#### Abstract

We describe the on-shell method to derive the Renormalization Group (RG) evolution of Wilson coefficients of high dimensional operators at one-loop, which is a necessary part in the on-shell construction of the Standard Model Effective Field Theory (SMEFT), and exceptionally efficient based on the amplitude basis in hand. The UV divergence is obtained by first calculating the coefficients of scalar bubble integrals by unitary cuts, then subtracting the IR divergence in the massless bubbles, which can be easily read from the collinear factors we obtained for the Standard Model fields. Examples of deriving the anomalous dimensions at dimension six are presented in a pedagogical manner. We also give the results of contributions from the dimension- $8 H^{4} D^{4}$ operators to the running of $V^{+} V^{-} H^{2}$ operators, as well as the running of $B^{+} B^{-} H^{2} D^{2 n}$ from $H^{4} D^{2 n+4}$ for general $n$.

## 1 Introduction

The discovery of the Higgs with a mass around $125 \mathrm{GeV}[1,2]$ completes the last missing piece of the Standard Model (SM) and indicates that the SM precisely describes the fundamental interactions at lower energy scale. But with the discovery of Higgs, the Higgs naturalness problem is still mysterious and remains to be solved in the next decades. To solve this problem, the new physics (NP) should be introduced at TeV scale, such as SUSY [3, 4] and composite Higgs models [5-7]. So far the 14 TeV LHC has not found any new physics, which may indicate that the NP scale is so high that beyond the reach of current experiment searches. With such a high NP scale, the precise measurements of the SM interactions at lower scale is an available way to search for the hints of NP, which can be well parametrized by high dimensional operators of the SM Effective Filed Theory (SMEFT). So it becomes important to understand the SMEFT for the search of NP imprints. Since the running of Wilson coefficients can significantly affect the contributions of NP to SM processes at loop
level, the anomalous dimensions of effective operators are crucial for correctly calculating the experiment observables in SMEFT without loosing any infrared informations of the NP.

Recently it was found that on-shell scattering amplitudes have remarkable advantages for the study of SMEFT, comparing with the traditional Lagrangian language. The high dimension operators can be described by unfactorizable amplitudes [8, 9], called amplitude basis, without boring with the redundancies from the equation of motion and integration by part (these redundancies are automatically removed by the intrinsic properties of on-shell method: on-shell conditions and momentum conservation). With this new basis, the calculation in SMEFT can be implemented without referring to the Lagrangian. Some surprising relations and properties of EFTs, which are not manifest in quantum field theory, can be easily seen via this method. For example, some EFTs can be described by scattering equations [10] uniformly or constructed/classified systematically from soft limits [11-13]. The running of Wilson coefficients of SMEFT can be strongly constrained by selection rules [14-16] based on unitarity cut method.

Since the on-shell scattering amplitudes are only described by the physical degrees of freedom, the calculations in SMEFT can be very efficient via on-shell method without involving gauge fixings and ghosts. Particularly, the one-loop amplitudes can be decomposed into the sum of a basis of scalar integrals plus rational functions. And the coefficients of the scalar integrals are determined by the product of the tree-level on-shell amplitudes from the generalized unitary cuts [17-19]. So the one-loop amplitudes can be obtained through simple tree-level calculations without involving any loop integrations. In the basis of scalar integrals, only the bubble integrals are UV divergent, so the anomalous dimension matrix is simply determined by the coefficients of massive and massless bubbles, which can be obtained by Stokes's Theorem [20] or other methods [11, 21-23] (for massive bubble integrals) and collinear divergences of tree level amplitudes (for massless bubble integrals) [24-26]. Notice that UV divergences from massless bubble integrals are universal and only determined by renormalizable interactions so they can be directly read out without any calculations [26]. Comparing with the existing calculation of the anomalous dimension matrix of dimension six [27-31] via Feynman diagrams, the on-shell method appears to be more convenient and powerful, especially when applied in the calculations involving higher dimension operators.

In this paper we demonstrate how to use the on-shell method to derive the anomalous dimension matrix via tree-level amplitudes and give some non-trivial examples, such as $F^{3}$ type operators and dimension 8 operators (the complete dimension 8 operator basis can be found in $[32,33]$ ). Since the UV divergence from a massless bubble integral is universal (only depends on the external legs attached to this bubble diagram), we list all the UV divergent factors from massless bubbles for all the SM fields. So people can directly use these results to calculate the renormalization of SMEFT operators at one-loop level without calculating this kind of UV divergences again. We find that the custodial symmetry can also explain some zeros in anomalous dimension matrices, which can not be explained by the existing selection rules. Based on unitary cuts, the anomalous dimension matrices of the operators with arbitrary dimensions that contribute to $2 \rightarrow 2$ processes can be easily expressed in universal
forms and we explicitly show the universal expressions for the running of $B^{+} B^{-} H^{2} D^{n}$ type operators generated from the insertion of general $H^{4} D^{2 n+4}$ type operators at one-loop level.

The structure of this paper is organized as follows. A detailed discussion about the anomalous dimension calculation in SMEFT via the on-shell method is presented in Sec. 2, and some examples are shown in Sec. 3. The anomalous dimension matrix for dimension 8 amplitude basis $V^{+} V^{-} H^{2}$ is obtained in Sec. 4. We show the universal results of anomalous dimensions for general amplitude basis $B^{+} B^{-} H^{2} D^{2 n}$ in Sec. 5 and conclude in Sec. 6. A simple example of deriving collinear divergent factor and detailed calculation of the anomalous dimension of $\mathcal{O}_{e W}$ via on-shell method are presented in App. A and App. B.

## 2 The on-shell loop method based on unitary cut

Since the renormalization of on-shell SMEFT is induced by UV divergent part of amplitudes, in this section we explain how to derive the full UV divergences of the amplitudes via unitary cut and collinear singularities of tree-level amplitudes.

The non-renormalizable interactions of the on-shell SMEFT can be described by the amplitude basis $\sum_{i} c_{i} \mathcal{M}_{\mathcal{O}^{i}}$, where $c_{i}$ is the Wilson coefficient. To obtain the RG equations for $c_{i}$, we consider the amplitude which receives tree-level contribution from $\mathcal{M}_{\mathcal{O}^{i}}$ as well as loop contributions with another amplitude basis $\mathcal{M}_{\mathcal{O}^{j}}$ insertion. The full amplitude takes the form of

$$
\begin{equation*}
\mathcal{A}_{i}^{1-\operatorname{loop}} \sim c_{i}(\mu)-\gamma_{i j} \frac{1}{16 \pi^{2}} c_{j}(\mu)\left(\frac{1}{2 \epsilon}+\log \mu+\ldots\right) \tag{2.1}
\end{equation*}
$$

where the terms $\frac{1}{2 \epsilon}+\log \mu$ come from the UV divergence with dimension regularization $D=$ $4-2 \epsilon$ and $\mu$ is the renormalization scale. By demanding the full amplitude being independent of the scale $\mu$, one directly obtains the renormalization group (RG) equation

$$
\begin{equation*}
\frac{\mathrm{d} c_{i}(\mu)}{\mathrm{d} \log \mu}=\sum_{j} \frac{1}{16 \pi^{2}} \gamma_{i j} c_{j}(\mu) \tag{2.2}
\end{equation*}
$$

where $\gamma_{i j}$ is the the anomalous dimension matrix governing the RG running.

### 2.1 Unitarity cut and bubble coefficients

To extract the UV divergence in the one-loop amplitude, a convenient way is to decompose it into the combination of a basis of scalar integrals including boxes, triangles and bubbles plus rational functions [17, 18]

$$
\begin{equation*}
\mathcal{A}^{1 \text {-loop }}=\sum_{k} C_{4}^{k} I_{4}^{k}+\sum_{j} C_{3}^{j} I_{3}^{j}+\sum_{k} C_{2}^{i} I_{2}^{i}+R \tag{2.3}
\end{equation*}
$$

Here the index $i(j$ or $k)$ labels the distinct integrals with different partition of the external legs. These integrals capture the branch cuts of the loop amplitudes and their coefficients $C_{4,3,2}^{i}$ can be obtained from tree level amplitudes by generalized unitary cut [34-36]. The

Figure 1. $K_{i}$-channel double cut.
scalar bubbles are the only UV divergent integrals in four dimensions. With dimension regularization it takes the form:

$$
\begin{equation*}
I_{2}^{i} \equiv-i \int \frac{d^{d} l}{(2 \pi)^{d}} \frac{1}{l^{2}(l-K)^{2}}=\frac{1}{(4 \pi)^{2}}\left(\frac{1}{\epsilon}-\log \frac{-K^{2}}{\mu^{2}}+\ldots\right) . \tag{2.4}
\end{equation*}
$$

So the only job to derive anomalous dimension matrix is to extract the bubble coefficients. They can be easily obtained by using Stokes's theorem based on unitary cut [20]. In the following section, we will briefly discuss about this method.

### 2.2 Extraction of bubble coefficient

Since there are two propagators in the loop of bubble integrals, the bubble coefficients can be extracted by double cuts. To extract the coefficient $C_{2}^{i}$, the $K_{i}$-channel double cut should be implemented to $\mathcal{A}^{1 \text {-loop }}$ in eq. 2.3, as illustrated in Fig. 1. The left hand side of this equation becomes

$$
\begin{equation*}
\operatorname{Cut}_{K_{i}}\left[\mathcal{A}^{1 \text {-loop }}\right]=\int d \operatorname{LIPS}_{i} \sum_{h_{i}} \mathcal{A}_{L}^{\text {tree }}\left(l_{1}, l_{2}, h_{i}\right) \mathcal{A}_{R}^{\text {tree }}\left(-l_{1},-l_{2},-h_{i}\right) \tag{2.5}
\end{equation*}
$$

where $d \operatorname{LIPS}_{i}=d l_{1}^{4} d^{4} l_{2}^{4} \delta^{(+)}\left(l_{1}^{2}\right) \delta^{(+)}\left(l_{2}^{2}\right) \delta\left(l_{1}+l_{2}-K_{i}\right)$ is the Lorentz-invariant phase space associated with the $K_{i}$-channel cut, $l_{1,2}^{\mu}$ is momentum of the propagators, $\mathcal{A}_{L}^{\text {tree }}, \mathcal{A}_{R}^{\text {tree }}$ are tree level amplitudes on each side of the cut and $h_{i}$ is the polarization configuration of the cutted internal legs.

The coefficient of bubble is proportional to the rational terms of the double cut, because the un-cutted propagators in the $I_{3,4}$ will make the integration variable $l_{1}$ appear in the denominators and thus contribute only irrational terms. So the bubble coefficients is given by

$$
\begin{equation*}
C_{2}^{i}=-\frac{1}{2 \pi i} \text { Rational }\left[\int d \operatorname{LIPS}_{i} \sum_{h_{i}} \mathcal{A}_{L}^{\text {tree }} \mathcal{A}_{R}^{\text {tree }}\right] \tag{2.6}
\end{equation*}
$$

where the factor $-2 \pi i$ is from the double cut on bubble integral $I_{2}^{i}$ (will be seen in the following discussion). To efficiently calculate the phase space integral, the loop momentum can be parametrized as

$$
\begin{equation*}
\left(l_{1}\right)_{a \dot{a}}=t \lambda_{a} \tilde{\lambda}_{\dot{a}} \tag{2.7}
\end{equation*}
$$

so that the phase space integral can be written as

$$
\begin{equation*}
\int d \operatorname{LIPS}_{i}=\int t d t \int_{\tilde{\lambda}=\tilde{\lambda}} \frac{\langle\lambda d \lambda\rangle[\tilde{\lambda} d \tilde{\lambda}]}{\left.\langle l| K_{i} \mid l\right]} \delta\left(t-\frac{K_{i}^{2}}{\left.\langle l| K_{i} \mid l\right]}\right) . \tag{2.8}
\end{equation*}
$$

Notice that we are integrating over the contour $\bar{\lambda}=\tilde{\lambda}$ so that the loop momentum is real. The spinor variables $\lambda(\tilde{\lambda})$ can be further decomposed into a basis of two massless spinors with a complex coefficient $z$,

$$
\begin{equation*}
|\lambda\rangle=|p\rangle+z|q\rangle, \mid \lambda]=\mid p]+\bar{z} \mid q], \tag{2.9}
\end{equation*}
$$

where $p_{\mu}$ and $q_{\mu}$ are two null momenta satisfying $K_{\mu}^{i}=p_{\mu}+q_{\mu}$. With this parametrization, the phase space integral can be expressed in terms of the integration of complex variable $z$,

$$
\begin{equation*}
\int d \operatorname{LIPS}_{i}=\oint d z \int d \bar{z} \int d t t^{2} \delta\left(t-\frac{1}{(1+z \bar{z})}\right) . \tag{2.10}
\end{equation*}
$$

Then the cut of the bubble integral can be easily evaluated and equal to

$$
\begin{equation*}
\operatorname{Cut}\left[I_{2}^{i}\right]=\oint d z \int d \bar{z} \int t^{2} d t \delta\left(t-\frac{1}{(1+z \bar{z})}\right)=\int d z \frac{-1}{(1+z \bar{z}) z}=-2 \pi i . \tag{2.11}
\end{equation*}
$$

In the last two step, we first integrate over $\bar{z}$ and then sum over the residues at all poles of $z$. This result explains the $-2 \pi i$ factor in Eq. 2.6. Under this parametrization the cutted amplitude becomes

$$
\begin{equation*}
\Delta_{i}(z, \bar{z}) \equiv \int d \operatorname{LIPS}_{i} \sum_{h_{i}} \mathcal{A}_{L}^{\text {tree }} \mathcal{A}_{R}^{\text {tree }}=\left.\oint d z \int d \bar{z} t^{2} \sum_{h_{i}} \mathcal{A}_{L}(t, z, \bar{z}) \mathcal{A}_{R}(t, z, \bar{z})\right|_{t=\frac{1}{1+z \bar{z}}}( \tag{2.12}
\end{equation*}
$$

After perform the $z$-integration via Cauchy's Residue Theorem, finally $C_{2}^{i}$ in Eq. 2.6 can be easily evaluted via the following expression,

$$
\begin{equation*}
C_{2}=\frac{\Delta_{i}^{\text {Rational }}}{-2 \pi i}=-\operatorname{Res}_{z=0} F^{\text {Rational }}(z, \bar{z})-\operatorname{Res}_{z \neq 0} F^{\text {Rational }}(z, \bar{z}), \tag{2.13}
\end{equation*}
$$

where $F^{\text {Rational }}$ is the rational part of $F(z, \bar{z})=\left.\int d \bar{z} t^{2} \sum_{h_{i}} \mathcal{A}_{L}(t, z, \bar{z}) \mathcal{A}_{R}(t, z, \bar{z})\right|_{t=\frac{1}{1+z \bar{z}}}$.

### 2.3 Collinear divergence

Using unitary cut we can not get the full UV divergences of loop amplitudes. Only the coefficients of massive bubble ( $K_{i}^{2}>0$ ) can be obtained via unitary cut. Massless bubbles with $K_{i}^{2}=0$ also contain UV divergences, which simply vanish in dimension regularization due to the cancellation between UV and collinear IR divergence. Since the physical cross section is free of collinear divergences, the collinear divergences of the tree amplitudes must be cancelled by collinear loop IR divergences. So the UV divergence in massless bubbles can be extracted by calculating collinear divergences of the corresponding tree amplitudes. The one-loop collinear IR divergence can be parametrized as [24-26]

$$
\begin{equation*}
\mathcal{A}_{\mathrm{n}, \mathrm{col}}^{1 \text {-loop }}=-\left(\frac{1}{4 \pi}\right)^{2} \sum_{a}^{n} \frac{\gamma(a)}{\epsilon} \mathcal{A}^{\text {tree }}, \tag{2.14}
\end{equation*}
$$

where the sum is over all external legs and $\gamma(a)$ is the collinear factor for each particle $a$. We want to emphasize that the collinear factors only depend on the external legs and are universal for SMEFT. In Appendix A we show one example of deriving the collinear factors. For all the SM fields the collinear factors are obtained to be,

$$
\begin{align*}
\gamma\left(H^{a}\right) & =\gamma\left(H^{\dagger \dot{a}}\right)=2 y_{h}^{2} g_{1}^{2}-\frac{1}{2} \operatorname{Tr}\left[N_{c} Y_{u}^{\dagger} Y_{u}+N_{c} Y_{d}^{\dagger} Y_{d}+Y_{e}^{\dagger} Y_{e}\right]+2 g_{2}^{2} C_{2}(2) \\
\gamma(B) & =-\frac{g_{1}^{2}}{3}\left[n_{g} N_{c}\left(y_{q}^{2}+y_{u}^{2}+y_{d}^{2}\right)+n_{g}\left(y_{\ell}^{2}+y_{e}^{2}\right)+y_{h}^{2}\right], \\
\gamma\left(W^{a}\right) & =g_{2}^{2}\left[\frac{11}{3}-\frac{1}{3}\left(\frac{n_{g}}{2} N_{c}+\frac{n_{g}}{2}+\frac{1}{4}\right)\right], \\
\gamma(g) & =g_{3}^{2}\left(\frac{11 N_{c}}{6}-\frac{1}{3} n_{g}\right), \\
\gamma(\ell) & =\frac{3}{2} g_{2}^{2} C_{2}(2)+\frac{3}{2} y_{\ell}^{2} g_{1}^{2}-\frac{1}{4} Y_{e}^{\dagger} Y_{e}, \\
\gamma(e) & =\frac{3}{2} y_{e}^{2} g_{1}^{2}-\frac{1}{2} Y_{e}^{\dagger} Y_{e}, \\
\gamma(q) & =\frac{3}{2} g_{3}^{2} C_{2}\left(N_{c}\right)+\frac{3}{2} g_{2}^{2} C_{2}(2)+\frac{3}{2} y_{q}^{2} g_{1}^{2}-\frac{1}{4}\left(Y_{u}^{\dagger} Y_{u}+Y_{d}^{\dagger} Y_{d}\right), \\
\gamma(u) & =\frac{3}{2} g_{3} C_{2}\left(N_{c}\right)+\frac{3}{2} y_{u}^{2} g_{1}^{2}-\frac{1}{2} Y_{u}^{\dagger} Y_{u}, \\
\gamma(d) & =\frac{3}{2} g_{3} C_{2}\left(N_{c}\right)+\frac{3}{2} y_{u}^{2} g_{1}^{2}-\frac{1}{2} Y_{d}^{\dagger} Y_{d} . \tag{2.15}
\end{align*}
$$

Here $q$ and $l$ are $S U(2)$ doublets for left hand quarks and leptons, while $u, d$ and $e$ are right hand singlets. $g_{3}, g_{2}$ and $g_{1}$ are the gauge couplings of $S U(3)_{C} \times S U(2)_{L} \times U(1)_{Y}$, with $y_{i}$ being the hypercharge. $Y_{u}, Y_{d}$ and $Y_{e}$ are Yukawa couplings. $N_{c}=3$ is QCD color number; $n_{g}=3$ is the number of generations. And $C_{2}(N)=\frac{N^{2}-1}{2 N}$.

So for any SMEFT loop calculation, the UV divergences of massless bubbles can be directly read from Eq. 2.15 without any calculation.

Combining the UV divergences from massive bubbles with collinear IR divergences, we can finally obtain the anomalous dimension matrix correctly. In the next section we will give some non-trivial examples to clearly show how to get the anomalous dimension matrix systematically via on-shell method.

## 3 Examples for calculation of anomalous dimension matrix

In this section we give some examples to demonstrate the on-shell loop method for calculating the RG running of SMEFT in detail.

## $3.1 \mathcal{O}_{H B}$

We first focus on a simplest case: the contributions proportional to $U(1)_{Y}$ gauge interactions to the running of the dimension 6 operator $\mathcal{O}_{H B}=H^{\dagger} H B^{\mu \nu} B_{\mu \nu}$. In the amplitude basis, this operator corresponds to the local amplitude

$$
\begin{equation*}
\mathcal{A}\left(B^{+}, B^{+}, H^{\alpha}, H^{\dagger \dot{\beta}}\right)=2 C_{H B} \delta^{\alpha \dot{\beta}}[12]^{2} . \tag{3.1}
\end{equation*}
$$

Figure 2. Unitary cuts in calculating the running of $O_{H B}$. The upper plot is the $s$ channel cut and the lower two plots are $t$ channel cuts.

Here the superscript " + " denotes the positive helicity.
The Higgs $U(1)_{Y}$ gauge interactions and quartic term can be expressed as

$$
\begin{equation*}
\mathcal{L}=-\frac{1}{4} B_{\mu \nu} B^{\mu \nu}+\left|D_{\mu} H\right|^{2}-\frac{1}{4} \lambda|H|^{4} . \tag{3.2}
\end{equation*}
$$

where $D_{\mu}=\partial_{\mu}-i g_{1} y_{h} B_{\mu}$.
Now let's consider the amplitude $\mathcal{A}\left(B^{+}, B^{+}, H^{\dagger \dot{\alpha}}, H^{\alpha}\right)$ at one-loop. As shown in Fig. 2, applying different double cuts, this amplitude are separated into dimension 6 part and dimension 4 part. The dimension 6 part can be read from Eq. 3.1 and the dimension 4 part can be derived from Eq. 3.2,

$$
\begin{align*}
& \mathcal{A}^{4}\left(H^{\alpha} H^{\dagger \dot{\alpha}} B^{+} B^{-}\right)=-2 y_{h}^{2} g_{1}^{2} \delta^{\alpha \dot{\alpha}} \frac{\langle 14\rangle\langle 24\rangle}{\langle 13\rangle\langle 23\rangle}  \tag{3.3}\\
& \mathcal{A}^{4}\left(H^{\alpha} H^{\dagger \dot{\alpha}} H^{\beta} H^{\dagger \dot{\beta}}\right)=\left(\delta^{\alpha \dot{\alpha}} \delta^{\beta \dot{\beta}}+\delta^{\alpha \dot{\beta}} \delta^{\beta \dot{\alpha}}\right)\left(-\frac{\lambda}{2}+y_{h}^{2} g_{1}^{2}\right)+2 y_{h}^{2} g_{1}^{2}\left[\delta^{\alpha \dot{\alpha}} \delta^{\beta \dot{\beta}} \frac{\langle 24\rangle[24]}{\langle 12\rangle[12]}+\delta^{\alpha \dot{\beta}} \delta^{\beta \dot{\beta}} \frac{\langle 24\rangle[24]}{\langle 14\rangle[14]}\right] \tag{3.4}
\end{align*}
$$

First consider the $s$-channel cut (the upper plot in Fig. 2). With the tree level amplitudes Eq. 3.1 and Eq. 3.4 it can be expressed as

$$
\begin{align*}
& \operatorname{Cut}_{12}\left[\mathcal{A}\left(B^{+}\left(p_{1}\right) B^{+}\left(p_{2}\right) H^{\dagger \dot{\alpha}}\left(p_{3}\right) H^{\alpha}\right)\left(p_{4}\right)\right] \\
= & \int d \operatorname{LIPS} \mathcal{A}_{L}\left(B^{+}\left(p_{1}\right) B^{+}\left(p_{2}\right) H^{\beta}\left(l_{1}\right) H^{\dagger \dot{\beta}}\left(l_{2}\right)\right) \delta^{\beta \dot{\sigma}} \delta^{\sigma \dot{\beta}} \mathcal{A}_{R}\left(H^{\dagger \dot{\phi}}\left(-l_{1}\right) H^{\sigma}\left(-l_{2}\right) H^{\dagger \dot{\alpha}}\left(p_{3}\right) H^{\alpha}\left(p_{4}\right)\right) \\
= & \int d \operatorname{LIPS} C_{H B} \delta^{\sigma \dot{\sigma}}[12]^{2}\left[\left(\delta^{\sigma \dot{\sigma}} \delta^{\alpha \dot{\alpha}}+\delta^{\sigma \dot{\alpha}} \delta^{\alpha \dot{\sigma}}\right)\left(-\frac{\lambda}{2}+y_{h}^{2} g_{1}^{2}\right)\right. \\
& \left.+2 y_{h}^{2} g_{1}^{2}\left(\delta^{\sigma \dot{\sigma}} \delta^{\alpha \dot{\alpha}} \frac{\left\langle-l_{2} 3\right\rangle\left[-l_{2} 3\right]}{\left\langle-l_{1}-l_{2}\right\rangle\left[-l_{1}-l_{2}\right]}+\delta^{\sigma \dot{\alpha}} \delta^{\alpha \dot{\sigma}} \frac{\left\langle-l_{2} 3\right\rangle\left[-l_{2} 3\right]}{\left\langle-l_{1} 3\right\rangle\left[-l_{1} 3\right]}\right)\right], \tag{3.5}
\end{align*}
$$

where $l_{1,2}$ is the momentum of the cutted internal Higgs leg. We then use the relations $|-l\rangle=i|l\rangle, \mid-l]=i \mid l]^{1}$ and $l_{1}+l_{2}=p_{3}+p_{4}$ to express it as function of $l_{1}$. Following the procedure presented in the previous section, we should parametrize the loop momentum as

$$
\begin{equation*}
\left.\left.\left.\left|l_{1}\right\rangle=\sqrt{t}(|3\rangle+z|4\rangle) \quad \mid l_{1}\right]=\sqrt{t}(\mid 3]+\bar{z} \mid 4\right]\right) \tag{3.6}
\end{equation*}
$$

and then the bubble coefficient can be extracted through Stokes' Theorem,

$$
\begin{align*}
\Delta_{12} & =\left.[12]^{2} \delta^{\alpha \dot{\alpha}} \oint d z \int d \bar{z} t^{2}\left(\left(-\frac{3}{2} \lambda+3 y_{h}^{2} g_{1}^{2}\right)+2 y_{h}^{2} g_{1}^{2}\left(-2 t^{3}+\frac{1}{z \bar{z}} t^{2}\right)\right)\right|_{t=(1+z \bar{z})^{-1}} \\
& =[12]^{2} \delta^{\alpha \dot{\alpha}} \oint d z\left(\left(-\frac{3}{2} \lambda+3 y_{h}^{2} g_{1}^{2}\right) \frac{-1}{z(1+z \bar{z})}+2 y_{h}^{2} g_{1}^{2}\left(\frac{1}{z(1+z \bar{z})^{2}}+\frac{1}{z(1+z \bar{z})}+\frac{\log (-z \bar{z})-\log (1+z \bar{z})}{z}\right)\right) \\
& =2 \pi i[12]^{2} \delta^{\alpha \dot{\alpha}}\left(\frac{3}{2} \lambda+y_{h}^{2} g_{1}^{2}\right) \tag{3.7}
\end{align*}
$$

In the last step we discard the $\log$ terms, take the residue at $z=0$ and set $\bar{z}=z$. Finally we can get the bubble coefficient from s-channel double cut

$$
\begin{equation*}
C_{2}^{12}=-\left(y_{h}^{2} g_{1}^{2}+\frac{3 \lambda}{2}\right) C_{H B} \delta^{\alpha \dot{\alpha}}[12]^{2} \tag{3.8}
\end{equation*}
$$

Following the same procedure, The contribution from t-channel cut is given by

$$
\begin{align*}
& \operatorname{Cut}_{13}\left[\mathcal{A}\left(B^{+}\left(p_{1}\right) B^{+}\left(p_{2}\right) H^{\dagger \dot{\alpha}}\left(p_{3}\right) H^{\alpha}\right)\left(p_{4}\right)\right] \\
= & \mathcal{A}_{L}\left(B^{+}\left(p_{1}\right) H^{\dagger \dot{\alpha}}\left(p_{3}\right) B^{+}\left(l_{1}\right) H^{\beta}\left(l_{2}\right)\right) \delta^{\beta \dot{\beta}} \mathcal{A}_{R}\left(B^{-}\left(-l_{1}\right) H^{\dagger \dot{\beta}}\left(-l_{2}\right) B^{+}\left(p_{2}\right) H^{\alpha}\left(p_{3}\right)\right) \\
+ & \mathcal{A}_{L}\left(B^{+}\left(p_{2}\right) H^{\alpha}\left(p_{4}\right) B^{+}\left(-l_{1}\right) H^{\dagger \dot{\beta}}\left(-l_{2}\right)\right) \delta^{\beta \dot{\beta}} \mathcal{A}_{R}\left(B^{-}\left(-l_{1}\right) H^{\beta}\left(-l_{2}\right) B^{+}\left(p_{1}\right) H^{\dagger \dot{\alpha}}\left(p_{3}\right)\right) \\
= & -2 y_{h}^{2} g_{1}^{2} C_{H B} \delta^{\alpha \dot{\alpha}}\left[1 l_{1}\right]^{2} \frac{\left\langle 4-l_{1}\right\rangle\left\langle-l_{2}-l_{1}\right\rangle}{\langle 42\rangle\left\langle-l_{2} 2\right\rangle}+(1 \leftrightarrow 2,3 \leftrightarrow 4) \tag{3.9}
\end{align*}
$$

Using Stokes' Theorem again after proper parametrization, we can get the bubble coefficient for t-channel cut,

$$
\begin{equation*}
C_{2}^{13}=-2 y_{h}^{2} g_{1}^{2} C_{H B} \delta^{\alpha \dot{\alpha}}[12]^{2} \tag{3.10}
\end{equation*}
$$

The u-channel cut is the same as t-channel cut under $p_{1} \leftrightarrow p_{2}$ and we get

$$
\begin{equation*}
C_{2}^{13}=C_{2}^{14} \tag{3.11}
\end{equation*}
$$

So the total contribution from massive bubble integral is

$$
\begin{equation*}
C_{2}=C_{2}^{13}+C_{2}^{14}+C_{2}^{12}=-\left(5 y_{h}^{2} g_{1}^{2}+\frac{3 \lambda}{2}\right) C_{H B} \delta^{\alpha \dot{\alpha}}[12]^{2} \tag{3.12}
\end{equation*}
$$

The parts of UV divergences cancelled by IR divergences can be read from Eq. 2.15 according to the external legs:

$$
\begin{equation*}
C_{I R}=-(2 \gamma(B)+2 \gamma(H)) \delta^{a \dot{a}} C_{H B}[12]^{2} \tag{3.13}
\end{equation*}
$$

[^0]So we can find the total UV divergences of operator $\mathcal{O}_{H B}$ from $U(1)_{Y}$ gauge interactions at one-loop level as

$$
\begin{align*}
C_{U V} & =C_{2}-C_{I R}=-\left[y_{h}^{2} g_{1}^{2}(5-2 \gamma(H)-2 \gamma(B))+\frac{3 \lambda}{2}\right] \frac{1}{(4 \pi)^{2}} \delta^{a \dot{a}} C_{H B}[12]^{2} \\
& =-\left[\frac{5}{3} y_{h}^{2} g_{1}^{2}+\frac{3 \lambda}{2}\right] \frac{1}{(4 \pi)^{2}} \delta^{a \dot{a}} C_{H B}[12]^{2} . \tag{3.14}
\end{align*}
$$

So the running of $C_{H B}$ is

$$
\begin{equation*}
\dot{C}_{H B}=2\left[\frac{5}{3} y_{h}^{2} g_{1}^{2}+\frac{3 \lambda}{2}\right] C_{H B} \tag{3.15}
\end{equation*}
$$

where $\dot{C}_{H B} \equiv(4 \pi)^{2} \mu \frac{d C_{H B}}{d \mu}$. This expression is exactly the same as the results in [29, 30].

## $3.2 \quad F^{3}$ type operators

For the $F^{3}$ type operators, with $F$ denoting the field strength of non-Abelien gauge fields, the leading amplitude is three-point scattering amplitude, which does not depend on any UV scale if the three external legs are on-shell. So its UV divergences can not be extracted through unitarity cut. However we can calculate its next leading 4-points amplitude to derive its RG running. The color-ordered leading amplitude of dimension 6 operator $\mathcal{O}_{G^{3}}=C_{G^{3}} \operatorname{Tr}\left[G_{\mu \nu}^{3}\right]$ can be expressed as

$$
\begin{equation*}
\mathcal{A}\left(g_{1}^{+} g_{2}^{+} g_{3}^{+}\right)=C_{G^{3}}[12][23][31] . \tag{3.16}
\end{equation*}
$$

It contributes to the 4-point all plus tree-level amplitude, which can be constructed through all-line shift [37],

$$
\begin{equation*}
\mathcal{A}^{\text {tree }}\left(g_{1}^{+} g_{2}^{+} g_{3}^{+} g_{4}^{+}\right)=2 g_{3} C_{G^{3}} \frac{[12][13][42]}{\langle 34\rangle} \tag{3.17}
\end{equation*}
$$

According to unitary cut, it is easy to find that the loops with quark internal legs does not contain UV divergences, because the the helicity selection rules forbid the tree level amplitude for two quarks and two $g^{+}$at dimension 4. So only $\mathcal{O}_{G^{3}}$ insertion contribute to itself RG running. Following the same procedures as above, we can get the coefficients of the bubble integral,

$$
\begin{equation*}
C_{2}=-6 g_{3}^{2} N_{c} \mathcal{A}^{\text {tree }}\left(g_{1}^{+} g_{2}^{+} g_{3}^{+} g_{4}^{+}\right) \tag{3.18}
\end{equation*}
$$

After including the massless bubble contributions which can be directly read from Eq. 2.15, the total divergences in the one-loop amplitude is

$$
\begin{equation*}
C_{U V}=\frac{\left(-6 g_{3}^{2} N_{c}+4 g_{3}^{2} \gamma(g)\right)}{(4 \pi)^{2}} \mathcal{A}^{\text {tree }}\left(g_{1}^{+} g_{2}^{+} g_{3}^{+} g_{4}^{+}\right) \tag{3.19}
\end{equation*}
$$

These divergences of this four-point amplitude contain both the gauge coupling $g_{s}$ and $C_{G^{3}}$ renormalization and with requirement that the amplitude independent on the renormalizable scale we can get the following RG equation

$$
\begin{equation*}
(4 \pi)^{2} \beta_{g_{3}} C_{G^{3}}+g_{3} \dot{C}_{G^{3}}=4 g_{3}^{3}\left(3 N_{c}-2 \gamma(g)\right) C_{G^{3}} \tag{3.20}
\end{equation*}
$$

where $\beta_{g_{3}}$ is the beta function of gauge coupling $g_{3}$. We can also derive $\beta_{g_{3}}$ through on-shell method,

$$
\begin{equation*}
\beta_{g_{3}}=-\frac{2 g_{3}^{3}}{(4 \pi)^{2}} \gamma(g) \tag{3.21}
\end{equation*}
$$

Substituting the expression of $\beta_{g_{3}}$ into the Eq. 3.20, we can get the RG running of $C_{G^{3}}$

$$
\begin{equation*}
\dot{C}_{G^{3}}=\left[12 N_{c}-6 \gamma(g)\right] g_{3}^{2} C_{G^{3}} \tag{3.22}
\end{equation*}
$$

With these examples we can find that on-shell method is very efficient to calculate SMEFT RG running. We do not need to do loop calculation. All the divergences can be extracted from the tree level amplitudes. We also present more complicated calculations for the operator $\mathcal{O}_{e W}$ in App. B.

## 4 Anomalous dimensions at dimension 8: the $V^{+} V^{-} H^{2}$ example

The method introduced above can be applied to efficiently obtain the RG running of higher dimension operators. In this section we consider the running at dimension 8. In particular we present the contribution from the $H^{4}$ type local amplitudes to the RG running of the coefficients of the $V^{+} V^{-} H^{2}$ type amplitude.

The $V^{+} V^{-} H^{2}$ amplitude at dimension 8 is important in phenomenology because it gives leading BSM correction to the $V V H H$ scattering in the SMEFT, due to the non-interference at dimension 6 [38]. Also this amplitude basis is only generated at one-loop order when we integrate out some heavy particles in a weakly coupled UV theory [16, 39-42], which makes the contribution from the mixing with a potentially tree level generated local amplitude (operator) important. So in this section we calculate the RG running of this coupling from the mixing with $H^{4}$ amplitude basis at dimension 8 . Notice that if we ignore the fermions, this is the only leading contribution. All others, including the contributions from the loops containing two dimension 6 amplitude basis, are more than one-loop suppressed if we take into account the tree/loop classification of the local amplitude.

There are three independent $H^{4}$ type local amplitudes at dimension 8. It is convenient to write them in the following form:
$\mathcal{A}\left(H^{\alpha} H^{\beta} H^{\dagger \dot{\alpha}} H^{\dagger \dot{\beta}}\right)_{\operatorname{dim} 8} \supset T_{\alpha \beta \dot{\alpha} \dot{\beta}}^{+} C_{0,2}^{H^{4}+}\left(s_{13}-s_{23}\right)^{2}, T_{\alpha \beta \dot{\alpha} \dot{\beta}}^{+} C_{2,0}^{H^{4}+} s_{12}^{2}, \quad T_{\alpha \beta \dot{\alpha} \dot{\beta}}^{-} C_{1,1}^{H^{4}-} s_{12}\left(s_{13}-s_{23}\right)$,
where $T_{\alpha \beta \dot{\alpha} \dot{\beta}}^{ \pm} \equiv \delta_{\alpha \dot{\alpha}} \delta_{\beta \dot{\beta}} \pm \delta_{\beta \dot{\alpha}} \delta_{\alpha \dot{\beta}}$.

The dimension $8 V^{+} V^{-} H^{2}$ type amplitudes can be written as:

$$
\left.\left.\begin{array}{rl}
\mathcal{A}\left(B^{+} B^{-} H^{\alpha} H^{\dagger \dot{\beta}}\right)_{\operatorname{dim} 8} & =C_{H^{2} B^{+} B^{-}} \delta_{\alpha \dot{\beta}}[1|3| 2\rangle^{2}, \\
\mathcal{A}\left(W^{a+} W^{b-} H^{\alpha} H^{\dagger \dot{\beta}}\right)_{\operatorname{dim} 8} & \supset C_{H^{2} W^{+} W^{-}}^{+} T_{\alpha \dot{\beta}}^{a b+}[1|3| 2\rangle^{2}, \\
\mathcal{A}\left(W^{a+} B^{-} H^{\alpha} H^{\dagger}{ }^{\dagger} W^{+} W_{\operatorname{dim} 8}\right. & T_{\alpha \dot{\beta}}^{a b-}[1|3| 2\rangle^{2}, \\
\mathcal{A}\left(B^{+} W^{a-} H^{\alpha} H^{\dagger \dot{\beta}}\right)_{\operatorname{dim} 8} & =C_{H^{2} W^{+} B^{+} B^{-}} \tau_{\dot{\beta} \alpha}^{a}[1|3| 2\rangle^{2},  \tag{4.2}\\
\dot{\beta} \alpha
\end{array}\right]|3| 2\right\rangle^{2},, ~ l
$$

where $\tau_{\alpha \dot{\beta}}^{a}$ is Pauli matrix, $T_{\alpha \dot{\beta}}^{a b+}=\delta^{a b} \delta_{\alpha \dot{\beta}}$ and $T_{\alpha \dot{\beta}}^{a b-}=i \epsilon^{a b c} \tau_{\alpha \dot{\beta}}^{c}$.
The loop contributions to the running can be obtained by gluing the $H^{4}$ amplitude basis in Eq. 4.1 with the $V^{+} V^{-} H^{2}$ amplitudes in SM, which are

$$
\begin{align*}
\mathcal{A}^{\mathrm{SM}}\left(H^{\beta}, H^{\dagger \dot{\alpha}}, B^{+}, W^{i-}\right) & =-g_{1} g_{2} y_{h}\left(\tau^{i}\right)_{\beta}^{\dot{\alpha}} \frac{\langle 14\rangle\langle 24\rangle}{\langle 13\rangle\langle 23\rangle},  \tag{4.3}\\
\mathcal{A}^{\mathrm{SM}}\left(H^{\beta}, H^{\dagger \dot{\alpha}}, W^{+}, B^{i-}\right) & =-g_{1} g_{2} y_{h}\left(\tau^{i}\right)_{\beta}^{\dot{\alpha}} \frac{\langle 14\rangle\langle 24\rangle}{\langle 13\rangle\langle 23\rangle},  \tag{4.4}\\
\mathcal{A}^{\mathrm{SM}}\left(H^{\beta}, H^{\dagger \dot{\alpha}}, W^{a+}, W^{b-}\right) & =-2 g_{2}^{2} \frac{\langle 4| 1 \mid 3]^{2}}{\langle 34\rangle[34]}\left(\frac{\left(t^{b} t^{a}\right)_{\beta}^{\dot{\alpha}}}{\langle 24\rangle[24]}+\frac{\left(t^{a} t^{b}\right)_{\beta}^{\dot{\beta}}}{\langle 23\rangle[23]}\right), \tag{4.5}
\end{align*}
$$

in addition to the $B^{+} B^{-} H^{\dagger} H$ amplitude in Eq. 3.4. Here $t^{a}=\tau^{a} / 2$ are the $S U(2)$ generators.
Applying the unitary method, we obtain the RG running of $V^{+} V^{-} H^{2}$ type operators as following:

$$
\begin{align*}
\dot{C}_{H^{2} B^{+} B^{-}} & =-2 g_{1}^{2} y_{h}^{2}\left(C_{0,2}^{H^{4}+}+C_{2,0}^{H^{4}+}+\frac{1}{3} C_{1,1}^{H^{4}-}\right) \\
\dot{C}_{H^{2} B^{+} W^{-}} & =-\frac{1}{3} g_{1} g_{2} y_{h}\left(C_{0,2}^{H^{4}+}+C_{2,0}^{H^{4}+}-C_{1,1}^{H^{4}-}\right), \\
\dot{C}_{H^{2} W^{+} B^{-}} & =-\frac{1}{3} g_{1} g_{2} y_{h}\left(C_{0,2}^{H^{4}+}+C_{2,0}^{H^{4}+}-C_{1,1}^{H^{4}-}\right), \\
\dot{C}_{H^{2} W^{+} W^{-}}^{+} & =-\frac{1}{2} g_{2}^{2}\left(C_{0,2}^{H^{4}+}+C_{2,0}^{H^{4}+}+\frac{1}{3} C_{1,1}^{H^{4}-}\right), \\
\dot{C}_{H^{2} W^{+} W^{-}}^{-} & =0 . \tag{4.6}
\end{align*}
$$

The dependence of these equations on the specific combinations $\left(C_{0,2}^{H^{4}+}+C_{2,0}^{H^{4}+}+\frac{1}{3} C_{1,1}^{H^{4}-}\right)$ and $\left(C_{0,2}^{H^{4}+}+C_{2,0}^{H^{4}+}+\frac{1}{3} C_{1,1}^{H^{4}-}\right)$ are expected by demanding the right angular momentum and $S U(2)_{L}$ quantum number[16]. The zero in the last equation can be understood from the fact that the there is $S O(4)$ custodial symmetry in both $H^{4}$ operators and $\mathcal{A}^{S M}\left(H^{\beta} H^{\dagger \dot{\alpha}} W^{a+} W^{b-}\right)$, while dimension 8 amplitude basis $\mathcal{A}\left(W^{a+} W^{b-} H^{\alpha} H^{\dagger \dot{\beta}}\right)_{\operatorname{dim} 8}=C_{H^{2} W^{+} W^{-}}^{-} T_{\alpha \dot{\beta}}^{a b-}[1|3| 2\rangle^{2}$ violate this symmetry. So custodial symmetry can provide some new selection rules, which can not be explained by existing selection rules, based on on-shell method.

## 5 Universal results for anomalous dimensions

From above examples, we find that the anomalous dimension matrix is strongly dependent on the external legs of amplitude basis. With on-shell method, the structure of anomalous
dimension matrix can be clearly seen and some universal results for the RG running of the amplitude basis can be obtained. For example, notice that the bubble coefficients of any four point amplitudes are determined by the product of two four point tree level amplitudes. And since the four point amplitude basis of any dimension can be expressed in a uniform way: the product of spinor contractions and polynomials of Mandestam variables $s$ and $t$, the RG running of this kind of basis should also be able to expressed in the uniform form. Since in this work we focus on how to use on-shell method to derive the RG running in SMEFT, we just give a simple example to confirm this claim. More universal results will be presented in the future work. We will show the RG running for $H^{2} B^{+} B^{-} D^{2 n}$ type amplitude basis at any dimensions generated from the general $H^{4} D^{2 n+4}$ type amplitude basis. These basis can be expressed uniformly as

$$
\begin{align*}
\mathcal{A}\left(H^{\alpha} H^{\beta} H^{\dagger \dot{\alpha}} H^{\dagger \dot{\beta}}\right) & \supset T_{\alpha \beta \dot{\alpha} \dot{\beta}}^{+} C_{m, 2 n}^{H^{4}+} s_{12}^{m}\left(s_{13}-s_{23}\right)^{2 n}, T_{\alpha \beta \dot{\alpha} \dot{\beta}}^{-} C_{m, 2 n+1}^{H^{4}-} s_{12}^{m}\left(s_{13}-s_{23}\right)^{2 n+1} \\
\mathcal{A}\left(B^{+} B^{-} H^{\alpha} H^{\dagger \dot{\beta}}\right) & =C_{m, n}^{H^{2} B^{+} B^{-}}\left[1\left|p_{3}\right| 2\right\rangle^{2} s_{12}^{m}\left(s_{13}-s_{23}\right)^{n} \tag{5.1}
\end{align*}
$$

Applying the on-shell method as above, we can obtain the universal RG running for $C_{m, n}^{H^{2} B^{+} B^{-}}$, compactly collected as,

$$
\begin{align*}
\dot{C}_{m, n}^{H^{2} B^{+} B^{-}} & =-4 y_{h}^{2}\left(\sum_{i+2 j=m+n+2}^{i, j} 3 C_{i, 2 j}^{H^{4}+} F(m, n, i, 2 j)+\sum_{i^{\prime}+2 j^{\prime}=m+n+1}^{i^{\prime}, j^{\prime}} C_{i^{\prime}, 2 j^{\prime}+1}^{H^{4}-} F\left(m, n, i^{\prime}, 2 j^{\prime}+1\right)\right) \\
F(m, n, i, k) & =\sum_{2 g+f+h=n}^{g, f, h, l, d}\left(\frac{1}{4}\right)^{l-1}(-1)^{g} C_{i}^{2 l-d} C_{2 j}^{d} C_{l-1}^{g} C_{i-2 l+d}^{h} C_{2 l}^{l+1} C_{2 j-d}^{l} \\
& \times \int_{0}^{1}\left(1-\frac{1}{2 t}\right)^{h}\left(-\frac{1}{2 t}\right)^{m-2 l+d-h}\left(-\frac{1}{2}+\frac{t}{2}+\frac{1}{2 t}\right)^{f}\left(\frac{3}{2}+\frac{t}{3}-\frac{1}{2 t}\right)^{2 j-d-f}\left(\frac{1}{t}-1\right)^{l} t^{d+i} d t .(5.2) \tag{5.2}
\end{align*}
$$

So the anomalous dimensions for $H^{2} B^{+} B^{-} D^{2 n}$ basis at any dimension can be readily read from this universal expression. For example, the amplitude basis at dimension 8 , or $(m=$ $0, n=0$ ), can get three contributions in above sum,

$$
\begin{gather*}
(i=0, j=1, d=2, l=1, g=h=f=0) \\
(i=2, j=0, d=0, l=1, g=h=f=0) \\
\left(i^{\prime}=1, j^{\prime}=0, d=1, l=1, g=h=f=0\right) \tag{5.3}
\end{gather*}
$$

With a simple integral $\int_{0}^{1}\left(\frac{1}{t}-1\right) t^{2}=\frac{1}{6}$, we can obtain its RG running,

$$
\begin{equation*}
\dot{C}_{00}^{H^{2} B^{+} B^{-}}=-2 g_{1}^{2} y_{h}^{2}\left(C_{0,2}^{H^{4}+}+C_{2,0}^{H^{4}+}+\frac{1}{3} C_{1,1}^{H^{4}-}\right) \tag{5.4}
\end{equation*}
$$

which recovers the result we obtained in previous section.

## 6 Conclusion

The on-shell amplitude methods have remarkable advantages in studying SMEFT. The nonrenormalizable interactions can be described by unfactorizable amplitude basis without worrying about redundancies. Comparing with Feynman diagrams calculations, the loop-level amplitudes can be constructed by unitary cut very efficiently, because there are no unphysical degrees of freedom in on-shell amplitudes. Especially, since the UV divergences of one-loop amplitudes are only from scalar bubble integrals and the bubble coefficients are related to the tree-level amplitudes, the on-shell method is very convenient to obtain the renormalization group running of higher dimension operators (amplitude basis).

In this work we demonstrate in detail how to extract the full UV divergences of the loop amplitudes. The coefficients of massive bubble integrals can be extracted by Stokes' Theorem analytically. However, the UV divergences from massless bubble integrals are canceled by collinear IR divergences so they can not be obtained by unitary cut. However, they can be extracted from the collinear divergences of tree-level amplitudes. Since they are universal in SMEFT, we calculate the collinear divergence factors for all the standard model fields and list them in Eq. 2.15. So the UV divergences from the massless bubbles can be directly read from the list.

We present some examples to show how to derive the anomalous dimension matrix correctly. Some selection rules can be easily observed based on this method, like the ones from angular momentum conservation or global symmetries observed in our calculations for some dimension 8 operators. This method makes the structure of anomalous dimension matrix transparent, so the running of the general 4-point amplitude basis can be expressed in a universal form. We present the universal expressions for the anomalous dimension matrix of the general amplitude basis $H^{2} B^{+} B^{-} D^{2 n}$ generated from the contributions of general $H^{4} D^{2 n+4}$ type amplitude basis at one-loop level.

## Note added

While this paper was being finalized, Ref. [43, 44] appeared, which presents a similar topic. [43] uses both form factors and on-shell amplitudes in their calculations and gives the anomalous dimensions at two loops. [44] uses the on-shell unitary cut similar to us but considers only the mixing between different operators, for which there are no IR contributions. In this paper, we take a pure on-shell method and demonstrate the complete procedure in deriving the anomalous dimension at one loop, obtaining the bubble coefficients and subtracting the collinear divergences. We also give new results in dimension 8 as well as universal expressions in general dimensions.

## A Example of deriving the collinear factor for Higgs and Hypercharge gauge boson

In this appendix, we show how to get the collinear divergence factor for Higgs in $U(1)_{Y}$ gauge theory, following the procedure in [24, 25]. To get the collinear factor of Higgs leg generated from $U(1)_{Y}$ gauge interactions, we consider the scattering amplitude $H H^{\dagger} \rightarrow$ $B^{+} B^{-}$. We suppose the Higgs leg $H$ with momentum $p_{1}$ and $B^{+}$with momentum $p_{3}$ become collinear, which makes the Higgs propagator attached with these two legs on-shell and leads to divergence. We can parametrize the momenta as

$$
\begin{equation*}
|1\rangle=\sqrt{z}|P\rangle, \quad|3\rangle=\sqrt{1-z}|P\rangle \tag{A.1}
\end{equation*}
$$

where $0<z<1$ and $P$ is the momentum of the Higgs propagator.
In the collinear limit, the four point amplitudes $\mathcal{A}\left(H H^{\dagger} B^{+} B^{-}\right)$factorize into the product of three point amplitude and a singular splitting function

$$
\begin{equation*}
\mathcal{A}\left(H\left(p_{1}\right) H^{\dagger}\left(p_{2}\right) B^{+}\left(p_{3}\right) B^{-}\left(p_{4}\right)\right) \rightarrow \operatorname{Split}_{H}\left(H\left(p_{1}\right), B^{+}\left(p_{3}\right)\right) \mathcal{A}\left(H(P) H^{\dagger}\left(p_{2}\right) B^{-}\left(p_{4}\right)\right) \tag{A.2}
\end{equation*}
$$

where the spliting function $\operatorname{Split}_{H}\left(H\left(p_{1}\right), B^{+}\left(p_{3}\right)\right)=\sqrt{2} g_{1} y_{h} \frac{\sqrt{z}}{\sqrt{1-z}\langle 13\rangle}$, and the three point amplitude $\mathcal{A}\left(H(P) H^{\dagger}\left(p_{2}\right) B^{-}\left(p_{4}\right)\right)=\sqrt{2} g_{1} y_{h} \frac{\langle 4 P\rangle\langle 42\rangle}{\langle P 2\rangle}$. The collinear factor $c_{F}^{H B \rightarrow H^{\dagger}}$ can be expressed as

$$
\begin{equation*}
c_{F}^{H B \rightarrow H^{\dagger}}=\sum_{i= \pm} \operatorname{Split}_{H}\left(H\left(p_{1}\right), B^{i}\left(p_{3}\right)\right) \operatorname{Split}_{H}^{\dagger}\left(H\left(p_{1}\right), B^{i}\left(p_{3}\right)\right)=\frac{4 g_{1}^{2} y_{h}^{2}}{\langle 13\rangle[13]} \frac{z}{1-z} \tag{A.3}
\end{equation*}
$$

Notice that the contributions from different polarizations of the gauge boson $B_{\mu}$ should be included. The phase space of these two collinear legs can be expressed as [24]

$$
\begin{equation*}
d P_{c o l}^{\epsilon}\left(p_{1}, p_{3}, z\right)=\frac{(4 \pi)^{\epsilon}}{16 \pi^{2} \Gamma(1-\epsilon)} d s_{13} d z\left[s_{13} z(1-z)\right]^{-\epsilon} \theta\left(s_{\text {min }}-s_{13}\right) . \tag{A.4}
\end{equation*}
$$

Putting these together, we can get the collinear divergence of the process $H H^{\dagger} \rightarrow B^{+} B^{-}$

$$
\begin{equation*}
\int c_{F}^{H B \rightarrow H^{\dagger}} d P_{c o l}^{\epsilon}\left(p_{1}, p_{3}, z\right)=\frac{g_{1}^{2} y_{h}^{2}}{4 \pi^{2}} \frac{1}{\cdot} \Gamma(1-\epsilon) \frac{1}{\epsilon} . \tag{A.5}
\end{equation*}
$$

The tree level collinear divergences should be cancelled by IR divergence from loop amplitudses. If we parametrize the one-loop collinear divergences as

$$
\begin{equation*}
\mathcal{A}_{\mathrm{n}, \mathrm{col}}^{1 \text {-loop }}=-\left(\frac{1}{4 \pi}\right)^{2} \sum_{a}^{n} \frac{\gamma(a)}{\epsilon} \mathcal{A}^{\text {tree }}, \tag{A.6}
\end{equation*}
$$

the collinear divergence factor for Higgs leg (only including the $U(1)_{Y}$ gauge corrections) can be extracted to be

$$
\begin{equation*}
\gamma(H)=2 g_{1}^{2} y_{h}^{2} \tag{A.7}
\end{equation*}
$$

Following the same procedure, we can extract the spliting function for vetex $H\left(p_{1}\right) H^{\dagger}\left(p_{2}\right) \rightarrow$ $B$ from the process $H^{a} H^{\dagger \dot{b}} \rightarrow H^{c} H^{\dagger \dot{d}}$, $\operatorname{Split}_{B^{ \pm}}\left(H^{a}, H^{\dagger \dot{b}}\right)=\delta^{a \dot{b}} \sqrt{2} g_{1} y_{h} \sqrt{z(1-z)} /\langle 12\rangle$. The collinear factor is given by

$$
\begin{equation*}
c_{F}^{H\left(p_{1}\right) H^{\dagger}\left(p_{2}\right) \rightarrow B^{ \pm}}=\sum_{a, \dot{b}} \operatorname{Split}_{B^{ \pm}}\left(H^{a}, H^{\dagger \dot{b}}\right) \operatorname{Split}_{B^{ \pm}}^{\dagger}\left(H^{a}, H^{\dagger \dot{b}}\right)=\frac{4 g_{1}^{2} y_{h}^{2}}{\langle 12\rangle[12]} z(1-z) . \tag{A.8}
\end{equation*}
$$

Do the same integration as in Eq. A.5, we can easily get the collinear divergence factor for the $U(1)_{Y}$ gauge boson legs (only include the Higgs doublet corrections)

$$
\begin{equation*}
\gamma\left(B^{ \pm}\right)=-\frac{g_{1}^{2} y_{h}^{2}}{3} \tag{A.9}
\end{equation*}
$$

## B The anomalous dimension of $O_{e W}$

In this appendix we present the full calculation of the running of $O_{e W}=\left(\bar{l} \sigma^{\mu \nu} e\right) \tau^{I} H W_{\mu \nu}^{I}$. The contribution from different unitary cuts are summarized in table.1, where $\mathcal{A}^{6}$ and $\mathcal{A}^{\mathrm{SM}}$ are dimension 6 and SM on-shell amplitudes at the two sides of the cut respectively. The relevant form of dimension 6 operators and expression of SM amplitudes are summarized in table. 2

Combined with the contributions from collinear divergences read from Eq.2.15:

$$
\begin{equation*}
\dot{C}_{e W}=-2(\gamma(W)+\gamma(H)+\gamma(l)+\gamma(e)) C_{e W} \tag{B.1}
\end{equation*}
$$

we obtain the same result as that calculated from Feynman diagrams[28-30] ${ }^{2}$.

| $\mathcal{A}^{6}$ | $\mathcal{A}^{\text {SM }}$ | Contribution to $\dot{C}_{e W}$ |
| :---: | :---: | :---: |
| $\mathcal{A}\left(W^{i-} W^{i-} H^{\dagger \dot{\alpha}} H^{\alpha}\right)=2\left(C_{H W}+i C_{H \tilde{W}}\right) \delta^{\alpha \dot{\alpha}}\langle 12\rangle^{2}$ | $\mathcal{A}\left(l^{\dot{\alpha}-} e^{-} W^{i+} H^{\beta}\right)$ | $Y_{e}^{\dagger} g_{2}\left(C_{H W}+i C_{H \widetilde{W}}\right)$ |

[^0]:    ${ }^{1}$ For internal fermion leg, the complex factor $i$ can be removed because the fermion statistic cancels the minus sign from momentum flipping.

[^1]:    ${ }^{2}$ There is a relative minus signs for terms linear in $g_{i}$ due to conventions.
