q_{R,0} &= (-)^{\text{op}} \circ Q_{L,1}; \\
Q_{R,1} &= (-)^{\text{co}} \circ Q_{L,1}; \\
\int_{L,0} &= \int_{L,1} \circ (-)^{\text{co-op}}; \\
\int_{R,0} &= \int_{L,1} \circ (-)^{\text{op}}; \\
\int_{R,1} &= \int_{L,1} \circ (-)^{\text{co}};
\end{align*}
\]

Proof. It suffices to prove the first three items, which follow from Lemma 5.5.

As we did in Section 5, from here on we will work exclusively with left positive cones except where noted, using the subscript \((L, 1)\) only where the potential for ambiguity arises.

The analogous functor \(Q: \text{sSet} \to \text{cSet}_0\), which we will denote \(Q_0\), was previously studied in [KLW19]. In that paper, the objects \(Q^n_0\) were described as quotients of \(\square^n_0\) under a certain equivalence relation; this relation is precisely that of Lemma 5.8 in the case \(m = 0\). We begin by recalling some of the theory developed in that paper, and adapting it to the present setting.

Lemma 6.8. We have a commuting triangle of adjunctions:

\[
\begin{array}{ccc}
\text{sSet} & \xrightarrow{Q} & \text{cSet} \\
\downarrow{\int_{W,\varepsilon}} & & \downarrow{i^*} \\
\text{cSet}_0 & \xleftarrow{i_*} & \text{cSet}
\end{array}
\]

Proof. It is easy to show that \(i_!Q_0^n \cong Q^n\); the general result follows from this, using the fact that \(i_!\) preserves colimits as a left adjoint.

Lemma 6.9. For any \(X \in \text{cSet}\), the counit \(Q \int X \to X\) is a monomorphism.

Proof. By Lemma 6.8, the counit of \(Q \dashv \int\) is the natural map \(i_!Q_0 \int_0 i^* X \to X\) for \(X \in \text{cSet}\). Applying Corollary 1.20, we wish to show that this map sends non-degenerate cubes to non-degenerate cubes, and does so injectively.
By Lemma 1.28 the action of this map on non-degenerate cubes coincides with that of its adjunct map $Q_0 \int_0 i^* X \to i^* X$. This map is a monomorphism by [KLW19] Lem. 4.2, hence it maps the non-degenerate cubes of $Q_0 \int_0 i^* X$ injectively to non-degenerate cubes of $i^* X$ by the analogue of Corollary 1.20 in $cSet_0$. The non-degenerate cubes of $i^* X$ consist of the non-degenerate cubes of $X$, together with the degenerate cubes of $X$ which cannot be expressed as degeneracies or negative connections. Therefore, to show that $Q \int X \to X$ is a monomorphism, it suffices to show that it does not send any non-degenerate cubes of $Q \int X$ to degenerate cubes of $X$ whose standard forms contain positive connection maps.

Note that every non-degenerate $n$-cube of $Q \int X$ is a $(0,n)$-cone – this follows from Lemmas 1.23 and 5.11. Thus the images of such cones under any cubical set map will also be $(0,n)$-cones. By Corollary 5.17 their standard forms will therefore contain no positive connection maps. □

This lemma shows that for any cubical set $X$, $Q \int X$ is a subcomplex of $X$. Specifically, it is the subcomplex whose non-degenerate $n$-cubes, for each $n$, are those which factor through $Q^n$ – in other words, they are the non-degenerate $(0,n)$-cones in $X$.

**Theorem 6.10.** The functor $Q : sSet \to cSet$ is fully faithful.

**Proof.** That $Q_0$ is fully faithful follows from [KLW19] Thm. 3.9. Since $i_!$ is faithful, it follows from Lemma 6.8 that $Q$ is faithful as well. In general, $i_!$ is not full; we will show, however, that it is full on the image of $Q_0$, which suffices to show that the composite $Q$ is fully faithful.

Let $X,Y \in sSet$, and consider a map $f : QX \to QY$. By Corollary 1.19 $f$ is determined by its action on the non-degenerate cubes of $QX$. Let $x : \Box^n \to QX$ be non-degenerate; then $x$ is a $(0,n)$-cone, hence so is $fx$. Therefore, by Corollary 5.17 the standard form of $fx$ contains no positive connection maps; thus $fx$ corresponds to a cube of $Q_0 Y$.

Thus we see that the action of $f$ on the non-degenerate cubes of $QX$ (which coincide with those of $Q_0 X$) defines a map $Q_0 X \to Q_0 Y$; the image of this map under $i_!$ is precisely $f$. □

Our next goal is to show the following:

**Proposition 6.11.** The adjunction $Q \dashv \int$ is Quillen.

To prove this, we will show that this adjunction satisfies the hypotheses of Corollary 1.12.

**Lemma 6.12.** $Q$ preserves monomorphisms.

**Proof.** $Q_0$ preserves monomorphisms by [KLW19] Lem. 4.5. The stated result thus follows from Lemma 6.8 and the fact that $i_!$ preserves monomorphisms. □

**Lemma 6.13.** The image under $Q$ of an inner horn inclusion $\Lambda^n_i \subseteq \Delta^n$ is a trivial cofibration.

**Proof.** Because $Q$ preserves colimits, $Q \Lambda^n_i$ is the subcomplex of $Q^n$ consisting of the images of the maps $Q \partial_j : Q^{n-1} \to Q^n$ for which $j \neq i$. By Proposition 6.3 we can see that this subcomplex is the image of $\Gamma^n_{i-1,-i+1,0}$ under the quotient map $\Box^n \to Q^n$. We thus have the following commuting square:
It is easy to see that this square is a pushout. Furthermore, the critical edge of the open box
\[ \Box^n \rightarrow Q^n \]
\[ \nabla_{n-i+1,0} \rightarrow Q\Lambda^n_i \]
\[ \nabla^n \rightarrow Q^n \]

is degenerate by Lemma 5.15. Thus \( Q\Lambda^n_i \hookrightarrow Q^n \) is a trivial cofibration, as an
inner open box filling.

Lemma 6.14. \( QJ \cong K \).

Proof of Proposition 6.11. By Lemma 6.12 \( Q \) preserves cofibrations. By Lemma 6.13 the image
under \( Q \) of an inner-horn inclusion is a trivial cofibration. By Lemma 6.14 the image under \( Q \)
of an endpoint inclusion \( \Delta^0 \rightarrow J \) is an endpoint inclusion \( \Box^0 \rightarrow K \), hence a trivial cofibration by
Lemma 6.12. Thus the adjunction is Quillen by Corollary 1.12.

Corollary 6.15. \( Q \) preserves weak equivalences.

Proof. Since all simplicial sets are cofibrant in the Quillen model structure, this follows from Propo-
sition 6.11 and Ken Brown’s lemma.

Next we will concern ourselves with the relationship between \( Q \) and the triangulation functor. Our
goal will be to develop a natural weak categorical equivalence \( TQ \Rightarrow \text{id}_{\text{Set}} \).

For \( n \geq 0 \), we have a poset map \( G: [n] \rightarrow [1]^n \) defined by:

\[
(Ga)_i = \begin{cases} 
0 & i \leq n-a \\
1 & i \geq n-a+1
\end{cases}
\]

Lemma 6.16. For all \( n \), the functor \( G \) defined above has both a right and a left adjoint.

Proof. The category \([n]\) is complete and co-complete, and \( G \) preserves all limits and colimits. The
stated result thus follows from the adjoint functor theorem for posets.

For a given \( n \), let \( F: [1]^n \rightarrow [n] \) denote the left adjoint of \( G \).

Lemma 6.17. For \( n \geq 0, b \in [1]^n \), we have \( Fb = n - i + 1 \), where \( i \in \{1, ..., n+1\} \) is maximal such
that \( b_j = 0 \) for all \( j < i \).

Proof. Let \( a \in [n], b \in [1]^n \); by assumption, \( Fb \leq a \) if and only if \( b \leq Ga \). The latter condition
holds if and only if \( b_j = 0 \) for all \( j \leq n-a \) in other words, if and only if \( i \geq n-a+1 \). Thus, for
any \( a \in [n], Fb \leq a \) if and only if \( n-i+1 \leq a \), implying \( Fb = n-i+1 \).

Proposition 6.18. For all \( n \), \( F \) induces a map of simplicial sets \( TQ^n \rightarrow \Delta^n \).
Proof. First, observe that by applying the nerve functor \( N : \text{Cat} \to \text{sSet} \), we get an induced map \( NF : (\Delta^1)^n \to \Delta^n \).

The simplicial set \( TQ^n \) is a quotient of \( T\Box^n = (\Delta^1)^n \). Specifically, since \( N \) is fully faithful, we may regard \( n \)-simplices \( \Delta^n \to (\Delta^1)^n \) as poset maps \( [n] \to [1]^n \). Then by an argument analogous to the proof of Lemma 5.8 using Proposition 1.29 and the fact that \( T \) preserves colimits, \( TQ^n \) is obtained by identifying two such maps \( f, g \) if there exists \( i \) such that \( f_j = g_j \) for \( j \leq i \) and \( f_i = g_i = \text{const}_1 \). \( NF \) then acts on such maps by post-composition with \( F \). By Lemma 6.17, \( F \) depends only on the position of the first \( 1 \) in an object of \( [1]^n \); therefore, maps which are identified in \( TQ^n \) agree after post-composition with \( F \). Thus \( NF \) factors through the quotient \( TQ^n \). \( \square \)

Let \( \bar{F} : TQ^n \to \Delta^n \) denote the map constructed above. Then we can show:

**Lemma 6.19.** The maps \( \bar{F} : TQ^n \to \Delta^n \) form a natural transformation of co-simplicial objects in \( \text{sSet} \). That is, for any map \( \phi : [m] \to [n] \) in \( \Delta \), we have a commuting diagram:

\[
\begin{array}{ccc}
TQ^m & \xrightarrow{TQ\phi} & TQ^n \\
\downarrow \bar{F} & & \downarrow \bar{F} \\
\Delta^m & \xrightarrow{\phi} & \Delta^n
\end{array}
\]

Proof. It suffices to show that this holds for the generating morphisms of \( \Delta \), namely the face and degeneracy maps. For each such map \( \phi : [m] \to [n] \) we have a corresponding map \( \phi' : [1]^m \to [1]^n \) in \( \Box \), as described in Proposition 6.3.

- For \( \partial_0 : [n-1] \to [n], \partial'_0 = \partial_{n,1} \);
- For \( i \geq 1, \partial_i : [n-1] \to [n], \partial'_i = \partial_{n-i+1,0} \);
- For \( \sigma_0 : [n] \to [n-1], \sigma'_0 = \sigma_n \);
- For \( \sigma_i : [n] \to [n-1], \sigma'_i = \gamma_{n-i,0} \).

For every such \( \phi \) we have a commuting diagram in \( \text{cSet} \), where the vertical maps \( \Box^m \to Q^m \) are the quotient maps:

\[
\begin{array}{ccc}
\Box^m & \xrightarrow{\phi'} & \Box^n \\
\downarrow \downarrow & & \downarrow \downarrow \\
Q^m & \xrightarrow{Q\phi} & Q^n
\end{array}
\]

Furthermore, by direct computation using Lemma 6.17 we have commuting diagrams in \( \text{Cat} \):

\[
\begin{array}{ccc}
[1]^m & \xrightarrow{\phi'} & [1]^n \\
\downarrow F & & \downarrow F \\
[m] & \xrightarrow{\phi} & [n]
\end{array}
\]
Now consider the following diagram in $sSet$:

$$
\begin{array}{ccc}
(\Delta^1)^m \xrightarrow{T\phi'} (\Delta^1)^n \\
\downarrow \quad \quad \downarrow \\
TQ^m \xrightarrow{TQ\phi} TQ^n \\
\downarrow \quad \quad \downarrow \\
\Delta^m \xrightarrow{\phi} \Delta^n
\end{array}
$$

The top square commutes, as it is obtained by applying $T$ to Diagram 6.1; the outer rectangle also commutes, as it is obtained by applying $N$ to Diagram 6.2. We wish to show that the bottom square commutes, i.e. that $\phi \circ \bar{F} = \bar{F} \circ TQ\phi$. Since the quotient map $(\Delta^1)^m \to TQ^m$ is an epimorphism, we can show the desired equality by pre-composing with this map and performing a simple diagram chase. □

**Corollary 6.20.** $\bar{F}$ extends to a natural transformation $\bar{F}: TQ \Rightarrow \text{id}_{sSet}$.

**Proof.** Immediate from Lemma 6.19 and the fact that $T$ and $Q$ preserve colimits. □

**Proposition 6.21.** For every simplicial set $X$, the map $\bar{F}: TQX \to X$ is a weak categorical equivalence.

**Proof.** We begin by proving the statement for the case where $X$ is $m$-skeletal for some $m \geq 0$, proceeding by induction on $m$. For $m = 0$ or $m = 1$, the map in question is an isomorphism.

Now let $m \geq 2$, and suppose that the statement holds for any $(m-1)$-skeletal $X$. Then in particular, it holds for any horn $\Lambda^m_i$. For any $0 < i < n$, consider the following commuting diagram:

$$
\begin{array}{ccc}
TQ\Lambda^m_i \xrightarrow{\sim} TQ^m \\
\downarrow \quad \quad \downarrow \\
\Lambda^m_i \xrightarrow{\sim} \Delta^m
\end{array}
$$

The left-hand map is a weak equivalence by the induction hypothesis; the bottom map is a trivial cofibration as an inner horn inclusion; and the top map is a trivial cofibration by Proposition 4.11 and Proposition 4.27. Thus $\bar{F}: TQ^m \to \Delta^m$ is a weak equivalence by the two-out-of-three property. Extending this result to an arbitrary $m$-skeletal simplicial set $X$ is a straightforward application of the gluing lemma, using the fact that both $T$ and $Q$ preserve colimits.

Now let $X$ be an arbitrary simplicial set; then $\bar{F}$ is a weak equivalence on the $n$-skeleton of $X$ for each $n \geq 0$. Thus $\bar{F}: TQX \to X$ is a weak equivalence, using the fact that sequential colimits of cofibrations preserve weak equivalences. □

**Proposition 6.22.** $Q$ reflects weak categorical equivalences.

**Proof.** Let $f: X \to Y$ be a map of simplicial sets, such that $Qf$ is a weak categorical equivalence. We have a commuting diagram:
The top horizontal map is a weak categorical equivalence by Proposition 1.31 as are the vertical maps by Proposition 6.21 Thus \( f \) is a weak categorical equivalence by the 2-out-of-3 property. 

We have shown that the adjunction \( Q \dashv f \) satisfies the hypotheses of Corollary 1.14(b). To show that it is a Quillen equivalence, therefore, we will prove the following:

**Proposition 6.23.** For any cubical quasicategory \( X \), the counit \( \varepsilon : Q \int X \hookrightarrow X \) is anodyne.

**Proof.** Let \( X \) be a cubical quasicategory. By Theorem 5.24 we may equip \( X \) with a coherent family of composites \( \theta \). We will build \( X \) from \( Q \int X \) via successive inner open box fillings, thereby showing that the inclusion of \( Q \int X \) into \( X \) is anodyne.

For \( m \geq 2, n \geq -1 \), let \( X^{m,n} \) denote the smallest subcomplex of \( X \) containing all \((m', n')\)-cones of \( X \), as well as all cones of the form \( \theta^{m', n'}(x) \), for \( m' < m \) or \( m' = m, n' \leq n \). In particular, this means \( X^{2, -1} = Q \int X \), since all cubes in the image of \( \theta^{0,n} \) or \( \theta^{1,n} \) are degenerate.

For \( m < m' \) or \( m = m', n \leq n' \), we have \( X^{m,n} \subseteq X^{m',n'} \). Thus we obtain a sequence of inclusions:

\[
Q \int X = X^{2, -1} \hookrightarrow X^{2, 0} \hookrightarrow \ldots \hookrightarrow X^{3, -1} \hookrightarrow X^{3, 0} \hookrightarrow \ldots \hookrightarrow X^{m,n} \hookrightarrow \ldots
\]

Observe that the colimit of this sequence is \( X \). Furthermore, for each \( m \), \( X^{m,-1} \) is the union of all subcomplexes \( X^{m',n} \) for \( m' < m \), i.e. the colimit of the sequence of inclusions \( Q \int X \hookrightarrow \ldots \hookrightarrow X^{m',n} \hookrightarrow \ldots \). So to show that \( Q \int X \hookrightarrow X \) is anodyne, it suffices to show that each map \( X^{m,n-1} \hookrightarrow X^{m,n} \) for \( n \geq 0 \) is anodyne.

Fix \( m \geq 2, n \geq 0 \), and let \( S \) denote the set of non-degenerate \((m, n)\)-cones of \( X \) which are not \((m - 1, n + 1)\)-cones, and are not in the image of \( \theta^{m,n} \) — in other words, those \((m, n)\)-cones which fall under case (6) of Definition 5.24. To construct \( X^{m,n} \) from \( X^{m,n-1} \), we must adjoin to \( X^{m,n-1} \) all \((m,n)\)-cones of \( X \), and images of such cones under \( \theta^{m,n} \), which are not already present in \( X^{m,n} \).

Using Lemmas 5.11, 5.16 and 5.32 and the identities (\( \Theta_1 \)) to (\( \Theta_8 \)), we can see that these are precisely the cones in \( S \) and their images under \( \theta^{m,n} \).

Let \( x \in S \); we will analyze the faces of \( \theta^{m,n}(x) \) to determine which of them are contained in \( X^{m,n-1} \). For \( i \leq n \) we have \( \theta^{m,n}(x) \partial_{i,0} = \theta^{m,n-1}(x) \partial_{i,0} \) by (\( \Theta_1 \)) while for \( i \geq n + 2 \) or \( \varepsilon = 1 \), \( \theta^{m,n}(x) \partial_{i,\varepsilon} \) is an \((m - 1, n + 1)\)-cone by Lemma 5.11. Thus we see that the only face of \( \theta^{m,n}(x) \) which is not contained in \( X^{m,n-1} \) is \( \theta^{m,n}(x) \partial_{n+1,0} = x \). Furthermore, the critical edge of \( \theta^{m,n}(x) \) with respect to the \((n + 1, 0)\)-face is degenerate; for \( n = 0 \) this follows from Lemma 5.33 while for \( n \geq 1 \) it follows from Lemma 5.15. Thus the faces of \( \theta^{m,n}(x) \) which are contained in \( X^{m,n-1} \) form an \((m, n + 1)\)-inner open box.

Constructing \( X^{m,n} \) from \( X^{m,n-1} \) amounts to filling all of these inner open boxes; in other words, we have a pushout diagram:
Thus $X^{m,n-1} \hookrightarrow X^{m,n}$ is anodyne, as a pushout of a coproduct of anodyne maps. \hfill \Box

**Theorem 6.24.** The adjunction $Q : s\text{Set} \rightleftarrows c\text{Set} : f$ is a Quillen equivalence.

**Proof.** The adjunction is Quillen by Proposition 6.11. $Q$ preserves and reflects the weak equivalences of the Quillen model structure on $s\text{Set}$ by Corollary 6.15 and Proposition 6.22. Thus $Q \dashv f$ satisfies the hypotheses of Corollary 1.14 item (ii) and we can apply Proposition 6.23 to conclude that it is a Quillen equivalence. \hfill \Box

**Corollary 6.25.** For all $W \in \{L, R\}, \varepsilon \in \{0, 1\}$, the adjunction $Q_{W, \varepsilon} \dashv f_{W, \varepsilon}$ is a Quillen equivalence.

**Proof.** Immediate from Proposition 4.25, Lemma 6.7, and Theorem 6.24. \hfill \Box

**Proof of Theorem 6.1.** The adjunction $T \dashv U$ is Quillen by Proposition 4.27. To see that it is a Quillen equivalence, note that because all objects in both $c\text{Set}$ and $s\text{Set}$ are cofibrant, the left derived functor $L(TQ)$ is the composite of the left derived functors $LT$ and $LQ$, while the left derived functor of the identity is the identity; this can easily be seen from [Hov99, Def. 1.36]. By Corollary 6.20 we have a natural weak equivalence $TQ \Rightarrow id_{s\text{Set}}$. In the homotopy category $Ho s\text{Set}$, this natural weak equivalence becomes a natural isomorphism $LT \circ LQ \cong id_{Ho s\text{Set}}$. By Theorem 6.24 $LQ$ is an equivalence of categories, thus $LT$ is an equivalence of categories as well. \hfill \Box

The proofs in this section can easily be adapted to show that $Q \dashv f$ is a Quillen equivalence between the standard model structures for $\infty$-groupoids on $s\text{Set}$ and $c\text{Set}$. (The analogue of this result for $c\text{Set}_0$ was essentially stated as [KLW19, Prop. 5.3], but the proof supplied there only shows that $Q_0$ and $f_0$ form a Quillen adjunction.)

**Proposition 6.26.** The adjunction $Q : s\text{Set} \rightleftarrows c\text{Set} : f$ is a Quillen equivalence between the Quillen model structure on $s\text{Set}$ and the Grothendieck model structure on $c\text{Set}$.

**Proof.** Proposition 4.27 and Proposition 6.11 both have natural analogues, showing that $T \dashv U$ and $Q \dashv f$ are Quillen adjunctions between these model structures (implying in particular that $Q$ preserves weak equivalences). Since every weak equivalence in the Joyal model structure is also a weak equivalence in the Quillen model structure, $\mathcal{P}$ is a natural weak equivalence in the Quillen model structure as well. Thus the proof of Proposition 6.22 adapts to show that $Q$ reflects the weak equivalences of the Quillen model structure. Corollary 1.14 item (ii) and Proposition 6.23 then imply the analogue of Theorem 6.24 since every cubical Kan complex is a cubical quasicategory and every weak equivalence in the cubical Joyal model structure is a weak equivalence in the Grothendieck model structure. \hfill \Box
We thus obtain a new proof of the following result, previously shown in [Cis06, Prop. 8.4.30] for cubical sets without connections:

**Theorem 6.27.** $T - U$ is a Quillen equivalence between the Grothendieck model structure on $cSet$ and the Quillen model structure on $sSet$. □

7. **Mapping spaces in cubical quasicategories**

One of the advantages of working with cubical quasicategories as opposed to their simplicial analogues is a clean definition of a mapping space between two objects in a cubical quasicategory. In this section we introduce this concept, and show that categorical equivalences can be characterized in terms of these mapping spaces and the homotopy category construction of Section 2.

Our arguments in this section, up to the proof of our main result, Theorem 7.10 do not rely on connections, thus they are valid in all of the categories of cubical sets shown in the diagram (†) at the end of Section 1. Some of the subsequent results, which relate cubical mapping spaces and homotopy categories to their simplicial analogues, make use of the adjunction $Q - F$ developed in Section 6, so those results which involve these functors can only be adapted to $cSet_0$ or $cSet_1$.

**Definition 7.1.** For $X \in cSet$ and $x_0, x_1 : □^0 \to X$, we define the mapping space $\text{Map}_X(x_0, x_1)$ by the following pullback:

\[
\begin{array}{ccc}
\text{Map}_X(x_0, x_1) & \rightarrow & \text{hom}_L(□^1, X) \\
\downarrow & & \downarrow \\
□^0 & \rightarrow & \text{hom}_L(\partial □^1, X)
\end{array}
\]

From this definition, we can derive a more concrete description of the cubical mapping space. For $X \in cSet$, $x_0, x_1 : □^0 \to X$, we have:

\[
\text{Map}_X(x_0, x_1)_n = \left\{ \square^{n+1} \xrightarrow{s} X \mid s\partial_{n+1, \varepsilon} = x_{\varepsilon} \right\},
\]

with the cubical operations given by those of $X$. Note that $x_{\varepsilon}$ here refers to the degeneracy of the vertex $x_{\varepsilon}$ in the appropriate dimension.

There is a clear geometric intuition behind this definition, as the example below shows.

**Example 7.2.** Given a cubical set $X$ and 0-cubes $x_0, x_1 : □^0 \to X$, we have that:

- a 0-cube in $\text{Map}_X(x_0, x_1)$ is a 1-cube from $x_0$ to $x_1$ in $X$;
- a 1-cube in $\text{Map}_X(x_0, x_1)$ is a 2-cube in $X$ of the form

\[
\begin{array}{cc}
x_0 & x_0 \\
\downarrow & \downarrow \\
x_1 & x_1
\end{array}
\]
Given a cubical set map \( f : X \to Y \), for any \( x_0, x_1 : \square^0 \to X \) there is a natural map \( f_* : \text{Map}_X(x_0, x_1) \to \text{Map}_Y(f x_0, f x_1) \) induced by a natural map between the pullbacks of Definition 7.1. Thus the mapping space construction defines a functor \( \text{Map} : \partial \square \downarrow \text{cSet} \to \text{cSet} \). In fact, this functor has a left adjoint, which we will now describe.

**Definition 7.3.** For \( X \in \text{cSet} \), the suspension of \( X \) is the bi-pointed cubical set \( \Sigma X \in \partial \square \downarrow \text{cSet} \) defined by the following pushout diagram:

\[
\begin{array}{ccc}
X \sqcup X & \longrightarrow & \partial \square^1 \\
\downarrow & & \downarrow \\
X \otimes \partial \square^1 & \longrightarrow & \Sigma X
\end{array}
\]

The chosen map \( \partial \square^1 \to \Sigma X \) is that which appears in the diagram above. We denote the basepoints of \( \Sigma X \), i.e. the images under this map of the vertices \( 0, 1 \in \partial \square^1 \), by \( 0 \) and \( 1 \), respectively. For \( f : X \to Y \), we define \( \Sigma f : \Sigma X \to \Sigma Y \) to be the natural map between pushouts induced by \( f \).

**Proposition 7.4.** The functor \( \Sigma : \text{cSet} \to \partial \square \downarrow \text{cSet} \) is left adjoint to \( \text{Map} : \partial \square \downarrow \text{cSet} \to \text{cSet} \).

**Proof.** Let \( X, Y \in \text{cSet}, y_0, y_1 : \square^0 \to Y \). By the universal property of the pullback, maps \( X \to \text{Map}_Y(y_0, y_1) \) correspond to diagrams of the form

\[
\begin{array}{ccc}
X & \xrightarrow{f} & \text{hom}_L(\square^1, Y) \\
\downarrow & & \downarrow \\
\square^0 & \xrightarrow{(y_0, y_1)} & \text{hom}_L(\partial \square^1, Y)
\end{array}
\]

The map \( \text{hom}_R(\square^1, Y) \to \text{hom}_R(\partial \square^1, Y) \) is the pullback exponential \( (\partial \square^1 \to \square^1) \rhd (Y \to \square^0) \). Using the duality between pushout products and pullback exponentials, and observing that the pushout object \( X \otimes \square^1 \cup X \otimes \partial \square^1 \) is precisely \( \Sigma X \), we have a natural bijection between such diagrams and diagrams of the form

\[
\begin{array}{ccc}
\Sigma X & \xrightarrow{\overline{f}} & Y \\
\downarrow & & \downarrow \\
\square^1 & \rightarrow & \square^0
\end{array}
\]

in which \( \overline{f} \) maps the basepoints \( 0 \mapsto y_0, 1 \mapsto y_1 \). In other words, cubical set maps \( X \to \text{Map}_Y(y_0, y_1) \) are in natural bijection with bi-pointed cubical set maps \( (\Sigma X, 0, 1) \to (Y, y_0, y_1) \).

By using \( \text{hom}_R \) rather than \( \text{hom}_L \) in the pullback diagram of Definition 7.1 we obtain the left mapping space functor \( \text{Map}_L : \partial \square \downarrow \text{cSet} \to \text{cSet} \).

\[
\begin{array}{ccc}
\text{Map}_X(x_0, x_1) & \longrightarrow & \text{hom}_R(\square^1, X) \\
\downarrow & & \downarrow \\
\square^0 & \xrightarrow{(x_0, x_1)} & \text{hom}_R(\partial \square^1, X)
\end{array}
\]

This functor admits the following explicit description:
Once again, cubical operations are given by those of $X$ and connections.

Map^L also has a left adjoint, the left suspension $\Sigma_L : \text{cSet} \to \partial \Box^1 \downarrow \text{cSet}$, with $\Sigma_L X$ defined as a quotient of $\Box^1 \otimes X$. Where the potential for confusion may arise, we will refer to Map and $\Sigma$ as the right mapping space and right suspension, denoting them by $\text{Map}^R$ and $\Sigma_R$.

**Lemma 7.5.** The left and right mapping space constructions are related by the following formulas:

- $\text{Map}^L_X(x_0, x_1)^{co} \cong \text{Map}^R_X(x_0, x_1)$,
- $\text{Map}^L_X(x_0, x_1)^{co-op} \cong \text{Map}^R_{\Sigma_X}(x_0, x_1)$,
- $\text{Map}^L_X(x_0, x_1)^{op} \cong \text{Map}^R_{\Sigma_X}(x_0, x_1)$.

**Proof.** This follows from applying the involutions $(-)^{co}, (-)^{co-op}$, and $(-)^{op}$ to the pullback diagrams defining $\text{Map}^L$ and $\text{Map}^R$, and applying Corollary 1.42.

From here on, we will work exclusively with right mapping spaces unless otherwise noted, omitting the superscript $R$, with the understanding that our results may be adapted to left mapping spaces using the formulas of Lemma 7.5.

**Proposition 7.6.** $\Sigma : \text{Map}$ is a Quillen adjunction between the Grothendieck model structure on $\text{cSet}$ and the cubical Joyal model structure on $\partial \Box^1 \downarrow \text{cSet}$.

**Proof.** That $\Sigma$ preserves cofibrations follows from the description of the geometric product in Proposition 1.24. To show that $\Sigma$ preserves trivial cofibrations, it suffices to show that $\Sigma$ sends all open box inclusions to trivial cofibrations in the cubical Joyal model structure. To see this, observe that $\Sigma \Box^n$ is the quotient of $\Box^{n+1}$ in which the faces $\partial_{n+1,0}, \partial_{n+1,1}$ are quotiented down to vertices, while $\Sigma \Box_{\underline{i},\varepsilon}^n$ is the corresponding quotient of $\Box^{n+1}_{\underline{i},\varepsilon}$. For $i \leq n, \varepsilon \in \{0, 1\}$, the critical edge of $\Box^{n+1}_{\underline{i},\varepsilon}$ with respect to the face $\partial_{\underline{i},\varepsilon}$ is an edge of the face $\partial_{n+1,1-\varepsilon}$, hence its image in $\Sigma \Box^{n+1}$ is degenerate. Thus the inclusion $\Sigma \Box_{\underline{i},\varepsilon}^n \to \Sigma \Box^n$ is a trivial cofibration.

**Corollary 7.7.** If $f : X \to Y$ is a (trivial) fibration in the cubical Joyal model structure, then each induced map $f_* : \text{Map}_X(x_0, x_1) \to \text{Map}_Y(fx_0, fx_1)$ is a (trivial) fibration in the Grothendieck model structure.

In particular, if $X$ is a cubical quasicategory then all mapping spaces $\text{Map}_X(x_0, x_1)$ are cubical Kan complexes.

We can characterize categorical equivalences in terms of these mapping spaces and the homotopy categories defined in Section 2.2.

**Definition 7.8.** Let $X$ be a cubical quasicategory. We define the homotopy category $\text{Ho} X$ to be the homotopy category of the marked cubical quasicategory $X^2$.

**Lemma 7.9.** For a cubical quasicategory $X$, we have the following natural isomorphisms:
Let \( K \subset X \) be an intersection in \( X \). In other words, this intersection is the image in \( X \) of its boundary \( \partial K \). For all \( K \in \mathcal{K} \) and \( n \geq 0 \), let \( K^n \subset X \) denote the image of \( \square^n \times \{ \varepsilon \} \subset \square^{n+1} \) in \( X \). For \( \varepsilon \in \{0,1\} \), let \( K^n_\varepsilon \subset X \) denote the image of \( \{ \varepsilon \} \times \square^n \subset \square^{n+1} \) in \( X \). Let \( \overline{K} \subset X \) denote the intersection of \( K^n_0 \) and \( K^n_1 \), i.e. the image in \( X \) of the boundary of \( (1,\varepsilon) \)-face. Note that the inclusion \( \overline{K}_0 \hookrightarrow K_0^n \) is isomorphic to \( \partial \square^n \hookrightarrow \square^n \). Similarly, \( \overline{K}_1 \hookrightarrow K_1^n \) is isomorphic to the quotient of \( \partial \square^n \hookrightarrow \square^n \) where the \( (1,1-\varepsilon) \)-face is a degeneracy of a vertex.

**Lemma 7.12.** For all \( n \geq 0 \), the inclusion \( \overline{K}_0 \hookrightarrow \overline{K} \) is anodyne.

**Proof.** Let \( E \subset X \) denote the union of \( \overline{K}_0 \) with the image of \( \square^1 \times \{0\} \times \square^n \subset \overline{K} \). We first show that the inclusion \( \overline{K}_0 \hookrightarrow E \) is anodyne. To see this, observe that the intersection of \( \overline{K}_0 \) with \( E \) is the image in \( X \) of \( \{0\} \times \{0\} \times \square^n \). This coincides with the image in \( X \) of \( \partial \square^1 \times \{0\} \times \square^n \cup \overline{K} \). Thus \( \overline{K}_0 \hookrightarrow E \) is a pushout of the image in \( X \) of the inclusion \( \partial \square^1 \times \{0\} \times \square^n \cup \overline{K} \). This map can be written as a composite of open box fillings; in \( X \), the critical edges of each of these open boxes will be degenerate, hence the map will be anodyne.

To see that \( E \hookrightarrow \overline{K} \) is anodyne, observe that \( E \) consists of the images in \( X \) of the boundary of \( (1,0) \)-face together with the \( (2,\varepsilon) \)-faces. For \( 2 \leq i \leq n+2 \), let \( E_i \) consist of the images in \( X \) of the boundary of \( (1,0) \)-face together with the \( (j,\varepsilon) \)-faces for \( j \leq i \) and \( E_2 = E \) while \( E_{n+1} = \overline{K} \). So it suffices to show that each map \( E_i \hookrightarrow E_{i+1} \) is anodyne. To see this, observe that for \( i \geq 2 \) and \( \varepsilon \in \{0,1\} \), the intersection of the image in \( X \) of the \( (i+1,\varepsilon) \)-face with \( E_i \) consists of the images of its \( (1,0) \)-face and its \( (j,\varepsilon) \)-faces for \( j \leq i \) (this can be seen from the cubical identities). In other words, this intersection is the image in \( X \) of \( \square^n \times \{0\} \times \square^{n+2-2(i+1)} \). Thus the inclusion
\[ E_i \hookrightarrow E_{i+1} \] is a pushout of \( \sqcap_{i,1} \otimes \partial \square \otimes \square - (i+1) \hookrightarrow \square - (i+1) \). Moreover, the image in \( K^n \) of \( \square - \{0, \ldots, 0\} \otimes \partial \square - (i+1) \) is degenerate in the first dimension. Thus this map is a pushout of the anodyne map \( \sqcup_{i,1} \otimes \partial \square - (i+1) \hookrightarrow \hat{\sqcup}_{i,1} \otimes \partial \square - (i+1) \).

**Lemma 7.13.** For \( n \geq 0 \), the inclusion \( K^n_0 \hookrightarrow K^n \) is anodyne.

**Proof.** Consider the following diagram:

\[
\begin{array}{ccc}
K^n_0 & \sim & K^n \\
\downarrow & & \downarrow \\
K^n_0 & \sim & K^n_0 \cup K^n_0 \quad K^n \\
\downarrow & & \downarrow \\
K^n & & K^n & \uparrow \\
\end{array}
\]

The inclusion \( K^n_0 \hookrightarrow K^n_0 \cup K^n_0 \) is anodyne as a pushout of an anodyne map. The inclusion \( K^n_0 \cup K^n_0 \hookrightarrow K^n \) is a \((1,1)\)-open box filling; as the critical edge is the degenerate edge \( \square - \{0, \ldots, 0\} \), this is an inner open box filling. \( \square \)

**Lemma 7.14.** Let \( X \to Y \) be a fibration between cubical quasicategories. Let \( x : \square^n \to X \), for \( n \geq 0 \), and \( \varepsilon \in \{0, 1\} \). Consider all diagrams of the form:

\[
\begin{array}{ccc}
\partial \square^{n+1} & \longrightarrow & X \\
\downarrow & & \downarrow \\
\square^{n+1} & \longrightarrow & Y \\
\end{array}
\]

for which the \((1,\varepsilon)\)-face of the boundary \( \square^{n+1} \to X \) is \( x \). A lift exists in every such diagram if and only if a lift exists in every such diagram for which the \((1,1-\varepsilon)\)-face of \( \partial \square^{n+1} \to X \) is a degeneracy of a vertex.

**Proof.** Fix \( x \) and a diagram of the form depicted above; we will obtain a lift in the given diagram under the assumption that a lift exists for all such diagrams in which the \((1,1-\varepsilon)\)-face of \( \partial \square^{n+1} \to X \) is a degeneracy of a vertex. By duality, it suffices to consider the case \( \varepsilon = 0 \).

By Lemmas 7.12 and 7.13 we have an injective trivial cofibration from \( K^n_0 \hookrightarrow K^n_0 \to K^n \hookrightarrow K^n \), regarding these maps as objects in the morphism category \( \text{cSet}^{\to} \). (Note that the injective model structure on \( \text{cSet}^{\to} \) coincides with the Reedy model structure by Corollary 1.17.) Furthermore, the map \( X \to Y \) is injective fibrant, as a fibration between fibrant objects. Therefore, identifying \( \partial \square^{n+1} \leftrightarrow \square^{n+1} \) with \( K^n_0 \hookrightarrow K^n_0 \), the given diagram factors as:

\[
\begin{array}{ccc}
\tilde{K}^{n+1} & \longrightarrow & \tilde{K}^n \\
\downarrow & & \downarrow \\
K^n_0 & \longrightarrow & K^n & \uparrow \\
\end{array}
\]

Thus, to obtain a lift in the original diagram, it suffices to obtain a lift in the right-hand diagram above. For this, observe that the inclusion \( K^n_0 \cup \tilde{K} \hookrightarrow K^n \) is a \((1,0)\)-inner open box filling,
whose critical edge is the degenerate edge $\square^1 \otimes \{1,\ldots,1\}$; thus this map is anodyne. Therefore, it suffices to obtain a lift in the diagram:

\[
\begin{array}{ccc}
K^n & \rightarrow & X \\
\downarrow & & \downarrow \\
K^n & \rightarrow & Y
\end{array}
\]

For this, in turn, it suffices to obtain a lift in the diagram:

\[
\begin{array}{ccc}
K^n & \rightarrow & X \\
\downarrow & & \downarrow \\
K^n & \rightarrow & Y
\end{array}
\]

The boundary $\partial \square^{n+1} \rightarrow K^n_1 \rightarrow X$ has $x$ as its $(1,0)$-face; this follows from the fact that the image in $K^n$ of the $(2,0)$-face is degenerate in the first dimension. Similarly, the $(1,1)$-face of this boundary is a degeneracy of a vertex, as it is precisely the image of $\{1\} \otimes \{1\} \otimes \square^n$. Thus this diagram admits a lift by assumption.

\[\square\]

**Corollary 7.15.** For $n \geq 0$, a fibration between cubical quasicategories has the right lifting property against $\partial \square^{n+1} \hookrightarrow \square^{n+1}$ if and only if it has the right lifting property against $\Sigma \partial \square^n \hookrightarrow \Sigma \square^n$.

**Proof.** The forward implication follows from the fact that $\Sigma \partial \square^n \hookrightarrow \Sigma \square^n$ is a pushout of $\partial \square^{n+1} \hookrightarrow \square^{n+1}$. For the reverse implication, observe that $\Sigma \partial \square^n$ (resp. $\Sigma \square^n$) is precisely the quotient of $\partial \square^{n+1}$ (resp. $\square^{n+1}$) in which the $(1,0)$ and $(1,1)$-faces are degeneracies of vertices. The result then follows from applying Lemma 7.14 twice, once with $\varepsilon = 0$ and once with $\varepsilon = 1$. \[\square\]

**Proof of Theorem 7.10** First let $f : X \rightarrow Y$ be a categorical equivalence between cubical quasicategories. That $\text{Ho}f$ is an equivalence of categories follows from Lemma 2.23 and Proposition 4.23 (ii). That each map $\text{Map}_X(x_0,x_1) \rightarrow \text{Map}_Y(fx_0,fx_1)$ is a homotopy equivalence follows from Proposition 7.6.

Now let $f : X \rightarrow Y$ be a map between cubical quasicategories inducing an equivalence on homotopy categories and homotopy equivalences on all mapping spaces. We will show that $f$ is a categorical equivalence. By factoring an arbitrary map as a composite of a trivial cofibration with a fibration and applying the implication which we have already proven, we may assume $f$ is a fibration. By Proposition 7.6 this implies that $f$ induces fibrations on all cubical mapping spaces. Thus we wish to show that, given a fibration of cubical quasicategories $f : X \rightarrow Y$ such that $\text{Ho}f$ is an equivalence of categories and each map $\text{Map}_X(x_0,x_1) \rightarrow \text{Map}_Y(fx_0,fx_1)$ is a trivial fibration, $f$ is a trivial fibration.

We begin by showing that $f$ has the right lifting property with respect to the map $\emptyset \rightarrow \square^0$ – in other words, that $f$ is surjective on vertices. To this end, let $y$ be a vertex of $Y$. Then since $\text{Ho}f$ is essentially surjective, there is a vertex $x : \square^0 \rightarrow X$ such that $fx \cong y$ in $\text{Ho}Y$. Thus we have a commuting diagram in $\text{cSet}$:
Since $f$ is a fibration, this diagram has a lift; the restriction of this lift to the endpoint $1: \Box^0 \to K$ gives a vertex $x': \Box^0 \to X$ with $fx' = y$.

To complete the proof, we must show that $f$ has the right lifting property with respect to all boundary inclusions $\partial \Box^{n+1} \hookrightarrow \Box^{n+1}$ for $n \geq 0$. By Corollary 7.15, it suffices to show that $f$ has the right lifting property with respect to all maps $\Sigma \partial \Box^n \hookrightarrow \Sigma \Box^n$. But by Proposition 7.4, this is equivalent to our assumption that $f$ induces trivial fibrations on all mapping spaces. □

The following result shows that, in verifying the conditions of Theorem 7.10 for a map $f: X \to Y$, it suffices to show that $\text{Ho } X$ is essentially surjective and that $f$ induces homotopy equivalences on all mapping spaces.

**Proposition 7.16.** Let $f: X \to Y$ be a map between cubical quasicategories. If $f$ induces homotopy equivalences on all mapping spaces, then $\text{Ho } X \to \text{Ho } Y$ is fully faithful.

**Proof.** Factoring an arbitrary map as a trivial cofibration followed by a fibration and applying Theorem 7.11 we see that it suffices to consider the case where $f$ is a fibration. By Proposition 7.6 this implies that each map $\text{Map}_X(x_0, x_1) \to \text{Map}_Y(f x_0, f x_1)$ is a trivial fibration.

For $x_0, x_1: \Box^0 \to X$, $\text{Map}_X(x_0, x_1) \to \text{Map}_Y(f x_0, f x_1)$ is surjective on vertices, implying that every edge of $Y$ from $fx_0$ to $fx_1$ is the image under $f$ of some edge of $X$ from $x_0$ to $x_1$. Thus $\text{Ho } f$ is full. To see that it is faithful, let $p, q: \Box^1 \to X$ be a pair of edges from $x_0$ to $x_1$, such that the morphisms in $\text{Ho } Y(f x_0, f x_1)$ corresponding to $fp$ and $fq$ are equal. Applying Lemma 2.21 this implies that there is a 2-cube in $Y$ of the form:

\[
\begin{array}{ccc}
fx_0 & \to & f x_0 \\
p & \downarrow & f q \\
fx_1 & \to & f x_1
\end{array}
\]

This 2-cube corresponds to an edge from $fp$ to $fq$ in $\text{Map}_Y(f x_0, f x_1)$; thus we have a commuting diagram:

\[
\begin{array}{ccc}
\partial \Box^1 & \to & \text{Map}_X(x_0, x_1) \\
(p, q) & \downarrow & \downarrow \\
\Box^1 & \to & \text{Map}_Y(f x_0, f x_1)
\end{array}
\]

Since $\text{Map}_X(x_0, x_1) \to \text{Map}_Y(f x_0, f x_1)$ is a trivial fibration, this diagram has a lift, implying that $p = q$ in $\text{Ho } X(x_0, x_1)$. Thus we see that $\text{Ho } f$ is faithful. □

The Quillen equivalences $T \dashv U$ and $Q_{W, \varepsilon} \dashv \int_{W, \varepsilon}$ relate the cubical homotopy category and mapping space constructions to their simplicial analogues. Before examining these relationships, we recall the corresponding constructions in sSet, developed in [Joy09] and [Lur09].
Definition 7.17. Let $X \in \sSet$ be a quasicategory. The homotopy category of $X$, denoted $\text{Ho}X$, is defined as follows:

- the objects of $\text{Ho}X$ are the 0-simplices of $X$;
- the morphisms from $x$ to $y$ in $\text{Ho}X$ are the equivalence classes of edges $X_1(x,y)/\sim$, where $\sim$ denotes the equivalence relation defined by $f \sim g$ if and only if there exists a 2-simplex in $X$ of the form:

$$
\begin{array}{c}
\text{y} \\
\quad \Downarrow f
\end{array}
\quad 
\begin{array}{c}
\quad \Downarrow g \\
\text{x}
\end{array}
\quad 
\begin{array}{c}
\text{y}
\end{array}

- the identity map on $x \in X_0$ is given by $x\sigma$;
- the composition of $f : x \to y$ and $g : y \to z$ is given by filling the horn

$$
\begin{array}{c}
\text{f} \\
\quad \Downarrow \\
\text{x}
\end{array}
\quad 
\begin{array}{c}
\quad \Downarrow g_f \\
\text{y}
\end{array}
\quad 
\begin{array}{c}
\text{y}
\end{array}
$$

Definition 7.18. Let $x_0$ and $x_1$ be 0-simplices in a simplicial set $X$. The mapping space from $x_0$ to $x_1$ is the simplicial set $\text{Hom}_X(x_0, x_1)$ given by the following pullback.

$$
\begin{array}{ccc}
\text{Hom}_X(x_0, x_1) & \to & X^{\Delta^1} \\
\downarrow & \searrow \downarrow X \Delta^1 \\
\Delta^0 & \to & \partial_1\Delta^1
\end{array}
$$

As in the cubical case, the simplicial mapping space admits the following concrete description:

$$
\text{Hom}_X(x_0, x_1)_n = \left\{ \Delta^n \times \Delta^1 \xrightarrow{s} X \mid s \circ (\Delta^n \times \partial_{1-\varepsilon}) = x_\varepsilon \right\},
$$

with simplicial operations induced by those of $X$.

From this description we can see that, in contrast to the cubical case, the simplices of $\text{Hom}_X(x_0, x_1)$ are not simplices of $X$. Thus it is often preferable to work with the left and right mapping spaces in a simplicial set, defined below.

Definition 7.19. Let $X \in \sSet, x_0, x_1: \Delta^0 \to X$. The left mapping space $\text{Hom}^L_X(x_0, x_1)$ is defined by:

$$
\text{Hom}^L_X(x_0, x_1)_n = \left\{ \Delta^{n+1} \xrightarrow{s} X \mid s|_{\Delta^{n+1}} = x_0, s\partial_0 = x_1 \right\},
$$

with simplicial operations induced by those of $X$, meaning that the face map $\partial_i$ of $\text{Hom}^L_X(x_0, x_1)$ corresponds to the face map $\partial_{i+1}$ of $X$, and similarly for degeneracies.

Similarly, the right mapping space $\text{Hom}^R_X(x_0, x_1)$ is defined by:
CUBICAL MODELS OF $(\infty, 1)$-CATEGORIES

$$\Hom^R_X(x_0, x_1)_n = \left\{ \Delta^{n+1} \xrightarrow{s \partial_{n+1}} X \mid s \partial_{n+1} = x_0, \ s|_{\Delta^{(n+1)}} = x_1 \right\},$$

with simplicial operations induced by those of $X$, meaning that the face map $\partial_i$ of $\Hom^R_X(x_0, x_1)$ corresponds to the face map $\partial_i$ of $X$, and similarly for degeneracies.

A routine calculation shows:

**Lemma 7.20.** For $X \in s\Set, x_0, x_1 : \square^0 \to X$, we have a natural isomorphism $\Hom^R_X(x_0, x_1)^{\text{op}} \cong \Hom^R_{X^{\text{op}}}(x_1, x_0)$. □

**Lemma 7.21.** We have the following natural isomorphisms relating the homotopy categories of quasicategories and cubical quasicategories:

(i) For a quasicategory $X$, $\Ho X \cong \Ho UX$;

(ii) For a cubical quasicategory $X$ and $W \in \{L, R\}$, $\Ho X \cong \Ho \int^W X$;

(iii) For a cubical quasicategory $X$ and $W \in \{L, R\}$, $\Ho X \cong (\Ho \int^W X)^{\text{op}}$.

**Proof.** For (i) first note that $X$ and $UX$ have the same edges and vertices. The equivalence relations defining the morphisms of $\Ho X$ and $\Ho UX$ coincide by a simple argument involving Lemma 2.21 and its simplicial analogue. A similar argument proves (ii) and (iii) then follows from Lemmas 6.7 and 7.9. □

**Lemma 7.22.** For $X \in s\Set, x_0, x_1 : \Delta^0 \to X$, and $W \in \{L, R\}$, we have a natural isomorphism $\text{UMap}_X^W(x_0, x_1) \cong \Hom_{X^{\text{op}}}(x_1, x_0)$.

**Proof.** Observe that the simplicial mapping space construction defines a functor $\text{Hom} : \partial \Delta^1 \downarrow s\Set \to s\Set$. An argument similar to the proof of Proposition 7.4 shows that this functor has a left adjoint $\Sigma : s\Set \to \partial \Delta^1 \downarrow s\Set$, given by the following pushout diagram:

$\begin{array}{ccc}
X \sqcup X & \to & \partial \Delta^1 \\
\downarrow & & \downarrow \\
\Delta^1 \times X & \to & \Sigma X
\end{array}$

Thus we have the following square of adjunctions:

$\begin{array}{ccc}
\partial \square^1 \downarrow \text{cSet} & \xrightarrow{\Sigma} & \partial \Delta^1 \downarrow \text{sSet} \\
\downarrow & & \downarrow \\
\text{cSet} & \to & \text{sSet}
\end{array}$

We wish to show that the square of right adjoints commutes (up to natural isomorphism); for this, it suffices to show that the square of left adjoints commutes, i.e. that $T \Sigma_W \cong \Sigma T$. To see this, we may apply $T$ to the pushout square which defines the (left or right) suspension of a cubical set. Using Proposition 1.20 and the fact that $T$ preserves pushouts, we obtain a natural isomorphism $T \Sigma_W X \cong \Sigma TX$ for $X \in \text{cSet}$. □

**Lemma 7.23.** For $X \in \text{cSet}, x_0, x_1 : \square^0 \to X$, we have the following natural isomorphisms:
\[ \int_{L,0} \text{Map}_L^L(x_0, x_1) \cong \text{Hom}_{L \times L}^R(x_1, x_0); \]
\[ \int_{L,1} \text{Map}_L^L(x_0, x_1) \cong \text{Hom}_{L \times L}^R(x_1, x_0); \]
\[ \int_{R,1} \text{Map}_R^R(x_0, x_1) \cong \text{Hom}_{R \times R}^R(x_1, x_0); \]
\[ \int_{R,0} \text{Map}_R^R(x_0, x_1) \cong \text{Hom}_{R \times 1}^R(x_1, x_0). \]

Proof. It suffices to prove the identity for \( \int_{R,1} \); the others then follow from Lemmas \( \text{6.7 and 7.5} \).

Observe that maps \( \Delta^n \to \int_{R,1}^1 \text{Map}_R^R(x_0, x_1) \) correspond to maps \( \Sigma^R Q_n \to X \) mapping the basepoints \( 0 \mapsto x_0, 1 \mapsto x_1 \). By the universal property of the pushout, these correspond to commuting diagrams of the form:

\[
\begin{array}{ccc}
Q_{n,1}^n \cup Q_{n,1}^n & \xrightarrow{\partial^1} & \partial^1 \\
\downarrow & & \downarrow \\
Q_{n,1}^n \otimes \{1\} & \to & X
\end{array}
\]

In other words, these are maps \( Q_{n,1}^n \otimes \{1\} \to X \) such that for \( \varepsilon \in \{0, 1\} \), the subcomplex \( Q_{n,1}^n \otimes \{\varepsilon\} \) is mapped to \( x_\varepsilon \).

On the other hand, maps \( s: \Delta^{n+1} \to \int_{R,1}^1 \text{X} \), i.e. \( Q_{n,1}^{n+1} \to X \), which map the terminal vertex to \( x_1 \) correspond to commuting diagrams of the form:

\[
\begin{array}{ccc}
Q_{n,1}^n & \xrightarrow{\partial^0} & \partial^0 \\
Q_{n,1}^n \otimes \partial^0 & \downarrow & \downarrow \\
Q_{n,1}^n \otimes \{1\} & \to & X
\end{array}
\]

In other words, these are maps \( Q_{n,1}^n \to X \) such that \( Q_{n,1}^n \otimes \{1\} \) is mapped to \( x_1 \). By Proposition \( \text{6.5} \), the condition \( s \partial_{n+1} = x_0 \) corresponds to the condition that \( Q_{n,1}^n \otimes \{0\} \) is mapped to \( x_0 \).

Remark 7.24. One may observe that applying a functor \( \int_{W,\varepsilon}^1 \) to a compatible cubical mapping space always produces a simplicial right mapping space, regardless of the values of \( W \) and \( \varepsilon \). Lemma \( \text{7.20} \) shows that the alternative definitions of \( Q_{W,\varepsilon}^n \) discussed in Remark \( \text{6.6} \) would instead produce formulas relating cubical mapping spaces to simplicial left mapping spaces.

These results allow us to transfer Theorem \( \text{7.10} \) along the Quillen equivalence \( T \dashv U \), obtaining a new proof of the analogous result for the Joyal model structure on \( sSet \) that can be found, e.g., in \( \text{Rez20} \).

Theorem 7.25 (\( \text{Rez20} \) Props. 34.2 and 43.2]). Let \( f: X \to Y \) be a map between quasicategories. Then \( f \) is a categorical equivalence if and only if the following two conditions are satisfied:

\[ \text{Ho}f: \text{Ho}X \to \text{Ho}Y \text{ is an equivalence of categories}; \]
\[ \text{for all pairs of vertices } x_0, x_1: \Delta^0 \to X, \text{ the induced map } \text{Hom}_X(x_0, x_1) \to \text{Hom}_Y(fx_0, fx_1) \text{ is a homotopy equivalence in the Quillen model structure}. \]
Proof. By Proposition 1.13 and Theorem 6.1, \( f \) is a categorical equivalence if and only if \( Uf : UX \to UY \) is a categorical equivalence. Similarly, by Proposition 1.13 and Theorem 6.27, each map \( \text{Hom}_X(x_0, x_1) \to \text{Hom}_Y(f x_0, f x_1) \) is a homotopy equivalence if and only if \( U\text{Hom}_X(x_0, x_1) \to U\text{Hom}_Y(f x_0, f x_1) \) is a homotopy equivalence. The stated result thus follows from Theorem 7.10 together with Lemmas 7.21 and 7.22.

\[ \square \]

Remark 7.26. One can similarly prove Theorem 7.10 from Theorem 7.25, using Theorem 6.24 and Lemma 7.23, and the natural trivial cofibration \( \text{Hom}_R^X(x_0, x_1) \hookrightarrow \text{Hom}_X(x_0, x_1) \) for quasicategories \( X \).

Appendix A. Verification of identities on \( \theta \)

Here we prove that the construction \( \theta^{m,n} \) of Definition 5.29 satisfies the identities of Definition 5.23. Fix a cubical quasicategory \( X \), \( m \geq 2 \), and \( n \geq 0 \), and assume that we have defined \( \theta^{m',n'} \) satisfying all necessary identities for all pairs \( m' \leq m, n' \leq n \) for which at least one of these inequalities is strict. Then we may define \( \theta^{m,n} \) by the case analysis of Definition 5.29. We will show that a function \( \theta^{m,n} \) defined in this way satisfies all identities of Definition 5.23, starting with the identities involving faces.

Throughout these proofs we will conduct a number of case analyses, many of which will involve the standard forms of cones; for these computations we will often reduce the number of cases to be considered using Lemma 5.16.

Proposition A.1. \( \theta^{m,n} \) satisfies \( (\Theta 1) \) and \( (\Theta 2) \) that is, for \( x : C^{m,n} \to X \) and \( i \leq n \), \( \theta^{m,n}(x) \partial_i,0 = \theta^{m,n-1}(x \partial_i,0) \), while \( \theta^{m,n}(x) \partial_{n+1},0 = x \).

Proof. We will prove this via a case analysis, based on the six cases of Definition 5.29. First, let \( x = z \sigma_{ap} \) in standard form, for \( ap \geq n + 1 \). By the induction hypotheses, for \( m' < m \) or \( m' = m \) and \( n' < n \), \( \theta^{m',n'} \) satisfies all the identities of Definition 5.23 (in future computations we will often use this assumption without comment). So for \( i \leq n \) we have:

\[
\theta^{m,n}(x) \partial_i,0 = \theta^{m-1,n}(z) \sigma_{ap+1} \partial_i,0 \\
= \theta^{m-1,n}(z) \partial_i,0 \sigma_{ap} \\
= \theta^{m-1,n-1}(z \partial_i,0) \sigma_{ap} \\
= \theta^{m,n-1}(z \partial_i,0 \sigma_{ap-1}) \\
= \theta^{m,n-1}(z \sigma_{ap} \partial_i,0) \\
= \theta^{m,n-1}(x \partial_i,0)
\]

And for \( i = n + 1 \) we have:
\[
\theta^{m,n}(x)\partial_{n+1,0} = \theta^{m-1,n}(z)\sigma_{a,p+1}\partial_{n+1,0} \\
= \theta^{m-1,n}(z)\partial_{n+1,0}\sigma_{a,p} \\
= z\sigma_{a,p} \\
= x
\]

Now suppose that the standard form of \(x\) is \(z\gamma_{b,q,0}\), where \(b_q \leq n - 1\). Note that we must have \(b_q \geq 1\), so this case can only occur when \(n \geq 2\). Now for \(i \leq b_q - 1\) we have:

\[
\theta^{m,n}(x)\partial_{i,0} = \theta^{m,n-1}(z)\gamma_{b,q,0}\partial_{i,0} \\
= \theta^{m,n-1}(z)\partial_{i,0}\gamma_{b,q-1,0} \\
= \theta^{m,n-2}(z\partial_{i,0})\gamma_{b,q-1,0} \\
= \theta^{m,n-1}(z\partial_{i,0}\gamma_{b,q-1,0}) \\
= \theta^{m,n-1}(z\gamma_{b,q,0}\partial_{i,0}) \\
= \theta^{m,n-1}(x\partial_{i,0})
\]

For \(i = b_q\) or \(i = b_q + 1\) we have:

\[
\theta^{m,n}(x)\partial_{i,0} = \theta^{m,n-1}(z)\gamma_{b,q,0}\partial_{i,0} \\
= \theta^{m,n-1}(z) \\
= \theta^{m,n-1}(z\gamma_{b,q,0}\partial_{i,0}) \\
= \theta^{m,n-1}(x\partial_{i,0})
\]

For \(b_q + 2 \leq i \leq n\) we have:

\[
\theta^{m,n}(x)\partial_{i,0} = \theta^{m,n-1}(z)\gamma_{b,q,0}\partial_{i,0} \\
= \theta^{m,n-1}(z)\partial_{i-1,0}\gamma_{b,q,0} \\
= \theta^{m,n-2}(z\partial_{i-1,0})\gamma_{b,q,0} \\
= \theta^{m,n-1}(z\partial_{i-1,0}\gamma_{b,q,0}) \\
= \theta^{m,n-1}(z\gamma_{b,q,0}\partial_{i,0}) \\
= \theta^{m,n-1}(x\partial_{i,0})
\]

And for \(i = n + 1\) we have:
Next we consider the case where the standard form of \( x \) is \( z\gamma_{b_q,\varepsilon}, b_q \geq n + 1 \). Then for \( 1 \leq i \leq n \) we have:

\[
\theta^{m,n}(x)\partial_{i,0} = \theta^{m-1,n}(z)\gamma_{b_q+1,\varepsilon}\partial_{i,0} \\
= \theta^{m-1,n}(z)\partial_{i,0}\gamma_{b_q,\varepsilon} \\
= \theta^{m-1,n}(z\partial_{i,0})\gamma_{b_q,\varepsilon} \\
= \theta^{m,n-1}(z\gamma_{b_q,\varepsilon}\partial_{i,0}) \\
= \theta^{m,n}(x\partial_{i,0})
\]

And for \( i = n + 1 \) we have:

\[
\theta^{m,n}(x)\partial_{n+1,0} = \theta^{m-1,n}(z)\gamma_{b_q+1,\varepsilon}\partial_{n+1,0} \\
= \theta^{m-1,n}(z)\partial_{n+1,0}\gamma_{b_q,\varepsilon} \\
= z\gamma_{b_q,\varepsilon} \\
= x
\]

Next, we consider case (4) of Definition 5.29: let \( x \) be an \((m-1,n+1)\)-cone not falling under any of cases (1)-(3). By Lemma 5.11 (i), every face \( x\partial_{i,0} \) for \( i \leq n \) is an \((m-1,n)\)-cone, and therefore \( \theta^{m,n-1}(x\partial_{i,0}) = x\partial_{i,0}\gamma_{n,0} \) by the induction hypothesis. Now, for \( i \leq n \), we can compute:

\[
\theta^{m,n}(x)\partial_{i,0} = x\gamma_{n+1,0}\partial_{i,0} \\
= x\partial_{i,0}\gamma_{n,0} \\
= \theta^{m,n-1}(x\partial_{i,0})
\]

And \( \theta^{m,n}(x)\partial_{n+1,0} = x\gamma_{n+1,0}\partial_{n+1,0} = x \).

Next, we consider case (5): consider an \((m,n)\)-cone \( \theta^{m,n-1}(x') \) not falling under any of cases (1) through (4). Then for \( 1 \leq i \leq n - 1 \) we have:
\[ \theta_{m,n}(\theta_{m,n-1}(x')) \partial_{i,0} = \theta_{m,n-1}(x') \gamma_{n,0} \partial_{i,0} \\
= \theta_{m,n-1}(x') \partial_{i,0} \gamma_{n-1,0} \\
= \theta_{m,n-2}(x' \partial_{i,0}) \gamma_{n-1,0} \\
= \theta_{m,n-1}(\theta_{m,n-2}(x' \partial_{i,0})) \\
= \theta_{m,n-1}(\theta_{m,n-1}(x') \partial_{i,0}) \]

For \( i = n \) we have:

\[ \theta_{m,n}(\theta_{m,n-1}(x')) \partial_{n,0} = \theta_{m,n-1}(x') \gamma_{n,0} \partial_{n,0} \\
= \theta_{m,n-1}(x') \\
= \theta_{m,n-1}(\theta_{m,n-1}(x') \partial_{n,0}) \]

And for \( i = n + 1 \) we have \( \theta_{m,n}(\theta_{m,n-1}(x')) \partial_{n+1,0} = \theta_{m,n-1}(x') \gamma_{n,0} \partial_{n+1,0} = \theta_{m,n-1}(x') \).

Finally, we consider case (6); in this case the identities hold by Lemma 5.28. \( \square \)

**Proposition A.2.** \( \theta_{m,n} \) satisfies (\( \Theta 3 \)) that is, for \( x: C^{m,n} \to X \) and \( i \geq n + 2 \), we have \( \theta_{m,n}(x) \partial_{i,1} = \theta_{m-1,n}(x \partial_{i-1,1}) \).

**Proof.** Throughout the proof, we fix \( i \geq n + 2 \). First we consider case (1) of Definition 5.29. Suppose that the standard form of \( x \) is \( z \sigma_{a_{p}} \), for some \( a_{p} \geq n + 1 \). Here we must consider various cases based on a comparison of \( i \) with \( a_{p} \). First suppose that \( i \leq a_{p} \); note that this implies \( a_{p} \geq n + 2 \). Then we have:

\[ \theta_{m,n}(x) \partial_{i,1} = \theta_{m,n-1,n}(z) \sigma_{a_{p}+1} \partial_{i,1} \\
= \theta_{m,n-1,n}(z) \partial_{i,1} \sigma_{a_{p}} \\
= \theta_{m,n-2,n}(z \partial_{i-1,1}) \sigma_{a_{p}} \\
= \theta_{m,n-1,n}(z \partial_{i-1,1} \sigma_{a_{p}-1}) \\
= \theta_{m,n-1,n}(z \sigma_{a_{p}} \partial_{i-1,1}) \\
= \theta_{m,n-1,n}(x \partial_{i-1,1}) \]

To obtain the fourth equality, we have used (\( \Theta 4 \)) and the fact that \( a_{p} - 1 \geq n + 1 \).

Next suppose that \( i = a_{p} + 1 \); then we have:
\( \theta^{m,n}(x) \partial_{a_p+1,1} = \theta^{m-1,n}(z) \sigma_{a_p+1} \partial_{a_p+1,1} \\
= \theta^{m-1,n}(z) \\
= \theta^{m-1,n}(z \sigma_{a_p} \partial_{a_p,1}) \\
= \theta^{m-1,n}(x \partial_{a_p,1}) \\
\)

Finally, suppose \( i \geq a_p + 2 \); note that this implies \( i \geq n + 3 \). Then we have:

\( \theta^{m,n}(x) \partial_{i,1} = \theta^{m-1,n}(z) \sigma_{a_p+1} \partial_{i,1} \\
= \theta^{m-1,n}(z) \partial_{i-1,1} \sigma_{a_p+1} \\
= \theta^{m-2,n}(z \partial_{i-2,1}) \sigma_{a_p+1} \\
= \theta^{m-1,n}(z \partial_{i-2,1} \sigma_{a_p}) \\
= \theta^{m-1,n}(z \partial_{i-2,1} \partial_{i-1,1}) \\
= \theta^{m-1,n}(x \partial_{i-1,1}) \)

Next we consider case (2): suppose that \( x = z \gamma_{b_q,0} \) in standard form, where \( b_q \leq n - 1 \). Then \( i \geq b_q + 3 \), and we have:

\( \theta^{m,n}(x) \partial_{i,1} = \theta^{m-1,n}(z) \gamma_{b_q,0} \partial_{i,1} \\
= \theta^{m-1,n}(z) \partial_{i-1,1} \gamma_{b_q,0} \\
= \theta^{m-2,n}(z \partial_{i-2,1}) \gamma_{b_q,0} \\
= \theta^{m-1,n}(z \partial_{i-2,1} \gamma_{b_q,0}) \\
= \theta^{m-1,n}(z \gamma_{b_q,0} \partial_{i-1,1}) \\
= \theta^{m-1,n}(x \partial_{i-1,1}) \)

Next we consider case (3): suppose that \( x = z \gamma_{b_q,\varepsilon} \) in standard form, where \( b_q \geq n + 1 \). Once again, we must perform a case analysis. First suppose that \( i \leq b_q \), implying \( b_q \geq n + 2 \). Then we can compute:
\[ \theta^{m,n}(x) \partial_{i,1} = \theta^{m-1,n}(z) \gamma_{b_q+1,1} \partial_{i,1} \\
= \theta^{m-1,n}(z) \partial_{i,1} \gamma_{b_q,1} \]
\[= \theta^{m-2,n}(z \partial_{i-1,1}) \gamma_{b_q,1} \]
\[= \theta^{m-1,n}(z \partial_{i-1,1} \gamma_{b_q-1,1}) \]
\[= \theta^{m-1,n}(z \gamma_{b_q,1} \partial_{i-1,1}) \]
\[= \theta^{m-1,n}(z \partial_{i-1,1}) \]

Next suppose that \( i = b_q + 1 \) or \( b_q + 2 \), and \( \varepsilon = 0 \). Then we have:

\[ \theta^{m,n}(x) \partial_{i,1} = \theta^{m-1,n}(z) \gamma_{b_q+1,0} \partial_{i,1} \]
\[= \theta^{m-1,n}(z) \partial_{b_q+1,0} \partial_{b_q+1} \]
\[= \theta^{m-2,n}(z \partial_{b_q+1}) \sigma_{b_q+1} \]
\[= \theta^{m-1,n}(z \partial_{b_q+1} \sigma_{b_q}) \]
\[= \theta^{m-1,n}(z \gamma_{b_q,0} \partial_{i-1,1}) \]
\[= \theta^{m-1,n}(z \partial_{i-1,1}) \]

To obtain the third equality, we used [Ω3] for \( \theta^{m-1,n} \) and the assumption that \( b_q \geq n + 1 \). Next suppose that \( i = b_q + 1 \) or \( b_q + 2 \), and \( \varepsilon = 1 \). Then we have:

\[ \theta^{m,n}(x) \partial_{i,1} = \theta^{m-1,n}(z) \gamma_{b_q+1,1} \partial_{i,1} \]
\[= \theta^{m-1,n}(z) \gamma_{b_q,1} \partial_{i-1,1} \]
\[= \theta^{m-1,n}(z \gamma_{b_q,1} \partial_{i-1,1}) \]
\[= \theta^{m-1,n}(z \partial_{i-1,1}) \]

Finally, suppose \( i \geq b_q + 3 \), implying \( i \geq n + 4 \). Then we have:
Next we consider case (4): let $x$ be an $(m - 1, n + 1)$-cone not covered under any of cases (1) through (3). Then $x \partial_{i-1,1}$ is an $(m - 2, n + 1)$-cone by Lemma 5.11(iii) so $\theta^{m-1,n}(x \partial_{i-1,1}) = x \partial_{i-1,1} \gamma_{n+1,0}$ by (Ω8) for $\theta^{m-1,n}$. Furthermore, note that by Lemma 5.14, $x \partial_{n+1,1} = x \partial_{m+n+1,0} \partial_{n+1,1} \sigma_{n+1} \ldots \sigma_{m+n}$. Using the cubical identities, we can rewrite this as $x \partial_{m+n+1,0} \partial_{n+1,1} \sigma_{n+1} \ldots \sigma_{m+n}$. Then for $i = n + 2$, we can compute:

$$
\theta^{m,n}(x) \partial_{n+2,1} = x \gamma_{n+1,0} \partial_{n+2,1}
= x \partial_{n+1,1} \gamma_{n+1,0}
= x \partial_{m+n+1,0} \ldots \partial_{n+1,1} \sigma_{n+1} \ldots \sigma_{m+n}
= x \partial_{n+1,1} \gamma_{n+1,0}
= \theta^{m-1,n}(x \partial_{n+1,1})
$$

While for $i \geq n + 3$, we have:

$$
\theta^{m,n}(x) \partial_{i,1} = x \gamma_{n+1,0} \partial_{i,1}
= x \partial_{i-1,1} \gamma_{n+1,0}
= \theta^{m-1,n}(x \partial_{i-1,1})
$$

Next we consider case (5). Let $x': C^{m,n-1} \to X$, and consider $\theta^{m,n}(\theta^{m,n-1}(x'))$. Then we can compute:
Finally, in case (6), the identity holds by Lemma 5.28. \(\Box\)

Next we consider the identities involving degeneracies and connections.

**Proposition A.3.** \(\theta_{m,n}\) satisfies \([\Theta 4]\), \([\Theta 5]\) and \([\Theta 6]\). That is:

- for \(x: C^{m-1,n} \rightarrow X\) and \(i \geq n + 1\), \(\theta_{m,n}(x\sigma_i) = \theta_{m,n}(x)\sigma_{i+1}\);
- for \(x: C^{m,n-1} \rightarrow X\) and \(i \leq n - 1\), \(\theta_{m,n}(x\gamma_{i,0}) = \theta_{m,n}(x)\gamma_{i,0}\);
- for \(x: C^{m-1,n} \rightarrow X\) and \(i \geq n + 1\), \(\theta_{m,n}(x\gamma_{i,\varepsilon}) = \theta_{m,n}(x)\gamma_{i+1,\varepsilon}\).

**Proof.** For each identity, we will perform a case analysis based on the standard form of \(x\). For \([\Theta 4]\) consider an \((m,n)\)-cone \(x\sigma_i\), where \(i \geq n + 1\) and the standard form of \(x\) is \(y\gamma_{b_1,c_1}\cdots\gamma_{b_q,c_q}\sigma_{a_1}\cdots\sigma_{a_p}\). If the string of degeneracy maps in the standard form of \(x\) is empty, or \(a_p < i\), then the standard form of \(x\sigma_i\) ends with \(\sigma_i\), so \(\theta_{m,n}(x\sigma_i) = \theta_{m,n}(x)\sigma_{i+1}\) by definition. So suppose that \(a_p \geq i\). Then:

\[
\theta_{m,n}(x\sigma_i) = \theta_{m,n}(y\gamma_{b_1,c_1}\cdots\gamma_{b_q,c_q}\sigma_{a_1}\cdots\sigma_{a_p}\sigma_i) = \theta_{m,n}(y\gamma_{b_1,c_1}\cdots\gamma_{b_q,c_q}\sigma_{a_1}\cdots\sigma_{a_{p-1}}\sigma_i\sigma_{a_p+1})
\]

By assumption, all the indices \(a_1,\ldots,a_{p-1}\), are less than \(a_p\). Rearranging the expression on the right-hand side of the equation into standard form using the cubical identities will not increase any of these indices by more than 1, so the rightmost map in the standard form of \(x\sigma_i\), i.e. the degeneracy map with the highest index, is \(\sigma_{a_p+1}\). Therefore, we can compute:

\[
\theta_{m,n}(y\gamma_{b_1,c_1}\cdots\gamma_{b_q,c_q}\sigma_{a_1}\cdots\sigma_{a_{p-1}}\sigma_i\sigma_{a_p+1}) = \theta_{m,n-1}(y\gamma_{b_1,c_1}\cdots\gamma_{b_q,c_q}\sigma_{a_1}\cdots\sigma_{a_{p-1}}\sigma_i)\sigma_{a_p+2} = \theta_{m-2,n}(y\gamma_{b_1,c_1}\cdots\gamma_{b_q,c_q}\sigma_{a_1}\cdots\sigma_{a_{p-1}})\sigma_{i+1}\sigma_{a_p+2} = \theta_{m-2,n}(y\gamma_{b_1,c_1}\cdots\gamma_{b_q,c_q}\sigma_{a_1}\cdots\sigma_{a_{p-1}})\sigma_{a_{p+1}}\sigma_{i+1} = \theta_{m-1,n}(y\gamma_{b_1,c_1}\cdots\gamma_{b_q,c_q}\sigma_{a_1}\cdots\sigma_{a_{p-1}}\sigma_{a_p})\sigma_{i+1} = \theta_{m-1,n}(x)\sigma_{i+1}
\]
So $\theta^{m,n}$ satisfies (Θ4)

Next we will verify (Θ6). Consider an $(m,n)$-cone $x_{\gamma_{i,\varepsilon}}$, where $i \geq n + 1$ and the standard form of $x$ is as above. If this standard form contains no degeneracy maps, and either $b_q < i$, $b_q = i$ while $\varepsilon_q \neq \varepsilon$, or $x$ is non-degenerate, then the standard form of $x_{\gamma_{i,\varepsilon}}$ ends with $\gamma_{i,\varepsilon}$, so the identity holds by definition. The remaining possibilities for the standard form of $x$ can be divided into various cases. First, suppose that the string of degeneracy maps in the standard form of $x$ is non-empty, i.e. $x = z \sigma_{a_p}$ in standard form. By Lemma 5.11, $x = x_{\gamma_{i,\varepsilon}}$ is an $(m-1,n)$-cone, so $a_p \geq n + 1$ by Lemma 5.16 (i). Now we must break this into further cases based on a comparison between $i$ and $a_p$. If $i < a_p$ then, using the cubical identities, (Θ4) for $\theta^{m,n}$, and (Θ6) for $\theta^{m-1,n}$, we can compute:

$$\theta^{m,n}(x_{\gamma_{i,\varepsilon}}) = \theta^{m,n}(z \sigma_{a_p} \gamma_{i,\varepsilon})$$

$$= \theta^{m,n}(z \gamma_{i,\varepsilon} \sigma_{a_p+1})$$

$$= \theta^{m-1,n}(z \gamma_{i,\varepsilon} \sigma_{a_p+2})$$

$$= \theta^{m-2,n}(z \gamma_{i+1,\varepsilon} \sigma_{a_p+2})$$

$$= \theta^{m-2,n}(z \sigma_{a_p+1} \gamma_{i+1,\varepsilon})$$

$$= \theta^{m-1,n}(z \sigma_{a_p} \gamma_{i+1,\varepsilon})$$

$$= \theta^{m-1,n}(x) \gamma_{i+1,\varepsilon}$$

Next we consider the case $i = a_p$:

$$\theta^{m,n}(x_{\gamma_{a_p,\varepsilon}}) = \theta^{m,n}(z \sigma_{a_p} \gamma_{a_p,\varepsilon})$$

$$= \theta^{m,n}(z \sigma_{a_p} \sigma_{a_p+1})$$

$$= \theta^{m-1,n}(z \sigma_{a_p} \sigma_{a_p+2})$$

$$= \theta^{m-2,n}(z \sigma_{a_p} \sigma_{a_p+1} \sigma_{a_p+2})$$

$$= \theta^{m-2,n}(z \sigma_{a_p} \gamma_{a_p+1,\varepsilon})$$

$$= \theta^{m-1,n}(z \sigma_{a_p} \gamma_{a_p+1,\varepsilon})$$

$$= \theta^{m-1,n}(x) \gamma_{a_p+1,\varepsilon}$$

Now we consider the case $i > a_p$. Note that this implies $i \geq n + 2$, so $i - 1 \geq n + 1$. Thus we can compute:
Then, using the cubical identities,\( (\Theta 4) \)

As above, we begin with the case where the string of degeneracy maps in the standard form of

and the identity holds by definition. Once again, the remaining cases will require computation.

\[ \varepsilon \]

while

Next we will verify \( (\Theta 6) \) in the case where the standard form of \( x \) contains no degeneracy maps, and either \( i < b_q \) or \( i = b_q \) and \( \varepsilon = \varepsilon_q \). In this case we can compute:

\[
\theta^{m,n}(x^i,\varepsilon) = \theta^{m,n}(y^{\gamma b_1,\varepsilon_1} \cdots y^{\gamma b_q,\varepsilon_q} \gamma_i,\varepsilon) \\
= \theta^{m,n}(y^{\gamma b_1,\varepsilon_1} \cdots y^{\gamma b_{q-1},\varepsilon_{q-1}} \gamma_{i-1,\varepsilon} y^{\gamma_{i+1,\varepsilon} b_q+1,\varepsilon_q})
\]

Similarly to what we saw when verifying \( (\Theta 4) \), after we have rearranged the expression on the right-hand side of this equation into standard form, the rightmost map in the expression will still be \( \gamma_{b_q+1,\varepsilon_q} \). Thus we can apply the definition of \( \theta^{m,n} \) to compute:

\[
\theta^{m,n}(y^{\gamma b_1,\varepsilon_1} \cdots y^{\gamma b_{q-1},\varepsilon_{q-1}} \gamma_{i+1,\varepsilon} y^{\gamma_{i+1,\varepsilon} b_q+1,\varepsilon_q}) = \theta^{m-1,n}(y^{\gamma b_1,\varepsilon_1} \cdots y^{\gamma b_{q-1},\varepsilon_{q-1}} \gamma_{i-1,\varepsilon} y^{\gamma_{i+1,\varepsilon} b_q+1,\varepsilon_q}) \\
= \theta^{m-2,n}(y^{\gamma b_1,\varepsilon_1} \cdots y^{\gamma b_{q-1},\varepsilon_{q-1}} \gamma_{i+1,\varepsilon} y^{\gamma_{i+1,\varepsilon} b_q+1,\varepsilon_q}) \\
= \theta^{m-2,n}(y^{\gamma b_1,\varepsilon_1} \cdots y^{\gamma b_{q-1},\varepsilon_{q-1}} \gamma_{i+1,\varepsilon} y^{\gamma_{i+1,\varepsilon} b_q+1,\varepsilon_q}) \\
= \theta^{m-1,n}(y^{\gamma b_1,\varepsilon_1} \cdots y^{\gamma b_{q-1},\varepsilon_{q-1}} \gamma_{i+1,\varepsilon} y^{\gamma_{i+1,\varepsilon} b_q+1,\varepsilon_q}) \\
= \theta^{m-1,n}(y^{\gamma b_1,\varepsilon_1} y^{\gamma b_{q-1},\varepsilon_{q-1}} \gamma_{i+1,\varepsilon} y^{\gamma_{i+1,\varepsilon} b_q+1,\varepsilon_q})
\]

Thus \( \theta^{m,n} \) satisfies \( (\Theta 6) \).

Finally we will verify \( (\Theta 5) \). Consider an \( (m,n) \)-cone \( x^i,0 \), where \( i \leq n - 1 \) and the standard form of \( x \) is as above. Once again, we must consider several possible cases based on the standard form of \( x \). As with \( (\Theta 6) \) if the standard form of \( x \) contains no degeneracy maps, and either \( b_q < i \), \( b_q = i \) while \( \varepsilon_q = 1 \), or \( x \) is non-degenerate, then \( \gamma_{i,0} \) is the rightmost map in the standard form of \( x^i,0 \), and the identity holds by definition. Once again, the remaining cases will require computation.

As above, we begin with the case where the string of degeneracy maps in the standard form of \( x \) is non-empty. By Lemma \ref{lemma:cone}(i) \( x = x^i,0 \partial_{i,0} \) is an \( (m,n-1) \)-cone, so \( a_p \geq n \) by Lemma \ref{lemma:cone} Then, using the cubical identities, \( (\Theta 4) \) for \( \theta^{m,n} \), and \( (\Theta 5) \) for \( \theta^{m-1,n} \), we can compute:
\[
\theta^{m,n}(x_{\gamma i,0}) = \theta^{m,n}(z\sigma_{ap}\gamma_{i,0}) \\
= \theta^{m,n}(z\gamma_{i,0}\sigma_{ap+1}) \\
= \theta^{m-1,n}(z\gamma_{i,0})\sigma_{ap+2} \\
= \theta^{m-1,n-1}(z\gamma_{i,0})\sigma_{ap+2} \\
= \theta^{m-1,n-1}(z)\sigma_{ap+1}\gamma_{i,0} \\
= \theta^{m,n-1}(z\sigma_{ap})\gamma_{i,0} \\
= \theta^{m,n-1}(x)\gamma_{i,0}
\]

Next we consider the cases in which the standard form of \(x\) contains no degeneracy maps; first, suppose that \(b_q \geq n\). Then, using the cubical identities, \([\Theta_6]\) for \(\theta^{m,n}\), and \([\Theta_5]\) for \(\theta^{m-1,n}\), we can compute:

\[
\theta^{m,n}(x_{\gamma i,0}) = \theta^{m,n}(z\gamma_{b_q,\epsilon_{q}}\gamma_{i,0}) \\
= \theta^{m,n}(z\gamma_{i,0}\gamma_{b_q+1}\epsilon_q) \\
= \theta^{m-1,n}(z\gamma_{i,0})\gamma_{b_q+2}\epsilon_q \\
= \theta^{m-1,n-1}(z)\gamma_{b_q+2}\epsilon_q\gamma_{i,0} \\
= \theta^{m-1,n-1}(z)\gamma_{b_q+1}\epsilon_q\gamma_{i,0} \\
= \theta^{m,n-1}(z\gamma_{b_q,\epsilon_q})\gamma_{i,0} \\
= \theta^{m,n-1}(x)\gamma_{i,0}
\]

Next we consider the case \(b_q = n-1\). Note that \(x = x_{\gamma i,0}\partial_{i,0}\) is an \((m, n-1)\)-cone by Lemma 5.11 (3) thus \(\epsilon_q = 0\) by Lemma 5.16 (3). Here we can compute:

\[
x_{\gamma i,0} = y_{\gamma_{b_1,\epsilon_1}}..._{\gamma_{b_{q-1},\epsilon_{q-1}}}\gamma_{n-1,0}\gamma_{i,0} \\
= y\gamma_{b_1,\epsilon_1}..._{\gamma_{b_{q-1},\epsilon_{q-1}}}\gamma_{i,0}\gamma_{n,0}
\]

As in previous cases, after rearranging this expression into standard form, the rightmost map will still be \(\gamma_{n,0}\). Thus \(x_{\gamma i,0}\) belongs to case (4) by Corollary 5.13 so:

\[
\theta^{m,n}(x_{\gamma i,0}) = x_{\gamma i,0}\gamma_{n+1,0} \\
= x_{\gamma n,0}\gamma_{i,0}
\]

By Lemma 5.11 (4) \(x = x_{\gamma i,0}\partial_{i,0}\) is an \((m, n-1)\)-cone, so the fact that \(b_q = n-1\) implies that \(x\) also belongs to case (4). Thus \(x_{\gamma n,0} = \theta^{m,n-1}(x)\), so \([\Theta_5]\) is satisfied in this case.
Finally, we consider the case $i \leq b_q \leq n - 2$. Once again, we have $\varepsilon_q = 0$ by Lemma 5.16 (ii). Now we can compute:

$$\theta^{m,n}(x_{\gamma_i,0}) = \theta^{m,n}(y_{b_1,\varepsilon_1} \cdots y_{b_q,0} \gamma_i,0)$$

As in previous computations, once the expression on the right-hand side of the equation has been rearranged into standard form, its rightmost map will still be $\gamma_{b_q+1},0$. By assumption, $b_q+1 \leq n-1$, so using the cubical identities, the definition of $\theta^{m,n}$, and $(\Theta 5)$ for $\theta^{m,n-1}$, we can compute:

$$\theta^{m,n}(y_{b_1,\varepsilon_1} \cdots y_{b_{q-1},\varepsilon_{q-1}} \gamma_{i,0} y_{b_q+1,0}) = \theta^{m,n-2}(y_{b_1,\varepsilon_1} \cdots y_{b_{q-1},\varepsilon_{q-1}} \gamma_{i,0} y_{b_q,0})\gamma_{i,0}$$

Thus $\theta^{m,n}$ satisfies $(\Theta 5)$. 

**Proposition A.4.** $\theta^{m,n}$ satisfies $(\Theta 7)$. That is, for $x : C^{m,n-1} \to X$, $\theta^{m,n}(\theta^{m,n-1}(x)) = \theta^{m,n-1}(x)\gamma_{n,0}$.

**Proof.** We proceed by a case analysis on $x$, based on the cases of Definition 5.29. In our computations, we will freely use the identities for $\theta^{m,n}$ which we have already proven. First suppose that $x = z\sigma_{a_p}$ in standard form, for some $a_p \geq n$. Then we can compute:

$$\theta^{m,n}(\theta^{m,n-1}(x)) = \theta^{m,n}(\theta^{m,n-1}(z\sigma_{a_p}))$$

Next let the standard form of $x$ be $z\gamma_{b_q,0}$ where $b_q \leq n - 2$. Then we can compute:
Now let the standard form of $x$ be $z\gamma_{b,q}$ where $b_q \geq n$. Then we can compute:

\[
\theta^{m,n}(x) = x\gamma_{n,0}
\]

Next we consider case (5): suppose that $x$ is equal to $\theta^{m,n-2}(x')$ for some $x': C^{m,n-2} \to X$. Then we can compute:

\[
\theta^{m,n}(x') = \theta^{m,n-1}(x)
\]
\[ \theta^{m,n}(\theta^{m,n-1}(x)) = \theta^{m,n}(\theta^{m,n-1}(\theta^{m,n-2}(x'))) \]
\[ = \theta^{m,n}(\theta^{m,n-2}(x')\gamma_{n-1,0}) \]
\[ = \theta^{m,n-1}(\theta^{m,n-2}(x'))\gamma_{n-1,0} \]
\[ = \theta^{m,n-2}(x')\gamma_{n-1,0}\gamma_{n-1,0} \]
\[ = \theta^{m,n-1}(\theta^{m,n-2}(x'))\gamma_{n,0} \]
\[ = \theta^{m,n-1}(x)\gamma_{n,0} \]

Finally, suppose \( x \) falls under case (6). Then by Lemma \ref{lemma:5.32}, \( \theta^{m,n-1}(x) \) falls under case (5), so \( \theta^{m,n}(\theta^{m,n-1}(x)) = \theta^{m,n-1}(x) \gamma_{n,0} \) by definition.

\begin{proposition}
\( \theta^{m,n} \) satisfies (Θ8) That is, for \( x: C^{m-1,n+1} + X, \theta^{m,n}(x) = x\gamma_{n+1,0} \).
\end{proposition}

\begin{proof}
As in previous proofs, we proceed via case analysis on \( x \), based on the cases of Definition \ref{def:5.29}.

First suppose that \( x \) is an \((m-1,n+1)\)-cone whose standard form is \( z\gamma_{a_p,0} \). By Lemma \ref{lemma:5.16}(i), \( a_p \geq n+2 \). Therefore, by Lemma \ref{lemma:5.11}(ii), \( x\partial_{a_p,0} = z \) is an \((m-2,n+1)\)-cone, so \( \theta^{m,n-1}(z) = z\gamma_{n+1,0} \) by (Θ8) for \( \theta^{m,n-1} \). Thus we can compute:

\[ \theta^{m,n}(x) = \theta^{m,n-1}(z)\gamma_{a_p,0+1} \]
\[ = z\gamma_{n+1,0}\gamma_{a_p+1} \]
\[ = z\gamma_{n+1,0} \]
\[ = x\gamma_{n+1,0} \]

Now let \( x \) be an \((m-1,n+1)\)-cone whose standard form is \( z\gamma_{b_q,0} \), \( b_q \leq n-1 \). Then by Lemma \ref{lemma:5.11}(i) \( x\partial_{b_q,0} = z \) is an \((m-1,n)\)-cone. So by (Θ8) for \( \theta^{m,n-1} \), we have \( \theta^{m,n-1}(z) = z\gamma_{n,0} \). Thus we can compute:

\[ \theta^{m,n}(x) = \theta^{m,n-1}(z)\gamma_{b_q,0} \]
\[ = z\gamma_{n,0}\gamma_{b_q,0} \]
\[ = z\gamma_{b_q,0} \gamma_{n+1,0} \]
\[ = x\gamma_{n+1,0} \]

Next let \( x \) be an \((m-1,n+1)\)-cone whose standard form is \( z\gamma_{b_q,\varepsilon} \), where \( b_q \geq n+1 \). (Note that if \( b_q = n+1 \), then we may assume \( \varepsilon = 0 \) by Lemma \ref{lemma:5.16}(ii).) Then by Lemma \ref{lemma:5.11} \( x\partial_{b_q+1,\varepsilon} = z \) is an \((m-2,n+1)\)-cone, so \( \theta^{m-1,n}(z) = z\gamma_{n+1,0} \) by (Θ8) for \( \theta^{m-1,n} \). Thus we can compute:
Finally, case (4) consists of all \((m - 1, n + 1)\)-cones not falling under any of the previous cases, and in this case \([\Theta_8]\) holds by definition.

\[ \theta^{m,n}(x) = \theta^{m-1,n}(z) \gamma_{b_q+1, \varepsilon}^n \]
\[ = z \gamma_{n+1,0} \gamma_{b_q+1, \varepsilon} \]
\[ = z \gamma_{b_q, \varepsilon} \gamma_{n+1,0} \]
\[ = x \gamma_{n+1,0} \]
