# BIDERIVATIONS AND COMMUTING LINEAR MAPS ON HOM-LIE ALGEBRAS 

BING SUN, YAO MA AND LIANGYUN CHEN

#### Abstract

The purpose of this paper is to determine skew-symmetric biderivations $\operatorname{Bider}_{\mathrm{s}}(L, V)$ and commuting linear maps $\operatorname{Com}(L, V)$ on a Hom-Lie algebra $(L, \alpha)$ having their ranges in an $(L, \alpha)$-module $(V, \rho, \beta)$, which are both closely related to $\operatorname{Cent}(L, V)$, the centroid of $(V, \rho, \beta)$. Specifically, under appropriate assumptions, every $\delta \in \operatorname{Bider}_{\mathrm{s}}(L, V)$ is of the form $\delta(x, y)=$ $\beta^{-1} \gamma([x, y])$ for some $\gamma \in \operatorname{Cent}(L, V)$, and $\operatorname{Com}(L, V)$ coincides with $\operatorname{Cent}(L, V)$. Besides, we give the algorithm for describing $\operatorname{Bider}_{\mathrm{s}}(L, V)$ and $\operatorname{Com}(L, V)$ respectively, and provide several examples.

Keywords: Biderivation, commuting linear map, centroid, Hom-Lie algebra.
MSC(2020): 17B40, 17B61, 16R60.

## 1. Introduction

The notion of biderivations appeared in different areas. Maksa used biderivations to study real Hilbert space [25]. Vukman investigated symmetric biderivations in the prime and semiprime rings [30]. The well-known result that every biderivation on a noncommutative prime ring $A$ is of the form $\lambda[x, y]$ for some $\lambda$ belonging to the extended centroid of $A$, was discovered independently by Bresar et al [5], Skosyrskii [28], and Farkas and Letzter [13], where biderivations were connected with noncommutative Jordan algebras by Skosyrskii and with Poisson algebras by Farkas and Letzter, respectively. Besides their wide applications, biderivations are interesting in their own right and have been introduced to Lie algebras [32], which were studied by many authors recently. In particular, biderivations are closely related to the theory of commuting linear maps that has a long and rich history, and we refer to the survey [4] for the development of commuting maps and their applications. It is worth mentioning that Brešar and Zhao considered a general but simple approach for describing biderivations and commuting linear maps on a Lie algebra $L$ that having their ranges in an $L$-module [6], which covered most of the results in [11, 14, 22, 29, 31], and inspires us to generalize their method to Hom-Lie algebras.

Hom-Lie algebras are a generalization of Lie algebras, the notion of which was initially introduced in [15], motivated by the study of quantum deformations or $q$-deformations of the Witt and the Virasoro algebras via twisted derivations, after several investigations of various quantum deformations of Lie algebras [2, 8, 12, 16, 18]. Due to the close relation to discrete and deformed vector fields and differential calculus, this kind of algebraic structures have been studied extensively during the last decade, which we mention here just a few: representations,

[^0](co)homology and deformations of Hom-Lie algebras [1,3,23,27,34]; structure theory of simple and semisimple Hom-Lie algebras [9, 17, 33]; Hom-Lie structures on Kac-Moody algebras [24]; extensions of Hom-Lie algebras [7, 19]; geometric generalization of Hom-Lie algebras [21,26]; integration of Hom-Lie algebras [20].

Hence it would be natural to generalize known theories from Lie algebras to Hom-Lie algebras, and we are interested in determining biderivations and commuting linear maps on a Hom-Lie algebra follows from [6]. The paper is organized as follows.

In Section 2, after recalling some preliminaries on Hom-Lie algebras, we introduce the notion of Hom-Lie algebra module homomorphisms, and give the Schur's lemma for adjoint Hom-Lie algebra modules.

In Section 3, we define biderivations on a Hom-Lie algebra $(L, \alpha)$ having their ranges in an $(L, \alpha)$-module $(V, \rho, \beta)$ as well as the centroid of $(V, \rho, \beta)$, and derive that skew-symmetric biderivations arise from the centroid provided that $(L, \alpha)$ is perfect, $\alpha$ is surjective, $\beta$ is invertible and $Z_{V}(L)=\{0\}$ (see Theorem 3.6). In particular, every skew-symmetric biderivation on a simple $(L, \alpha)$ with $\alpha$ invertible having its range in the $\alpha^{k}$-adjoint $(L, \alpha)$-module is of the form $\lambda \alpha^{k}([x, y])$ (see Theorem 3.7). We also give an algorithm to find all skew-symmetric biderivations and apply it to several examples.

In Section 4, we give the definition of commuting linear maps from a Hom-Lie algebra $(L, \alpha)$ to an $(L, \alpha)$-module $(V, \rho, \beta)$, which coincides with the centroid of $(V, \rho, \beta)$ if $\alpha$ is surjective, $\beta$ is invertible and $Z_{V}\left(L^{\prime}\right)=\{0\}$ (see Theorem4.3). An algorithm to describe all commuting linear maps on $(L, \alpha)$ is also provided.

Throughout this paper, all the vector spaces are over a fixed field $\mathbb{F}$ such that $\operatorname{char}(\mathbb{F}) \neq 2$ unless otherwise stated.

## 2. The Schur's lemma for adjoint modules over a Hom-Lie algebra

We begin with some definitions concerning Hom-Lie algebras.
Definition 2.1. [27] A Hom-Lie algebra $(L, \alpha)$ is an $\mathbb{F}$-vector space $L$ endowed with a bilinear map $[-,-]: L \times L \rightarrow L$ and a linear homomorphism $\alpha: L \rightarrow L$ satisfying that for any $x, y, z \in L$,

$$
\begin{gathered}
{[x, y]=-[y, x], \text { (skew-symmetry) }} \\
{[\alpha(x),[y, z]]+[\alpha(y),[z, x]]+[\alpha(z),[x, y]]=0 . \text { (Hom-Jacobi identity) }}
\end{gathered}
$$

In particular, a Hom-Lie algebra $(L, \alpha)$ is called multiplicative, if $\alpha$ is an algebra homomorphism, i.e., $\alpha([x, y])=[\alpha(x), \alpha(y)]$, for all $x, y \in L$.

For the structural study of $(L, \alpha)$ in this paper, we need the stability properties that the multiplicative condition of $\alpha$ offers, so in the sequel, we will say Hom-Lie algebras when referring to multiplicative Hom-Lie algebras.

Moreover, a subspace $I$ of $(L, \alpha)$ is called an ideal, if $[I L] \subseteq I$ and $\alpha(I) \subseteq I$. If $(L, \alpha)$ has no proper ideals and is not abelian, then we call it simple. $(L, \alpha)$ is called perfect if $L^{\prime}:=[L, L]=L$.

The center of a Hom-Lie algebra $(L, \alpha)$, denoted by $Z(L)$, is the set $\{z \in L \mid[z, L]=0\}$. For more details of these definitions, we refer to [7,9,24].

Definition 2.2. [27, 34] For a Hom-Lie algebra $(L, \alpha)$, a triple $(V, \rho, \beta)$ consisting of a vector space $V$, a linear map $\rho: L \rightarrow \operatorname{End}(V)$ and $\beta \in \operatorname{End}(V)$ is said to be a representation of $(L, \alpha)$ or an $(L, \alpha)$-module, if for all $x, y \in L$, the following equalities are satisfied

$$
\begin{gather*}
\beta \circ \rho(x)=\rho(\alpha(x)) \circ \beta,  \tag{2.1}\\
\rho([x, y]) \circ \beta=\rho(\alpha(x)) \circ \rho(y)-\rho(\alpha(y)) \circ \rho(x) . \tag{2.2}
\end{gather*}
$$

For brevity of notation, we usually put $x v=\rho(x)(v), \forall x \in L, v \in V$, just like the case in Lie algebras. A subspace $W$ of $V$ is called a submodule of $(V, \rho, \beta)$ if $W$ is both $\beta$-invariant and $L$-invariant, i.e., $\beta(W) \subset W$ and $x W \subset W, \forall x \in L$.

Example 2.3. (1) For any integer $k$, $\left(L, \operatorname{ad}_{k}, \alpha\right)$ with $\operatorname{ad}_{k}(x)(y):=\left[\alpha^{k}(x), y\right]$ is an $(L, \alpha)$-module by [27, Lemma 6.2], called the $\alpha^{k}$-adjoint $(L, \alpha)$-module. Note that $\alpha$ need to be invertible in case $k$ is negative.
(2) If $(V, \rho, \beta)$ is an $(L, \alpha)$-module, then $\left(V, \rho_{k}:=\rho \alpha^{k}, \beta\right)$ is also an $(L, \alpha)$-module, which follows from the equalities that

$$
\begin{aligned}
\beta \rho_{k}(x)(v) & =\beta \rho\left(\alpha^{k}(x)\right)(v) \stackrel{\text { 2.1) }}{=} \rho\left(\alpha^{k+1}(x)\right) \beta(v)=\rho_{k}(\alpha(x)) \beta(v), \\
\rho_{k}([x, y]) \beta(v) & =\rho \alpha^{k}([x, y]) \beta(v)=\rho\left(\left[\alpha^{k}(x), \alpha^{k}(y)\right]\right) \beta(v) \\
(\text { by (2.2) }) & =\rho\left(\alpha^{k+1}(x)\right) \rho\left(\alpha^{k}(y)\right)(v)-\rho\left(\alpha^{k+1}(y)\right) \rho\left(\alpha^{k}(x)\right)(v) \\
& =\rho_{k}(\alpha(x)) \rho_{k}(y)(v)-\rho_{k}(\alpha(y)) \rho_{k}(x)(v) .
\end{aligned}
$$

Remark 2.4. If $I$ is a submodule of $\left(L, \operatorname{ad}_{k}, \alpha\right)$ and $\alpha^{k}(L)=L$, then $I$ is an ideal of $L$. In fact,

$$
\alpha(I) \subset I \text { and }[L, I]=\left[\alpha^{k}(L), I\right]=\operatorname{ad}_{k}(L)(I) \subset I .
$$

Next we introduce the notion of homomorphisms between representations of a Hom-Lie algebra $(L, \alpha)$ and show that the Schur's Lemma holds for finite-dimensional adjoint $(L, \alpha)$ modules.

Definition 2.5. Let $\left(V_{1}, \rho_{1}, \beta_{1}\right)$ and $\left(V_{2}, \rho_{2}, \beta_{2}\right)$ be two $(L, \alpha)$-modules. A linear map $f: V_{1} \rightarrow V_{2}$ is said to be a homomorphism of $(L, \alpha)$-modules, if $\beta_{2} \circ f=f \circ \beta_{1}$ and $f \circ \rho_{1}(x)=\rho_{2}(\alpha(x)) \circ$ $f, \forall x \in L$, or, in terms of two commutative diagrams,

Note that the identity map is no longer a natural homomorphism on a Hom-Lie algebra module in general, which is actually twisted by $\alpha$ in some way.

Example 2.6. For any integers $k, s$, it follows that $\alpha^{s+1}:\left(L, \mathrm{ad}_{k}, \alpha\right) \rightarrow\left(L, \mathrm{ad}_{k+s}, \alpha\right)$ is a homomorphism of $(L, \alpha)$-modules, since $\alpha \circ \alpha^{s+1}=\alpha^{s+1} \circ \alpha$ and

$$
\alpha^{s+1} \operatorname{ad}_{k}(x)(y)=\alpha^{s+1}\left[\alpha^{k}(x), y\right]=\left[\alpha^{k+s+1}(x), \alpha^{s+1}(y)\right]=\operatorname{ad}_{k+s}(\alpha(x)) \alpha^{s+1}(y) .
$$

In particular, $\alpha^{0}=\mathrm{id}_{L}$ is a homomorphism from $\left(L, \mathrm{ad}_{0}, \alpha\right)$ to $\left(L, \mathrm{ad}_{-1}, \alpha\right)$ in the case that $\alpha$ is invertible.

By direct calculations, we have the following property.
Proposition 2.7. Let $\left(V_{1}, \rho_{1}, \beta_{1}\right)$ and $\left(V_{2}, \rho_{2}, \beta_{2}\right)$ be two $(L, \alpha)$-modules and $f: V_{1} \rightarrow V_{2}$ a module homomorphism. Then $\operatorname{ker} f$ is a submodule of $\left(V_{1}, \rho_{1}, \beta_{1}\right)$.

Theorem 2.8 (Schur's lemma). Let $(L, \alpha)$ be a Hom-Lie algebra with $\alpha$ invertible, which is called regular in [27]. Let the base field $\mathbb{F}$ be algebraically closed. If $(L, \alpha)$ is simple and finite-dimensional, and $f:\left(L, \mathrm{ad}_{k}, \alpha\right) \rightarrow\left(L, \mathrm{ad}_{k+s}, \alpha\right)$ is a homomorphism of $(L, \alpha)$-modules, then

$$
f=\lambda \alpha^{s+1}, \text { for some } \lambda \in \mathbb{F} .
$$

Proof. We know that $f \alpha^{-s-1}: L \rightarrow L$ is a linear map. Then use the facts that $(L, \alpha)$ is finitedimensional and $\mathbb{F}$ is algebraically closed to find an eigenvector $0 \neq x_{0} \in L$ of $f \alpha^{-s-1}$ for some eigenvalue, say $\lambda \in \mathbb{F}$, i.e., $f \alpha^{-s-1}\left(x_{0}\right)=\lambda x_{0}$. Since $f \circ \alpha=\alpha \circ f, f\left(x_{0}\right)=\lambda \alpha^{s+1}\left(x_{0}\right)$.

By Example 2.6, $\lambda \alpha^{s+1}:\left(L, \mathrm{ad}_{k}, \alpha\right) \rightarrow\left(L, \mathrm{ad}_{k+s}, \alpha\right)$ is an $(L, \alpha)$-module homomorphism, which implies that $f-\lambda \alpha^{s+1}$ is also an $(L, \alpha)$-module homomorphism. Then $\operatorname{ker}\left(f-\lambda \alpha^{s+1}\right)$ is a non-zero submodule of $\left(L, \mathrm{ad}_{k}, \alpha\right)$, so is a non-zero ideal of $(L, \alpha)$, by Remark 2.4. Hence $\operatorname{ker}\left(f-\lambda \alpha^{s+1}\right)=L$ by the simplicity of $(L, \alpha)$, that is, $f=\lambda \alpha^{s+1}$.

## 3. Biderivations of Hom-Lie algebras

Let $(V, \rho, \beta)$ be an $(L, \alpha)$-module. A bilinear map $\delta: L \times L \rightarrow V$ is said to be a biderivation if

$$
\begin{gather*}
\beta \boldsymbol{\delta}(x, y)=\boldsymbol{\delta}(\alpha(x), \alpha(y)),  \tag{3.1}\\
\boldsymbol{\delta}(\alpha(z),[x, y])=\alpha(x) \boldsymbol{\delta}(z, y)-\alpha(y) \boldsymbol{\delta}(z, x),  \tag{3.2}\\
\boldsymbol{\delta}([x, y], \alpha(z))=\alpha(x) \boldsymbol{\delta}(y, z)-\alpha(y) \boldsymbol{\delta}(x, z), \tag{3.3}
\end{gather*}
$$

for all $x, y, z \in L$. We say that a biderivation $\delta$ is skew-symmetric, if

$$
\begin{equation*}
\boldsymbol{\delta}(x, y)=-\boldsymbol{\delta}(y, x) \tag{3.4}
\end{equation*}
$$

If this is the case, Eqs. (3.2) and (3.3) coincide. Hence, a bilinear map $\delta: L \times L \rightarrow V$ is a skew-symmetric biderivation provided that $\delta$ satisfies (3.4), (3.1), and any one of (3.2) or (3.3).

Denote by $\operatorname{Bider}(L, V)$ (resp. $\operatorname{Bider}_{\mathrm{s}}(L, V)$ ) the set of all biderivations (resp. skew-symmetric biderivations) $\delta: L \times L \rightarrow V$. In particular, we write $\operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$ as the set of all skewsymmetric biderivations on $(L, \alpha)$ for the adjoint module $\left(L, \mathrm{ad}_{k}, \alpha\right)$.

Using the Hom-Jacobi identity, it is easy to see that a skew-symmetric biderivation $\delta: L \times$ $L \rightarrow V$ is a generalization of the Hom-Lie bracket $[-,-]: L \times L \rightarrow L$, where the last $L$ is viewed as $\left(L, \mathrm{ad}_{0}, \alpha\right)$.

Now we would like to explain the terminology "biderivation". Note that the notion of derivations on a Hom-Lie algebra $(L, \alpha)$ was introduced in [27], where a linear map $D: L \rightarrow L$ is called an $\alpha^{k}$-derivation of $(L, \alpha)$, if $D \circ \alpha=\alpha \circ D$ and

$$
D[x, y]=\left[\alpha^{k}(x), D(y)\right]-\left[\alpha^{k}(y), D(x)\right], \forall x, y \in L .
$$

Under the above definition, for any nonnegative integer $k$ and any $z \in L$ satisfying $\alpha(z)=z$, a linear map $D_{k}(z): L \rightarrow L$ defined by

$$
D_{k}(z)(x)=\left[z, \alpha^{k}(x)\right], \forall x \in L
$$

becomes an $\alpha^{k+1}$-derivation, which implies that $[z,-]$ and $[-, z]$ are $\alpha$-derivations, then it is reasonable to call $[-,-]$ a biderivation. Finally, its generalization $\delta$ can be called by the same name.

We've already seen that $[-,-] \in \operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{0}\right)$. To provide more examples of biderivations, we define the centroid of $(V, \rho, \beta)$ as

$$
\operatorname{Cent}(L, V)=\{\gamma: L \rightarrow V \mid \gamma([x, y])=\alpha(x) \gamma(y) \text { and } \beta \circ \gamma=\gamma \circ \alpha\} .
$$

Clearly, $\operatorname{Cent}(L, V)$ is just the space of $(L, \alpha)$-module homomorphisms from $\left(L, \operatorname{ad}_{0}, \alpha\right)$ to $(V, \rho, \beta)$. In particular, we write $\operatorname{Cent}\left(L, \mathrm{ad}_{k}\right)$ as the centroid of the adjoint module $\left(L, \operatorname{ad}_{k}, \alpha\right)$.

Example 3.1. Let $(V, \rho, \beta)$ be a representation of a $\operatorname{Hom-Lie}$ algebra $(L, \alpha)$ with $\beta$ invertible. If $\gamma \in \operatorname{Cent}(L, V)$, then

$$
\delta(x, y)=\beta^{-1} \gamma([x, y]), \forall x, y \in L,
$$

is a skew-symmetric biderivation.
In fact, $\delta$ is clearly skew-symmetric; (3.1) holds since

$$
\delta(\alpha(x), \alpha(y))=\beta^{-1} \gamma([\alpha(x), \alpha(y)])=\beta^{-1} \gamma \alpha([x, y])=\gamma([x, y])=\beta \delta(x, y), \forall x, y \in L
$$

(3.3) holds since

$$
\begin{aligned}
\delta([x, y], \alpha(z)) & =\beta^{-1} \gamma([[x, y], \alpha(z)]) \\
\text { (by Hom-Jacobi identity) } & =\beta^{-1} \gamma([\alpha(x),[y, z]])-\beta^{-1} \gamma([\alpha(y),[x, z]]) \\
& =\beta^{-1}\left(\alpha^{2}(x) \gamma([y, z])-\beta^{-1} \alpha^{2}(y) \gamma([x, z])\right. \\
\text { (by (2.1) }) & =\alpha(x) \beta^{-1} \gamma([y, z])-\alpha(y) \beta^{-1} \gamma([x, z]) \\
& =\alpha(x) \delta(y, z)-\alpha(y) \delta(x, z)
\end{aligned}
$$

From the example above we could see that for an $(L, \alpha)$-module $(V, \rho, \beta)$ such that $\beta$ is invertible, each $\gamma \in \operatorname{Cent}(L, V)$ induces a skew-symmetric biderivation $\delta(x, y)=\beta^{-1} \gamma([x, y])$. Later, we will show that, under appropriate assumptions, all biderivations are of this form, i.e., Theorem 3.6 to prove which we need the following technical lemmas.

In Lemmas 3.2, 3.3, 3.4 and 3.5, $(V, \rho, \beta)$ is a representation of a Hom-Lie algebra $(L, \alpha)$ and $\delta \in \operatorname{Bider}_{\mathrm{s}}(L, V)$. Moreover, we denote by

$$
Z_{V}(S)=\{v \in V \mid s v=0, \forall s \in S\}
$$

the subspace of $V$ that is killed by any subset $S$ of $L$. Note that for an adjoint module $\left(L, \operatorname{ad}_{k}, \alpha\right)$ with $\alpha$ surjective, $Z_{L}(L)$ is an ideal of $(L, \alpha)$ that coincides with $Z(L)$, the center of $(L, \alpha)$.

Lemma 3.2. $\beta([x, y] \boldsymbol{\delta}(z, w)+[z, w] \boldsymbol{\delta}(x, y))=0, \forall x, y, z, w \in L$.
Proof. Consider the following quaternary linear map

$$
\begin{aligned}
\varphi: L \times L \times L \times L & \rightarrow V \\
(x, y, z, w) & \mapsto[x, y] \delta(z, w)+[z, w] \delta(x, y) .
\end{aligned}
$$

Then it suffices to prove $\beta \varphi(x, y, z, w)=0, \forall x, y, z, w \in L$.
Clearly, $\varphi$ satisfies $\varphi(x, y, z, w)=\varphi(z, w, x, y)$ and

$$
\begin{equation*}
\varphi(x, y, z, w)=-\varphi(y, x, z, w) \tag{3.5}
\end{equation*}
$$

by the definition.
We'll prove $\beta \varphi(x, y, z, w)=\beta \varphi(z, y, x, w)$, by computing $\delta([x, y],[z, w])$ in two ways. For any $x, y, z, w \in L$, we have

$$
\begin{aligned}
& \delta(\alpha([x, y]), \alpha([z, w])) \\
= & \delta([\alpha(x), \alpha(y)], \alpha([z, w])) \\
= & \alpha^{2}(x) \boldsymbol{\delta}(\alpha(y),[z, w])-\alpha^{2}(y) \boldsymbol{\delta}(\alpha(x),[z, w]) \\
= & \alpha^{2}(x)(\alpha(z) \delta(y, w)-\alpha(w) \delta(y, z))-\alpha^{2}(y)(\alpha(z) \boldsymbol{\delta}(x, w)-\alpha(w) \delta(x, z)) \\
= & \alpha^{2}(x) \alpha(z) \boldsymbol{\delta}(y, w)-\alpha^{2}(x) \alpha(w) \boldsymbol{\delta}(y, z)-\alpha^{2}(y) \alpha(z) \boldsymbol{\delta}(x, w)+\alpha^{2}(y) \alpha(w) \boldsymbol{\delta}(x, z) .
\end{aligned}
$$

On the other hand,

$$
\begin{aligned}
& \delta(\alpha([x, y]), \alpha([z, w])) \\
= & \delta(\alpha([x, y]),[\alpha(z), \alpha(w)]) \\
= & \alpha^{2}(z) \delta([x, y], \alpha(w))-\alpha^{2}(w) \delta([x, y], \alpha(z)) \\
= & \alpha^{2}(z)(\alpha(x) \delta(y, w)-\alpha(y) \delta(x, w))-\alpha^{2}(w)(\alpha(x) \delta(y, z)-\alpha(y) \delta(x, z)) \\
= & \alpha^{2}(z) \alpha(x) \delta(y, w)-\alpha^{2}(z) \alpha(y) \delta(x, w)-\alpha^{2}(w) \alpha(x) \delta(y, z)+\alpha^{2}(w) \alpha(y) \delta(x, z) .
\end{aligned}
$$

Comparing above relations and using (2.2), we have

$$
[\alpha(x), \alpha(z)] \beta \delta(y, w)+[\alpha(y), \alpha(w)] \beta \delta(x, z)=[\alpha(y), \alpha(z)] \beta \delta(x, w)+[\alpha(x), \alpha(w)] \beta \delta(y, z)
$$

By (2.1), it follows that $\beta \varphi(x, z, y, w)=\beta \varphi(y, z, x, w)$, which implies

$$
\begin{equation*}
\beta \varphi(x, y, z, w)=\beta \varphi(z, y, x, w), \forall x, y, z, w \in L . \tag{3.6}
\end{equation*}
$$

Then

$$
\begin{equation*}
\beta \varphi(x, y, z, w) \stackrel{(3.6}{=} \beta \varphi(z, y, x, w) \stackrel{(3.5}{=}-\beta \varphi(y, z, x, w) \stackrel{3.6}{=}-\beta \varphi(x, z, y, w) . \tag{3.7}
\end{equation*}
$$

It follows that
$\beta \varphi(x, y, z, w) \stackrel{(3.5}{=}-\beta \varphi(y, x, z, w) \stackrel{3.7}{=} \beta \varphi(y, z, x, w) \stackrel{3.5}{=}-\beta \varphi(z, y, x, w) \stackrel{3.6}{=}-\beta \varphi(x, y, z, w)$.
The proof is complete.
Lemma 3.3. $\circlearrowleft_{x, y, z} \delta([x, y], \alpha(z))=2(\alpha(z) \boldsymbol{\delta}(x, y)-\delta(\alpha(z),[x, y])), \forall x, y, z \in L$, where $\circlearrowleft_{x, y, z}$ denotes the sum over cyclic permutations of $x, y, z$.

Proof. Note that

$$
\begin{aligned}
& \circlearrowleft_{x, y, z} \boldsymbol{\delta}([x, y], \alpha(z)) \\
= & \boldsymbol{\delta}([x, y], \alpha(z))+\boldsymbol{\delta}([y, z], \alpha(x))+\boldsymbol{\delta}([z, x], \alpha(y)) \\
= & \alpha(x) \boldsymbol{\delta}(y, z)-\alpha(y) \boldsymbol{\delta}(x, z)+\alpha(y) \boldsymbol{\delta}(z, x)-\alpha(z) \boldsymbol{\delta}(y, x)+\alpha(z) \boldsymbol{\delta}(x, y)-\alpha(x) \boldsymbol{\delta}(z, y) \\
= & 2(\alpha(x) \boldsymbol{\delta}(y, z)-\alpha(y) \boldsymbol{\delta}(x, z)+\alpha(z) \boldsymbol{\delta}(x, y)) \\
= & 2(\boldsymbol{\alpha}(z) \boldsymbol{\delta}(x, y)-\boldsymbol{\delta}(\alpha(z),[x, y])) .
\end{aligned}
$$

Hence the lemma follows.
Lemma 3.4. If $\beta$ is invertible, then

$$
\delta(\alpha(u),[x, y])-\alpha(u) \delta(x, y) \in Z_{V}\left(L^{\prime}\right), \forall x, y, u \in L
$$

Proof. By Lemma3.2 and (2.1), we have

$$
[\alpha(x), \alpha(y)] \beta \delta(z, w)+[\alpha(z), \alpha(w)] \beta \delta(x, y)=0 .
$$

Then

$$
\begin{aligned}
0 & =\circlearrowleft_{x, u, y}\left(\left[[\alpha(x), \alpha(u)], \alpha^{2}(y)\right] \beta \delta(z, w)+[\alpha(z), \alpha(w)] \beta \delta([x, u], \alpha(y))\right) \\
& =\circlearrowleft_{x, u, y}\left[[\alpha(x), \alpha(u)], \alpha^{2}(y)\right] \beta \delta(z, w)+\circlearrowleft_{x, u, y}[\alpha(z), \alpha(w)] \beta \delta([x, u], \alpha(y)) \\
& =-[\alpha(z), \alpha(w)] \beta\left(\circlearrowleft_{x, y, u} \delta([x, y], \alpha(u))\right) \\
& =2 \beta([z, w](\delta(\alpha(u),[x, y])-\alpha(u) \delta(x, y)),
\end{aligned}
$$

where the last equality uses Lemma 3.3 and (2.1). Hence the lemma follows from the fact that $\beta$ is invertible and char $\mathbb{F} \neq 2$.

Lemma 3.5. If $\beta$ is invertible and $(L, \alpha)$ is a perfect Hom-Lie algebra with $\alpha$ surjective, then $\boldsymbol{\delta}(z,[x, y])=z \boldsymbol{\delta}(x, y), \forall x, y, z \in L$.

Proof. Since $(L, \alpha)$ is a perfect Hom-Lie algebra with $\alpha$ surjective, for any $x, y, z \in L$, there exist $u_{i}, v_{i}(1 \leq i \leq m), s, t \in L$ such that $z=\sum_{i=1}^{m}\left[\alpha\left(u_{i}\right), \alpha\left(v_{i}\right)\right]$ and $[x, y]=[\alpha(s), \alpha(t)]$. Then

$$
\begin{aligned}
& \delta(z,[x, y])-z \delta(x, y) \\
= & \sum_{i=1}^{m}\left(\delta\left(\left[\alpha\left(u_{i}\right), \alpha\left(v_{i}\right)\right],[\alpha(s), \alpha(t)]\right)-\left[\alpha\left(u_{i}\right), \alpha\left(v_{i}\right)\right] \delta(\alpha(s), \alpha(t))\right) \\
= & \sum_{i=1}^{m}\left(\delta\left(\left[\alpha\left(u_{i}\right), \alpha\left(v_{i}\right)\right], \alpha([s, t])\right)-\left[\alpha\left(u_{i}\right), \alpha\left(v_{i}\right)\right] \beta \delta(s, t)\right)
\end{aligned}
$$

$$
\begin{aligned}
& =\sum_{i=1}^{m}\left(\alpha^{2}\left(u_{i}\right) \delta\left(\alpha\left(v_{i}\right),[s, t]\right)-\alpha^{2}\left(v_{i}\right) \delta\left(\alpha\left(u_{i}\right),[s, t]\right)-\alpha^{2}\left(u_{i}\right) \alpha\left(v_{i}\right) \delta(s, t)+\alpha^{2}\left(v_{i}\right) \alpha\left(u_{i}\right) \delta(s, t)\right) \\
& =\sum_{i=1}^{m}\left(\alpha^{2}\left(u_{i}\right)\left(\delta\left(\alpha\left(v_{i}\right),[s, t]\right)-\alpha\left(v_{i}\right) \delta(s, t)\right)-\alpha^{2}\left(v_{i}\right)\left(\delta\left(\alpha\left(u_{i}\right),[s, t]\right)-\alpha\left(u_{i}\right) \delta(s, t)\right)\right) .
\end{aligned}
$$

By Lemma 3.4, we obtain that the last equation above is equal to zero.
Theorem 3.6. Let $(L, \alpha)$ be a perfect Hom-Lie algebra with $\alpha$ surjective and $(V, \rho, \beta)$ an $(L, \alpha)$-module with $\beta$ invertible such that $Z_{V}(L)=0$. Then for all $\delta \in \operatorname{Bider}_{\mathrm{s}}(L, V)$, there exists $\gamma \in \operatorname{Cent}(L, V)$ such that $\delta(x, y)=\beta^{-1} \gamma([x, y]), \forall x, y \in L$.

Proof. Since $L=L^{\prime}$, for any $z \in L$, we have $z=\sum_{i=1}^{m}\left[z_{i}^{\prime}, z_{i}^{\prime \prime}\right]$ for some $z_{i}^{\prime}, z_{i}^{\prime \prime} \in L$. Define $\gamma: L \rightarrow V$ by

$$
\gamma\left(\sum_{i=1}^{m}\left[z_{i}^{\prime}, z_{i}^{\prime \prime}\right]\right)=\sum_{i=1}^{m} \beta \delta\left(z_{i}^{\prime}, z_{i}^{\prime \prime}\right) .
$$

Then it suffices to show that $\gamma$ is well-defined as well as $\gamma([x, y])=\alpha(x) \gamma(y), \forall x, y \in L$. Indeed,
If $\sum_{i=1}^{m}\left[z_{i}^{\prime}, z_{i}^{\prime \prime}\right]=0$, then for any $u \in L$,

$$
0=\boldsymbol{\delta}\left(u, \sum_{i=1}^{m}\left[z_{i}^{\prime}, z_{i}^{\prime \prime}\right]\right)=\sum_{i=1}^{m} \boldsymbol{\delta}\left(u,\left[z_{i}^{\prime}, z_{i}^{\prime \prime}\right]\right)=u \sum_{i=1}^{m} \boldsymbol{\delta}\left(z_{i}^{\prime}, z_{i}^{\prime \prime}\right),
$$

and hence $\sum_{i=1}^{m} \delta\left(z_{i}^{\prime}, z_{i}^{\prime \prime}\right)=0$ follows from $Z_{V}(L)=0$. So $\sum_{i=1}^{m} \beta \delta\left(z_{i}^{\prime}, z_{i}^{\prime \prime}\right)=0$, which implies that $\gamma$ is well-defined. Furthermore, suppose $y_{i}^{\prime}, y_{i}^{\prime \prime} \in L$ such that $y=\sum_{i=1}^{k}\left[y_{i}^{\prime}, y_{i}^{\prime \prime}\right]$, then

$$
\begin{aligned}
\gamma([x, y]) & =\beta \delta(x, y)=\delta(\alpha(x), \alpha(y))=\delta\left(\alpha(x), \sum_{i=1}^{k}\left[\alpha\left(y_{i}^{\prime}\right), \alpha\left(y_{i}^{\prime \prime}\right)\right]\right)=\sum_{i=1}^{k} \alpha(x) \delta\left(\alpha\left(y_{i}^{\prime}\right), \alpha\left(y_{i}^{\prime \prime}\right)\right) \\
& =\sum_{i=1}^{k} \alpha(x) \beta \delta\left(y_{i}^{\prime}, y_{i}^{\prime \prime}\right)=\sum_{i=1}^{k} \alpha(x) \gamma\left(\left[y_{i}^{\prime}, y_{i}^{\prime \prime}\right]\right)=\alpha(x) \gamma(y) .
\end{aligned}
$$

Therefore, $\gamma \in \operatorname{Cent}(L, V)$.
Now we turn to $\operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$, which is easy to determine in the case that $(L, \alpha)$ is centerless and perfect, or in particular, $(L, \alpha)$ is simple.

Theorem 3.7. If $(L, \alpha)$ is a centerless and perfect Hom-Lie algebra with $\alpha$ invertible, then every skew-symmetric biderivation $\delta: L \times L \rightarrow\left(L, \mathrm{ad}_{k}, \alpha\right)$ is of the form

$$
\delta(x, y)=\alpha^{-1} \gamma([x, y]),
$$

where $\gamma \in \operatorname{Cent}\left(L, \operatorname{ad}_{k}\right)$. Moreover, if $(L, \alpha)$ is simple and finite-dimensional, then

$$
\delta(x, y)=\lambda \alpha^{k}([x, y]), \text { for some } \lambda \in \mathbb{F} .
$$

Proof. The first assertion is an immediate corollary to Theorem 3.6 when $(L, \alpha)$ is centerless and perfect. Now let $(L, \alpha)$ be simple and finite-dimensional.

If $\delta=0$, then take $\lambda=0$ and we are done.
Suppose $\delta \neq 0$. Using Theorem 3.6, there exists $\gamma \in \operatorname{Cent}\left(L, \mathrm{ad}_{k}\right)$ such that $\delta(x, y)=\alpha^{-1} \gamma([x, y])$. Note that $\gamma:\left(L, \operatorname{ad}_{0}, \alpha\right) \rightarrow\left(L, \mathrm{ad}_{k}, \alpha\right)$ is a module homomorphism over a finite-dimensional
simple Hom-Lie algebra $(L, \alpha)$ together with the fact that $\alpha$ is invertible. By Theorem 2.8, $\gamma=\lambda \alpha^{k+1}$ and $\delta(x, y)=\lambda \alpha^{k}([x, y])$.

In general, on a Hom-Lie algebra $(L, \alpha)$ such that $\alpha$ is invertible, we would like to give an algorithm to find all skew-symmetric biderivations in $\operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$. To this end, we need the notions of central and special biderivations.

Definition 3.8. Let $(L, \alpha)$ be a Hom-Lie algebra and $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$. $\delta$ is called central if

$$
\delta(L, L) \subset Z(L)=Z_{L}(L)
$$

$\delta$ is called special if

$$
\delta(L, L) \subset Z_{L}\left(L^{\prime}\right) \text { and } \delta\left(L^{\prime}, L^{\prime}\right)=0
$$

Denote by $\operatorname{CBider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$ and $\operatorname{SBider}_{\mathrm{s}}\left(L, \mathrm{ad}_{k}\right)$ the sets consisting of all central and special skew-symmetric biderivations in $\operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$, respectively.

Remark 3.9. Clearly, each $\delta \in \operatorname{CBider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$ satisfies $\delta\left(L, L^{\prime}\right)=0$. Then it follows that $\operatorname{CBider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right) \subseteq \operatorname{SBider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$, and any skew-symmetric bilinear map $\delta$ satisfying

$$
\begin{gathered}
\beta \delta(x, y)=\delta(\alpha(x), \alpha(y)), \forall x, y \in L, \\
\delta\left(L, L^{\prime}\right)=0, \\
\delta(L, L) \subseteq Z(L)
\end{gathered}
$$

automatically belongs to $\operatorname{CBider}_{\mathrm{s}}\left(L, \mathrm{ad}_{k}\right)$.
Example 3.10. Every Hom-Lie algebra ( $L, \alpha$ ) with nontrivial center and such that the codimension of $L^{\prime}$ in $L$ is no less than 2 has nonzero special biderivations. Indeed, by the codimension assumption, there exists a nonzero skew-symmetric bilinear form $\omega: L \times L \rightarrow \mathbb{F}$ such that $\omega\left(L, L^{\prime}\right)=0$, and taking any nonzero $z_{0} \in Z(L)$, we have that $\delta(x, y):=\omega(x, y) z_{0}$ is a nonzero central biderivation as well as a nonzero special biderivation.

Suppose that $(L, \alpha)$ is a Hom-Lie algebra with $\alpha$ surjective and $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$. The motivation for our algorithm is the following observation.

Note that for any $x, y \in L, z \in Z(L)$ we have

$$
0=\boldsymbol{\delta}([z, x], \alpha(y))=\left[\alpha^{k+1}(z), \delta(x, y)\right]-\left[\alpha^{k+1}(x), \delta(z, y)\right]=-\left[\alpha^{k+1}(x), \delta(z, y)\right]
$$

which implies $\delta(Z(L), L) \subset Z(L)$. Since $Z(L)$ is an ideal of $(L, \alpha)$, we consider the quotient Hom-Lie algebra $(\bar{L}, \bar{\alpha})$ and its quotient adjoint module $\left(\bar{L}, \overline{\operatorname{ad}}_{k}, \bar{\alpha}\right)$, where $\bar{L}:=L / Z(L)$, $\bar{\alpha}(\bar{x}):=\overline{\alpha(x)}$, and $\overline{\operatorname{ad}}_{k}(\bar{x})(\bar{y}):=\overline{\left[\alpha^{k}(x), y\right]}$, for all $x, y \in L$. Then we can define a skew-symmetric biderivation $\bar{\delta} \in \operatorname{Bider}_{\mathrm{s}}\left(\bar{L}, \overline{\mathrm{ad}}_{k}\right)$ by

$$
\bar{\delta}(\bar{x}, \bar{y})=\overline{\delta(x, y)}, \forall \bar{x}, \bar{y} \in \bar{L} .
$$

If $\delta_{1}$ and $\delta_{2}$ satisfy $\bar{\delta}_{1}=\bar{\delta}_{2}$, then $\hat{\delta}:=\delta_{1}-\delta_{2}$ is a skew-symmetric biderivation with $\hat{\delta}(L, L) \subset$ $Z(L)$, so $\hat{\delta}$ is a central biderivation on $(L, \alpha)$. Then we derive the following lemma.

Lemma 3.11. Let $(L, \alpha)$ be a Hom-Lie algebra with $\alpha$ surjective. Up to $\operatorname{CBider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$, the map $\delta \rightarrow \bar{\delta}$ is a 1-1 map from $\operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$ to $\operatorname{Bider}_{\mathrm{s}}\left(\bar{L}, \overline{\operatorname{ad}}_{k}\right)$.

Hence, $\operatorname{Bider}_{\mathrm{s}}\left(L, \mathrm{ad}_{k}\right)$ are determined by $\operatorname{CBider}_{\mathrm{s}}\left(L, \mathrm{ad}_{k}\right)$ and $\operatorname{Bider}_{\mathrm{s}}\left(\bar{L}, \overline{\mathrm{ad}}_{k}\right)$. We define a sequence of quotient Hom-Lie algebras

$$
\begin{equation*}
\left(L^{(0)}, \alpha^{(0)}\right)=(L, \alpha), \cdots,\left(L^{(r+1)}, \alpha^{(r+1)}\right)=\left(L^{(r)} / Z\left(L^{(r)}\right), \overline{\alpha^{(r)}}\right) \tag{3.8}
\end{equation*}
$$

and write $\left(L^{(r)}, \mathrm{ad}_{k}^{(r)}, \alpha^{(r)}\right)$ for the quotient adjoint module of $\left(L^{(r)}, \alpha^{(r)}\right)$. If there exists $r \in \mathbb{N}$ such that $Z\left(L^{(r)}\right)=\{0\}$, then $\operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$ are characterized by $\operatorname{CBider}_{\mathrm{s}}\left(L^{(i)}, \operatorname{ad}_{k}^{(i)}\right)(0 \leq i \leq$ $r-1)$ and $\operatorname{Bider}_{\mathrm{s}}\left(L^{(r)}, \operatorname{ad}_{k}^{(r)}\right.$, where $\operatorname{Bider}_{\mathrm{s}}\left(L^{(r)}, \mathrm{ad}_{k}^{(r)}\right)$ can be determined by Theorem 3.7 in case $\left(L^{(r)}, \alpha^{(r)}\right)$ is perfect and $\alpha$ is invertible.

However, we still don't know how to determine $\operatorname{Bider}_{\mathrm{s}}\left(L^{(r)}, \mathrm{ad}_{k}^{(r)}\right)$ if $\left(L^{(r)}, \alpha^{(r)}\right)$ is not perfect, which inspires us to consider skew-symmetric biderivations on derived Hom-Lie algebras.

Now let $(L, \alpha)$ be an arbitrary centerless Hom-Lie algebra such that $\alpha$ is invertible and $\delta \in$ $\operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$. Then $\delta$ satisfies

$$
\begin{equation*}
\boldsymbol{\delta}(\alpha(u),[x, y])=\left[\alpha^{k+1}(x), \delta(u, y)\right]-\left[\alpha^{k+1}(y), \delta(u, x)\right] \in L^{\prime}, \forall x, y, u \in L . \tag{3.9}
\end{equation*}
$$

Thus we could restrict $\delta$ to $L^{\prime} \times L^{\prime}$ to get a skew-symmetric biderivation $\delta^{\prime} \in \operatorname{Bider}_{\mathrm{s}}\left(L^{\prime}, \operatorname{ad}_{k}\right)$, which makes sense since $L^{\prime}$ is $\alpha$-invariant. If $\delta_{1}, \delta_{2} \in \operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$ such that $\left.\delta_{1}\right|_{L^{\prime} \times L^{\prime}}=$ $\left.\delta_{2}\right|_{L^{\prime} \times L^{\prime}}$, then $\tilde{\delta}:=\delta_{1}-\delta_{2} \in \operatorname{SBider}_{\mathrm{s}}\left(L, \mathrm{ad}_{k}\right)$.

In fact, it suffices to prove $\tilde{\delta}(L, L) \subset Z_{L}\left(L^{\prime}\right)$, since $\tilde{\delta}\left(L^{\prime}, L^{\prime}\right)=0$ is obvious. Note that $\tilde{\delta}\left(L, L^{\prime}\right) \subset Z_{L}\left(L^{\prime}\right)$ holds by taking $u, y \in L^{\prime}$ in (3.9). Then for any $x, y, z, u, v \in L$, we have

$$
\begin{aligned}
{[[[x, y], \tilde{\delta}(u, v)], \alpha(z)] } & =[[[x, y], z], \alpha \tilde{\delta}(u, v)]+[\alpha([x, y]),[\tilde{\delta}(u, v), z]] \\
& =[[[x, y], z], \tilde{\delta}(\alpha(u), \alpha(v))]-[[\alpha(x), \alpha(y)],[z, \tilde{\delta}(u, v)]]
\end{aligned}
$$

$(\alpha$ is isomorphic $)=\left[\alpha^{k}([[\tilde{x}, \tilde{y}], \tilde{z}]), \tilde{\delta}(\alpha(u), \alpha(v))\right]$

$$
-\left[\left[\alpha^{k+1}(\tilde{x}), \alpha^{k+1}(\tilde{y})\right],\left[\alpha^{k}(\tilde{z}), \tilde{\delta}(u, v)\right]\right]
$$

(by Lemmas 3.2 and 3.4) $=-\left[\left[\alpha^{k+1}(u), \alpha^{k+1}(v)\right], \tilde{\delta}([\tilde{x}, \tilde{y}], \tilde{z})\right]$

$$
-\left[\left[\alpha^{k+1}(\tilde{x}), \alpha^{k+1}(\tilde{y})\right], \tilde{\delta}(\tilde{z},[u, v])\right]
$$

$\left(\right.$ by $\left.\tilde{\delta}\left(L, L^{\prime}\right) \subset Z_{L}\left(L^{\prime}\right)\right)=0$.
It follows that $\tilde{\delta}(L, L) \subset Z_{L}\left(L^{\prime}\right)$, since $(L, \alpha)$ is centerless. Thus, $\tilde{\delta} \in \operatorname{SBider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$, and we deduce the following lemma.

Lemma 3.12. Suppose that $(L, \alpha)$ is a centerless Hom-Lie algebra with $\alpha$ invertible. Then any $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$, up to $\operatorname{SBider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$, is an extension of a unique $\delta^{\prime} \in \operatorname{Bider}_{\mathrm{s}}\left(L^{\prime}, \operatorname{ad}_{k}\right)$.

Hence, for centerless but not perfect Hom-Lie algebra $\left(L^{(r)}, \alpha^{(r)}\right), \operatorname{Bider}_{\mathrm{s}}\left(L^{(r)}, \mathrm{ad}_{k}^{(r)}\right)$ are determined by $\operatorname{SBider}_{\mathrm{s}}\left(L^{(r)}, \operatorname{ad}_{k}^{(r)}\right)$ and $\operatorname{Bider}_{\mathrm{s}}\left(L^{(r)^{\prime}}, \operatorname{ad}_{k}^{(r)}\right)$. Taking $(L, \alpha)=\left(L^{(r)^{\prime}}, \alpha^{(r)}\right)$ and repeating the above arguments based on (3.8), then we continue the algorithms.

Now we apply our method to several concrete examples.
Example 3.13. Let $(L, \alpha)$ belong to one class of multiplicative Heisenberg Hom-Lie algebras in [3, Corollary 2.3]. Specifically, $L=\mathbb{F} e_{1} \oplus \mathbb{F} e_{2} \oplus \mathbb{F} e_{3}$ as a vector space with $\left[e_{1}, e_{2}\right]=e_{3}$,
$\left[e_{2}, e_{3}\right]=\left[e_{1}, e_{3}\right]=0$, and $\alpha=\left(\begin{array}{ccc}\lambda & 0 & 0 \\ 1 & \lambda & 0 \\ 0 & 0 & \lambda^{2}\end{array}\right)$ for some nonzero $\lambda \in \mathbb{F}$. Note that $Z(L)=\mathbb{F} e_{3}$. As in (3.8), we have

$$
\left(L^{(0)}, \alpha^{(0)}\right)=(L, \alpha), \quad\left(L^{(1)}, \alpha^{(1)}\right)=(L / Z(L), \bar{\alpha})=\left(\mathbb{F} \bar{e}_{1} \oplus \mathbb{F} \bar{e}_{2},\left(\begin{array}{cc}
\lambda & 0 \\
1 & \lambda
\end{array}\right)\right)
$$

Since $\left(L^{(1)}, \alpha^{(1)}\right)$ is abelian, $\left(L^{(2)}, \alpha^{(2)}\right)=(\{0\}, 0)$. $\operatorname{Then}^{\operatorname{Bider}_{s}}\left(L^{(2)}, \mathrm{ad}_{k}^{(2)}\right)=\{0\}$, and we need $\operatorname{CBider}_{\mathrm{s}}\left(L^{(0)}, \operatorname{ad}_{k}^{(0)}\right)$ and $\operatorname{CBider}_{\mathrm{s}}\left(L^{(1)}, \operatorname{ad}_{k}^{(1)}\right)$ to determine $\operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$.

Let $\delta^{(1)} \in \operatorname{CBider}_{\mathrm{s}}\left(L^{(1)}, \operatorname{ad}_{k}^{(1)}\right)$. Assume $\boldsymbol{\delta}^{(1)}\left(\bar{e}_{1}, \bar{e}_{2}\right)=k_{1} \bar{e}_{1}+k_{2} \bar{e}_{2}$. Note that $\delta^{(1)}$ satisfies

$$
\alpha^{(1)} \delta^{(1)}\left(\bar{e}_{1}, \bar{e}_{2}\right)=\delta^{(1)}\left(\alpha^{(1)}\left(\bar{e}_{1}\right), \alpha^{(1)}\left(\bar{e}_{2}\right)\right)
$$

which implies

$$
k_{1} \lambda \bar{e}_{1}+\left(k_{1}+k_{2} \lambda\right) \bar{e}_{2}=\lambda^{2}\left(k_{1} \bar{e}_{1}+k_{2} \bar{e}_{2}\right)
$$

Then

$$
\delta^{(1)}\left(\bar{e}_{1}, \bar{e}_{2}\right)= \begin{cases}k_{2} \bar{e}_{2}, & \lambda=1  \tag{3.10}\\ 0, & \lambda \neq 1\end{cases}
$$

The above $\delta^{(1)}$ clearly satisfies (3.2) or (3.3) since $\left(L^{(1)}, \alpha^{(1)}\right)$ is an abelian Hom-Lie algebra. Note also that $\operatorname{Bider}_{\mathrm{s}}\left(L^{(2)}, \operatorname{ad}_{k}^{(2)}\right)=\{0\}$. Then any $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L^{(1)}, \mathrm{ad}_{k}^{(1)}\right)$ must be some $\boldsymbol{\delta}^{(1)}$ in (3.10).

Let $\delta^{(0)} \in \operatorname{CBider}_{\mathrm{s}}\left(L^{(0)}, \mathrm{ad}_{k}^{(0)}\right)$. By Definition 3.8, Remark 3.9 and $L^{\prime}=Z(L)=\mathbb{F} e_{3}$, we could set

$$
\begin{equation*}
\delta^{(0)}\left(e_{1}, e_{2}\right)=k_{3} e_{3}, \delta^{(0)}\left(e_{1}, e_{3}\right)=\delta^{(0)}\left(e_{2}, e_{3}\right)=0 \tag{3.11}
\end{equation*}
$$

It is straightforward to verify that the above $\delta^{(0)}$ satisfies (3.1)-(3.3).
Now let $\hat{\delta} \in \operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$. Then $\hat{\delta}$ induces a skew-symmetric biderivation that belongs to $\operatorname{Bider}_{\mathrm{s}}\left(L^{(1)}, \mathrm{ad}_{k}^{(1)}\right)$, which is of the form in (3.10). Set

$$
\hat{\delta}\left(e_{1}, e_{2}\right)=\left\{\begin{array}{ll}
k_{2} e_{2}, & \lambda=1 ;  \tag{3.12}\\
0, & \lambda \neq 1,
\end{array} \quad \hat{\delta}\left(e_{1}, e_{3}\right)=\hat{\delta}\left(e_{2}, e_{3}\right)=0\left(\forall \lambda \in \mathbb{F}^{*}\right)\right.
$$

One could check that $\hat{\delta}$ satisfies (3.1)-(3.3).
Therefore, every $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L, \mathrm{ad}_{k}\right)$ is of the form

$$
\delta=\delta^{(0)}+\hat{\delta}
$$

for some $\delta^{(0)}$ in (3.11) and $\hat{\delta}$ in (3.12). In particular,

$$
\delta\left(e_{1}, e_{2}\right)=\left\{\begin{array}{ll}
k_{2} e_{2}+k_{3} e_{3}, & \lambda=1 ; \\
k_{3} e_{3}, & \lambda \neq 1,
\end{array} \quad \delta\left(e_{1}, e_{3}\right)=\delta\left(e_{2}, e_{3}\right)=0\left(\forall \lambda \in \mathbb{F}^{*}\right)\right.
$$

Example 3.14. Suppose that $(L, \alpha)$ belongs to the second class of multiplicative Hom-Lie algebras in [10, Theorem 4.7]. For simplicity of calculations, we consider $L=\mathbb{F} x \oplus \mathbb{F} y \oplus \mathbb{F} z$ as a vector space with $[x, y]=y,[x, z]=[y, z]=0$ and $\alpha=\left(\begin{array}{ccc}1 & 0 & 0 \\ a & \lambda & 0 \\ b & 0 & \mu\end{array}\right)$ for $a, b \in \mathbb{F}$ and $\lambda, \mu \in \mathbb{F}^{*}$. Note that $Z(L)=\mathbb{F} z$. As in (3.8), we have

$$
\left(L^{(0)}, \alpha^{(0)}\right)=(L, \alpha), \quad\left(L^{(1)}, \alpha^{(1)}\right)=\left(\mathbb{F} \bar{x} \oplus \mathbb{F} \bar{y},\left(\begin{array}{cc}
1 & 0 \\
a & \lambda
\end{array}\right)\right) .
$$

Then $\left(L^{(1)}, \alpha^{(1)}\right)$ is centerless but not perfect since $L^{(1)^{\prime}}=\mathbb{F} \bar{y}$. Hence $\operatorname{Bider}_{\mathrm{s}}\left(L^{(1)}, \mathrm{ad}_{k}^{(1)}\right)$ is determined by $\operatorname{SBider}_{\mathrm{s}}\left(L^{(1)}, \mathrm{ad}_{k}^{(1)}\right)$ and $\operatorname{Bider}_{\mathrm{s}}\left(L^{(1)^{\prime}}, \mathrm{ad}_{k}^{(1)}\right)$, where the latter is $\{0\}$ since $\operatorname{dim} L^{(1)^{\prime}}=1$. So we only need $\operatorname{CBider}_{\mathrm{s}}\left(L^{(0)}, \operatorname{ad}_{k}^{(0)}\right)$ and $\operatorname{SBider}_{\mathrm{s}}\left(L^{(1)}, \mathrm{ad}_{k}^{(1)}\right)$ to determine $\operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$.

Let $\tilde{\delta} \in \operatorname{SBider}_{\mathrm{s}}\left(L^{(1)}, \operatorname{ad}_{k}^{(1)}\right)$. Note that $Z_{L^{(1)}}\left(L^{(1)^{\prime}}\right)=L^{(1)^{\prime}}=\mathbb{F} \bar{y}$. We set

$$
\begin{equation*}
\tilde{\delta}(\bar{x}, \bar{y})=k \bar{y}, \tag{3.13}
\end{equation*}
$$

which can be verified to be a skew-symmetric biderivation. Then all skew-symmetric biderivations in $\operatorname{Bider}_{\mathrm{s}}\left(L^{(1)}, \mathrm{ad}_{k}^{(1)}\right)$ are of the form given by (3.13), since there is no nonzero element in $\operatorname{Bider}_{\mathrm{s}}\left(L^{(1)^{\prime}}, \mathrm{ad}_{k}^{(1)}\right)$.

Let $\delta^{(0)} \in \operatorname{CBider}_{\mathrm{s}}\left(L^{(0)}, \operatorname{ad}_{k}^{(0)}\right)$. Since $L^{\prime}=\mathbb{F} y$ and $Z(L)=\mathbb{F} z$, we could set

$$
\delta^{(0)}(x, z)=l z, \delta^{(0)}(x, y)=\delta^{(0)}(y, z)=0 .
$$

It is easy to check that the above $\delta^{(0)}$ is a skew-symmetric biderivation, then such $\delta^{(0)}$ are precisely all elements in $\operatorname{CBider}_{\mathrm{s}}\left(L^{(0)}, \mathrm{ad}_{k}^{(0)}\right)$.

Set

$$
\begin{equation*}
\boldsymbol{\delta}(x, y)=k y, \boldsymbol{\delta}(x, z)=\boldsymbol{\delta}(y, z)=0 . \tag{3.14}
\end{equation*}
$$

Then $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$ and $\delta$ induces a skew-symmetric biderivation in $\operatorname{Bider}_{\mathrm{s}}\left(L^{(1)}, \operatorname{ad}_{k}^{(1)}\right)$, which is of the form in (3.13).

Therefore, every $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L, \mathrm{ad}_{k}\right)$ is of the following form

$$
\boldsymbol{\delta}(x, y)=k y, \delta(x, z)=l z, \delta(y, z)=0
$$

Example 3.15. Consider the loop algebra $L=\mathfrak{s l}_{2} \otimes \mathbb{F}\left[t, t^{-1}\right]$ with $\left[x \otimes t^{m}, y \otimes t^{n}\right]=[x, y] \otimes t^{m+n}$ and $\alpha=\check{\alpha} \otimes \mathrm{id}$, where $\check{\alpha}$ is an involution of $\mathfrak{s l}_{2}$ such that

$$
\check{\alpha}(e)=-e, \check{\alpha}(f)=-f, \check{\alpha}(h)=h .
$$

Then $(L, \alpha)$ is an infinite-dimensional Hom-Lie algebra (cf. [33, Corollaries 3.1 and 3.3]). Moreover, $(L, \alpha)$ is perfect and centerless, so each $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$ is of the form

$$
\delta(x, y)=\alpha^{-1} \gamma([x, y]), \forall x, y \in L,
$$

for some $\gamma \in \operatorname{Cent}\left(L, \mathrm{ad}_{k}\right)$.

Let $\gamma \in \operatorname{Cent}\left(L, \operatorname{ad}_{k}\right)$. Then $\gamma \alpha=\alpha \gamma$ and for all $a, b \in \mathfrak{s l}_{2}$ and $m, n \in \mathbb{Z}$,

$$
\gamma\left(\left[a \otimes t^{m}, b \otimes t^{n}\right]\right)=\left[\alpha^{k+1}\left(a \otimes t^{m}\right), \gamma\left(b \otimes t^{n}\right)\right]
$$

Take $a \otimes t^{m}=h \otimes 1$. It follows that $\gamma\left([h, b] \otimes t^{n}\right)=\left[h \otimes 1, \gamma\left(b \otimes t^{n}\right)\right]$. In particular,

$$
-2 \gamma\left(f \otimes t^{n}\right)=\left[h \otimes 1, \gamma\left(f \otimes t^{n}\right)\right], 0=\left[h \otimes 1, \gamma\left(h \otimes t^{n}\right)\right], 2 \gamma\left(e \otimes t^{n}\right)=\left[h \otimes 1, \gamma\left(e \otimes t^{n}\right)\right],
$$

which implies that $\gamma\left(f \otimes t^{n}\right), \gamma\left(h \otimes t^{n}\right)$ and $\gamma\left(e \otimes t^{n}\right)$ are eigenvectors for the operator $[h \otimes 1,-]$ with eigenvalues $-2,0$ and 2 respectively. Then there exist $\Phi_{f}^{n}(t), \Phi_{h}^{n}(t), \Phi_{e}^{n}(t) \in \mathbb{F}\left[t, t^{-1}\right]$ such that

$$
\gamma\left(f \otimes t^{n}\right)=f \otimes \Phi_{f}^{n}(t), \gamma\left(h \otimes t^{n}\right)=h \otimes \Phi_{h}^{n}(t), \gamma\left(e \otimes t^{n}\right)=e \otimes \Phi_{e}^{n}(t) .
$$

Note that

$$
\begin{aligned}
-2 f \otimes \Phi_{f}^{n}(t) & =-2 \gamma\left(f \otimes t^{n}\right)=\gamma\left(\left[h \otimes t^{n}, f \otimes 1\right]\right) \\
& =\left[h \otimes t^{n}, \gamma(f \otimes 1)\right]=\left[h \otimes t^{n}, f \otimes \Phi_{f}^{0}(t)\right]=-2 f \otimes t^{n} \Phi_{f}^{0}(t) .
\end{aligned}
$$

Then $\Phi_{f}^{n}(t)=t^{n} \Phi_{f}^{0}(t), \forall n \in \mathbb{Z}$. Similarly, $\Phi_{e}^{n}(t)=t^{n} \Phi_{e}^{0}(t)$. Note also that

$$
\begin{aligned}
2 f \otimes \Phi_{f}^{n}(t) & =2 \gamma\left(f \otimes t^{n}\right)=\gamma\left(\left[f \otimes 1, h \otimes t^{n}\right]\right) \\
& =\left[(-1)^{k+1} f \otimes 1, \gamma\left(h \otimes t^{h}\right)\right]=\left[(-1)^{k+1} f \otimes 1, h \otimes \Phi_{h}^{n}(t)\right]=2 f \otimes(-1)^{k+1} \Phi_{h}^{n}(t) .
\end{aligned}
$$

Then we have $\Phi_{h}^{n}(t)=t^{n} \Phi_{h}^{0}(t)$ and $\Phi_{f}^{0}(t)=(-1)^{k+1} \Phi_{h}^{0}(t)$. Substituting $f$ with $e$ in the above equality one obtains $\Phi_{e}^{0}(t)=(-1)^{k+1} \Phi_{h}^{0}(t)$. Hence

$$
(-1)^{k+1} \Phi_{f}^{0}(t)=(-1)^{k+1} \Phi_{e}^{0}(t)=\Phi_{h}^{0}(t) .
$$

Set $\Phi(t)=\Phi_{h}^{0}(t)$ and define $\phi \in \operatorname{End}\left(\mathbb{F}\left[t, t^{-1}\right]\right)$ by $\phi(g(t))=\Phi(t) g(t)$. It follows that $\gamma=$ $\check{\alpha}^{k+1} \otimes \phi$.

Conversely, for any $\Phi(t) \in \mathbb{F}\left[t, t^{-1}\right]$, the $\gamma$ defined as above belongs to $\operatorname{Cent}\left(L, \operatorname{ad}_{k}\right)$. Therefore,

$$
\operatorname{Cent}\left(L, \operatorname{ad}_{k}\right)=\left\{\check{\alpha}^{k+1} \otimes \phi \mid \Phi(t) \in \mathbb{F}\left[t, t^{-1}\right]\right\}
$$

and so every $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L, \operatorname{ad}_{k}\right)$ is of the following form:

$$
\delta(x, y)=\alpha^{-1}\left(\check{\alpha}^{k+1} \otimes \phi\right)([x, y])=\left(\check{\alpha}^{-1} \otimes \operatorname{id}\right)\left(\check{\alpha}^{k+1} \otimes \phi\right)([x, y])=\left(\check{\alpha}^{k} \otimes \phi\right)([x, y]), \forall x, y \in L .
$$

## 4. Commuting linear maps on Hom-Lie algebras

In this section, we consider linear maps from a Hom-Lie algebra $(L, \alpha)$ to an $(L, \alpha)$-module $(V, \rho, \beta)$ that are also closely related to $\operatorname{Cent}(L, V)$.

Definition 4.1. Let $(L, \alpha)$ be a Hom-Lie algebra and $(V, \rho, \beta)$ an $(L, \alpha)$-module. A linear map $f: L \rightarrow V$ is called a commuting linear map if

$$
\alpha(x) f(x)=0 \text { and } \beta \circ f=f \circ \alpha, \forall x \in L .
$$

Denote by $\operatorname{Com}(L, V)$ the set of all commuting linear maps $f: L \rightarrow V$. In particular, we write $\operatorname{Com}\left(L, \mathrm{ad}_{k}\right)$ as the set of all commuting linear maps on $(L, \alpha)$ for the adjoint module $\left(L, \mathrm{ad}_{k}, \alpha\right)$,

Clearly, $\operatorname{Cent}(L, V) \subseteq \operatorname{Com}(L, V)$. We will show $\operatorname{Cent}(L, V)=\operatorname{Com}(L, V)$, under the assumption that $\beta$ is invertible and $Z_{V}\left(L^{\prime}\right)=0$.

Lemma 4.2. Let $(L, \alpha)$ be a Hom-Lie algebra and $(V, \rho, \beta)$ an $(L, \alpha)$-module with $\beta$ invertible. If $f \in \operatorname{Com}(L, V)$, then

$$
[\alpha(v), \alpha(w)] \alpha^{2}(u)(f([x, y])-\alpha(x) f(y))=0, \forall x, y, z, u, v \in L .
$$

Proof. By the definition of the commuting linear map, we get

$$
\begin{equation*}
\alpha(x) f(y)=-\alpha(y) f(x), \forall x, y \in L \tag{4.1}
\end{equation*}
$$

which induces a skew-symmetric bilinear map $\delta: L \times L \rightarrow V$ defined by

$$
\begin{equation*}
\delta(x, y)=\beta^{-1}(\alpha(x) f(y)), \forall x, y \in L \tag{4.2}
\end{equation*}
$$

Moreover, $\delta$ is a skew-symmetric biderivation, since

$$
\begin{aligned}
\beta \delta(x, y) & =\alpha(x) f(y)=\alpha(x) \beta^{-1} \beta f(y) \\
\text { (by Definition 4.1) } & =\alpha(x) \beta^{-1} f(\alpha(y)) \\
(\text { by (2.1) }) & =\beta^{-1} \alpha^{2}(x) f(\alpha(y)) \\
& =\delta(\alpha(x), \alpha(y))
\end{aligned}
$$

and

$$
\begin{aligned}
\delta(\alpha(x),[y, z]) & =\beta^{-1}\left(\alpha^{2}(x) f([y, z])\right) \\
(\text { by (4.1) }) & =-\beta^{-1}(\alpha([y, z]) f(\alpha(x)))=-\beta^{-1}([\alpha(y), \alpha(z)] \beta f(x)) \\
(\text { by (2.2) }) & =-\beta^{-1}\left(\alpha^{2}(y) \alpha(z) f(x)-\alpha^{2}(z) \alpha(y) f(x)\right) \\
(\text { by (2.1) }) & =-\alpha(y) \beta^{-1}(\alpha(z) f(x))+\alpha(z) \beta^{-1}(\alpha(y) f(x)) \\
& =-\alpha(y) \delta(z, x)+\alpha(z) \delta(y, x) \\
& =\alpha(y) \delta(x, z)-\alpha(z) \delta(x, y) .
\end{aligned}
$$

Note that Lemma 3.4 says that for any $v, w \in L,[v, w](\boldsymbol{\delta}(\alpha(u),[x, y])-\alpha(u) \boldsymbol{\delta}(x, y))=0$. It follows that for all $x, y, u, v, w \in L$,

$$
\begin{aligned}
0 & =\beta([v, w](\delta(\alpha(u),[x, y])-\alpha(u) \delta(x, y))) \\
(\text { by (2.1) }) & =\alpha([v, w]) \beta(\delta(\alpha(u),[x, y])-\alpha(u) \delta(x, y)) \\
(\text { by (2.1) }) & =\alpha([v, w])\left(\beta \delta(\alpha(u),[x, y])-\alpha^{2}(u) \beta \delta(x, y)\right) \\
(\text { by (4.2) }) & =[\alpha(v), \alpha(w)]\left(\alpha^{2}(u) f([x, y])-\alpha^{2}(u) \alpha(x) f(y)\right) \\
& =[\alpha(v), \alpha(w)] \alpha^{2}(u)(f([x, y])-\alpha(x) f(y)),
\end{aligned}
$$

as required.

Theorem 4.3. Let $(L, \alpha)$ be a Hom-Lie algebra with $\alpha$ surjective and $(V, \rho, \beta)$ an $(L, \alpha)$-module with $\beta$ invertible. If $Z_{V}\left(L^{\prime}\right)=0$, then $\operatorname{Cent}(L, V)=\operatorname{Com}(L, V)$.

Proof. It suffices to prove $\operatorname{Com}(L, V) \subseteq \operatorname{Cent}(L, V)$.
Take $f \in \operatorname{Com}(L, V)$. Note that $Z_{V}(L) \subseteq Z_{V}\left(L^{\prime}\right)=0$. Then $f([x, y])=\alpha(x) f(y)$ by Lemma 4.2, so $f \in \operatorname{Cent}(L, V)$.

Now we would like to describe $\operatorname{Com}(L, V)$, which need the following notions of central and special commuting linear maps.

Definition 4.4. Let $(L, \alpha)$ be a Hom-Lie algebra and $(V, \rho, \beta)$ an $(L, \alpha)$-module. A commuting linear map $f \in \operatorname{Com}(L, V)$ is called central if

$$
f(L) \subset Z_{V}(L)
$$

$f$ is called special if

$$
f(L) \subset Z_{V}\left(L^{\prime}\right) \text { and } f\left(L^{\prime}\right)=0
$$

Denote by $\operatorname{CCom}(L, V)$ and $\operatorname{SCom}(L, V)$ the sets consisting of all central and special commuting linear maps in $\operatorname{Com}(L, V)$, respectively.

Clearly, every linear map $f: L \rightarrow Z_{V}(L)$ satisfying $\beta \circ f=f \circ \alpha$ is automatically a central commuting linear map.

Note that $Z_{V}(S)$ is a submodule of $V$ when $S$ is an ideal of $(L, \alpha)$ such that $\alpha(S)=S$. In fact, for any $s \in S$ and $v \in Z_{V}(S)$, there exists $t \in S$ satisfying $s=\alpha(t)$. Then $Z_{V}(S)$ is $\beta$-invariant by

$$
s \beta(v)=\alpha(t) \beta(v)=\beta(t v)=0
$$

$Z_{V}(S)$ is $L$-invariant by

$$
s x v=\alpha(t) x v=[t, x] \beta(v)+\alpha(x) t v=0, \forall x \in L .
$$

Now consider a Hom-Lie algebra $(L, \alpha)$ with $\alpha$ surjective. Since $L^{\prime}$ is an ideal of $(L, \alpha)$, $Z_{V}\left(L^{\prime}\right)$ becomes a submodule of $(V, \rho, \beta)$, which induces a quotient module $\left(V / Z_{V}\left(L^{\prime}\right), \bar{\rho}, \bar{\beta}\right)$. Then for any $f \in \operatorname{Com}(L, V)$, we can define $\bar{f} \in \operatorname{Com}\left(L, V / Z_{V}\left(L^{\prime}\right)\right)$ by $\bar{f}(x)=f(x)+Z_{V}\left(L^{\prime}\right)$.

If $f_{1}, f_{2} \in \operatorname{Com}(L, V)$ such that $\bar{f}_{1}=\bar{f}_{2}$, then $f:=f_{1}-f_{2}$ satisfies $f(L) \subset Z_{V}\left(L^{\prime}\right)$. Note that

$$
0=\alpha([x, y]) f(z)=-\alpha(z) f([x, y]), \forall x, y, z \in L,
$$

which implies $f\left(L^{\prime}\right) \subset Z_{V}(L)$. Let $\hat{f}: L \rightarrow Z_{V}(L) \in \operatorname{Com}(L, V)$ such that $\left.\hat{f}\right|_{L^{\prime}}=\left.f\right|_{L^{\prime}}$. Then $\tilde{f}:=f-\hat{f}$ satisfies

$$
\tilde{f}\left(L^{\prime}\right)=0 \text { and } \tilde{f}(L) \subset Z_{V}\left(L^{\prime}\right),
$$

that is, $\tilde{f} \in \operatorname{SCom}(L, V)$. Hence $f=f_{1}-f_{2}=\hat{f}+\tilde{f} \in \operatorname{CCom}(L, V)+\operatorname{SCom}(L, V)$. Then we prove the following property.

Proposition 4.5. Let $(L, \alpha)$ be a Hom-Lie algebra with $\alpha$ surjective and $(V, \rho, \beta)$ an $(L, \alpha)$ module. Up to $\operatorname{CCom}(L, V)+\operatorname{SCom}(L, V)$, the map $f \rightarrow \bar{f}$ is a 1-1 map from $\operatorname{Com}(L, V)$ to $\operatorname{Com}\left(L, V / Z_{V}\left(L^{\prime}\right)\right)$.

Hence, in case $(V, \rho, \beta)$ is an $(L, \alpha)$-module with $\alpha$ surjective, $\operatorname{Com}(L, V)$ are determined by $\operatorname{CCom}(L, V), \operatorname{SCom}(L, V)$ and $\operatorname{Com}\left(L, V / Z_{V}\left(L^{\prime}\right)\right)$. Then we could give an algorithm for describing $\operatorname{Com}(L, V)$ as follows. Define a sequence of quotient modules

$$
\left(V^{[0]}, \rho^{[0]}, \beta^{[0]}\right)=(V, \rho, \beta), \cdots,\left(V^{[r+1]}, \rho^{[r+1]}, \beta^{[r+1]}\right)=\left(V^{[r]} / Z_{V^{[r]}}\left(L^{\prime}\right), \overline{\rho^{[r]}}, \overline{\left.\beta^{[r]}\right]}\right)
$$

If there exists $r \in \mathbb{N}$ such that $Z_{V[r]}\left(L^{\prime}\right)=\{0\}$, then $\operatorname{Com}(L, V)$ are determined by $\operatorname{Com}\left(L, V^{(i)}\right)$, $\operatorname{SCom}\left(L, V^{(i)}\right)(0 \leq i \leq r-1)$ and $\operatorname{Com}\left(L, V^{[r]}\right)$, where $\operatorname{Com}\left(L, V^{[r]}\right)$ is precisely $\operatorname{Cent}\left(L, V^{[r]}\right)$ in case $\beta$ is required to be invertible.

Now we apply our method to a concrete example.
Example 4.6. Let $(L, \alpha)$ be the multiplicative Hom-Lie algebras in Example 3.14 with $\alpha=$ $\left(\begin{array}{ccc}1 & 0 & 0 \\ 0 & \lambda & 0 \\ 0 & 0 & \mu\end{array}\right)$ and $(V, \rho, \beta)=\left(L, \operatorname{ad}_{k}, \alpha\right)$. Let's determine $\operatorname{Com}\left(L, \mathrm{ad}_{k}\right)$.

Note that $L^{\prime}=\mathbb{F} y$ and $Z_{L}\left(L^{\prime}\right)=\mathbb{F} y \oplus \mathbb{F} z$. Then $\left(L^{[1]}, \mathrm{ad}_{k}^{[1]}, \alpha^{[1]}\right)=(\mathbb{F} \bar{x}, 0, \mathrm{id})$. For $f^{[1]} \in$ $\operatorname{Com}\left(L, L^{[1]}\right)$, suppose

$$
\begin{equation*}
f^{[1]}(x)=k_{1} \bar{x}, f^{[1]}(y)=k_{2} \bar{x}, f^{[1]}(z)=k_{3} \bar{x} . \tag{4.3}
\end{equation*}
$$

Then $f^{[1]}$ clearly satisfies $\left[\overline{\alpha^{k+1}(x)}, f^{[1]}(x)\right]=\left[\overline{\alpha^{k+1}(y)}, f^{[1]}(y)\right]=\left[\overline{\alpha^{k+1}(z)}, f^{[1]}(z)\right]=\overline{0} ; f^{[1]}$ satisfies id $\circ f^{[1]}=f^{[1]} \circ \alpha$, iff

$$
\begin{equation*}
k_{2}(\lambda-1)=k_{3}(\mu-1)=0 \tag{4.4}
\end{equation*}
$$

Hence every $f^{[1]} \in \operatorname{Com}\left(L, L^{[1]}\right)$ is defined by (4.3) and (4.4).
Suppose that $f \in \operatorname{Com}\left(L, \mathrm{ad}_{k}\right)$ such that $\bar{f}=f^{[1]}$. Set $f(y)=k_{2} x+k_{2}^{\prime} y+k_{2}^{\prime \prime} z$. Then $k_{2}=0$, which follows from

$$
0=\left[\alpha^{k+1}(y), f(y)\right]=\left[\lambda^{k+1} y, k_{2} x+k_{2}^{\prime} y+k_{2}^{\prime \prime} z\right]=-k_{2} \lambda^{k+1} y
$$

Hence $f^{[1]} \in \operatorname{Com}\left(L, L^{[1]}\right)$ is induced from some $f \in \operatorname{Com}\left(L, \operatorname{ad}_{k}\right)$ only if $f^{[1]} \in \operatorname{Com}\left(L, L^{[1]}\right)$ is defined by (4.3) such that $k_{3}(\mu-1)=0$. Define a linear map $f: L \rightarrow L$ by

$$
f(x)=k_{1} x, f(y)=0, f(z)=k_{3} x,\left(k_{1}, k_{3} \in \mathbb{F}, k_{3}(\mu-1)=0\right) .
$$

It is straightforward to verify that $f \in \operatorname{Com}\left(L, \operatorname{ad}_{k}\right)$.
Now it remains to compute $\operatorname{CCom}\left(L, \operatorname{ad}_{k}\right)$ and $\operatorname{SCom}\left(L, \operatorname{ad}_{k}\right)$. Let $\hat{f} \in \operatorname{CCom}\left(L, \operatorname{ad}_{k}\right)$ and $\tilde{f} \in \operatorname{SCom}\left(L, \operatorname{ad}_{k}\right)$. Since $Z_{L}(L)=\mathbb{F} z, L^{\prime}=\mathbb{F} y$ and $Z_{L}\left(L^{\prime}\right)=\mathbb{F} y \oplus \mathbb{F} z$, set

$$
\begin{gathered}
\hat{f}(x)=l_{1} z, \hat{f}(y)=l_{2} z, \hat{f}(z)=l_{3} z \\
\tilde{f}(x)=a_{11} y+a_{21} z, \tilde{f}(y)=0, \tilde{f}(z)=a_{12} y+a_{22} z
\end{gathered}
$$

By a direct computation, $\hat{f}$ is a commuting linear map iff $l_{1}(\mu-1)=l_{2}(\lambda-\mu)=0 ; \tilde{f}$ satisfies $\left[\alpha^{k+1}(x), \tilde{f}(x)\right]=\left[\alpha^{k+1}(y), \tilde{f}(y)\right]=\left[\alpha^{k+1}(z), \tilde{f}(z)\right]=0$ iff $a_{11}=0 ; \tilde{f}$ satisfies $\alpha \circ \tilde{f}=\tilde{f} \circ \alpha$, iff

$$
a_{11}(\lambda-1)=a_{21}(\mu-1)=a_{12}(\lambda-\mu)=0 .
$$

Hence, $\tilde{f}$ is of the form

$$
\tilde{f}(x)=a_{21} z, \tilde{f}(y)=0, \tilde{f}(z)=a_{12} y+a_{22} z
$$

where $a_{21}, a_{12}, a_{22} \in \mathbb{F}$ such that $a_{21}(\mu-1)=a_{12}(\lambda-\mu)=0$.
Therefore, every $f \in \operatorname{Com}\left(L, \mathrm{ad}_{k}\right)$ is of the form

$$
f(x)=c_{1} x+c_{2} z, f(y)=c_{3} z, f(z)=c_{4} x+c_{5} y+c_{6} z
$$

for all $c_{1}, c_{2}, c_{3}, c_{4}, c_{5}, c_{6} \in \mathbb{F}$ such that

$$
c_{2}(\mu-1)=c_{3}(\lambda-\mu)=c_{4}(\mu-1)=c_{5}(\lambda-\mu)=0 .
$$

Finally, we would like to describe the relationship between skew-symmetric biderivations and commuting linear maps on a Hom-Lie algebra $(L, \alpha)$ for the adjoint module $\left(L, \mathrm{ad}_{k}, \alpha\right)$.

Proposition 4.7. Let $(L, \alpha)$ be a Hom-Lie algebra with $\alpha$ invertible and $\left(L, \mathrm{ad}_{k}, \alpha\right)$ an adjoint $(L, \alpha)$-module such that every $\delta \in \operatorname{Bider}_{\mathrm{s}}\left(L, \mathrm{ad}_{k}\right)$ is of the form $\delta(x, y)=\alpha^{-1} \gamma([x, y])$, where $\gamma \in \operatorname{Cent}\left(L, \mathrm{ad}_{k}\right)$. Then every $f \in \operatorname{Com}\left(L, \mathrm{ad}_{k}\right)$ is of the form $f=\gamma+\mu$ for some $\gamma \in \operatorname{Cent}\left(L, \operatorname{ad}_{k}\right)$ and $\mu \in \operatorname{CCom}\left(L, \mathrm{ad}_{k}\right)$.

## Proof. Define

$$
\delta(x, y)=\alpha^{-1}\left[\alpha^{k+1}(x), f(y)\right],
$$

which belongs to $\operatorname{Bider}_{\mathrm{s}}\left(L, \mathrm{ad}_{k}\right)$, by the proof of Lemma4.2 when $(V, \rho, \beta)$ is taken as $\left(L, \mathrm{ad}_{k}, \alpha\right)$.
Thus there exists $\gamma \in \operatorname{Cent}\left(L, \operatorname{ad}_{k}\right)$ such that $\gamma([x, y])=\alpha \boldsymbol{\delta}(x, y)=\left[\alpha^{k+1}(x), f(y)\right]$. Note that $\gamma([x, y])=\left[\alpha^{k+1}(x), \gamma(y)\right]$, which implies $\left[\alpha^{k+1}(x),(f-\gamma)(y)\right]=0$, then $f-\gamma \in \operatorname{Com}\left(L, \operatorname{ad}_{k}\right)$.
