On a probabilistic approach to synthesize control policies from example datasets

Davide Gagliardi, Giovanni Russo

Abstract

This paper is concerned with the design of control policies from example datasets. The case considered is when just a black box description of the system to be controlled is available and the system is affected by actuation constraints. These constraints are not necessarily fulfilled by the (possibly, noisy) example dataset and the system under control is not necessarily the same as the one from which this dataset is collected. In this context, we introduce a number of theoretical results to compute a control policy from example datasets that: (i) makes the behavior of the closed-loop system similar to the one illustrated in the dataset; (ii) guarantees compliance with the constraints. We recast the control problem as a finite-horizon optimal control problem and give an explicit expression for its optimal solution. Moreover, we turn our findings into an algorithmic procedure. The procedure gives a systematic tool to compute the policy. The effectiveness of our approach is illustrated via a numerical example, where we use real data collected from test drives to synthesize a control policy for the merging of a car on a highway.

1 Introduction

Model-based control is a key paradigm to design control systems: the design of platoons (Stüdi et al., 2017), fault tolerant (LeBlanc et al., 2013) and biochemical systems (DelVecchio et al., 2018) are just few of the frontier applications where this approach has been successfully used. Unfortunately, detailed mathematical models in the form of e.g. differential/difference equations, are not always available and, when available, can be hard to identify. Hence, a paradigm that is becoming increasingly popular is to synthesize control policies directly from data, see e.g. (De Persis and Tesi, 2020; Van Waarde et al., 2020; Hou and Wang, 2013) and references therein.

As noted in these papers, this approach aims at designing policies while bypassing the need to devise/identify a mathematical model and can be useful in applications where first-principle models cannot be obtained and/or system identification is too computationally expensive.

An appealing framework to design controllers from data is that of using example datasets. This learning from demonstrations approach involves learning actions by observing an expert (Hanawal et al., 2019; Wabersich and Zeilinger, 2018; Zhu et al., 2020). In this context, we consider the key challenge of designing control policies from noisy example datasets for systems affected by actuation constraints. These constraints might not be fulfilled by the behavior observed in the example dataset and, in turn, the system used to collect such dataset might be different from the one under control. Motivated by this, we aim at synthesizing control policies that make the behavior of the closed loop system similar to the behavior in the example dataset while fulfilling the system-specific actuation constraints. This is done for systems for which just a probabilistic characterization is known, without requiring that the constraints are fulfilled in the example dataset and that the system used to collect such dataset is the same as the system under control. Situations where our results are of interest naturally arise in the context of e.g. autonomous urban driving, where one is often interested in designing policies from driving examples of multiple drivers (Bansal et al., 2018), while ensuring that the control (e.g. speed, acceleration) signal fulfills certain properties with some acceptable/design probability level (Vitus and Tomlin, 2013). We now briefly survey some related works on data-driven control and learning from example datasets.

Data-driven control. As noted in e.g. (De Persis and Tesi, 2020; Van Waarde et al., 2020), work on data-driven control can be traced back to (Ziegler and Nichols, 1942) and their results on the tuning of PID controllers. Re-
cently, driven by the explosion in the amount of available data, the problem of finding control policies from datasets has gained increasing attention, see e.g. [Hou and Xu, 2009]. For example, [Van Waarde et al., 2020] studies data-driven control in LTI systems when the data available are not persistently exciting and where, therefore, it is impossible to perform subspace identification. Recent works also include [Tanaskovic et al., 2017], where a direct data-driven design approach is introduced for discrete-time stabilizable systems with Lipschitz nonlinearities and e.g. [Markovsky and Rapisarda, 2007] Gonçalves da Silva et al., [2019] Baggio et al., [2019] that consider the problem of designing controllers for systems that have an underlying linear dynamics. We also recall here [De Persis and Tesi, 2020] that derives a parametrization of linear feedback systems using data-dependent linear matrix inequalities. Besides works on e.g. data-based tuning of PID controllers [Keel and Bhattacharyya, 2008] other remarkable results have been obtained by taking inspiration from the rich literature on Model Predictive Control (MPC). These include [Rosolia and Borrelli, 2018], where an MPC learning algorithm is introduced for iterative tasks when the system dynamics is partially known, [Salvador et al., 2018] where a data-based predictive control algorithm is presented for unknown time-invariant systems and [Conlon et al., 2019a,b], that, by taking a behavioral systems perspective, introduce a data-enabled predictive control algorithm for data generated by LTI systems.

Learning from example datasets. At their roots, learning from demonstration techniques largely rely on inverse optimal control [Bryson, 1996]. Nowadays, these techniques, which essentially aim at finding/improving a policy from an initial demonstration dataset [Bertsekas, 2021], are recognized as a convenient framework to learn parametrized policies from success stories [Argall et al., 2009] and potential applications include planning [Englert et al., 2017] and medical prescriptions learning [Xu and Paschalidis, 2019]. There is then no surprise that, over the years, a number of techniques have been developed to tackle the problem of learning parametrized control policies from demonstrations, mainly in the context of Markov Decision Processes [Sutton and Barto, 1998]. Results include [Hanawal et al., 2019] where parametrized policies consistent with data for a Markov decision process are learned via regularized logistic regression and regret bounds are given, [Ratliff et al., 2009], which leverages a linear programming approach, [Ratliff et al., 2006] which relies on a maximum margin approach, [ziebart et al., 2008] that makes use of the maximum entropy principle, [Ramachandran and Amir, 2007] that formalizes the problem via Bayesian statistics and [Abbeel and Ng, 2004], where rewards are learned by expressing them as a combination of known features. We also recall the recent [Edwards et al., 2019], where an approach based on characterizing causal effects of latent actions is proposed to tackle imitation learning problems. A Bayesian approach [Peterka, 1981] to dynamical systems is also at the basis of works such as [Kárný, 1996] Kárný and Guy, [2006] Herzallah, [2015] Pegueroles and Russo, [2019] Guy et al., 2018 Kárný and Kroupa, [2012] see also (Kappen et al., 2012; Todorov, 2009; 2007) and references therein, which formalize the control problem as the problem of minimizing a cost that captures the discrepancy between an ideal probability density function and the actual probability density function of the system under control. In this context, we also recall here (Russo, 2021) Garrabé and Russo, 2021, where policies are obtained from the minimization of similar costs by leveraging multiple, specialized, datasets.

Contributions of this paper

We introduce a framework to design policies from example datasets for systems for which just a probabilistic description is known. Specifically, we consider the case where the system under control has actuation constraints that are not necessarily fulfilled in the example dataset and the system used to collect such dataset is not necessarily the same as the system under control. With our results, we aim at synthesizing control policies that make the behavior of the closed loop system similar (in a sense defined in Section 3.1) to the one seen in the example dataset, while still fulfilling the system-specific actuation constraints. To the best of our knowledge, the formulation presented here is novel and these are the first results to synthesize control policies from example datasets for systems affected by actuation constraints that, simultaneously: (i) do not require assumptions on the linearity of the underlying stochastic dynamics that is generating the data; (ii) allow for the example dataset to be noisy and collected from a system that is not necessarily the same as the one that is under control; (iii) do not need the actuation constraints to be necessarily fulfilled in the example dataset; (iv) do not need an a-priori parametrization of the policy. In the context of the above literature, our key technical contributions are summarized as follows:

- we recast the control problem as a constrained infinite dimensional, finite-horizon, optimal control problem. The decision variables of the problem are probability density functions and the constraints are linear functionals in these densities. The formulation allows to consider control problems where the actuation constraints affecting the system are not fulfilled in the example dataset and where the system used to collect the example dataset is not necessarily the same as the system under control;
- we introduce a number of theoretical results to tackle the control problem. Specifically, we prove that the finite-horizon optimal control problem can be split into infinite-dimensional sub-problems, with each of these sub-problems having a probability density (i.e. the control policy) as decision variable. After showing that each of the sub-problems
is convex, we solve them explicitly. By leveraging this, we show that the control problem can be solved iteratively via a backward recursion. This leads to an explicit expression of the optimal policy. These novel results allow to consider systems for which the underlying dynamics can be unknown, nonlinear and stochastic. Further, the results do not need an a-priori policy parametrization;

• the results are turned into an algorithmic procedure to compute, without requiring a-priori parametrizations, the optimal policy solving our control problem;

• we illustrate the effectiveness of the results via a numerical example that involves the use of real data.

The paper is organized as follows. After introducing some mathematical preliminaries in Section 2, we formalize the control problem (Problem 1, in Section 3). This problem is solved with the technical results presented in Section 4 (some of the proofs are in the appendix). Specifically, in this section we first introduce, and discuss, an auxiliary problem (i.e. Problem 2). With Lemma 1 we then give an explicit expression for the optimal solution of Problem 2 and this result is used iteratively to prove Theorem 1, which gives the optimal solution to Problem 1. We conclude Section 4 by highlighting a connection between our approach and maximum likelihood density estimation to solve Problem 1. We conclude Section 4 by highlighting a connection between our approach and maximum entropy. The results are turned into an algorithmic procedure (Section 5) and a numerical example is presented in Section 6. Concluding remarks are given in Section 7.

2 Mathematical Preliminaries

Sets, as well as operators, are denoted by calligraphic characters, while vector quantities are denoted in bold. Random (row) vectors (i.e. a multidimensional random variable) are denoted by upper-case bold letters and their realization is denoted by lower-case bold letters. For example, \( Z \) denotes a multi-dimensional random variable and its realization is denoted by \( z \). The probability density function (or simply pdf) in what follows) of a continuous \( Z \) is denoted by \( f(z) \). The support of \( f(z) \) is denoted by \( S(f) \) and, analogously, the expectation of a function \( h(\cdot) \) of \( Z \) is indicated with \( \mathbb{E}_f[h(Z)] \) and defined as \( \mathbb{E}_f[h(Z)] := \int_{S(f)} h(z) f(z) dz \). For notational convenience, whenever it is clear from the context, we omit the domain of integration in the integral. We also remark here that: (i) whenever we apply the averaging operator to a given function, we use an upper-case letter for the function argument as this is a random vector; (ii) to stress the linearity of certain functionals or operators with respect to a specific argument, we include that argument in square brackets. The joint pdf of two (non independent) random vectors, say \( Z \) and \( Y \), is denoted by \( f(z,y) \). The conditional probability density function (or cpdf in what follows) of \( Z \) with respect to \( Y \) is denoted by \( f(z|y) \) and, whenever the context is clear, we use the shorthand notation \( f_z \). Finally, given \( Z \subseteq \mathbb{R}^{n_z} \), its indicator function is denoted by \( \mathbb{I}_Z(z) \). That is, \( \mathbb{I}_Z(z) = 1, \forall z \in Z \) and 0 otherwise. We also make use of the internal product between tensors, which is denoted by \( \langle \cdot, \cdot \rangle \), while \( \mathcal{A} \backslash \mathcal{B} \) is the set difference between \( \mathcal{A} \) and \( \mathcal{B} \). We indicate (ordered) countable sets as \( \{ w_k \}_k := \{ w_k \}_{k=k_1}^{k_n} \), where \( w_k \) is the generic element belonging to the set and \( k_1, k_n \) are the indices of the first and last element respectively.

3 Formulation of the Control Problem

Let: (i) \( \mathcal{K} := \{ k \}_{k=1}^{n} \) and \( \mathcal{K}_0 := \mathcal{K} \cup \{ 0 \} \) and \( \mathcal{T} := \{ t_k : k \in \mathcal{K}_0 \} \); (ii) \( x_k \in \mathbb{R}^{n_x} \) and \( u_k \in \mathbb{R}^{n_u} \) be, respectively, the system state and input at time \( t_k \in \mathcal{T} \); (ii) \( \Delta_k := \{ x_k, u_k \} \) be the dataset collected from the system at time \( t_k \in \mathcal{T} \) and \( \Delta^k \) the dataset collected from \( t_0 \in \mathcal{T} \) up to time \( t_k \in \mathcal{T} \) (\( t_k > t_0 \)). See also [Peterka, 1981], where it is shown that the system behavior can be described via the joint pdf of the observed dataset, say \( f(\Delta^k) \). Moreover, by making the standard assumption that Markov’s property holds (Kárny, 1996), the...
chain rule for pdfs leads to the following factorization for \( f(\Delta^n) \):

\[
f(\Delta^n) = \prod_{k \in K} f(x_k | u_k, x_{k-1}) f(u_k | x_{k-1}) f(x_0).
\]  

(3)

Throughout this work we refer to (3) as the probabilistic description of the closed loop system, or we simply say that (3) is our closed loop system.

**Remark 1** The cpdf \( f(x_k | u_k, x_{k-1}) \) describes the system behavior at time \( t_k \), given the previous state and the input at time \( t_k \). The input is generated by the cpdf \( f(u_k | x_{k-1}) \). This is a randomized control policy returning the input given the previous state. Note that the initial conditions are embedded in the probabilistic system description through the prior \( f(x_0) \).

In the rest of the paper we use the following shorthand notations: \( \tilde{f}_k^k := f(x_k | u_k, x_{k-1}), \tilde{f}_U^k := f(u_k | x_{k-1}), \tilde{f}^k := \tilde{f}_X^k \tilde{f}_U^k, f_0 := f(x_0) \) and \( f^n := f(\Delta^n) \). Hence, (3) can be compactly written as

\[
f^n = \left( \prod_{k \in K} \tilde{f}_X^k \tilde{f}_U^k \right) f_0.
\]  

(4)

### 3.1 The control problem

Our goal is to synthesize, from an example dataset, say \( \Delta^n \), the control pdf/policy, i.e. \( \tilde{f}_U^k \), that: (i) makes the closed loop system similar to the behavior illustrated in the dataset; (ii) satisfies the system actuation constraints even if these are not fulfilled by the examples. We specify the behavior illustrated in the examples through the reference pdf \( g(\Delta^n) \) extracted from the example dataset. Note that \( g(\Delta^n) \) can always be computed as e.g. the empirical distribution of the available dataset. By means of Markov’s property and the chain rule for pdfs we have \( g(\Delta^n) := \prod_{k \in K} g(x_k | u_k, x_{k-1}) g(u_k | x_{k-1}) g(x_0) \). Again, by setting \( \tilde{g}_X^k := g(x_k | u_k, x_{k-1}), \tilde{g}_U^k := g(u_k | x_{k-1}), \tilde{g}^k := \tilde{g}_X^k \tilde{g}_U^k, g_0 := g(x_0) \) and \( g^n := g(\Delta^n) \) we get:

\[
g^n = \left( \prod_{k \in K} \tilde{g}_X^k \tilde{g}_U^k \right) g_0.
\]  

(5)

We note that the pdf \( \tilde{g}_X^k \) is not necessarily the same as the pdf \( \tilde{f}_X^k \). This allows to consider situations of practical interest where e.g. the system used to collect the example dataset is not necessarily the same as the system under control. The control problem, formalized next, can then be recast as the problem of designing \( \tilde{f}_U^k \) so that \( f^n \) (i.e. the probabilistic description of the closed loop system) approximates \( g^n \) (i.e. the joint pdf extracted from the example dataset). This is formally stated as follows:

**Problem 1** Let, \( \forall k \in K \):

(i) \( n^k_1 \) and \( n^k_2 \) be positive integers;

(ii) \( h_{u,j}^k : U_k \subseteq \mathbb{R}^{n^k_1} \to \mathbb{R}, j = 1, \ldots, n^k_1 + n^k_2 \), be measurable mappings from \( U_k \subseteq \mathbb{R}^{n^k_1} \) into \( \mathbb{R} \);

(iii) \( H^k_{u,j} \in \mathbb{R}, j = 1, \ldots, n^k_1 + n^k_2 \), be constants;

(iv) \( h^k_{u,0} : = 1 \).

Find \( \{ \tilde{f}_U^k \}^K \in \text{arg min}_{\{ f_0^K \}} \mathcal{D}_{KL}(f^n || g^n) \)

s.t.: \( \tilde{g}_{u,j}^k \left[ \tilde{f}_U^k \right] = 0, \forall j \in \mathcal{E}^k_0, k \in K \),

\[
\tilde{g}_{u,j}^k \left[ \tilde{f}_U^k \right] \leq 0, \forall j \in \mathcal{T}^k, k \in K
\]  

(6)

where

\[
\tilde{g}_{u,j}^k \left[ \tilde{f}_U^k \right] := \mathbb{E}_{\tilde{f}_U^k} [h_{u,j}^k(U_k) - H_{u,j}^k]
\]  

(7)

and where \( \mathcal{E}^k_0 := \mathcal{E}^k \cup \{ 0 \} \) with \( \mathcal{E}^k := \{ j \}_{1}^{n^k_1} \), \( \mathcal{T}^k := \{ j \}_{n^k_1+1}^{n^k_1+n^k_2} \) are the equality and inequality constraints index sets at time \( t_k \) respectively.

The constraints in Problem 1 are specific to the system under control and we do not make any assumption on the fact that the behavior observed in the example dataset fulfills these constraints. We make the following remarks:

**Remark 2** Since the pdf \( \tilde{g}_X^k \) can be different from \( \tilde{f}_X^k \), we have that \( \tilde{g}_U^k \) is not, in general, the optimal solution to Problem 1. Further, since \( \tilde{g}_X^k \) might not satisfy the constraints in Problem 1, this pdf might not be feasible for the problem. The explicit expression for the optimal solution to Problem 1 is instead given in Theorem 1 and, as we shall see, it depends on \( \tilde{g}_U^k \).

**Remark 3** The control problem is cast as the problem of designing \( \tilde{f}_U^k \) so that \( \mathcal{D}_{KL}(f^n || g^n) \) is minimized, subject to the constraints. In this sense, the policy is designed so that \( f^n \) approximates \( g^n \) while still fulfilling the constraints. With Theorem 1 we give an explicit expression for the optimal solution \( \{ \tilde{f}_U^k \}^K \). The control input, say \( u_k \), applied to the system at time-step \( k \) is obtained by sampling from the pdf \( \{ \tilde{f}_U^k \}^K \).
update rules as the Linear Quadratic Regulator. The introduction of the constraints formalized in Problem 1 can be useful in situations of practical interest where the actuation capabilities of the system are different from the actuation capabilities of the system used to collect the example dataset and/or in situations where the example data are collected without necessarily knowing the specific constraints of the system under control. Also, by embedding actuation constraints into the problem formulation and by solving the resulting problem, one can export the policy (by e.g. using it to generate example simulation and by solving the resulting problem, one can embedding actuation constraints into the problem for the example dataset and/or in situations where the actuation capabilities of the system used to collect the dataset(s) that has been synthesized on a given system to other systems having different actuation capabilities.

As we shall see, the solution to Problem 1 depends on the conditional pdf $f_k^U$, i.e. the cpdf describing the behavior of the system under control, which therefore needs to be properly estimated. Hence, as for other data-driven control approaches that rely solely on the available data, these need to be sufficiently informative. We refer to e.g. Van Waarde et al. (2020), De Persis and Tesi (2020), van Waarde et al. (2020), Colin et al. (2020) for recent results on data informativity and to (van Waarde et al. 2021; Karlin and Studden 1966) for results on optimal experimental design and persistency of excitation.

**Remark 4** In Problem 1, the constraints are formalized as expectations and can be equivalently written as $\int_{\mathbb{R}_+^n} f^k U h^k_{i,j}(u) \, du = H^k_{i,j}$. The equality and inequality constraints, and their number, can change over time. In Problem 1, $n_k^e$ and $n_k^i$ denote, respectively, the number of equality and inequality constraints at time-step $k$ (see the definitions of the sets $E^k$ and $I^k$ in the problem statement). Finally, the first equality constraint is a normalization constraint on the solution of the problem.

**Remark 5** The constraints in (6) can be used to guarantee properties on e.g. the moments of the cpdfs $\left( f_k^U \right)^*$, i.e. on the optimal solution of the problem (see also Remark 9 and Remark 10). Additionally, we note that the inequality constraints in (6) can be used to capture bound constraints of the form $\mathbb{P}(U_k \in U_k) \geq 1 - \varepsilon$, where $U_k \subset U_k$ and $\varepsilon \geq 0$. Indeed, note that: $\mathbb{P}(U_k \in U_k) = \int_{\mathbb{R}_+^n} 1_{U_k}(u_k) f_k^U \, du_k = \mathbb{E}_U^k \left[ 1_{U_k}(U_k) \right]$. Hence, the constraint $\mathbb{P}(U_k \in U_k) \geq 1 - \varepsilon$ can be written as a constraint of the form of these in (6). Typically, in works on safe learning for stochastic systems, see e.g. McKinnon and Schoellig (2019), Nakka et al. (2021), $\varepsilon$ is a small constant and hence these types of constraints model the fact that the probability that the control variable is outside some (e.g. desired) set $U_k$ is smaller than some acceptable $\varepsilon$. When $\varepsilon = 0$, the constraint amounts at imposing that $\mathbb{P}(U_k \in U_k) = 1$, thus implying that the pdf $f_k^U$ is zero outside the set $U_k$.

**Remark 6** In relation to Remark 5, we also note how the constraint $\mathbb{P}(U_k \in U_k) = \mathbb{E}_U^k \left[ 1_{U_k}(U_k) \right] \geq 1 - \varepsilon$ is linear, and hence convex, in the decision variable even if the indicator function is not convex, see e.g. (Vitus and Tomlin 2013). This implies that, in Problem 1, these constraints can be handled without resorting to bound approximations. These approximations are typically used in the literature to handle the intrinsic non-convexity of the constraint arising in problems where the decision variable is $U_k$, see e.g. (Vitus and Tomlin 2013; Moser et al. 2017). Note indeed that, while $\mathbb{E}_{f_k^U} \left[ 1_{U_k}(U_k) \right]$ is convex in $f_k^U$, this is not convex in $U_k$.

4 Technical Results

We now introduce our main results. The key result behind the algorithm of Section 5 is Theorem 1. The proof of this theorem, given in this section, makes use of two technical results (i.e. Lemma 1 and Lemma 2). With our first result, i.e. Lemma 1, we tackle an auxiliary problem that is iteratively solved within the proof of Theorem 1. This auxiliary problem is formalized next.

**Problem 2** Let:

(i) $n_c, n_l$ be two positive integers;
(ii) $Z$ be a random vector, with $z \in Z \subseteq \mathbb{R}^{n_z}$;
(iii) $g(z)$ and $f(z)$ be two pdfs having support $Z$;
(iv) $\alpha : Z \mapsto \mathbb{R}$ be a mapping from $Z$ into $\mathbb{R}$, which is integrable under the measure given by $f(z)$;
(v) $h_j : Z \mapsto \mathbb{R}$, $j = 1, \ldots, n_c + n_l$, be measurable mappings from $Z$ into $\mathbb{R}$;
(vi) $H_j \in \mathbb{R}$, $j = 1, \ldots, n_c + n_l$, be a constant;
(vii) $h_0(z) := 1_Z(z)$ and $H_0 := 1$.

Find the pdf $f^*(z)$ such that:

$$f^*(z) \in \arg \min_{f(z)} \mathcal{L}(f(z))$$

s.t.: $c_j \left[ f(z) \right] = 0$, $\forall j \in \mathcal{E}_0$ \hspace{1cm} (8)

$$c_j \left[ f(z) \right] \leq 0$, $\forall j \in \mathcal{I}$$

where:

$$\mathcal{L}(f(z)) := D_{KL}(f(z)|g(z)) + \int f(z) \alpha(z) \, dz,$$ \hspace{1cm} (9)

with

$$c_j \left[ f(z) \right] := \int f(z) \, h_j(z) \, dz - H_j,$$ \hspace{1cm} (10)

and $\mathcal{E}_0 := \mathcal{E} \cup \{0\}$, $\mathcal{E} := \{j\}_{i=1}^{n_c}$, $\mathcal{I} := \{j\}_{i=n_c+1}^{n_c+n_l}$.

In Lemma 1 we give the optimal solution of Problem 2. Such a result is used in Theorem 1 to find the solution
to Problem 1. Consider the special case where, in Problem 1: (i) the function \( a(\cdot) \) is constant in \( Z \); (ii) the support \( Z \) is compact and \( g(\cdot) \) is uniform. Then, the cost in Problem 2 becomes \( \mathcal{L}(f(z)) = \int f(z) \log g(z) \, dz \). Hence, in this case, Problem 2 becomes a constrained entropy maximization problem. See also Remark 13. We consider feasible sets of constraints that satisfy the following constraint qualification condition (CQC):

**Definition 2** Consider the set of linear constraints

\[
\begin{align*}
    c_i[f(z)] &= 0, \quad i = 1, \ldots, n_c, \\
    c_j[f(z)] &\leq 0, \quad j = 1, \ldots, n_l.
\end{align*}
\]

The Slater’s CQC (or simply Slater’s condition in what follows) is said to hold for such a set if there exists a pdf, say \( f(z) \), such that \( c_i[f(z)] = 0, \forall i \in \{1, \ldots, n_c\} \) and \( c_j[f(z)] < 0, \forall j \in \{1, \ldots, n_l\} \).

**Remark 7** Slater’s condition is also known in the literature on infinite-dimensional optimization problems as a regularity condition on the constraint set \([\text{Rockafellar, 1976; Ben-Tal et al., 1988}].\) For a convex infinite-dimensional optimization problem, the fulfillment of such a condition guarantees strong duality \([\text{Ben-Tal et al., 1988; Nishiyama, 2020}].\)

We make the following:

**Assumption 1** The constraints sets in (6) and in (8) are feasible and satisfy Slater’s condition.

**Remark 8** Assumption 1 is widely used in the literature on e.g. infinite-dimensional optimization \([\text{Ben-Tal et al., 1988; Fan, 2018}].\) divergences optimization \([\text{Nishiyama, 2020}].\) and cross-entropy problems \([\text{Singh and Vishnoi, 2014; Bot et al., 2005,}].\) If the problems involve discrete constraints, then checking feasibility and the Slater’s condition implies solving (finite dimensional) systems of equalities and inequalities, see e.g. \([\text{Duffin et al., 1956; Fan, 1975; Hiebert, 1980; Censor and Elfving, 1982,}].\) For problems with continuous variables, an approach to check the condition consists in building an initial pdf for which equality constraints are satisfied and inequality constraints are satisfied strictly. This approach has been used in Section 6 to verify the fulfillment of Assumption 1 for our numerical example.

We are now ready to introduce the next result, which gives a solution to Problem 2.

**Lemma 1** Consider Problem 2. Then:

**(R1)** the problem has a unique solution and this is given by the pdf

\[
f^*(z) = g(z) \frac{e^{-\frac{\alpha(z)+\sum_j \in I_a(f^*(z)) \lambda^*_j h_j(z)}{\lambda^*_0}}}{e^{1+\lambda^*_0}}. \tag{11}
\]

In (11), \( \lambda^*_j \) is the Lagrange multiplier associated to the constraint \( c_j[f(z)] \) and \( I_a(f^*(z)) \) is the active index set defined as

\[
I_a(f) := E_0 \cup \{ j \in I : c_j[f] = 0 \}. \tag{12}
\]

In (11) the Lagrange multipliers

\[
\lambda^* := [\lambda^*_0, \lambda^*_1, \ldots, \lambda^*_n + n]^T,
\]

can be computed by solving the optimization problem

\[
\max_{\lambda} \mathcal{L}^D(\lambda) \quad \text{s.t.:} \quad \lambda_j \geq 0, \quad \forall j \in I
\]

where

\[
\mathcal{L}^D(\lambda) := -\langle \lambda, H \rangle - \int g(z) \, e^{-\{1+\alpha(z) + \langle \lambda, h(z) \rangle \}} \, dz. \tag{14}
\]

**(R2)** Moreover, the corresponding minimum is

\[
\mathcal{L}(f^*(z)) = - \left( 1 + \sum_{j \in I_a(f^*(z))} \lambda^*_j H_j \right). \tag{15}
\]

**Proof:** See the appendix. \( \square \)

Before introducing the next technical result, we make the following remarks on Lemma 1.

**Remark 9** The equality constraints in (10) can be used to impose parametric prescriptions on the solution. For example, one could impose that \( f^*(z) \) has the central moment of order \( i \) equal to some \( m^*_i z \). This is equivalent to impose that the solution satisfies \( \mathbb{E}_f(Z^i) = m^*_i z \), which in turn can be formalized as \( c_i[f(z)] := \int f(z) \, z^i \, dz = m^*_i z \).

These types of equality constraints, also arise within the literature on the approximation of spectral density functions with respect to the KL-divergence under moment constraints, where linear systems are typically considered. See e.g. \([\text{Georgiou and Lindquist, 2003; Pavon and Ferrante, 2006; Zhu and Baglio, 2019}].\)

**Remark 10** The inequality constraints in (10) can also be used to assign properties to the solution: with these constraints, one could express bounds on the expected value
of any function of \( Z \), say \( h(Z) \). For instance, the rectangular bound \( m_Z^2 \geq E[f(Z)] \leq M_Z^2 \) can be formalized with the pair of inequality constraints:

\[
\begin{align*}
c_a[f(Z)] & := \int f(z) z^2 \, dz - \overline{m}_Z^2, \\
c_b[f(Z)] & := -\int f(z) z^2 \, dz + \overline{m}_Z^2.
\end{align*}
\]

Remark 11 The Lagrange multiplier \( \lambda_0 \) in (11) can be expressed as a function of all the other Lagrange multipliers. This can be done by imposing the normalization constraint, i.e. \( c_0 \cdot f^*(Z) = 0 \), on the pdf solving the problem, i.e. (11). This yields:

\[
1 + \lambda_0 = \ln \left( \int g(z) e^{-\left\{ \alpha(z) + \sum_{j \in E \cup I} \lambda_j h_j(z) \right\}} \, dz \right).
\]

Note that (16) can also be obtained by imposing the stationarity condition of the Lagrange dual function with respect to \( \lambda_0 \). Also, the expression for \( \lambda_0 \) in (16) could be directly embedded in the dual cost function (14), yielding

\[
\mathcal{L}^D(\lambda) = -\sum_{j \in E \cup I} \lambda_j H_j - \ln \left( \int g(z) e^{-\left\{ \alpha(z) + \sum_{j \in E \cup I} \lambda_j h_j(z) \right\}} \, dz \right),
\]

and thus reducing by one the dimension of the search space of the dual problem.

We now introduce the following technical result that is also used in the proof of Theorem 1.

Lemma 2 Let \( f^n \) and \( g^n \) be the joint pdfs defined in (4) and (5), respectively. Then:

\[
\mathcal{D}_{KL}(f^n||g^n) = \mathcal{D}_{KL}(f^n-1||g^{n-1}) + \mathbb{E}_{f^{n-1}} \left[ \mathcal{D}_{KL}(\tilde{f}^n||\tilde{g}^n) \right],
\]

where \( \tilde{f}^n \) and \( \tilde{g}^n \) are the conditional pdfs defined as in Section 3, i.e. \( \tilde{f}^n := \tilde{f}^n_{\lambda} \tilde{f}^n_{\gamma} \) and \( \tilde{g}^n := \tilde{g}^n_{\lambda} \tilde{g}^n_{\gamma} \).

Proof: The result is obtained from Property 1 (see the appendix for a proof of this property) by setting \( Y := \{X_0, U_1, X_1, \ldots, U_{n-1}, X_{n-1}\} \) and \( Z := \{U_n, X_n\} \).

The main result behind the algorithm of Section 5, the proof of which makes use of the above technical results, is presented next.

Theorem 1 Consider Problem 1. Then:

\[
(R1) \quad \text{The control policy at time instant } t_k, \left( \tilde{f}_U^k \right)^*, \text{ composing } \left\{ \left( \tilde{f}_U^k \right)^* \right\}_k \text{ solving the problem is given by}
\]

\[
\left( \tilde{f}_U^k \right)^* = \tilde{g}_U^k e^{-\omega(u, x_{k-1}) + \sum_{j \in \Theta} \lambda_{u,j} h_{u,j}(u_k)},
\]

where:

- \( \omega(\cdot, \cdot) \) is generated via the backward recursion

\[
\dot{\omega}(u, x_{k-1}) = \ddot{\omega}(u, x_{k-1}) + \beta(u, x_{k-1}),
\]

with

\[
\ddot{\omega}(u, x_{k-1}) := \mathcal{D}_{KL}(\tilde{f}_X^k||\tilde{g}_X^k),
\]

and terminal conditions \( \dot{\beta}(u, x_{n-1}) = 0 \), \( \dot{\beta}(u, x_{n-1}) = \mathcal{D}_{KL}(\tilde{f}_X^n||\tilde{g}_X^n) \);

- \( \dot{\gamma}(\cdot) \) in (20) is defined as

\[
\dot{\gamma}(x_{k-1}) := \sum_{j \in \Theta} \dot{\gamma}_{u,j}(x_{k-1}),
\]

with

\[
\dot{\gamma}_{u,j}(x_{k-1}) = \exp \{ \lambda_{u,j}^k x_{k-1} \} + 1, \quad \dot{\gamma}_{u,j}^{n+1}(x_n) = 1,
\]

and

\[
\dot{\gamma}_{u,j}(x_{k-1}) = \exp \{ \lambda_{u,j}^k x_{k-1} \} H_{u,j}^k, \quad \dot{\gamma}_{u,j}^{n+1}(x_n) = 1,
\]

\forall j \in \Theta \cup \Theta_k;

- \( \lambda_{u,j}^k \) in (18) is the Lagrange multiplier associated to the constraint \( c_{u,j}^k \), while \( \Theta_k \) is the active index set associated to \( \left( \tilde{f}_U^k \right)^* \). In particular, the vector of Lagrange multipliers

\[
\lambda^k_u := \left( \lambda_{u,0}^k, \lambda_{u,1}^k, \ldots, \lambda_{u,n_k}^k \right)^T
\]

can be computed solving:

\[
\lambda^k_u \in \arg \max_{\lambda^k_u} \mathcal{L}^D(\lambda^k_u) \quad \text{s.t.: } \lambda_{u,j}^k \text{ free, } \forall j \in \Theta, \quad \lambda_{u,j}^k \geq 0, \forall j \in \Theta_k
\]
Moreover, the corresponding minimum at time \( t_k \) is given by:

\[
\tilde{B}^* := -\mathbb{E}_{p_X^{k-1}} [\ln \hat{\gamma} (X_{k-1})].
\]  

(26)

where \( p_X^{k} \) denotes the pdf of the state at time \( t_k \) (i.e. \( p_X^{k} := f(X_k) \)).

Before giving the proof we make the following remark:

Remark 12  The policy solving Problem 1, i.e. \( (\tilde{f}^k) \), directly depends on \( \tilde{g}^k_U \). This is the policy extracted from the examples and a natural choice is to estimate it from the dataset (see also the example in Section 6). In principle, one could use a \( \tilde{g}^k_U \) that, while not being extracted from the examples, embeds design preferences that might be known a-priori. If full knowledge of the system (and of its constraints) is available, one can build a synthetic joint pdf \( \tilde{g}^n \) that embeds the desired design properties. While our results can be used in this ideal situation, we remark here that building such synthetic pdf is not always possible in situations of practical interest where the example dataset is collected from a system that is not the same and/or does not have the same constraints as the system under control (or the constraints of the system under control are not fully known). Finally, another choice, for pdfs having compact supports, is to set \( \tilde{g}^k_U \) equal to the uniform distribution.

Proof: We prove the result by induction and the proof is organized in steps. First, in Step 1, we leverage Lemma 2 to show that Problem 1 can be split into sub-problems, where the optimization sub-problem for the last iteration, i.e. \( k = n \), can be solved independently on the others. We then (Step 2) make use of Lemma 1 to find an explicit solution for the sub-problem at \( k = n \). Once this is done, we update the cost of Problem 1 with the minimum found by solving the sub-problem at \( k = n \) and show, in Step 3, that the original problem can be again broken down into sub-problems. This time, the sub-problem at iteration \( k = n - 1 \) can be solved independently on the others. We then solve this sub-problem and note, in Step 4, how for all the remaining time-steps the structure of the optimization remains the same. From this, the desired conclusions are drawn.

Before proceeding with the proof note that, for notational convenience, we use the shorthand notation \( \{C^k_u\}_K \) to denote the set of constraints of Problem 1 at iteration \( k \). We also denote by \( \{C^k_u\}_1^{n-1} \) the set of constraints over \( K \) and by \( \{C^k_u\}_k^{n-1} \) the constraints from \( t_1 \) up to \( t_{n-1} \).

**Step 1.** Note that, following Lemma 2, Problem 1 can be re-written as

\[
\begin{align*}
\min_{\{f^k_U\}_K} & \mathcal{D}_{KL} (f^n||g^n) = \\
\text{s.t.:} & \{C^k_u\}_K \\
& = \min_{\{f^k_U\}_1^{n-1}} \mathcal{D}_{KL} (f^{n-1}||g^{n-1}) + B^n \\
& \text{s.t.:} \{C^k_u\}_1^{n-1} 
\end{align*}
\]  

(27)

where:

\[
B^n := \min_{f^k_U} B_n
\]

(28a)

and

\[
B_n := \mathbb{E}_{f^n-1} \left[ \mathcal{D}_{KL} \left( \tilde{f}^n || \tilde{g}^n \right) \right].
\]  

(28b)

That is, Problem 1 can be approached by solving first the optimization of the last iteration of the horizon \( K \) (the term \( B_n \) in (27)) and then by taking into account the result from this optimization problem in the optimization up to iteration \( n - 1 \).

**Step 2.** We first observe that, for \( B_n \) defined in (28a):

\[
B_n = \mathbb{E}_{f^n-1} \left[ \mathcal{D}_{KL} \left( \tilde{f}^n || \tilde{g}^n \right) \right] = \mathbb{E}_{p_X^{n-1}} \left[ \mathcal{D}_{KL} \left( \tilde{f}^n || \tilde{g}^n \right) \right].
\]

The above expression was obtained by noticing that, by definition of \( \tilde{f}^n \) and \( \tilde{g}^n \) (see soon before (4) and (5)), \( \mathcal{D}_{KL} \left( \tilde{f}^n || \tilde{g}^n \right) \) is a function of the previous state and, to stress this in the notation, we let \( \hat{A} (\cdot) := \mathcal{D}_{KL} \left( \tilde{f}^n || \tilde{g}^n \right) \). Hence, \( B_n \) can be written as

\[
B_n = \mathbb{E}_{p_X^{n-1}} \left[ \mathcal{D}_{KL} \left( \tilde{f}^n || \tilde{g}^n \right) \right] = \mathbb{E}_{p_X^{n-1}} \left[ \hat{A} (X_{n-1}) \right].
\]  

(29)
and the sub-problem in (28a) becomes:

$$B_n^* = \min_{\hat{f}_n^U} \mathbb{E}_{\hat{f}_n^U} \left[ \hat{A} (X_{n-1}) \right]$$

subject to: $$C_u^n$$  

Now, note that

$$\min_{\hat{f}_n^U} \mathbb{E}_{\hat{f}_n^U} \left[ \hat{A} (X_{n-1}) \right] = \mathbb{E}_{\hat{f}_n^U} \left[A_n^* \right],$$

subject to: $$C_u^n$$

where

$$A_n^* := \min_{\hat{f}_n^U} \hat{A} (x_{n-1})$$

subject to: $$C_u^n$$

Also, the equality in (31) was obtained by using the fact that the expectation operator is linear and the fact that the decision variable (i.e. $\hat{f}_n^U$) is independent on the pdf over which the expectation is performed (i.e. $\hat{f}_n^X$).

Following (31), we can obtain $B_n^*$ by solving (32) and then by averaging $A_n^*$ over $\hat{f}_n^X$. We now focus on solving problem (32). From (29), we get:

$$\hat{A} (x_{n-1}) = \int \hat{f}_n^X \ln \left( \frac{\hat{f}_n^X}{\hat{f}_n^U} \right) + \hat{\alpha} (u_n, x_{n-1}) \right] du_n,$$

$$\hat{\alpha} (u_n, x_{n-1}) := \mathcal{D}_{KL} \left( \hat{f}_n^X || \hat{f}_n^U \right).$$

In turn, (33a) can be compactly written as:

$$\hat{A} (x_{n-1}) = \mathcal{D}_{KL} \left( \hat{f}_n^X || \hat{f}_n^U \right) + \int \hat{f}_n^U \hat{\alpha} (u_n, x_{n-1}) \right] du_n,$$

where we used the definition of KL-divergence.

Hence, Lemma 1 can be used to solve the optimization problem in (32). Indeed, by applying Lemma 1 with: $Z = U_n$, $f (z) = f_n^X$, $g (z) = \hat{f}_n^U$, $\alpha (\cdot) = \hat{\alpha} (\cdot, x_{n-1})$, $h_j (z) = h_{u,j} (u_n)$, $H_j = H_{u,j}$, $c_j [\cdot] = c_{u,j} [\cdot]$, $\lambda_j = \lambda_{n}^{u,j}$, $\mathcal{E} = \mathcal{E}^n$, $I = I^n$, we get the following solution to (32):

$$\left( \hat{f}_n^X \right)^* = \hat{f}_n^U e^{-\left( \hat{\alpha} (u_n, x_{n-1}) + \sum_{j \in I_a^n \setminus (0)} \left( \lambda_{u,j}^n \right)^* h_{u,j} (u_n) \right)} e^{1 + \left( \lambda_{u,j}^n \right)^*},$$

where $I_a^n$ is the active set index associated to $\left( \hat{f}_n^X \right)^*$.

In the above pdf, $\left( \lambda_{u,j}^n \right)^*, j \in I_0^n \cup I^n$ are the Lagrange multipliers at the last iteration $k = n$. Now, following Lemma 1 and Remark 11, the Lagrange multipliers $\left( \lambda_{u,j}^n \right)^* = \left[ \left( \lambda_{u,0,j}^n \right)^*, \left( \lambda_{u,1,j}^n \right)^*, \ldots, \left( \lambda_{u,n^n,n+n}^n \right)^* \right]^T$ are computed by solving

$$(\lambda_{u,j}^n)^* \in \arg \max \mathcal{L}^D (\lambda_{u,j}^n)$$

subject to: $\lambda_{u,j}^n$ free, $\forall j \in \mathcal{E}^n$

$\lambda_{u,j}^n \geq 0$, $\forall j \in I^n$

choosing $\left[ \left( \lambda_{u,0,j}^n \right)^*, \ldots, \left( \lambda_{u,n^n,n+n}^n \right)^* \right] \mathcal{E}^n$ so that $\left( \hat{f}_n^U \right)^*$ is feasible. In the above expression $\mathcal{L}^D (\lambda_{u,j}^n)$ is defined as:

$$\mathcal{L}^D (\lambda_{u,j}^n) = -\sum_{j \in \mathcal{E}^n \cup I^n} \lambda_{u,j}^n H_{u,j} - \ln \left( \int \hat{f}_n^U e^{-\hat{\alpha} (u_n, x_{n-1})} e^{\left( \sum_{j \in I_a^n \setminus (0)} \lambda_{u,j}^n h_{u,j} (u_n) \right)} du_n \right),$$

and $\left( \lambda_{u,0,j}^n \right)^*$ can be obtained from all the other Lagrange multipliers by normalizing (34), i.e.:

$$\left( \lambda_{u,0,j}^n \right)^* + 1 = \ln \left( \int \hat{f}_n^U e^{-\hat{\alpha} (u_n, x_{n-1})} e^{\left( \sum_{j \in I_a^n \setminus (0)} \lambda_{u,j}^n h_{u,j} (u_n) \right)} du_n \right) = \ln \left( \hat{\gamma}_{u,0} (x_{n-1}) \right).$$

Moreover, from Lemma 1, the minimum of the problem in (32) is given by:

$$\hat{A}_n^* = - \left( 1 + \sum_{j \in I_a^n} \left( \lambda_{u,j}^n \right)^* H_{u,j} \right),$$

which, using the definitions in (22) and (23), can be equivalently written as:

$$\hat{A}_n^* = - \left[ \sum_{j \in I_a^n} \ln \left( \hat{\gamma}_{u,j} (x_{n-1}) \right) \right] = - \ln \hat{\gamma} (x_{n-1}).$$

Thus, we get:

$$B_n^* = - \mathbb{E}_{\hat{f}_n^X} \left[ \ln \hat{\gamma} (X_{n-1}) \right].$$

Step 3. Note now that the $B_n^*$ in (35) only depends on $X_{n-1}$ and therefore the original problem (27) can be split, following Lemma 2, as

$$\min_{\{\hat{f}_n^X\}_{k=1}^{n-1}} \left\{ \mathcal{D}_{KL} \left( f^{n-1} || g^{n-1} \right) + B_n^* \right\}$$

subject to: $\{C_{u,j}^k\}_{k=1}^{n-1}$

$$= \min_{\{\hat{f}_n^X\}_{k=1}^{n-2}} \left\{ \mathcal{D}_{KL} \left( f^{n-2} || g^{n-2} \right) + B_{n-1}^* \right\}$$

subject to: $\{C_{u,j}^k\}_{k=1}^{n-2}$
where:

\[ B_{n-1}^* := \min_{f_U^{-1}} B_{n-1} \tag{37a} \]

\[ \text{s.t.: } C_n^{-1} \]

and

\[ B_{n-1} := \mathbb{E}_{f_{U^{-1}}} \left[ D_{KL} \left( \tilde{f}^{-1}_X || g_n^{-1} \right) \right] + B_n^*. \tag{37b} \]

We approach the above problem in the same way we used to solve the problem in (30). We do this by finding a function, \( \hat{A} (x_{n-2}) \), such that

\[ B_{n-1} = \mathbb{E}_{p_{X}} \left[ \hat{A} (X_{n-2}) \right]. \]

Once this is done, we then get

\[ A_{n-1}^* := \min_{f_{U^{-1}}} \hat{A} (x_{n-2}) \tag{38} \]

\[ \text{s.t.: } C_n^{-1} \]

and obtain \( B_{n-1}^* \) as:

\[ B_{n-1}^* := \mathbb{E}_{p_{X}} \left[ A_{n-1}^* \right]. \]

To this end we first note that the following identities

\[ E_{p_{X}} \left[ \varphi (X_{n-1}) \right] = \mathbb{E}_{p_{X}} \left[ E_{f_{n-1}} \left[ \varphi (X_{n-1}) \right] \right] \tag{39a} \]

\[ E_{f_{n-1}} \left[ \varphi (X_{n-1}) \right] = E_{f_{n-2}} \left[ E_{f_{n-1}} \left[ \varphi (X_{n-1}) \right] \right] \tag{39b} \]

hold for any function \( \varphi \) of \( X_{n-1} \). Therefore, by means of (35) and (39a) we obtain, from (37b):

\[ B_{n-1} = \mathbb{E}_{f_{n-1}} \left[ D_{KL} \left( \tilde{f}^{-1}_X || g_n^{-1} \right) \right] + B_n^* = \mathbb{E}_{p_{X}} \left[ D_{KL} \left( \tilde{f}^{-1}_n || g_n^{-1} \right) \right] + B_n^* = \mathbb{E}_{p_{X}} \left[ D_{KL} \left( \tilde{f}^{-1}_n || g_n^{-1} \right) \right] - \mathbb{E}_{p_{X}} \left[ E_{f_{n-1}} \left[ \ln \hat{\gamma} (X_{n-1}) \right] \right] = \mathbb{E}_{p_{X}} \left[ D_{KL} \left( \tilde{f}^{-1}_n || g_n^{-1} \right) \right] + E_{f_{n-1}} \left[ - \ln \hat{\gamma} (X_{n-1}) \right], \]

and the term \( \hat{A} (x_{n-2}) \) can hence be recognized. Now, following the same reasoning we used to obtain \( \hat{A} (x_{n-1}) \), we explicitly write \( \hat{A} (x_{n-2}) \) in compact form as

\[ \hat{A} (x_{n-2}) = D_{KL} \left( \tilde{f}^{-1}_n || g_n^{-1} \right) + E_{f_{n-1}} \left[ E_{f_{n-2}} \left[ - \ln \hat{\gamma} (X_{n-1}) \right] \right] = \int \tilde{f}^{-1}_n \left( \ln \left( \frac{\tilde{f}^{-1}_n}{g_n} \right) + \hat{\omega} (u_{n-1}, x_{n-2}) \right) d u_{n-1}, \tag{40} \]

where \( \hat{\omega} (u_{n-1}, x_{n-2}) = \hat{\alpha} (u_{n-1}, x_{n-2}) + \hat{\beta} (u_{n-1}, x_{n-2}) \)

and

\[ \hat{\alpha} (u_{n-1}, x_{n-2}) := D_{KL} \left( \tilde{f}^{-1}_X || g_n^{-1} \right) \]

\[ \hat{\beta} (u_{n-1}, x_{n-2}) := - E_{f_{n-1}} \left[ \ln \hat{\gamma} (X_{n-1}) \right]. \]

The last expression we found for \( \hat{A} (x_{n-2}) \) in (40) enables us to use Lemma 1 in order to solve the optimization problem in (38). This time, by applying Lemma 1 with \( Z = U_{n-1} \), \( f (z) = f_{U^{-1}} \), \( g (z) = g_U^{-1} \), \( \alpha (\cdot) = \hat{\omega} (\cdot, x_{n-2}) \), \( h_j (z) = h_{U,j}^{-1} (u_{n-1}) \), \( H_j = H_{U,j}^{-1} \), \( c_j [\cdot] = c_{U,j}^{-1} [\cdot] \), \( \lambda_j = \lambda_{n-1,j} \), \( E = \mathcal{E}^{n-1} \), \( I = I^{n-1} \), we get the following solution to (38):

\[ \left( \tilde{f}^{-1}_n \right)^* = \mathbb{E}_{U} e^{- \left( \hat{\omega} (u_{n-1}, x_{n-2}) + \sum_{j \in I(n-1 \setminus \{0\})} (\lambda_{n-1,j}^{-1}) h_{n-1,j} (u_{n-1}) \right) \}, \]

where \( I^{n-1} \) is the active set index associated to \( \left( \tilde{f}^{-1}_n \right)^* \) and the Lagrange multipliers can again be obtained from Lemma 1. Namely:

- \( \left( \lambda_{U,0}^{n-1} \right)^* \) \ in \( \arg \max \mathcal{L}^D (\lambda_{n-1}^{n-1}) \)
- \( \lambda_{U,j}^{n-1} \) \ s.t.: \( \lambda_{U,j}^{n-1} \) \ free, \( \forall j \in \mathcal{E}^{n-1} \)
- \( \lambda_{U,j}^{n-1} \geq 0, \forall j \in I^{n-1} \)

where

\[ \mathcal{L}^D (\lambda_{n-1}^{n-1}) = - \sum_{j \in I(n-1 \setminus \{0\})} \left( \lambda_{U,j}^{n-1} H_{U,j}^{-1} \right) - \ln \left( \int \tilde{f}^{-1}_U e^{- \hat{\omega} (u_{n-1}, x_{n-2}) + e^{- \sum_{j \in I(n-1 \setminus \{0\})} (\lambda_{n-1,j}^{-1}) h_{n-1,j} (u_{n-1})} du_{n-1} \right), \]

- \( \left( \lambda_{U,0}^{n-1} \right)^* \) is given by

\[ \left( \lambda_{U,0}^{n-1} \right)^* \]

Moreover, from Lemma 1 we also obtain:

\[ B_{n-1}^* = - E_{f_{n-2}} \left[ \sum_{j \in I(n-1)} \ln \hat{\gamma}_{n-1} (X_{n-2}) \right] = - E_{f_{n-2}} \left[ \ln \hat{\gamma} (X_{n-2}) \right]. \]
Step 4. The proof can then be concluded by observing that, using $B^*_{n-1}$ in (36), the optimization can again be split in sub-problems, with the last sub-problem (i.e. the sub-problem corresponding to $k = n - 2$) being independent from the others and having the same structure as the problem we solved at $k = n - 1$. Hence, the solution at the generic iteration $k$, i.e. $(\hat{f}^k_U)^*$, will have the same structure as $(\hat{f}^{n-1}_U)^*$, with the functions $\hat{\beta}(\cdot, \cdot)$, $\hat{\varphi}(\cdot)$ given by (19) - (20) and the Lagrange multipliers given by (24) - (25). This leads to the expression in (18) with the minimum given in (26). Finally, for the last iteration ($k = n$) we note from (33b) that $\hat{\beta}(\mathbf{u}_n, \mathbf{x}_{n-1}) = 0$ which, by means of (21), implies that $\hat{\gamma}^{n+1}_{k,j}(\mathbf{x}_n) = 1$, $\forall j$. This gives the terminal conditions in (22) and (23). The proof is then completed. □

Finally, we close the section with the following remark:

Remark 13: From the proof of Theorem 1, we get that, at time-step $k$, $(\hat{f}^k_U)^*$ is obtained as

\[
\begin{align*}
(\hat{f}^k_U)^* & \in \arg \min \mathcal{D}_{KL}\left(\hat{f}^k_U \parallel \hat{g}^k_U\right) + \mathbb{E}_{\hat{f}^k_U} [\hat{\varphi}(\mathbf{U}_k, \mathbf{X}_{k-1})] \\
& \text{s.t.: } c^k_{\mathbf{u}, j} \left(\hat{f}^k_U\right) = 0, \ \forall j \in \mathcal{E}^k_0, \\
& c^k_{\mathbf{u}, j} \left(\hat{f}^k_U\right) \leq 0, \ \forall j \in \mathcal{I}^k,
\end{align*}
\]

where $\hat{\varphi}(\cdot, \cdot)$ is defined as in Theorem 1. Consider the case where, for the problem in (41): (i) $\hat{\varphi}(\cdot, \cdot)$ is constant in the first argument; (ii) $\hat{g}^k_U$ is a uniform distribution on a compact support. Then, the minimizer of the above problem can also be found via the constrained maximum entropy problem:

\[
\begin{align*}
(\hat{f}^k_U)^* & \in \arg \max \mathbb{E}_{\hat{f}^k_U} [\ln \hat{f}^k_U] \\
& \text{s.t.: } c^k_{\mathbf{u}, j} \left(\hat{f}^k_U\right) = 0, \ \forall j \in \mathcal{E}^k_0, \\
& c^k_{\mathbf{u}, j} \left(\hat{f}^k_U\right) \leq 0, \ \forall j \in \mathcal{I}^k,
\end{align*}
\]

5 An algorithm from Theorem 1

Theorem 1 gives an explicit expression for synthesizing the control policy and we leverage this to turn the result into an algorithmic procedure. The algorithm introduced here takes as input $g(\Delta^*_n)$, $\hat{f}^k_U := f(\mathbf{x}_k|\mathbf{u}_k, \mathbf{x}_{k-1})$ and the constraints of Problem 1 (if any). The pdfs, as further illustrated in the next section, can be obtained from the dataset. Given this input, the algorithm outputs $\left\{\left(\hat{f}^k_U\right)^*\right\}_{k \in K}$ solving Problem 1. Then, at each $k$, the control input, $\mathbf{u}_k$, applied to the system is obtained by sampling from the pdf $(\hat{f}^k_U)^*$. The key steps of the proposed algorithm are summarized as pseudo-code in Algorithm 1.

Algorithm 1 Pseudo-code

Inputs:
$g(\Delta^*_n)$, $\hat{f}^k_U$ and constraints of Problem 1
Output:
$\left\{\left(\hat{f}^k_U\right)^*\right\}_{k \in K}$ solving Problem 1
Initialize
$\hat{\gamma}^{n+1}_{n,j}(\mathbf{x}_n) = 1, \forall j$;
$\hat{\gamma}(\mathbf{x}_n) \leftarrow \exp \left[\sum_j \ln \left(\hat{\gamma}^{n+1}_{n,j}(\mathbf{x}_n)\right)\right]$;
for $k = n$ to 1 do
$\hat{\alpha}(\mathbf{u}_k, \mathbf{x}_{k-1}) \leftarrow \int \hat{f}^k_U \ln \hat{f}^k_U \, d\mathbf{x}_k$;
$\hat{\beta}(\mathbf{u}_k, \mathbf{x}_{k-1}) \leftarrow - \int \hat{f}^k_U \ln \left(\hat{\gamma}(\mathbf{x}_k)\right) \, d\mathbf{x}_k$;
$\hat{\varphi}(\mathbf{u}_k, \mathbf{x}_{k-1}) \leftarrow \hat{\alpha}(\mathbf{u}_k, \mathbf{x}_{k-1}) + \hat{\beta}(\mathbf{u}_k, \mathbf{x}_{k-1})$;
Compute $\left[\left(\lambda^k_{0,1}\right)^*, \ldots, \left(\lambda^k_{0,1} + n^k_{1}\right)^*\right]^T$ by solving (24) and $(\lambda^k_{0,1})^*$ using (25);
Compute the control policy:
$\left(\hat{f}^k_U\right)^* \leftarrow \hat{g}^k_U - \left(e^{\beta(\mathbf{x}_{k-1})} - \sum_{\mathbf{u} \in \mathcal{U}^k} \lambda^k_{0,1}(\mathbf{u}) \hat{f}^k_U\right)$;
Prepare variables for the next iteration, $k - 1$:
$\hat{\gamma}^{k}_{n,0}(\mathbf{x}_{k-1}) \leftarrow \exp \left\{\sum_j \ln \left(\hat{\gamma}^{k}_{n,0}(\mathbf{x}_{k-1})\right)\right\}$;
$\hat{\gamma}^{k}_{n,j}(\mathbf{x}_{k-1}) \leftarrow \exp \left\{\sum_j \ln \left(\hat{\gamma}^{k}_{n,j}(\mathbf{x}_{k-1})\right)\right\}, j \in \mathcal{E}^k \cup \mathcal{I}^k$;
$\hat{\gamma}(\mathbf{x}_{k-1}) \leftarrow \exp \left[\sum_j \ln \left(\hat{\gamma}^{k}_{n,j}(\mathbf{x}_{k-1})\right)\right]$;
end for

Algorithm 1 is used to compute the control policy for the example of the next section.

6 Numerical example

We now illustrate the effectiveness of the results via a numerical example where the algorithm of Section 5 is used to synthesize, from data measured during test drives, a policy for the merging of a car on a highway. Specifically, we leverage our results to synthesize a policy that makes the behavior of the controlled car similar to the behavior seen in the example dataset (collected through test drives) while satisfying some desired constraints on the control variable. We first describe the scenario considered and the experimental set-up. Then, we describe the data we collected from the test drives and the process we used to compute the pdfs for Algorithm 1. Finally, we discuss the results.

Scenario description and experimental set-up.

The scenario we considered is schematically illustrated in Figure 1, where a car is merging onto a highway.
The stretch of road where our experiments took place is outside University College Dublin (UCD) and the highway is Stillorgan Road in Dublin 4 (see Figure 2). Data were collected from a Toyota Prius using an OBD² connection with a smartphone running the Android apps **Hybrid Assistant** and its reporting tool **Hybrid Reporter**. We collected the car GPS position and its longitudinal speed using the hardware-in-the-loop architecture of Griggs et al. (2019). The apps and its longitudinal speed using the hardware-in-the-loop architecture of (Griggs et al., 2019). The apps on the smartphone provided raw data in a .txt file with each line reporting the quantities measured at a given time instant (the sampling period was of approximately 0.25s). Data were imported in Matlab and the car position was localized by cross-referencing these data with the road information from OpenStreetMap (OpenStreetMap contributors, 2017).

Collecting the data and building the datasets. We performed 100 test drives. In each of the tests, data were collected within a 300 meters observation window starting 200 m before the junction (i.e. after the UCD entrance). The raw data were processed to obtain the speed, acceleration and jerk profiles of the car as a function of the distance traveled within the observation window (see left panels in Figure 3). The dataset corresponding to these profiles is termed as complete dataset in what follows. The vertical line in each panel highlights the physical location of the junction of Figure 2. From the complete dataset we extracted a subset of profiles that would serve as example dataset. In particular, we selected the profiles with the lowest root mean square (RMS) value for the jerk, which is typically associated to a comfortable driving style, see e.g. (Bae et al., 2019).

We used as example driving profiles, those having a RMS value for the jerk of at most 0.16. This gave the subset of 20 driving profiles shown in the right panels of Figure 3.

Computing the pdfs. We let \( x_k \) be the position of the car at the \( k \)-th time-step (i.e. \( x_k = d_k \)) and \( u_k \) be its longitudinal speed (i.e. \( u_k = v_k \)). Following (Deng et al., 2019), we computed the joint probability density functions as empirical distributions to obtain \( f(x_{k-1}, u_k) \) and \( g(x_{k-1}, u_k) \) from the complete and the example dataset respectively (see Figure 4). Following the same process, we also obtained \( f(x_k, x_{k-1}, u_k) \) and \( g(x_k, x_{k-1}, u_k) \) and conditioned these joint pdfs to get \( f(x_k | x_{k-1}, u_k) = f(x_k, x_{k-1}, u_k) / f(x_{k-1}, u_k) \) and \( g(x_k | x_{k-1}, u_k) = g(x_k, x_{k-1}, u_k) / g(x_{k-1}, u_k) \). We then assumed \( f^k_X \) and \( g^k_X \), two inputs to Algorithm 1, to be normal distributions and estimated their parameters via least squares. This yielded \( f^k_X \sim N\left(a_x x_{k-1} + b_x u_k, \sigma_x^2 \right) \), \( g^k_X \sim N\left(a_x x_{k-1} + b_x u_k, \sigma_x^2 \right) \) with \( a_x = 0.9820, b_x = 0.2591, \sigma_x^2 = 2.6118 m^2 \) and \( a_x = 0.9811, b_x = 0.2723 s, \sigma_x^2 = 1.7622 m^2 \). Finally, \( g^k_U \) was obtained from the empirical pdfs as \( g^k_U = (g(x_{k-1}, u_k) / \int g(x_{k-1}, u_k) \, du_k) \).
**Remark 14** The Gaussian assumption for \( f_k \) and \( g_k \) is inspired by (Nguyen et al., 2017; Moser et al., 2015). These works considered the problem of making short-term predictions of vehicles’ trajectories. See also references therein and our concluding remarks in Section 7.

**Synthesis of the control policy.** Given this set-up, we used Algorithm 1 to solve Problem 1 and hence to synthesize from the examples a control policy allowing the car to merge on the highway. When synthesizing the control policy, we imposed, at each \( k \), the following set of constraints:

\[
\begin{align*}
\mathcal{C}_{u,0}^k \left[ \tilde{f}_U \right] &= 0, & j \in \{0, 1, 2\}, \quad (42a) \\
\mathcal{C}_{u,j}^k \left[ \tilde{g}_k^j \right] &= \mathbb{E}_{\tilde{g}_U^j} \left[U_k \right] - H_{u,0}^k, \quad (42b) \\
\mathcal{C}_{u,1}^k \left[ \tilde{f}_U \right] &= \mathbb{E}_{\tilde{f}_U} \left[U_k \right] - H_{u,1}^k, \quad (42c) \\
\mathcal{C}_{u,2}^k \left[ \tilde{f}_U \right] &= \mathbb{E}_{\tilde{f}_U} \left[U_k^2 \right] - H_{u,2}^k, \quad (42d) \\
\end{align*}
\]

where:

\[
\begin{align*}
H_{u,0}^k &= 1, \\
H_{u,1}^k &= \mathbb{E}_{\tilde{g}_U^j} \left[U_k \right], \quad (42e) \\
H_{u,2}^k &= 4 \left( \mathbb{E}_{\tilde{g}_U^j} \left[U_k^2 \right] - \mathbb{E}_{\tilde{g}_U^j} \left[U_k \right] \right) + \mathbb{E}_{\tilde{g}_U^j} \left[U_k \right]. \quad (42f)
\end{align*}
\]

At each \( k \), the fulfillment of the first constraint, corresponding to \( j = 0 \), guarantees that the solution to the problem is a pdf (this is the normalization constraint). Instead, the fulfillment of the other two constraints in (42) guarantees that, at each \( k \): (i) the expected value of the control variable of the closed loop system is the same as the one seen in the example dataset (constraint corresponding to \( j = 1 \)); and (ii) the variance of the control variable of the closed loop system is 4 times the variance of the control variable seen in the example dataset (constraint corresponding to \( j = 2 \)). Making the variance of the control variable of the closed loop system larger than the control variable from the example dataset corresponds in accounting for a reduced liability on the example dataset, allowing the closed loop system to depart from the behavior seen in the examples. Moreover, we note that the constraints in (42) satisfy Assumption 1. Indeed any pdf with the first two moments satisfying the constraints fulfills the assumption. We used Algorithm 1 to compute the solution to Problem 1 and approximated these pdfs via the Maximum Entropy Principle. This resulted into the truncated Gaussians of Figure 5. In such a figure, it is clearly shown how these pdfs have higher variance than the corresponding \( \tilde{g}_k^j \) extracted from the examples. In the figure, for clarity, \( \tilde{g}_k^j \) is also represented as a truncated Gaussian that has the same mean and variance as the pdf extracted from the data. At each time-step, the control input, \( u_k \), applied to the car was obtained by sampling from the pdfs of Figure 5 (in green). In particular, by sampling the \( u_k \)'s as the mean value of the random variable generated by these pdfs, we obtained the speed profile for the controlled car illustrated in Figure 6.

**7 Conclusions**

We considered the problem of synthesizing control policies from noisy example datasets for systems affected by actuation constraints. To tackle this problem, we introduced a number of technical results to explicitly compute the policy directly from certain pdfs obtained from the data and in compliance with the constraints. The optimal policy obtained with our results allows to approximate the behavior seen in the example dataset, while simultaneously fulfilling the system-specific actuation constraints. The results were also turned into an algorithmic procedure and their effectiveness was illustrated via a use-case. The use-case involved the synthesis, from measured data collected during test drives, of a control policy allowing a car to merge on a highway.
design sufficiently informative datasets for the probabilistic framework considered here. Finally, we will also explore the possibility of devising automated fitting procedures to extract suitable pdfs from the data in order to enable an end-to-end pipeline for our results.

A Appendix: proofs of the technical results

Here we give the proofs for Property 1 and Lemma 1.

A.1 Proof of Property 1

To prove this result we start from the definition of KL-divergence. In particular:

\[
\mathcal{D}_{KL}(\phi(y,z) \| g(y,z)) := \\
\int \int \phi(y,z) \ln \frac{\phi(y,z)}{g(y,z)} dy \, dz = \\
\int \int \phi(z|y) \phi(y) \ln \frac{\phi(z|y)}{g(z|y)} \frac{\phi(y)}{g(y)} dy \, dz = \\
\int \int \phi(z|y) \left[ \phi(y) \ln \frac{\phi(y)}{g(y)} \right] dy \, dz + \\
\int \int \phi(y) \left[ \phi(z|y) \ln \frac{\phi(z|y)}{g(z|y)} \right] dz \, dy.
\]

For the term (1) in the above expression we may continue as follows:

\[
\int \int \phi(z|y) \left[ \phi(y) \ln \frac{\phi(y)}{g(y)} \right] dy \, dz = \\
\int \phi(z|y) \left[ \int \phi(y) \ln \frac{\phi(y)}{g(y)} dy \right] dz = \\
\mathcal{D}_{KL}(\phi(y) \| g(y))
\]

where we used Fubini’s theorem, the fact that the term on the first line in square brackets is indepedent on \(Z\) and the fact that \(\int \phi(z|y) \, dz = 1\). By using again Fubini’s theorem, for the term (2) in the above expression instead we have:

\[
\int \int \phi(z|y) \left[ \phi(y) \ln \frac{\phi(z|y)}{g(z|y)} \right] dz \, dy = \\
\int \phi(y) \left[ \int \phi(z|y) \ln \frac{\phi(z|y)}{g(z|y)} dz \right] dy = \\
\int \phi(y) \left[ \mathbb{E}_\phi \left[ \mathcal{D}_{KL}(\phi(z|y) \| g(z|y)) \right] \right] dy = \\
\mathbb{E}_\phi \left[ \mathcal{D}_{KL}(\phi(z|Y) \| g(z|Y)) \right],
\]

thus proving the result. \(\Box\)
The proof is organized in 3 steps. In Step 1 we show that the optimization problem in (8) is a convex optimization problem (COP) and we then devise its augmented Lagrangian (this terminology is in accordance with Kirk [2004]). In Step 2 we explicit the Karush-Kuhn-Tucker (KKT) conditions and verify that these are satisfied by the solution in (11). Recall that, for a COP, KKT conditions are necessary and sufficient [Boyd and Vandenberghe, 2004] Chapter 5). Finally, in Step 3, we compute the minimum of the cost function corresponding to the optimal solution.

**Step 1.** We start with observing that the cost function \( L(f(z)) \) in (8) can be conveniently rewritten as:

\[
L(f(z)) = \int l(f(z)) \, dz,
\]

with

\[
l(f(z)) := f(z) \left[ \ln \left( \frac{f(z)}{g(z)} \right) + \alpha(z) \right].
\]

Clearly, \( L(\cdot) \) is twice differentiable and we now prove that it is also a strictly convex functional in \( f \). We do this by showing that its second variation is positive definite on the space of integrable functions and we explicit the first and second variation of \( L(f(z)) \), i.e. \( \delta L(f, \delta f) \) and \( \delta^2 L(f, \delta f) \), in terms of the first and second derivative of \( l(f(z)) \) with respect to \( f(z) \) (i.e. \( \frac{\partial l(f(z))}{\partial f} \) and \( \frac{\partial^2 l(f(z))}{\partial f^2} \), respectively). By computing \( \delta L(f, \delta f) \) we get:

\[
\delta L(f, \delta f) = \int \frac{\partial l(f(z))}{\partial f} \delta f \, dz,
\]

with

\[
\frac{\partial l(f(z))}{\partial f} = \ln f(z) + (\alpha(z) + 1 - \ln g(z)).
\]

This leads to the following expression for the second variation of \( L(f, \delta f) \)

\[
\delta^2 L(f, \delta f) = \int f(z) \left( \frac{\partial^2 l(f(z))}{\partial f^2} \right) \delta f \, dz \quad (A.1)
\]

To show convexity of \( L \) it then suffices to observe that, since \( f(z) \) is positive on its support, then the quantity under the integral in (A.1) is positive. In turn, this implies that \( \delta^2 L(f, \delta f) \) is strictly positive for any measurable, non-zero variation \( \delta f \) (see also Kirk [2004] Chapter 4) and Giaquinta and Hildebrandt [2004] for a detailed discussion). Hence, in order to conclude that the problem in (8) is a COP, it suffices to observe that the

| Primal feasibility: | \( c_j [f(z)] = 0 \), \( \forall j \in E_0 \) | \( c_j [f(z)] \leq 0 \), \( \forall j \in I \) |
| Dual feasibility: | \( \lambda_j \geq 0 \), \( \forall j \in I \) | \( \lambda_j c_j [f(z)] = 0 \), \( \forall j \in I \) |
| Complementary slackness: | | |
| Stationarity: | \( \delta L_{aug}(f, \delta f, \lambda) = 0 \), \( \forall \delta f \) |

Table A.1

KKT conditions for the problem (8) - \( L_{aug}(f, \delta f, \lambda) \) is the augmented Lagrangian.

The augmented Lagrangian of the COP in (8) is:

\[
L_{aug}(f(z), \lambda) := L(f(z)) + \sum_{j \in E_0 \cup I} \lambda_j c_j [f(z)], \quad (A.2)
\]

where \( \lambda := [\lambda_0, \lambda_1, \ldots, \lambda_{n+1}]^T \) is the column vector stacking all the Lagrange multipliers.

**Step 2.** We showed that the problem in (8) is a COP and hence the KKT conditions are necessary and sufficient optimality conditions. That is, in order to be a unique minimizer of the problem (8), the candidate function \( f(z) \) must satisfy the conditions made explicit in Table A.1.

We now impose the stationarity condition (see Table A.1) and first note that the augmented Lagrangian (A.2) can be written as follows:

\[
L_{aug}(f(z), \lambda) := \int f(z) \left[ \ln \left( \frac{f(z)}{g(z)} \right) + \alpha(z) \right] \, dz + \langle \lambda, \int f(z) h(z) \, dz - H \rangle.
\]

Hence, the above expression can be compactly rewritten as

\[
L_{aug}(f(z), \lambda) = \int \tilde{l}(f(z), \lambda) \, dz - \langle \lambda, H \rangle, \quad (A.3)
\]

where the quantity under the integral is given by

\[
\tilde{l}(f(z), \lambda) := f(z) \left[ \ln \left( \frac{f(z)}{g(z)} \right) + \alpha(z) + \langle \lambda, h(z) \rangle \right].
\]

By computing the first variation of (A.3) with respect to \( \delta f \) we obtain

\[
\delta L_{aug}(f, \delta f, \lambda) = \int \frac{\partial \tilde{l}(f(z), \lambda)}{\partial f} \delta f \, dz,
\]

and thus, by imposing the stationarity condition (Nocedal and Wright 2006) condition (i.e. \( \delta L_{aug}(f, \delta f, \lambda) = 0 \), \( \forall \delta f \)), we get \( \frac{\partial \tilde{l}(f(z), \lambda)}{\partial f} = 0 \). That is,

\[
\frac{\partial \tilde{l}(f(z), \lambda)}{\partial f} = \ln \left( \frac{f(z)}{g(z)} \right) + \alpha(z) + \langle \lambda, h(z) \rangle + 1 = 0,
\]
from which it immediately follows that all the optimal solution candidates must be of the form
\[
\hat{f}^*(z, \lambda) := g(z) e^{-\left\{1 + \alpha(z) + \langle \lambda, h(z) \rangle \right\}}. \tag{A.4}
\]
In the above expression, the notation $\hat{f}^*$ was introduced to stress that the optimal solution candidate is a function of the Lagrange multipliers. These can be found by solving the following dual problem
\[
\lambda^* \in \arg \max_{\lambda} L^D(\lambda) \\
\text{s.t.: } \lambda_j \text{ free}, \forall j \in \mathcal{E}_0 \\
\lambda_j \geq 0, \forall j \in \mathcal{I}
\tag{A.5}
\]
choosing $\lambda^*$ so that $\hat{f}^*(z, \lambda^*)$ is primal feasible (see [Ben-Tal et al., 1988]). In the problem, $L^D(\lambda)$ is the Lagrange dual function
\[
L^D(\lambda) := \inf_{f(z) \geq 0} \mathcal{L}_{aug}(f(z), \lambda).
\]
Note that the vector $\lambda^*$ must satisfy the dual feasibility condition. Now, Assumption 1 implies strong duality (see Remark 7) and hence the complementary slackness condition (see Table A.1) is also fulfilled. Additionally, $\mathcal{L}_{aug}(f(z), \lambda)$ is strictly convex in $f(z)$ and hence
\[
\inf_{f(z) \geq 0} \mathcal{L}_{aug}(f(z), \lambda) = \mathcal{L}_{aug}(\hat{f}^*(z, \lambda), \lambda).
\]
Thus:
\[
L^D(\lambda) = \mathcal{L}(f^*(z, \lambda), \lambda)
\]
\[= -\int \hat{f}^*(z, \lambda) \, dz - \langle \lambda, H \rangle.
\]
Note now that the last equivalence gives (14) in the statement of the lemma and hence the problem in (13). Moreover, the complementary slackness condition on the pair of optimizers $f^*(z, \lambda^*)$ implies, for a COP, that there is no duality gap. That is, $L^D(\lambda^*) = \mathcal{L}(f^*(z))$. In turn, this means that the Lagrange multipliers associated to inactive inequality constraints must be equal to 0, while all the Lagrange multipliers associated to active inequality constraints must be non-negative. Therefore, the optimal solution of the COP in (8) is given by
\[
\hat{f}^*(z, \lambda^*) = f^*(z) = g(z) e^{-\left\{1 + \alpha(z) + \sum_{j \in \mathcal{I}_a(f^*(z))} \lambda_j^* h_j(z) \right\}},
\]
which was obtained by taking into account that only the Lagrange multipliers associated to the active constraints are non-zero. The above expression is equal to (11) where we highlighted the role of $\lambda_0$ as a normalization constant. This concludes the proof of (R1).

**Step 3.** Finally, since there is no duality gap, the minimum value of the primal problem (i.e. the COP in (8)) can be obtained from (A.6). This leads to
\[
\mathcal{L}(f^*(z)) = -\left(1 + \sum_{j \in \mathcal{I}_a(f^*(z))} \lambda_j^* H_j \right),
\]
and thus completes the proof. \(\square\)
