# Grassmann angle formulas and identities 

André L. G. Mandolesi *

December 31, 2021

#### Abstract

Grassmann angles improve upon similar concepts of angle between subspaces that measure volume contraction in orthogonal projections, working for real or complex subspaces, and being more efficient when dimensions are different. Their relations with contractions, inner and exterior products of multivectors are used to obtain formulas for computing these or similar angles in terms of arbitrary bases, and various identities for the angles with certain families of subspaces. These include generalizations of the Pythagorean trigonometric identity $\cos ^{2} \theta+\sin ^{2} \theta=1$ for high dimensional and complex subspaces, which are connected to generalized Pythagorean theorems for volumes, quantum probabilities and Clifford geometric product.

Keywords: Grassmann angle, angle between subspaces, Pythagorean identity, Grassmann algebra, exterior algebra.
MSC: 15A75, 51M05

## 1 Introduction

Measuring the separation between subspaces is important in many areas, from geometry and linear algebra to statistics [10], operator perturbation theory [14], data mining [12], etc. In high dimensions, no single number fully describes this separation, and different concepts are used: gap, principal angles, minimal angle, Friedrichs angle, and others. An often used angle concept [5, 7, 9, 11] combines principal angles in a way that shows how volumes contract when orthogonally projected between the subspaces. Research on it has been focused on real spaces, but many applications require complex ones.

The relation between angle and volume contraction changes significantly in the complex case. Taking this into account, in [15] we defined a Grassmann angle that works well in both cases, with only a few adjustments. It is based on that same angle, but has a subtly important difference, which makes it easier to use with subspaces of distinct dimensions: it is asymmetric, reflecting the

[^0]dimensional asymmetry between the subspaces in a way that leads to better properties and more general results. This angle is intrinsically connected with Grassmann algebra, and has found interesting applications in the geometry of Grassmannians, Clifford algebra, quantum theory, etc.

In [16] we expressed contractions, inner, exterior and Clifford products of blades (simple multivectors) in terms of Grassmann angles. In this article we use the products to get formulas for the angles in terms of arbitrary bases, and identities relating the angles with the subspaces of an orthogonal partition, with coordinate subspaces of orthogonal bases, and others. Some of them generalize the Pythagorean trigonometric identity $\cos ^{2} \theta+\sin ^{2} \theta=1$ for high dimensional and complex subspaces, being related to real and complex Pythagorean theorems for volumes [17] and quantum probabilities [18], and giving a geometric interpretation for an algebraic property of the Clifford product. Some of our results correspond, in the real case, to known ones, but our methods provide simpler proofs, while also extending them to the complex case.

Section 2 presents concepts and results which will be needed. We obtain formulas for computing Grassmann angles in section 3, generalized Pythagorean identities in section 4 , and other useful identities in section 5 .

## 2 Preliminaries

Here we review results we will use. See $[15,16]$ for proofs and more details.
In this article, $X$ is a $n$-dimensional vector space over $\mathbb{R}$ (real case) or $\mathbb{C}$ (complex case), with inner product $\langle\cdot, \cdot\rangle$ (Hermitian product in the complex case, with conjugate-linearity in the first argument). For subspaces $V, W \subset X$, $\operatorname{Proj}_{W}: X \rightarrow W$ and $\operatorname{Proj}_{W}^{V}: V \rightarrow W$ are orthogonal projections. A line is a 1-dimensional subspace.

### 2.1 Grassmann algebra and partial orthogonality

In the Grassmann algebra $\Lambda X[19,24]$, a $p$-blade is a simple multivector $\nu=$ $v_{1} \wedge \ldots \wedge v_{p} \in \Lambda^{p} X$ of grade $p$, where $v_{1}, \ldots, v_{p} \in X$. If $\nu \neq 0$, it represents the $p$-dimensional subspace $V=\operatorname{span}\left(v_{1}, \ldots, v_{p}\right)$, and $\Lambda^{p} V=\operatorname{span}(\nu)$. A scalar $\nu \in \Lambda^{0} X$ is a 0 -blade, representing $\{0\}$.

The inner product of $\nu=v_{1} \wedge \ldots \wedge v_{p}$ and $\omega=w_{1} \wedge \ldots \wedge w_{p}$,

$$
\langle\nu, \omega\rangle=\operatorname{det}\left(\left\langle v_{i}, w_{j}\right\rangle\right)=\left|\begin{array}{ccc}
\left\langle v_{1}, w_{1}\right\rangle & \cdots & \left\langle v_{1}, w_{p}\right\rangle \\
\vdots & \ddots & \vdots \\
\left\langle v_{p}, w_{1}\right\rangle & \cdots & \left\langle v_{p}, w_{p}\right\rangle
\end{array}\right|
$$

is extended linearly (sesquilinearly, in the complex case), with blades of distinct grades being orthogonal, and $\langle\nu, \omega\rangle=\bar{\nu} \omega$ for $\nu, \omega \in \Lambda^{0} X$. In the real case, the norm $\|\nu\|=\sqrt{\langle\nu, \nu\rangle}$ gives the $p$-dimensional volume of the parallelotope spanned by $v_{1}, \ldots, v_{p}$. In the complex case, $\|\nu\|^{2}$ gives the $2 p$-dimensional volume of the parallelotope spanned by $v_{1}, \mathrm{i} v_{1}, \ldots, v_{p}, \mathrm{i} v_{p}$.

Given a subspace $W \subset X$, let $P=\operatorname{Proj}_{W}$. The orthogonal projection of $\nu=v_{1} \wedge \ldots \wedge v_{p}$ on $\Lambda W \subset \Lambda X$ is $P \nu=P v_{1} \wedge \ldots \wedge P v_{p}$.

Orthogonality in $\Lambda^{p} X$ corresponds to a weaker orthogonality concept in $X$.
Definition. For subspaces $V, W \subset X, V$ is partially orthogonal to $W(V \wedge W)$ if there is a nonzero $v \in V$ such that $\langle v, w\rangle=0$ for all $w \in W$.

Proposition 2.1. Let $V, W \subset X$ and $U \subset V$ be subspaces, with $V$ represented by a blade $\nu$, and $P=\operatorname{Proj}_{W}$. Then:
i) $V \Perp W \Leftrightarrow \operatorname{dim} P(V)<\operatorname{dim} V$.
ii) If $V \Perp W$ then $P \nu=0$, otherwise $P \nu$ represents $P(V)$.
iii) If $V \not \& W$ then $U \not \subset W$.

Proposition 2.2. Let $V, W \subset X$ be nonzero subspaces, and $p=\operatorname{dim} V$. Then $V \perp W \Leftrightarrow \Lambda^{p} V \perp \Lambda^{p} W$.

### 2.2 Coordinate decomposition

Definition. For integers $1 \leq p \leq q$, let

$$
\mathcal{I}_{p}^{q}=\left\{\left(i_{1}, \ldots, i_{p}\right) \in \mathbb{N}^{p}: 1 \leq i_{1}<\ldots<i_{p} \leq q\right\}
$$

For any multi-index $I=\left(i_{1}, \ldots, i_{p}\right) \in \mathcal{I}_{p}^{q}$, we write $|I|=i_{1}+\ldots+i_{p}$ and, if $p<q$, $\hat{I}=\left(1, \ldots, \hat{i_{1}}, \ldots, \hat{i_{p}}, \ldots, q\right) \in \mathcal{I}_{q-p}^{q}$, where each $\hat{i_{k}}$ indicates that index has been removed. Also, let $\mathcal{I}_{0}^{q}=\{0\}$, and for $I \in \mathcal{I}_{0}^{q}$ let $|I|=0$ and $\hat{I}=(1, \ldots, q) \in \mathcal{I}_{q}^{q}$. For $I \in \mathcal{I}_{q}^{q}$ let $\hat{I}=0 \in \mathcal{I}_{0}^{q}$.

Definition. Given a basis $\beta=\left(w_{1}, \ldots, w_{q}\right)$ of $W \subset X$, and $1 \leq p \leq q$, the coordinate $p$-subspaces for $\beta$ are the $\binom{q}{p}$ subspaces

$$
W_{I}=\operatorname{span}\left(w_{i_{1}}, \ldots, w_{i_{p}}\right)
$$

for $I=\left(i_{1}, \ldots, i_{p}\right) \in \mathcal{I}_{p}^{q}$, which are represented by the coordinate $p$-blades of $\beta$,

$$
\begin{equation*}
\omega_{I}=w_{i_{1}} \wedge \ldots \wedge w_{i_{p}} \in \Lambda^{p} W_{I} \tag{1}
\end{equation*}
$$

For $I \in \mathcal{I}_{0}^{q}$ we have the coordinate 0-subspace $W_{I}=\{0\}$ and $\omega_{I}=1 \in \Lambda^{0} W_{I}$.
When $\beta$ is orthonormal, $\left\{\omega_{I}\right\}_{I \in \mathcal{I}_{p}^{q}}$ is an orthonormal basis of $\Lambda^{p} W$.
Definition. Given a decomposed nonzero blade $\omega=w_{1} \wedge \ldots \wedge w_{q} \in \Lambda^{q} X$, take the basis $\beta=\left(w_{1}, \ldots, w_{q}\right)$ of its subspace. For any $0 \leq p \leq q$ and $I \in \mathcal{I}_{p}^{q}$, the coordinate decomposition of $\omega$ (w.r.t. $I$ and $\beta$ ) is

$$
\begin{equation*}
\omega=\sigma_{I} \omega_{I} \wedge \omega_{\hat{I}} \tag{2}
\end{equation*}
$$

with $\omega_{I}$ and $\omega_{\hat{I}}$ as in (1), and $\sigma_{I}=(-1)^{|I|+\frac{p(p+1)}{2}}$.

### 2.3 Principal angles and vectors

Definition. The Euclidean angle $\theta_{v, w} \in[0, \pi]$ between nonzero vectors $v, w \in X$ is given by $\cos \theta_{v, w}=\frac{\operatorname{Re}\langle v, w\rangle}{\|v\|\|w\|}$. In the complex case, there is also a Hermitian angle $\gamma_{v, w} \in\left[0, \frac{\pi}{2}\right]$ defined by $\cos \gamma_{v, w}=\frac{|\langle v, w\rangle|}{\|v\|\|w\|}$.

The Hermitian angle is the Euclidean angle between $v$ and $\operatorname{span}_{\mathbb{C}}(w)$.
A list of principal angles $[4,13]$ is necessary to fully describe the relative position of high dimensional subspaces.

Definition. Let $V, W \subset X$ be nonzero subspaces, $p=\operatorname{dim} V, q=\operatorname{dim} W$ and $m=\min \{p, q\}$. Orthonormal bases $\left(e_{1}, \ldots, e_{p}\right)$ of $V$ and $\left(f_{1}, \ldots, f_{q}\right)$ of $W$ are associated principal bases, formed by principal vectors, with principal angles $0 \leq \theta_{1} \leq \ldots \leq \theta_{m} \leq \frac{\pi}{2}$, if

$$
\begin{equation*}
\left\langle e_{i}, f_{j}\right\rangle=\delta_{i j} \cos \theta_{i} \tag{3}
\end{equation*}
$$

A singular value decomposition $[4,6]$ gives such bases: for $P=\operatorname{Proj}_{W}^{V}$, the $e_{i}$ 's and $f_{i}$ 's are orthonormal eigenvectors of $P^{*} P$ and $P P^{*}$, respectively, and the $\cos \theta_{i}$ 's are square roots of the eigenvalues of $P^{*} P$, if $p \leq q$, or $P P^{*}$ otherwise. The $\theta_{i}$ 's are uniquely defined, but the $e_{i}$ 's and $f_{i}$ 's are not. $P$ is given in principal bases by a $q \times p$ diagonal matrix formed with the $\cos \theta_{i}{ }^{\prime}$ s, as

$$
P e_{i}= \begin{cases}f_{i} \cdot \cos \theta_{i} & \text { if } 1 \leq i \leq m  \tag{4}\\ 0 & \text { if } i>m\end{cases}
$$

A geometric interpretation of principal angles is that the unit sphere of $V$ projects to an ellipsoid in $W$ with semi-axes of lengths $\cos \theta_{i}$, for $1 \leq i \leq m$ (in the complex case there are 2 semi-axes for each $i$ ). They can also be described recursively with a minimization condition: $e_{1}$ and $f_{1}$ form the smallest angle $\theta_{1}$ between nonzero vectors of $V$ and $W$; in their orthogonal complements we obtain $e_{2}, f_{2}$ and $\theta_{2}$ in the same way; and so on.

### 2.4 Grassmann angles and blade products

Grassmann angles were introduced in [15], and related to blade products in [16].
Definition. Let $V, W \subset X$ be subspaces, $\nu$ be a nonzero blade representing $V$, and $P=\operatorname{Proj}_{W}$. The Grassmann angle $\Theta_{V, W} \in\left[0, \frac{\pi}{2}\right]$ is given by

$$
\begin{equation*}
\cos \Theta_{V, W}=\frac{\|P \nu\|}{\|\nu\|} \tag{5}
\end{equation*}
$$

As blade norms (squared, in the complex case) give volumes, $\Theta_{V, W}$ tells us how volumes in $V$ contract when orthogonally projected on $W$. In simple cases, where there is an unambiguous concept of angle between subspaces, $\Theta_{V, W}$ coincides with it, as when $V$ is a line, or $V$ and $W$ are planes in $\mathbb{R}^{3}$.

The main difference between Grassmann angles and similar ones [5, 7, 9, 11] is its asymmetry: $\Theta_{V, W}=\frac{\pi}{2}$ if $\operatorname{dim} V>\operatorname{dim} W$, so, in general, $\Theta_{V, W} \neq \Theta_{W, V}$
when dimensions are different. It reflects the dimensional asymmetry between the subspaces, leading to better and more general results. For example, the contraction and exterior product formulas in proposition 2.6 , or theorems 3.5 and 3.7 , only hold without any restrictions thanks to this asymmetry.

Grassmann angles work well in complex spaces, and this makes them useful for applications in areas like quantum theory. Differences due to volumes being given, in this case, by squared norms, have important implications [17, 18].

These angles have many useful properties, some of which are listed below.
Proposition 2.3. Let $V, W \subset X$ be subspaces, with principal angles $\theta_{1}, \ldots, \theta_{m}$, where $m=\min \{p, q\}$ for $p=\operatorname{dim} V$ and $q=\operatorname{dim} W$, and let $P=\operatorname{Proj}_{W}^{V}$.
i) $\Theta_{V, W}=\frac{\pi}{2} \Leftrightarrow V \perp W$.
ii) If $V=\operatorname{span}(v)$ and $W=\operatorname{span}(w)$ for nonzero $v, w \in X$ then $\Theta_{V, W}=$ $\min \left\{\theta_{v, w}, \pi-\theta_{v, w}\right\}$ in the real case, and $\Theta_{V, W}=\gamma_{v, w}$ in the complex one.
iii) If $V$ is a line and $v \in V$ then $\|P v\|=\|v\| \cos \Theta_{V, W}$.
iv) $\operatorname{vol} P(S)=\operatorname{vol} S \cdot \cos \Theta_{V, W}\left(\cos ^{2} \Theta_{V, W}\right.$ in complex case), where $S \subset V$ is a parallelotope and vol is the $p$-dimensional volume ( $2 p$ in complex case).
v) $\cos ^{2} \Theta_{V, W}=\operatorname{det}\left(\overline{\mathbf{P}}^{T} \mathbf{P}\right)$, where $\mathbf{P}$ is a matrix for $P$ in orthonormal bases of $V$ and $W$.
vi) If $p>q$ then $\Theta_{V, W}=\frac{\pi}{2}$, otherwise $\cos \Theta_{V, W}=\prod_{i=1}^{m} \cos \theta_{i}$.
vii) If $p=q$ then $\Theta_{V, W}=\Theta_{W, V}$.
viii) $\Theta_{T(V), T(W)}=\Theta_{V, W}$ for any orthogonal (unitary, in the complex case) transformation $T: X \rightarrow X$.
ix) If $V^{\prime}$ and $W^{\prime}$ are the orthogonal complements of $V \cap W$ in $V$ and $W$, respectively, then $\Theta_{V, W}=\Theta_{V^{\prime}, W^{\prime}}$.
x) $\Theta_{V, W}=\Theta_{W^{\perp}, V^{\perp}}$.

The Grassmann angle with an orthogonal complement has extra properties which grant it a special name and notation.

Definition. The complementary Grassmann angle $\Theta_{V, W}^{\perp} \in\left[0, \frac{\pi}{2}\right]$ of subspaces $V, W \subset X$ is $\Theta_{V, W}^{\perp}=\Theta_{V, W^{\perp}}$.

In general, this is not the usual complement, i.e. $\Theta_{V, W}^{\perp} \neq \frac{\pi}{2}-\Theta_{V, W}$.
Proposition 2.4. Let $V, W \subset X$ be subspaces.
i) $\Theta_{V, W}^{\perp}=0 \Leftrightarrow V \perp W$.
ii) $\Theta_{V, W}^{\perp}=\frac{\pi}{2} \Leftrightarrow V \cap W \neq\{0\}$.
iii) If $\theta_{1}, \ldots, \theta_{m}$ are the principal angles then $\cos \Theta_{V, W}^{\perp}=\prod_{i=1}^{m} \sin \theta_{i}$.
iv) If $V$ is a line then $\Theta_{V, W}^{\perp}=\frac{\pi}{2}-\Theta_{V, W}$.
v) $\Theta_{V, W}^{\perp}=\Theta_{W, V}^{\perp}$.

In section 3 we get a simpler way to prove (iii) than the one in [15].
Definition. The (left) contraction of $\nu \in \Lambda^{p} X$ on $\omega \in \Lambda^{q} X$ is the unique $\nu\lrcorner \omega \in \Lambda^{q-p} X$ such that, for all $\mu \in \Lambda^{q-p} X$,

$$
\begin{equation*}
\langle\mu, \nu\lrcorner \omega\rangle=\langle\nu \wedge \mu, \omega\rangle . \tag{6}
\end{equation*}
$$

This contraction coincides with the inner product when $p=q$, and it is asymmetric, with $\nu\lrcorner \omega=0$ if $p>q$. It differs from the one used in Clifford geometric algebra [3] by a reversion.

Proposition 2.5. For $\nu \in \Lambda^{p} X$ and any blade $\omega \in \Lambda^{q} X$, with $p \leq q$,

$$
\begin{equation*}
\nu\lrcorner \omega=\sum_{I \in \mathcal{I}_{p}^{q}} \sigma_{I}\left\langle\nu, \omega_{I}\right\rangle \omega_{\hat{I}} \tag{7}
\end{equation*}
$$

where $\sigma_{I}, \omega_{I}$ and $\omega_{\hat{I}}$ are as in (2) for any decomposition $\omega=w_{1} \wedge \ldots \wedge w_{q}$.
Proposition 2.6. Let $\nu, \omega \in \Lambda X$ be blades representing $V, W \subset X$, respectively.
i) $|\langle\nu, \omega\rangle|=\|\nu\|\|\omega\| \cos \Theta_{V, W}$, if $\nu$ and $\omega$ have equal grades.
ii) $\| \nu\lrcorner \omega\|=\| \nu\left\|\|\omega\| \cos \Theta_{V, W}\right.$.
iii) $\|\nu \wedge \omega\|=\|\nu\|\|\omega\| \cos \Theta_{V, W}^{\perp}$.

With a Grassmann angle $\boldsymbol{\Theta}_{V, W}$ for oriented subspaces (with orientations of $\nu, \omega \in \Lambda^{p} X$ ) given by $\cos \Theta_{V, W}=\frac{\langle\nu, \omega\rangle}{|\langle\nu, \omega\rangle|} \cos \Theta_{V, W}$ if $\langle\nu, \omega\rangle \neq 0$, otherwise $\boldsymbol{\Theta}_{V, W}=\frac{\pi}{2}$, we also have

$$
\begin{equation*}
\langle\nu, \omega\rangle=\|\nu\|\|\omega\| \cos \boldsymbol{\Theta}_{V, W} \tag{8}
\end{equation*}
$$

## 3 Formulas for Grassmann angles

Here we give formulas for computing Grassmann and complementary Grassmann angles in terms of arbitrary bases, thus generalizing proposition $2.3 v$. They can be adapted for use with similar angles [5, 7, 9, 11], with some dimensional restrictions $\left(\operatorname{dim} V \leq \operatorname{dim} W\right.$ in theorem $3.5, \operatorname{dim} V \leq \operatorname{dim} W^{\perp}$ in theorem 3.7) as these other angles are symmetric.

The first formula, for subspaces of same dimension, follows from proposition 2.6i. A similar result, for the real case, appears in [5].
Theorem 3.1. Given bases $\left(v_{1}, \ldots, v_{p}\right)$ and $\left(w_{1}, \ldots, w_{p}\right)$ of p-dimensional subspaces $V, W \subset X$, let $A=\left(\left\langle w_{i}, w_{j}\right\rangle\right), B=\left(\left\langle w_{i}, v_{j}\right\rangle\right)$ and $D=\left(\left\langle v_{i}, v_{j}\right\rangle\right)$. Then

$$
\cos ^{2} \Theta_{V, W}=\frac{|\operatorname{det} B|^{2}}{\operatorname{det} A \cdot \operatorname{det} D}
$$

Example 3.2. In $\mathbb{C}^{3}$, let $V=\operatorname{span}\left(v_{1}, v_{2}\right)$ and $W=\operatorname{span}\left(w_{1}, w_{2}\right)$ with $v_{1}=$ $(1,-\xi, 0), v_{2}=\left(0, \xi,-\xi^{2}\right), w_{1}=(1,0,0)$ and $w_{2}=(0, \xi, 0)$, where $\xi=e^{\mathrm{i} \frac{2 \pi}{3}}$. The theorem gives $\Theta_{V, W}=\arccos \frac{\sqrt{3}}{3}$. Since $v=\left(\xi, \xi^{2},-2\right) \in V$ and $w=$ $(1, \xi, 0) \in W$ are orthogonal to $V \cap W=\operatorname{span}\left(v_{1}\right)$, proposition $2.3 i i$ and $i x$ give $\Theta_{V, W}=\Theta_{\operatorname{span}(v), \operatorname{span}(w)}=\gamma_{v, w}$, and the Hermitian angle formula confirms the result.

The next formulas require some determinant identities.
Proposition 3.3 (Laplace's Expansion [22, p.80]). Given a $q \times q$ matrix $M$ and a multi-index $J \in \mathcal{I}_{p}^{q}$, with $1 \leq p<q$,

$$
\operatorname{det} M=\sum_{I \in \mathcal{I}_{p}^{q}}(-1)^{|I|+|J|} \operatorname{det} M_{I, J} \cdot \operatorname{det} M_{\hat{I}, \hat{J}}
$$

where $M_{I, J}$ is the $p \times p$ submatrix formed by entries with row indices in $I$ and column indices in $J$, and $M_{\hat{I}, \hat{J}}$ is the $(q-p) \times(q-p)$ submatrix formed by entries with row indices not in I and column indices not in $J$.
Proposition 3.4 (Schur's determinant identity [1]). Let $M=\left(\begin{array}{cc}A & B \\ D\end{array}\right)$ be $a(q+$ $p) \times(q+p)$ matrix, partitioned into $q \times q, q \times p, p \times q$ and $p \times p$ matrices $A$, $B, C$ and $D$, respectively. If $A$ is invertible then

$$
\begin{equation*}
\operatorname{det} M=\operatorname{det} A \cdot \operatorname{det}\left(D-C A^{-1} B\right) \tag{9}
\end{equation*}
$$

Likewise, if $D$ is invertible then

$$
\begin{equation*}
\operatorname{det} M=\operatorname{det} D \cdot \operatorname{det}\left(A-B D^{-1} C\right) \tag{10}
\end{equation*}
$$

Proof. Follows by decomposing $M$ into block triangular matrices, as $M=$ $\left(\begin{array}{ll}A & 0_{q \times p} \\ C & \mathbb{1}_{p \times p}\end{array}\right)\left(\begin{array}{cc}\mathbb{1}_{q \times q} & A^{-1} B \\ 0_{p \times q} & D-C A^{-1} B\end{array}\right)$ or $M=\left(\begin{array}{cc}A-B D^{-1} C & B D^{-1} \\ 0_{p \times q} & \mathbb{1}_{p \times p}\end{array}\right)\left(\begin{array}{cc}\mathbb{1}_{q \times q} & 0_{q \times p} \\ C\end{array}\right)$.

We now get a formula for distinct dimensions, simpler than one given in [7] for a similar angle (which corrects another formula from [23]).

Theorem 3.5. Given bases $\left(v_{1}, \ldots, v_{p}\right)$ of $V$ and $\left(w_{1}, \ldots, w_{q}\right)$ of $W$, let $A=$ $\left(\left\langle w_{i}, w_{j}\right\rangle\right), B=\left(\left\langle w_{i}, v_{j}\right\rangle\right)$, and $D=\left(\left\langle v_{i}, v_{j}\right\rangle\right)$. Then

$$
\cos ^{2} \Theta_{V, W}=\frac{\operatorname{det}\left(\bar{B}^{T} A^{-1} B\right)}{\operatorname{det} D}
$$

Proof. If $p>q$ then $\Theta_{V, W}=\frac{\pi}{2}$, and the determinant of $\bar{B}^{T} A^{-1} B$ vanishes as it is a $p \times p$ matrix with rank at most $q$.

If $p \leq q$, applying proposition 3.3 , with $J=(q+1, \ldots, q+p)$, to the $(q+p) \times(q+p)$ block matrix $M=\left(\begin{array}{cc}A & B \\ \bar{B}^{T} & 0_{p \times p}\end{array}\right)$, we get

$$
\operatorname{det} M=\sum_{I \in \mathcal{I}_{p}^{q}}(-1)^{|I|+p q+\frac{p(p+1)}{2}} \cdot \operatorname{det} B_{I} \cdot \operatorname{det} N_{\hat{I}}
$$

where $B_{I}$ is the $p \times p$ submatrix of $M$ formed by lines of $B$ with indices in $I$, and $N_{\hat{I}}=\binom{A_{\hat{I}}}{\bar{B}^{T}}$ is its $q \times q$ complementary submatrix, formed by lines of $A$ with indices not in $I$ and all of $\bar{B}^{T}$.

For $\nu=v_{1} \wedge \ldots \wedge v_{p}$ and $\omega=w_{1} \wedge \ldots \wedge w_{q}$ we have, by (6) and (7),

$$
\left.\| \nu\lrcorner \omega \|^{2}=\langle\nu \wedge(\nu\lrcorner \omega), \omega\right\rangle=\sum_{I \in \mathcal{I}_{p}^{q}} \sigma_{I}\left\langle\omega_{I}, \nu\right\rangle\left\langle\nu \wedge \omega_{\hat{I}}, \omega\right\rangle .
$$

Since $\operatorname{det} B_{I}=\left\langle\omega_{I}, \nu\right\rangle, \operatorname{det} N_{\hat{I}}=\left\langle\omega_{\hat{I}} \wedge \nu, \omega\right\rangle=(-1)^{p q+p}\left\langle\nu \wedge \omega_{\hat{I}}, \omega\right\rangle$ and $\sigma_{I}=$ $(-1)^{|I|+\frac{p(p+1)}{2}}$, we obtain $\left.\| \nu\right\lrcorner \omega \|^{2}=(-1)^{p} \operatorname{det} M$. Proposition $2.6 i i$ then gives $\cos ^{2} \Theta_{V, W}=\frac{(-1)^{p} \operatorname{det} M}{\operatorname{det} D \operatorname{det} A}$, and the result follows from (9).
Example 3.6. In $\mathbb{R}^{4}$, let $v=(1,0,1,0), w_{1}=(0,1,1,0)$, $w_{2}=(1,2,2,-1)$, $V=\operatorname{span}(v)$ and $W=\operatorname{span}\left(w_{1}, w_{2}\right)$. Then $A=\left(\begin{array}{cc}2 & 4 \\ 4 & 10\end{array}\right), B=\binom{1}{3}$ and $D=(2)$, and the theorem gives $\Theta_{V, W}=45^{\circ}$, as one can verify by projecting $v$ on $W$. Switching the roles of $V$ and $W$, we now have $A=(2), B=\left(\begin{array}{ll}1 & 3\end{array}\right), D=\left(\begin{array}{ll}2 & 4 \\ 4 & 10\end{array}\right)$ and $\Theta_{W, V}=90^{\circ}$, which is correct since $\operatorname{dim} W>\operatorname{dim} V$.

We now get formulas for the complementary Grassmann angle.
Theorem 3.7. Given bases $\left(v_{1}, \ldots, v_{p}\right)$ of $V$ and $\left(w_{1}, \ldots, w_{q}\right)$ of $W$, let $A=$ $\left(\left\langle w_{i}, w_{j}\right\rangle\right), B=\left(\left\langle w_{i}, v_{j}\right\rangle\right)$, and $D=\left(\left\langle v_{i}, v_{j}\right\rangle\right)$. Then

$$
\begin{equation*}
\cos ^{2} \Theta_{V, W}^{\perp}=\frac{\operatorname{det}\left(A-B D^{-1} \bar{B}^{T}\right)}{\operatorname{det} A} \tag{11}
\end{equation*}
$$

Proof. Let $\nu=v_{1} \wedge \ldots \wedge v_{p}$ and $\omega=w_{1} \wedge \ldots \wedge w_{q}$. The result is obtained applying proposition 2.6 iii to $\omega \wedge \nu$, and using (10) with $M=\left(\begin{array}{cc}A & B \\ \bar{B}^{T} & D\end{array}\right)$.

Corollary 3.8. If $\mathbf{P}$ is a matrix representing $\operatorname{Proj}_{W}^{V}$ in orthonormal bases of $V$ and $W$ then

$$
\begin{equation*}
\cos ^{2} \Theta_{V, W}^{\perp}=\operatorname{det}\left(\mathbb{1}_{q \times q}-\mathbf{P} \overline{\mathbf{P}}^{T}\right) \tag{12}
\end{equation*}
$$

This gives an easy way to prove proposition $2.4 i i i$, as in principal bases $\mathbf{P}$ is a diagonal matrix formed with the $\cos \theta_{i}$ 's.

Example 3.9. In example 3.6, (11) gives $\Theta_{V, W}^{\perp}=45^{\circ}$, in agreement with proposition 2.4iv. The same formula also gives $\Theta_{W, V}^{\perp}=45^{\circ}$, as expected by proposition 2.4v. Direct calculations show the principal angles of $V$ and $W^{\perp}$ are $0^{\circ}$ and $45^{\circ}$, as are those of $W$ and $V^{\perp}$, confirming the results.

Example 3.10. In example 3.2, using (11) with the bases $\left(v_{1}, v_{2}\right)$ and $\left(w_{1}, w_{2}\right)$, or (12) with the orthonormal bases $\left(\frac{v_{1}}{\sqrt{2}}, \frac{v}{\sqrt{6}}\right)$ and $\left(\frac{v_{1}}{\sqrt{2}}, \frac{w}{\sqrt{2}}\right)$, we get $\Theta_{V, W}^{\perp}=90^{\circ}$, as expected by proposition $2.4 i i$, since $V \cap W \neq\{0\}$.

Figure 1: Pythagorean identities for subspaces of equal dimensions.

## 4 Generalized Pythagorean identities

The Pythagorean trigonometric identity $\cos ^{2} \theta+\sin ^{2} \theta=1$ can be written as $\cos ^{2} \theta_{x}+\cos ^{2} \theta_{y}=1$, with $\theta_{x}$ and $\theta_{y}$ being angles a line in $\mathbb{R}^{2}$ makes with the axes. We give generalizations for Grassmann angles which, with proposition 2.3iv, lead to real and complex Pythagorean theorems for volumes [17]. Some correspond to known results in real spaces, which are now extended to the complex case, with important implications for quantum theory [18]. We also get a geometric interpretation for a property of the Clifford product.

The first identity relates the Grassmann angles of a (real or complex) line with all subspaces of an orthogonal partition of $X$.

Theorem 4.1. Given an orthogonal partition $X=W_{1} \oplus \cdots \oplus W_{k}$ and a line $L \subset X$,

$$
\begin{equation*}
\sum_{i=1}^{k} \cos ^{2} \Theta_{L, W_{i}}=1 \tag{13}
\end{equation*}
$$

Proof. Given a nonzero $v \in L$, as $\|v\|^{2}=\sum_{i}\left\|\operatorname{Proj}_{W_{i}} v\right\|^{2}$ the result follows from proposition 2.3iii.

Example 4.2. If $\theta_{x}, \theta_{y}$ and $\theta_{z}$ are the angles between a line in $\mathbb{R}^{3}$ and the axes (fig. 1a), then $\cos ^{2} \theta_{x}+\cos ^{2} \theta_{y}+\cos ^{2} \theta_{z}=1$.

This is a known identity for direction cosines and, like other examples we give, is only meant to illustrate the theorem in $\mathbb{R}^{3}$. The relevance of our result lies mainly in the complex case, where it has important connections with quantum theory.

Example 4.3. If $X$ is the complex Hilbert space of a quantum system, $L$ is the complex line of a quantum state vector $\psi$, and the $W_{i}$ 's are the eigenspaces of
a quantum observable, the probability of getting result $i$ when measuring $\psi$ is $p_{i}=\left\|\operatorname{Proj}_{W_{i}} \psi\right\|^{2} /\|\psi\|^{2}$ [2]. So, by proposition 2.3iii, $p_{i}=\cos ^{2} \Theta_{L, W_{i}}$, and (13) reflects the fact that the total probability is 1 .

By proposition $2.3 i v, \cos ^{2} \Theta_{L, W_{i}}$ measures area contraction in orthogonal projections of the complex line $L$. This is explored in [18] to get a new interpretation for quantum probabilities and derive the Born rule.

The next identities relate Grassmann angles of a (real or complex) subspace with coordinate subspaces of an orthogonal basis of $X$.

Theorem 4.4. If $V \subset X$ is a p-dimensional subspace, and $n=\operatorname{dim} X$,

$$
\sum_{I \in \mathcal{I}_{p}^{n}} \cos ^{2} \Theta_{V, W_{I}}=1
$$

where the $W_{I}$ 's are the coordinate p-subspaces of an orthogonal basis of $X$.
Proof. Without loss of generality, assume the basis is orthonormal, so its coordinate $p$-blades $\omega_{I}$ form an orthonormal basis of $\Lambda^{p} X$. For an unit blade $\nu \in \Lambda^{p} V \subset \Lambda^{p} X$ we have $\sum_{I}\left|\left\langle\nu, \omega_{I}\right\rangle\right|^{2}=1$, and the result follows from proposition 2.6 .

A similar result for the real case, in terms of products of cosines of principal angles, appears in [20]. The theorem extends to affine subspaces, as in the next example, which is a dual of example 4.2 via proposition $2.3 x$.

Example 4.5. If $\theta_{x y}, \theta_{x z}$ and $\theta_{y z}$ are the angles a plane in $\mathbb{R}^{3}$ makes with the coordinate planes (fig. 1b) then $\cos ^{2} \theta_{x y}+\cos ^{2} \theta_{x z}+\cos ^{2} \theta_{y z}=1$.

Example 4.6. Let $\xi, w_{1}, w_{2}$ and $V$ be as in example $3.2, w_{3}=\left(0,0, \xi^{2}\right)$ and $W_{i j}=\operatorname{span}\left(w_{i}, w_{j}\right)$. As the unitary transformation given by $T=\left(\begin{array}{lll}0 & 0 & \xi \\ \xi & 0 & 0 \\ 0 & \xi & 0\end{array}\right)$ maps $W_{12} \mapsto W_{23}, W_{23} \mapsto W_{13}$, and preserves $V$, proposition 2.3 viii gives $\Theta_{V, W_{12}}=$ $\Theta_{V, W_{23}}=\Theta_{V, W_{13}}$. Since $W_{12}, W_{13}$ and $W_{23}$ are the coordinate 2-subspaces of the orthogonal basis $\left(w_{1}, w_{2}, w_{3}\right)$ of $\mathbb{C}^{3}$, theorem 4.4 gives $\cos \Theta_{V, W_{i j}}=\frac{\sqrt{3}}{3}$, in agreement with that example.

A formula relating the geometric product of Clifford algebra [8] to Grassmann angles, given in [16], implies $\|A B\|^{2}=\|A\|^{2}\|B\|^{2} \sum_{J} \cos ^{2} \Theta_{V, Y_{J}}$, where $A$ and $B$ are $p$-blades representing subspaces $V$ and $W$, and the $Y_{J}$ 's are all coordinate $p$-subspaces of a certain orthogonal basis of $Y=V+W$. This gives a geometric interpretation for a simple yet important property of this product. Those in proposition 2.6 are submultiplicative for blades because they correspond to projections on single subspaces. The geometric product, on the other hand, involves projections on all $Y_{J}$ 's, and with theorem 4.4 we see this is what allows $\|A B\|=\|A\|\|B\|$.

Extending a result of [21], we also have identities for Grassmann angles with coordinate subspaces of a dimension different from $V$.

Theorem 4.7. Let $V \subset X$ be a p-dimensional subspace, $0 \leq q \leq n=\operatorname{dim} X$, and the $W_{I}$ 's be the coordinate $q$-subspaces of an orthogonal basis of $X$.
i) If $p \leq q$ then $\sum_{I \in \mathcal{I}_{q}^{n}} \cos ^{2} \Theta_{V, W_{I}}=\binom{n-p}{n-q}$.
ii) If $p>q$ then $\sum_{I \in \mathcal{I}_{q}^{n}} \cos ^{2} \Theta_{W_{I}, V}=\binom{p}{q}$.

Proof. We can assume $p, q \neq 0$ and that the basis is orthonormal. So, for $0 \leq r \leq n$ and with $\omega_{I}$ 's as in (1), $\left\{\omega_{I}\right\}_{I \in \mathcal{I}_{r}^{n}}$ and $\left\{\omega_{\hat{I}}\right\}_{I \in \mathcal{I}_{r}^{n}}$ are orthonormal bases of $\Lambda^{r} X$ and $\Lambda^{n-r} X$, respectively.
(i) For an unit blade $\nu \in \Lambda^{p} V$ and $I=\left(i_{1}, \ldots, i_{q}\right) \in \mathcal{I}_{q}^{n}$ we have, by (7),

$$
\nu\lrcorner \omega_{I}=\sum_{J \in \mathcal{I}_{p}^{q}} \sigma_{J}\left\langle\nu,\left(\omega_{I}\right)_{J}\right\rangle\left(\omega_{I}\right)_{\hat{J}}
$$

where $\left(\omega_{I}\right)_{J}=w_{i_{j_{1}}} \wedge \ldots \wedge w_{i_{j_{p}}}$ for $J=\left(j_{1}, \ldots, j_{p}\right)$, and likewise for $\left(\omega_{I}\right)_{\hat{J}}$. As the $\left(\omega_{I}\right)_{\hat{J}}$ 's are orthonormal, proposition $2.6 i i$ gives

$$
\left.\cos ^{2} \Theta_{V, W_{I}}=\| \nu\right\lrcorner \omega_{I} \|^{2}=\sum_{J \in \mathcal{I}_{p}^{q}}\left|\left\langle\nu,\left(\omega_{I}\right)_{J}\right\rangle\right|^{2},
$$

and therefore

$$
\begin{aligned}
\sum_{I \in \mathcal{I}_{q}^{n}} \cos ^{2} \Theta_{V, W_{I}} & =\sum_{I \in \mathcal{I}_{q}^{n}} \sum_{J \in \mathcal{I}_{p}^{q}}\left|\left\langle\nu,\left(\omega_{I}\right)_{J}\right\rangle\right|^{2} \\
& =\frac{\binom{n}{q}\binom{q}{p}}{\binom{n}{p}} \sum_{K \in \mathcal{I}_{p}^{n}}\left|\left\langle\nu, \omega_{K}\right\rangle\right|^{2}=\binom{n-p}{n-q}\|\nu\|^{2},
\end{aligned}
$$

where the binomial coefficients account for the number of times each $\omega_{K}$ appears as a $\left(\omega_{I}\right)_{J}$ in the double summation.
(ii) For each $I \in \mathcal{I}_{q}^{n}$, proposition $2.3 x$ gives $\Theta_{W_{I}, V}=\Theta_{V^{\perp}, W_{I} \perp}$. As $W_{I}^{\perp}=W_{\hat{I}}$ for $\hat{I} \in \mathcal{I}_{n-q}^{n}$, and $\operatorname{dim} V^{\perp}=n-p<n-q=\operatorname{dim} W_{I}{ }^{\perp}$, the result follows from the previous case.

The following examples are again duals of each other.
Example 4.8. If $\theta_{x y}, \theta_{x z}$ and $\theta_{y z}$ are the angles a line in $\mathbb{R}^{3}$ makes with the coordinate planes (fig. 2a) then $\cos ^{2} \theta_{x y}+\cos ^{2} \theta_{x z}+\cos ^{2} \theta_{y z}=2$.

Example 4.9. If $\theta_{x}, \theta_{y}$ and $\theta_{z}$ are the angles between the axes and a plane in $\mathrm{R}^{3}$ (fig. 2b) then $\cos ^{2} \theta_{x}+\cos ^{2} \theta_{y}+\cos ^{2} \theta_{z}=2$.

Figure 2: Pythagorean identities for subspaces of different dimensions.

## 5 Other identities

Using the Grassmann angle $\Theta_{V, W}$ for oriented subspaces, we have:
Theorem 5.1. Given p-dimensional oriented subspaces $V, W \subset X$,

$$
\cos \boldsymbol{\Theta}_{V, W}=\sum_{I \in \mathcal{I}_{p}^{n}} \cos \boldsymbol{\Theta}_{V, X_{I}} \cos \boldsymbol{\Theta}_{W, X_{I}}
$$

where the $X_{I}$ 's are the coordinate p-subspaces of an orthogonal basis of $X$, with orientations given by the corresponding coordinate p-blades.

Proof. The result follows by decomposing unit blades $\nu \in \Lambda^{p} V$ and $\omega \in \Lambda^{p} W$ (with the orientations of $V$ and $W$ ) in the orthonormal basis of $\Lambda^{p} X$ formed with the normalized coordinate $p$-blades, and applying (8).

This gives an inequality for $\cos \Theta_{V, W}=\left|\cos \boldsymbol{\Theta}_{V, W}\right|$, like one from [21].
Corollary 5.2. $\cos \Theta_{V, W} \leq \sum_{I} \cos \Theta_{V, X_{I}} \cos \Theta_{W, X_{I}}$.
Example 5.3. $\cos \theta=\cos \alpha_{x} \cos \beta_{x}+\cos \alpha_{y} \cos \beta_{y}+\cos \alpha_{z} \cos \beta_{z}$ for the angle $\theta \in[0, \pi]$ between 2 oriented lines in $\mathbb{R}^{3}$ forming angles $\alpha_{x}, \alpha_{y}, \alpha_{z}$ and $\beta_{x}, \beta_{y}, \beta_{z}$ (all in $[0, \pi]$ ) with the positive axes.

The last identities will require some preparation.
Definition. A coordinate subspace of a principal basis $\beta$ of $V$ w.r.t. $W$ is a principal subspace ${ }^{1}$ (of $V$ w.r.t. $W$, for $\beta$ ). Two or more subspaces of $V$ are coprincipal (w.r.t. $W$ ) if they are principal for the same $\beta$.

Note that a subspace being principal depends on both $V$ and $W$, even if they are left implicit. Also, $\{0\}$ is always principal.

[^1]Lemma 5.4. Let $V, W \subset X$ be nonzero subspaces and $U \subset V$ be any subspace. If $U \perp W$ then $U$ is principal w.r.t. $W$.

Proof. By (3), the union of an orthonormal basis of $U$ and a principal basis of $U^{\perp} \cap V$ w.r.t. $W$ gives a principal basis of $V$ w.r.t. $W$.

Lemma 5.5. Let $V, W \subset X$ be nonzero subspaces, with associated principal bases $\beta_{V}$ and $\beta_{W}, U \subset V$ be any subspace, and $P=\operatorname{Proj}_{W}$. Then:
i) $U$ is principal for $\beta_{V} \Leftrightarrow U^{\perp} \cap V$ is principal for $\beta_{V}$.
ii) $U$ is principal for $\beta_{V} \Rightarrow P(U)$ is principal for $\beta_{W}$. The converse holds if $V \not \& W$.

Proof. (i) If $U$ is spanned by some vectors of the orthogonal basis $\beta_{V}, U^{\perp} \cap V$ is spanned by the others. (ii) Follows from (4), and the converse from proposition 2.1 as well.

Proposition 5.6. Let $V, W \subset X$ be nonzero subspaces, $U \subset V$ be any subspace and $P=\operatorname{Proj}_{W}$. Then $U$ is principal $\Leftrightarrow P(U) \perp P\left(U^{\perp} \cap V\right)$.

Proof. ( $\Rightarrow$ ) Follows from (4). $(\Leftarrow)$ By lemmas 5.4 and $5.5 i$, we can assume $U$, $U^{\perp} \cap V, P(U)$ and $P\left(U^{\perp} \cap V\right)$ are not $\{0\}$. As $P(U) \perp P\left(U^{\perp} \cap V\right)$ implies $U \perp P\left(U^{\perp} \cap V\right)$ and $P(U) \perp U^{\perp} \cap V$, from associated principal bases of $U$ and $P(U)$, and of $U^{\perp} \cap V$ and $P\left(U^{\perp} \cap V\right)$, we form principal bases for $V$ and $P(V)$.

Proposition 5.7. Let $V, W \subset X$ be nonzero subspaces, $V_{1}, V_{2} \subset V$ be distinct $r$-dimensional coprincipal subspaces w.r.t. $W$, and $P=\operatorname{Proj}_{W}$. Then:
i) $V_{1} \Perp V_{2}$.
ii) If $V_{1} \not \perp W$ then $P\left(V_{1}\right) \Perp P\left(V_{2}\right)$.
iii) $\left\langle\nu_{1}, \nu_{2}\right\rangle=0$ and $\left\langle P \nu_{1}, P \nu_{2}\right\rangle=0$ for any $\nu_{1} \in \Lambda^{r} V_{1}, \nu_{2} \in \Lambda^{r} V_{2}$.

Proof. (i) $V_{1}$ has an element $e$ of the principal basis which $V_{2}$ does not. (ii) If $V_{1} \not \perp \not W$ then $P e \neq 0$, and by proposition $5.6 P(\operatorname{span}(e)) \perp P\left(V_{2}\right)$. (iii) By proposition 2.2, $\Lambda^{r} V_{1} \perp \Lambda^{r} V_{2}$ and, if $V_{1} \not \perp W, \Lambda^{r} P\left(V_{1}\right) \perp \Lambda^{r} P\left(V_{2}\right)$. If $V_{1} \perp W$ then $P \nu_{1}=0$, by proposition 2.1ii.

Theorem 5.8. Given nonzero subspaces $V, W \subset X$ and $U \subset V$, let $r=\operatorname{dim} U$ and $p=\operatorname{dim} V$. Then

$$
\cos ^{2} \Theta_{U, W}=\sum_{I \in \mathcal{I}_{r}^{p}} \cos ^{2} \Theta_{U, V_{I}} \cdot \cos ^{2} \Theta_{V_{I}, W}
$$

where the $V_{I}$ 's are coordinate r-subspaces of a principal basis $\beta$ of $V$ w.r.t. $W$.

Figure 3: $\cos ^{2} \beta=\cos ^{2} \alpha+\sin ^{2} \alpha \cos ^{2} \theta$

Proof. The coordinate $r$-blades $\nu_{I} \in \Lambda^{r} V_{I}$ of $\beta$ form an orthonormal basis of $\Lambda^{r} V$, so $P \mu=\sum_{I}\left\langle\nu_{I}, \mu\right\rangle P \nu_{I}$ for an unit $\mu \in \Lambda^{r} U$ and $P=\operatorname{Proj}_{W}$. By proposition 5.7 the $P \nu_{I}$ 's are mutually orthogonal, so $\|P \mu\|^{2}=\sum_{I}\left|\left\langle\mu, \nu_{I}\right\rangle\right|^{2}\left\|P \nu_{I}\right\|^{2}$. The result follows from proposition $2.6 i$ and (5).

By theorem $4.4 \sum_{I \in \mathcal{I}_{r}^{p}} \cos ^{2} \Theta_{U, V_{I}}=1$, so this result means $\cos ^{2} \Theta_{U, W}$ is a weighted average of the $\cos ^{2} \Theta_{V_{I}, W}$ 's, with weights given by the $\cos ^{2} \Theta_{U, V_{I}}$ 's.
Example 5.9. Given planes $V, W \subset \mathbb{R}^{3}$ and a line $U \subset V$, let $\alpha=\Theta_{U, V \cap W}$, $\beta=\Theta_{U, W}$ and $\theta=\Theta_{V, W}$ (fig. 3). As $V \cap W$ and $(V \cap W)^{\perp} \cap V$ are principal lines of $V$ w.r.t. $W$, we have $\cos ^{2} \beta=\cos ^{2} \alpha \cdot 1+\sin ^{2} \alpha \cdot \cos ^{2} \theta$.

Definition. A partition $V=\bigoplus_{i} V_{i}$ is principal w.r.t. $W$ if the $V_{i}$ 's are coprincipal subspaces of $V$ w.r.t. $W$.

Any principal partition is an orthogonal partition. Note that some subspaces of a partition can be $\{0\}$.

Proposition 5.10. Let $V, W \subset X$ be nonzero subspaces, $P=\operatorname{Proj}_{W}$, and $V=\bigoplus_{i} V_{i}$ be an orthogonal partition. The following are equivalent:
i) $V=\bigoplus_{i} V_{i}$ is a principal partition w.r.t. $W$.
ii) $P(V)=\bigoplus_{i} P\left(V_{i}\right)$ is a principal partition w.r.t. $V$.
iii) $P(V)=\bigoplus_{i} P\left(V_{i}\right)$ is an orthogonal partition.

Proof. ( $i \Rightarrow$ ii) The $P\left(V_{i}\right)$ 's are pairwise disjoint by proposition 5.6, and coprincipal by lemma 5.5ii. (ii $\Rightarrow$ iii) Immediate. $(i i i \Rightarrow i)$ As the $P\left(V_{i}\right)$ 's are mutually orthogonal, $V_{i} \perp P\left(V_{j}\right)$ if $i \neq j$. As the $V_{i}$ 's are also mutually orthogonal, by (3) the union of principal bases of theirs w.r.t. $W$ gives a principal basis of $V$.

In [15] we got $\cos \Theta_{V, W}=\prod_{i} \cos \Theta_{V_{i}, W}$ for a principal partition $V=\bigoplus_{i} V_{i}$. We now generalize this for orthogonal partitions and get a partial converse.

Theorem 5.11. Let $V_{1}, V_{2}, W \subset X$ be subspaces and $P=\operatorname{Proj}_{W}$. If $V_{1} \perp V_{2}$,

$$
\cos \Theta_{V_{1} \oplus V_{2}, W}=\cos \Theta_{V_{1}, W} \cdot \cos \Theta_{V_{2}, W} \cdot \cos \Theta_{P\left(V_{1}\right), P\left(V_{2}\right)}^{\perp}
$$

Proof. By propositions 2.1iii and 2.3i, we can assume $V_{1} \not \not \not \perp W$ and $V_{2} \not \perp W$. As $V_{1} \perp V_{2}$, if $\nu_{1}$ and $\nu_{2}$ are unit blades representing them, $\nu_{1} \wedge \nu_{2}$ is an unit blade representing $V_{1} \oplus V_{2}$. By (5), $\cos \Theta_{V_{1} \oplus V_{2}, W}=\left\|P\left(\nu_{1} \wedge \nu_{2}\right)\right\|=\left\|\left(P \nu_{1}\right) \wedge\left(P \nu_{2}\right)\right\|$, and the result follows from propositions 2.1ii and 2.6iii.

Corollary 5.12. Let $V, W \subset X$ be subspaces and $P=\operatorname{Proj}_{W}$. For an orthogonal partition $V=\bigoplus_{i=1}^{k} V_{i}$,

$$
\cos \Theta_{V, W}=\prod_{i=1}^{k} \cos \Theta_{V_{i}, W} \cdot \prod_{i=1}^{k-1} \cos \Theta_{P\left(V_{i}\right), P\left(V_{i+1} \oplus \ldots \oplus V_{k}\right)}^{\perp}
$$

Proposition 5.13. For nonzero subspaces $V, W \subset X$ with $V \not \subset W$, a partition $V=\bigoplus_{i} V_{i}$ is principal w.r.t. $W$ if, and only if, it is orthogonal and $\cos \Theta_{V, W}=$ $\prod_{i} \cos \Theta_{V_{i}, W}$.

Proof. Corollary 5.12 and propositions $2.4 i$ and 5.10 give the converse.
