Gradient solitons in statistical manifolds

Adara M. Blaga

Abstract

We provide necessary and sufficient conditions for some particular couples \((g, \nabla)\) of pseudo-Riemannian metric and affine connections to be statistical structures if we have gradient almost Einstein, almost Ricci, almost Yamabe solitons, or a more general type of solitons in the manifold. In particular cases, we establish a formula for the volume of the manifold and give a lower and an upper bound for the norm of the Ricci curvature tensor field.

1 Introduction

Information geometry was firstly studied by Amari [1] treating the properties of the geometrical structures, such as Riemannian metrics and affine connections, that naturally arise on a space of probability distributions. In this way, statistical structures became a link between information geometry and affine geometry. Such an example of Riemannian metric is the Fisher information metric defined on the manifold of probability distributions [35].

In differential geometry, a statistical structure on a smooth manifold \(M\) consists of a pseudo-Riemannian metric \(g\) and a torsion-free affine connection \(\nabla\) such that \(\nabla g\) is a Codazzi tensor field. For a pair \((g, \nabla)\), the dual connection \(\nabla^*\) is uniquely defined by

\[
X(g(Y, Z)) = g(\nabla_X Y, Z) + g(Y, \nabla^*_X Z), \quad X, Y, Z \in \mathfrak{X}(M)
\]

and \((\nabla, \nabla^*)\) is said to be a dualistic structure, this duality playing an important role in statistics.

2020 Mathematics Subject Classification. 35C08, 35Q51, 53B05.

Key words and phrases. Affine connections, statistical structures, gradient solitons.
A particular statistical structure when the curvature tensor field of $\nabla$ vanishes is the Hessian structure $[34]$. In this case, also the curvature tensor field of the dual connection $\nabla^*$ vanishes and the manifold is called dually flat.

We extend the notion of statistical structure in the following ways:

i) if $h$ is a symmetric $(0,2)$-tensor field and $\nabla$ is a torsion-free affine connection, we call $(h, \nabla)$ a nearly statistical structure on $M$ if

$$(\nabla_X h)(Y, Z) = (\nabla_Y h)(X, Z),$$

for any $X, Y, Z \in \mathfrak{X}(M)$;

ii) if $h$ is a $(0,2)$-tensor field and $\nabla$ is an affine connection, we call $(h, \nabla)$ a quasi-statistical structure on $M$ $[30]$ if $d^\nabla h = 0$, where

$$(d^\nabla h)(X, Y, Z) := (\nabla_X h)(Y, Z) - (\nabla_Y h)(X, Z) + h(T^\nabla (X, Y), Z),$$

for any $X, Y, Z \in \mathfrak{X}(M)$.

Considered as stationary solution of a geometric flow, the notion of soliton can be generalized in very natural ways. One question is if some of these generalizations may be regarded as coming from particular flows. Nevertheless, they reveal geometrical and topological properties of the manifold.

In the context of statistical geometry, we investigate the consequences of the existence of different kind of solitons, Ricci, Einstein, Yamabe or a more general type defined by an affine connection, with a special view towards curvature. By means of an arbitrary 1-form, we consider a statistical structure, which is equiaffine if the 1-form is exact, and study some geometrical and topological properties of the solitons defined by it. Precisely, we provide a lower and an upper bound for the Ricci curvature tensor’s norm, and in the compact case, using the classical Bochner formula, we determine a relation for the volume of the manifold. It is known that the Ricci curvature tensor field is a component of the curvature of space-time, related to the matter content of the universe by means of Einstein field equation, its lower bonds allowing to deduce global geometrical properties of the manifold. Notice that different ideas concerning Riemann, Ricci, Einstein or Yamabe solitons have been treated by the author and her collaborators in $[3] – [25, 27]$. 
Solitons and statistical structures

Consider \((M, g)\) a pseudo-Riemannian manifold and let \(\nabla^g\) be the Levi-Civita connection of \(g\).

If the Ricci tensor field, \(\text{Ric}\), is non-degenerate, then \(\text{Ric}\) is a pseudo-Riemannian metric and we denote by \(\nabla^{\text{Ric}}\) the Levi-Civita connection of \(\text{Ric}\). From Koszul’s formula, we deduce:

\[
2g(\nabla^{\text{Ric}}_X Y - \nabla^g_X Y, QZ) = g((\nabla^g_Y Q)X, Z) + g((\nabla^g_X Q)Y, Z) - g((\nabla^g_Z Q)X, Y),
\]

for any \(X, Y, Z \in \mathfrak{X}(M)\).

Remark the following facts [12]:

i) \((\text{Ric}, \nabla^g)\) is a statistical structure if and only if \((\nabla^g_X Q)Y = (\nabla^g_Y Q)X\), for any \(X, Y \in \mathfrak{X}(M)\), where \(Q\) is the Ricci operator defined by \(g(QX, Y) := \text{Ric}(X, Y)\); moreover, if \(Q\) is a Codazzi tensor field, then \(QT = \frac{1}{2}\nabla^g Q\), where \(T := \nabla^{\text{Ric}} - \nabla^g\);

ii) \((g, \nabla^{\text{Ric}})\) is a statistical structure if and only if \(g(X, T(Y, Z)) = g(Y, T(X, Z))\), for any \(X, Y, Z \in \mathfrak{X}(M)\), where \(T := \nabla^{\text{Ric}} - \nabla^g\);

iii) if \((g, \nabla)\) is a quasi-statistical structure, then \((\text{Ric}, \nabla)\) is a quasi-statistical structure if and only if \(g((\nabla^g_X Q)Z, Y) = g((\nabla^g_Y Q)Z, X)\), for any \(X, Y, Z \in \mathfrak{X}(M)\).

Let \(f\) be a smooth function on \(M\). If the Hessian of \(f\), \(\text{Hess}(f)\), is non-degenerate and of constant signature, then \(\text{Hess}(f)\) is a pseudo-Riemannian metric. Geometrical interpretation of Hessian metrics has recently appeared in mirror symmetry [28], their practical importance being also shown in [2].

If we denote by \(\nabla^{\text{Hess}(f)}\) the Levi-Civita connection of \(\text{Hess}(f)\), from Koszul’s formula, we deduce:

\[
2g(\nabla^{\text{Hess}(f)}_X Y - \nabla^g_X Y, \nabla^g Z \nabla f) = g((\nabla^g)^2_{Y, X} \nabla f, Z) + g((\nabla^g)^2_{X, Z} \nabla f, X) - g((\nabla^g)^2_{Z, X} \nabla f, Y),
\]

for any \(X, Y, Z \in \mathfrak{X}(M)\), where \(\nabla f\) denotes the gradient of \(f\) and we prove:

**Proposition 2.1.** \((\text{Hess}(f), \nabla^g)\) is a statistical structure on \(M\) if and only if the radial curvature vanishes, i.e. \(R^g_{XY}(X, Y)\nabla f = 0\), for any \(X, Y \in \mathfrak{X}(M)\).

**Proof.** \(d\nabla^g \text{Hess}(f) = 0\) is equivalent to

\[
(\nabla^g_X \text{Hess}(f))(Y, Z) = (\nabla^g_Y \text{Hess}(f))(X, Z),
\]
Gradient solitons in statistical manifolds

for any \( X, Y, Z \in \mathfrak{X}(M) \), which gives

\[
X(g(\nabla^g_Y \nabla f, Z)) - g(\nabla^g_{\nabla^g_X Y} \nabla f, Z) - g(Y, \nabla^g_{\nabla^g_X Z} \nabla f) =
\]

\[
= Y(g(\nabla^g_X \nabla f, Z)) - g(\nabla^g_{\nabla^g_X Y} \nabla f, Z) - g(X, \nabla^g_{\nabla^g_Y Z} \nabla f)
\]

\[
\iff X(g(\nabla^g_Y \nabla f, Z)) - g(\nabla^g_{\nabla^g_X Y} \nabla f, Z) - g(Y, \nabla^g_{\nabla^g_X Z} \nabla f) =
\]

\[
= Y(g(\nabla^g_X \nabla f, Z)) - g(\nabla^g_{\nabla^g_X Y} \nabla f, Z) - g(X, \nabla^g_{\nabla^g_Y Z} \nabla f)
\]

\[
\iff g(\nabla^g_X \nabla^g_Y \nabla f, Z) - g(\nabla^g_{\nabla^g_X Y} \nabla f, Z) = g(\nabla^g_{\nabla^g_X Y} \nabla f, Z) - g(\nabla^g_{\nabla^g_Y X} \nabla f, Z)
\]

\[
\iff g((\nabla^g)^2_{X,Y} \nabla f - (\nabla^g)^2_{Y,X} \nabla f, Z) = 0
\]

which is equivalent to

\[ R^{\nabla^g}(X, Y) \nabla f = 0. \]

\[ \square \]

**Proposition 2.2.** If \((g, \nabla)\) is a statistical structure, then \((\text{Hess}(f), \nabla)\) is a statistical structure if and only if

\[ R^\nabla(X, Y) \nabla f = 0, \]

for any \( X, Y \in \mathfrak{X}(M) \).

**Proof.** \( d^\nabla \text{Hess}(f) = 0 \) is equivalent to

\[
(\nabla_X \text{Hess}(f))(Y, Z) - (\nabla_Y \text{Hess}(f))(X, Z) + \text{Hess}(f)(T^\nabla(X, Y), Z) = 0,
\]

for any \( X, Y, Z \in \mathfrak{X}(M) \), which gives

\[
X(g(\nabla_Y \nabla f, Z)) - g(\nabla_{\nabla_X Y} \nabla f, Z) - g(Y, \nabla_{\nabla_X Z} \nabla f) -
\]

\[
- Y(g(\nabla_X \nabla f, Z)) + g(\nabla_{\nabla_Y X} \nabla f, Z) + g(X, \nabla_{\nabla_Y Z} \nabla f) + g(T^\nabla(X, Y), \nabla_Z \nabla f) = 0.
\]

Since \( \nabla \) is torsion-free, we can express its curvature in terms of the second order derivatives, namely \( R^\nabla(X, Y) = \nabla^2_{X,Y} - \nabla^2_{Y,X} \), where \( \nabla^2_{X,Y} := \nabla_X \nabla_Y - \nabla_{\nabla_X Y} \) and the above equation becomes:

\[
(\nabla_X g)(\nabla_Y \nabla f, Z) - (\nabla_Y g)(\nabla_X \nabla f, Z) + g(R^\nabla(X, Y) \nabla f, Z) = 0
\]

which, from \( d^\nabla g = 0 \), is equivalent to \( R^\nabla(X, Y) \nabla f = 0. \)

\[ \square \]
Remark that the radial curvature was introduced by Klingenberg [29] in the context of algebraic topology, to prove a homotopy sphere theorem.

Next we shall relate statistical structures to gradient solitons (see also [12, 20, 21]). Recall that, for a pseudo-Riemannian metric $g$ and two smooth functions, $f$ and $\lambda$, the triple $(g, f, \lambda)$ is called:

i) a gradient almost Ricci soliton if

$$\text{Hess}(f) + \text{Ric} = \lambda g,$$

where $\text{Hess}(f)$ is the Hessian of $f$ and $\text{Ric}$ is the Ricci curvature tensor field of $g$;

ii) a gradient almost Einstein soliton if

$$\text{Hess}(f) + \text{Ric} = \left(\lambda - \frac{\text{scal}}{2}\right) g,$$

where $\text{scal}$ is the scalar curvature of $(M, g)$;

iii) a gradient almost Yamabe soliton if

$$\text{Hess}(f) = \left(\lambda - \text{scal}\right) g.$$  

Taking now the covariant derivative in the soliton equations, we respectively obtain:

$$(\nabla^g_X \text{Hess}(f))(Y, Z) + (\nabla^g_X \text{Ric})(Y, Z) = X(\lambda) g(Y, Z),$$

$$(\nabla^g_X \text{Hess}(f))(Y, Z) + (\nabla^g_X \text{Ric})(Y, Z) = X \left(\lambda - \frac{\text{scal}}{2}\right) g(Y, Z),$$

$$(\nabla^g_X \text{Hess}(f))(Y, Z) = X(\lambda - \text{scal}) g(Y, Z),$$

for any $X, Y, Z \in \mathfrak{X}(M)$ and we can state:

**Proposition 2.3.** i) If $\lambda$ is constant in a gradient Ricci soliton, then $(\text{Hess}(f), \nabla^g)$ is a statistical structure on $M$ if and only if $(\text{Ric}, \nabla^g)$ is a statistical structure on $M$.

ii) If $\lambda$ is constant in a gradient Einstein or Yamabe soliton and $M$ is of constant scalar curvature, then $(\text{Hess}(f), \nabla^g)$ is a statistical structure on $M$ if and only if $(\text{Ric}, \nabla^g)$ is a statistical structure on $M$.

As particular cases, we deduce from [12] the followings:
Proposition 2.4. If $(g, f, \lambda)$ define a gradient almost Einstein soliton on the smooth manifold $M$ with non-degenerate Ricci tensor field, then $(\text{Ric}, \nabla^g)$ is a statistical structure on $M$ if and only if

\begin{equation}
\begin{split}
g(R^g \nabla^g (X, Y) \nabla f, Z) &= g((\nabla^g)^2_{Y,Z} \nabla f, X) - g((\nabla^g)^2_{X,Z} \nabla f, Y) + \\
&\quad + [2Y(\lambda) - Y(\text{scal})]g(Z, X) - [2X(\lambda) - X(\text{scal})]g(Z, Y),
\end{split}
\end{equation}

for any $X, Y, Z \in \mathfrak{X}(M)$, where $(\nabla^g)^2_{X,Y} := \nabla^g_X \nabla^g_Y - \nabla^g_{\nabla^g_X Y} Z$.

Proposition 2.5. If $(g, f, \lambda)$ define a gradient almost Ricci soliton on the smooth manifold $M$ with non-degenerate Ricci tensor field, then $(\text{Ric}, \nabla^g)$ is a statistical structure on $M$ if and only if

\begin{equation}
\begin{split}
g(R^g \nabla^g (X, Y) \nabla f, Z) &= g((\nabla^g)^2_{Y,Z} \nabla f, X) - g((\nabla^g)^2_{X,Z} \nabla f, Y) + \\
&\quad + 2Y(\lambda)g(Z, X) - 2X(\lambda)g(Z, Y),
\end{split}
\end{equation}

for any $X, Y, Z \in \mathfrak{X}(M)$, where $(\nabla^g)^2_{X,Y} := \nabla^g_X \nabla^g_Y - \nabla^g_{\nabla^g_X Y} Z$.

Proposition 2.6. If $(g, \nabla)$ is a statistical structure on the smooth manifold $M$ and $(g, f, \lambda)$ define a gradient almost Einstein soliton on $M$ with non-degenerate Ricci tensor field, then $(\text{Ric}, \nabla)$ is a statistical structure on $M$ if and only if

\begin{equation}
\begin{split}
g(R^\nabla (X, Y) \nabla f, Z) &= g((\nabla^g)^2_{Y,Z} \nabla f, X) - g((\nabla^g)^2_{X,Z} \nabla f, Y) + \\
&\quad + [2Y(\lambda) - Y(\text{scal})]g(Z, X) - [2X(\lambda) - X(\text{scal})]g(Z, Y),
\end{split}
\end{equation}

for any $X, Y, Z \in \mathfrak{X}(M)$, where $\nabla^2_{X,Y} := \nabla_X \nabla_Y - \nabla_{\nabla_X Y} Z$.

From the soliton equations, we deduce respectively the followings:

\begin{align*}
\nabla^g \xi + Q &= \lambda I, \\
\nabla^g \xi + Q &= \left(\lambda - \frac{\text{scal}}{2}\right) I, \\
\nabla^g \xi &= (\lambda - \text{scal}) I,
\end{align*}

where $Q$ stands for the Ricci operator $g(QX, Y) := \text{Ric}(X, Y)$ and $\xi := \nabla f$. These leads to a more general notion of soliton, precisely \cite{25}, we consider an almost $(\nabla, J, \xi, \lambda)$-soliton on $M$ as a data $(\nabla, J, \xi, \lambda)$ which satisfy the equation:

\begin{equation}
\nabla \xi + J = \lambda I,
\end{equation}
Gradient solitons in statistical manifolds

where $\nabla$ is an affine connection, $J$ is a $(1,1)$-tensor field, $\xi$ is a vector field and $\lambda$ is a smooth function on $M$.

A straightforward computation gives:

**Lemma 2.7.** If $(\nabla, J, \xi, \lambda)$ define an almost $(\nabla, J, \xi)$-soliton on the pseudo-Riemannian manifold $(M, g)$, then the 2-form $\Omega := g(J\cdot, \cdot)$ is symmetric if and only if the endomorphism $\nabla \xi$ is self-adjoint w.r.t. $g$, i.e.

$$g(\nabla_X \xi, Y) = g(X, \nabla_Y \xi),$$

for any $X, Y \in \mathfrak{X}(M)$.

**Lemma 2.8.** [12] The 2-form $\Omega := g(J\cdot, \cdot)$ satisfies $$(\nabla_X g)(JY, Z) - (\nabla_Y g)(JX, Z) = g((\nabla_Y J)X - (\nabla_X J)Y, Z).$$

In particular, $\Omega$ is a Codazzi tensor field, i.e. $$(\nabla^g_X \Omega)(Y, Z) = (\nabla^g_Y \Omega)(X, Z),$$

if and only if $J$ is a Codazzi tensor field, i.e. $$(\nabla^g_X J)Y = (\nabla^g_Y J)X.$$

**Remark 2.9.** If $\Omega$ is a Codazzi tensor field and $J$ is a Killing tensor field (i.e. $(\nabla^g_X J)X = 0$, for any $X \in \mathfrak{X}(M)$), then $J$ is $\nabla^g$-parallel.

As particular cases, we deduce from [12] the followings:

**Proposition 2.10.** Let $(\nabla, J, \xi, \lambda)$ define an almost $(\nabla, J, \xi)$-soliton on the pseudo-Riemannian manifold $(M, g)$. If $\Omega := g(J\cdot, \cdot)$ is symmetric and $\nabla$ is torsion-free, then $(\Omega, \nabla)$ is a nearly statistical structure on $M$ if and only if

$$g(R^\nabla(X, Y)\xi, Z) + (\nabla_X g)(JY, Z) - (\nabla_Y g)(JX, Z) = g(Y(\lambda)X - X(\lambda)Y, Z),$$

for any $X, Y, Z \in \mathfrak{X}(M)$.

**Corollary 2.11.** If $(\nabla^g, J, \xi, \lambda)$ define an almost $(\nabla^g, J, \xi)$-soliton on the pseudo-Riemannian manifold $(M, g)$ and $\Omega := g(J\cdot, \cdot)$ is symmetric, then $(\Omega, \nabla^g)$ is a nearly statistical structure on $M$ if and only if

$$R^{\nabla^g}(\cdot, \cdot)\xi = I \otimes d\lambda - d\lambda \otimes I.$$
Assume now $\xi = \nabla f$ and from the soliton equation (3) we get:

$$\text{Hess}^\nabla(f) + \Omega = \lambda g,$$

hence, $\nabla_X^\nabla \text{Hess}^\nabla(f) + \nabla_X^\nabla \Omega = X(\lambda)g$, for any $X \in \mathfrak{X}(M)$.

**Corollary 2.12.** Let $(\nabla^g, J, \xi, \lambda)$ define an almost $(\nabla^g, J, \xi)$-soliton on the pseudo-Riemannian manifold $(M, g)$ with $\lambda$ a constant and $\xi = \nabla f$. Then the following statements are equivalent:

i) $(\Omega, \nabla^g)$ is a nearly statistical structure on $M$;

ii) $R^\nabla^g(X, Y)\nabla f = 0$, for any $X, Y \in \mathfrak{X}(M)$;

ii) $(\text{Hess}^\nabla(f), \nabla^g)$ is a nearly statistical structure on $M$.

If $\nabla$ is torsion-free, then:

$$R^\nabla(X, \xi)\xi = \nabla_X^{\nabla^g}\xi - \nabla^g_{\xi,X}\xi = X(\lambda)\xi - (\nabla_X J)\xi - \xi(\lambda)X + (\nabla_\xi J)X,$$

for any $X \in \mathfrak{X}(M)$ and we get:

**Remark 2.13.** Let $(\nabla, J, \xi, \lambda)$ define an almost $(\nabla, J, \xi)$-soliton on the pseudo-Riemannian manifold $(M, g)$ with $\nabla$ torsion-free.

i) If $\xi$ is a Jacobi vector field and $\nabla = \nabla^g$ is the Levi-Civita connection of $g$, then $\nabla_X J = d\lambda(\xi)$.

ii) If $\xi = \nabla f$ and $(\nabla_X J)Y = (\nabla_Y J)X$, for any $X, Y \in \mathfrak{X}(M)$, then $\text{Ric}^\nabla(\xi, \xi) = -(n - 1)d\lambda(\xi)$ and $\text{Hess}^\nabla(\xi, \xi) = \frac{1}{2}d(|\xi|^2)(\xi)$ (does not depend on $\lambda$). In particular, if $\lambda = f$, then $\text{Ric}^\nabla(\xi, \xi) \leq 0$ provided $|\xi|^2_g \geq 0$.

### 3 Connections defined by 1-forms and solitons

Inspired by the property of projectively equivalence of connections, given an arbitrary 1-form $\eta$ on the pseudo-Riemannian manifold $(M, g)$, we defined \cite{19} the affine connection:

$$\nabla^\eta := \nabla^g + \eta \otimes I + I \otimes \eta + g \otimes \xi,$$

where $\nabla^g$ is the Levi-Civita connection of $g$ and $\xi$ is the $g$-dual vector field of $\eta$ (i.e. $\eta = i_\xi g$). We get:

$$T^{\nabla^\eta} = 0, \quad d^{\nabla^\eta} g = 0,$$

hence:
Proposition 3.1. For any 1-form \( \eta \) on the pseudo-Riemannian manifold \((M, g)\), the pair \((g, \nabla^n)\) is a statistical structure on \(M\) and \(\nabla^{-n}\) is the dual connection of \(\nabla^n\).

In particular, \(\nabla^n_\xi = \nabla^g_\xi + 3|\xi|^2_g \xi\), therefore, \(\xi\) is a geodesic vector field for \(\nabla^n\) if and only if \(\nabla^n_\xi = -3|\xi|^2_g \xi\). Moreover:

i) \(\xi\) is \(\nabla^n\)-parallel if and only if \((\nabla^g, J := 2\eta \otimes \xi, \xi, \lambda := |\xi|^2_g)\) is a soliton;

ii) \(\eta\) is \(\nabla^n\)-parallel if and only if \((\nabla^g, J := -2\eta \otimes \xi, \xi, \lambda := -|\xi|^2_g)\) is a soliton.

The curvature of the connection \(\nabla^n\) is given by:

\[
(R^{\nabla^n} - R^{\nabla^g})(X,Y)Z = [g(Y, \nabla^n_X \xi) - g(X, \nabla^n_Y \xi)]Z + [\eta(Y)\eta(Z) + g(Y, Z)|\xi|^2_g - g(Z, \nabla^n_Y \xi)]X - [\eta(X)\eta(Z) + g(X, Z)|\xi|^2_g - g(Z, \nabla^n_X \xi)]Y + g(Y, Z)\nabla^n_X \xi - g(X, Z)\nabla^n_Y \xi + [\eta(X)g(Y, Z) - \eta(Y)g(X, Z)]\xi,
\]

and we deduce that, if \(\xi\) is a g-null and \(\nabla^g\)-parallel vector field (i.e. \(\eta(\xi) = 0\) and \(\nabla^g \xi = 0\)), condition appearing in Walker manifolds [36], then \((R^{\nabla^n} - R^{\nabla^g})(X,Y)Z \in \ker \eta\), for any \(X, Y, Z \in \mathfrak{X}(M)\).

Example 3.2. Let \((M, \varphi, \xi, \eta, g)\) be a Kenmotsu manifold and let \(\nabla^n\) be the affine connection defined by the structure, \(\nabla^n := \nabla^g + \eta \otimes I + I \otimes \eta + g \otimes \xi\). Since \(\nabla^g \xi = I - \eta \otimes \xi\), we get \(\nabla^n \xi = 2I + \eta \otimes \xi\), and \((\nabla^n, J := -\eta \otimes \xi, \lambda = 2)\) is a soliton on \(M\).

The divergence operator w.r.t. \(\nabla^d\) is given by:

\[
\text{div}^{(g, \nabla^d)} = \text{div}^{(g, \nabla^g)} + (n + 2)df.
\]

In the compact case, from the divergence theorem, we obtain:

\[
\int_M \text{div}^{(g, \nabla^d)}(X) d\mu_g = (n + 2) \int_M g(\text{grad}_g(f), X) d\mu_g,
\]

for any \(X \in \mathfrak{X}(M)\). Moreover, if \(|\text{grad}_g(f)|_g\) is constant, then:

\[
\text{vol}(M) = \frac{1}{(n + 2)|\text{grad}_g(f)|_g^2} \int_M \text{div}^{(g, \nabla^d)}(\text{grad}_g(f)) d\mu_g.
\]

Denote by \(\Delta^g := \text{div}^{(g, \nabla^g)} \circ \text{grad}_g\) and \(\Delta^n := \text{div}^{(g, \nabla^n)} \circ \text{grad}_g\) the Laplace operators. Then:

\[
\Delta^d(f) = \Delta^g(f) + (n + 2)g(\text{grad}_g(f), \text{grad}_g(f)),
\]

for any smooth function \(\tilde{f}\) on \(M\).
Remark that if \( \tilde{f} \) is harmonic for \( \Delta^d f \), then \( \tilde{f} \) is also harmonic for \( \Delta^g \) if and only if the vector fields \( \text{grad}_g(f) \) and \( \text{grad}_g(\tilde{f}) \) are \( g \)-orthogonal.

In particular:
\[
\Delta^d f = \Delta^g f + (n + 2)|\text{grad}_g(f)|_g^2,
\]
hence:

i) if \( f \) is harmonic for \( \Delta^g \), then it is a subharmonic function for \( \Delta^d f \) (i.e. \( \Delta^d f \geq 0 \));

ii) if \( f \) is harmonic for \( \Delta^d f \) and \((M, g)\) is a compact Riemannian manifold, then \( f \) is constant.

Also, for any smooth function \( f \in C^\infty(M) \), if we denote by \( \text{Hess}^g(f) \) and \( \text{Hess}^\eta(f) \) the Hessian tensor fields w.r.t. \( \nabla^g \) and \( \nabla^\eta \), we have:

\[
\text{Hess}^\eta(f)(X, Y) := g(\nabla^\eta_X \text{grad}_g(f), Y) = \text{Hess}^g(f)(X, Y) + \eta(\text{grad}_g(f))g(X, Y) + 
\]
\[
+ \eta(X)df(Y) + \eta(Y)df(X)
\]
and by tracing this relation we get:
\[
\Delta^\eta(f) = \Delta^g(f) + (n + 2)\eta(\text{grad}_g(f)),
\]
where \( n = \dim(M) \).

In particular, if \( \xi = \text{grad}_g(f) \), then \( \eta = df \) and we obtain:

(4) \[ \text{Hess}^d f = \text{Hess}^g f + |\text{grad}_g(f)|_g^2g + 2df \otimes df. \]

Recall that a pseudo-Riemannian manifold \((M, g)\) with a pair of dual connections \((\nabla, \nabla^*)\) is called conjugate Ricci-symmetric \([31]\) if \( \text{Ric}^\nabla = \text{Ric}^{\nabla^*} \).

If we denote by \( \text{Ric}^g \) and \( \text{Ric}^\eta \) the Ricci curvature tensor fields for \( \nabla^g \) and \( \nabla^\eta \), from the curvature relation, we obtain the Ricci curvature of \( \nabla^\eta \), which is given by:

\[
\text{Ric}^\eta(Y, Z) = \text{Ric}^g(Y, Z) + g(Y, Z)\{n|\xi|^2 + \text{div}^{(g, \nabla^\eta)}(\xi)\} + (n - 2)\eta(Y)\eta(Z) + 
\]
\[
+ g(Y, \nabla^\eta_Z \xi) - (n + 1)g(Z, \nabla^\eta_Y \xi),
\]
where \( n = \dim(M) \) and we can state:

**Proposition 3.3.** \((M, g, \nabla^\eta, \nabla^{-\eta})\) is a conjugate Ricci-symmetric manifold.
An affine connection on $M$ is called equiaffine \cite{32} if it admits a parallel volume form on $M$. It is known that \cite{32} the necessary and sufficient condition for a torsion-free affine connection to be equiaffine is that the Ricci tensor to be symmetric. Since $\nabla^\eta$ is torsion-free, we get:

**Proposition 3.4.** $\nabla^\eta$ is an equiaffine connection on $M$ if and only if the endomorphism $\nabla^g\xi$ is self-adjoint w.r.t. $g$, i.e.

$$g(\nabla^\eta_X\xi, Y) = g(X, \nabla^\eta_Y\xi),$$

for any $X, Y \in \mathfrak{X}(M)$.

In particular, if $\xi = \text{grad}_g(f)$, then $\eta = df$ and we obtain:

$$\text{(5)} \quad \text{Ric}^d = \text{Ric}^g + \{n|\text{grad}_g(f)|^2_g + \Delta^g(f)\}g + (n - 2)df \otimes df - n\text{Hess}^g(f),$$

hence:

**Corollary 3.5.** $\nabla^df$ is an equiaffine connection on $M$.

Taking the trace in the previous relation, we get:

$$\text{scal}^{(g,\nabla_d)} = \text{scal}^{(g,\nabla_g)} + (n - 1)(n + 2)|\text{grad}_g(f)|^2_g,$$

which implies $\text{scal}^{(g,\nabla_d)} \geq \text{scal}^{(g,\nabla_g)}$ provided $|\text{grad}_g(f)|^2_g \geq 0$.

If we denote by $Q^g$ and $Q^df$ the Ricci operators defined by $g(Q^gX, Y) := \text{Ric}^g(X, Y)$ and $g(Q^dfX, Y) := \text{Ric}^df(X, Y)$, $X, Y \in \mathfrak{X}(M)$, then:

$$Q^df = Q^g + \{n|\text{grad}_g(f)|^2_g + \Delta^g(f)\}I + (n - 2)df \otimes \text{grad}_g(f) - n\nabla^g\text{grad}_g(f)$$

and by direct computations, we obtain:

**Proposition 3.6.** Let $(M, g)$ be an $n$-dimensional pseudo-Riemannian manifold, $\xi = \text{grad}_g(f)$ and $\eta = df$. Then:

i) $(\nabla^g, Q^g, \xi, \lambda)$ is a gradient almost soliton if and only if $(\nabla^g, Q^g + 2\eta \otimes \xi, \lambda - |\xi|^2_g)$ is a gradient almost soliton;

ii) $(\nabla^g, Q^g, \xi, \lambda)$ is a gradient almost soliton if and only if $(\nabla^g, \frac{1}{1-n}\{Q^g + (n - 2)\eta \otimes \xi\}, \frac{1}{1-n}\{\lambda - n|\xi|^2_g - \Delta^g(f)\})$ is a gradient almost soliton;

iii) $(\nabla^g, Q^g, \xi, \lambda)$ is a gradient almost soliton if and only if $(\nabla^g, \frac{1}{1-n}\{Q^g + n\eta \otimes \xi\}, \frac{1}{1-n}\{\lambda - (n + 1)|\xi|^2_g - \Delta^g(f)\})$ is a gradient almost soliton.
Now we shall relate the previously considered types of solitons to almost Ricci and \( \eta \)-Ricci solitons [7].

**Proposition 3.7.** Let \((M, g)\) be an \(n\)-dimensional pseudo-Riemannian manifold, \(\xi = \text{grad}_g(f)\) and \(\eta = df\).

1) \((\nabla^n, Q^n, \xi, \lambda)\) is a gradient almost soliton if and only if \((g, \xi, \lambda - |\xi|^2_g, -2)\) is a gradient almost \(\eta\)-Ricci soliton.

2) If \(\nabla g \xi = \eta \otimes \xi\), then:
   
   i) \((\nabla g, Q \eta, \xi, \lambda)\) is a gradient almost soliton if and only if \((g, \xi, \lambda - |\xi|^2_g)\) is a gradient almost \(\eta\)-Ricci soliton; in this case, \(\text{scal}(g, \nabla g) = n\lambda - |\xi|^2_g \geq n\lambda\) provided \(|\xi|^2_g \geq 0\);
   
   ii) \((\nabla, Q^n, \xi, \lambda)\) is a gradient almost soliton if and only if \((g, \xi, \lambda - (n + 2)|\xi|^2_g)\) is a gradient almost Ricci soliton; in this case, \(\text{scal}(g, \nabla g) = n\lambda - (n + 1)^2|\xi|^2_g \geq n\lambda\) provided \(|\xi|^2_g \geq 0\).

**Proof.** 1) \(\nabla^n \xi + Q^n = \lambda I\) is equivalent to \(\nabla^n \xi + Q^n = (\lambda - |\xi|^2_g)I - 2\eta \otimes \xi\).

2) From hypotheses we get \(\Delta^n(f) = |\xi|^2_g\). i) Taking the trace in

\[-\text{Hess}^g(f) + \text{Ric}^g = \{\lambda - (n + 1)|\xi|^2_g\}g,\]

we obtain \(\text{scal}(g, \nabla^g) = n\lambda - (n^2 + n - 1)|\xi|^2_g\), therefore, \(\text{scal}(g, \nabla^g) = n\lambda - |\xi|^2_g\). By a similar proof we get the conclusion from ii). □

We shall further give a formula for the volume of \(M\) in the presence of an almost soliton.

Computing the scalar product w.r.t. \(g\), we get:

\[
\langle \text{Ric}^d, df \otimes df \rangle_g = \text{Ric}^g(\text{grad}_g(f), \text{grad}_g(f)) - n\text{Hess}^g(f)(\text{grad}_g(f), \text{grad}_g(f)) + |\text{grad}_g(f)|^2_g|\Delta^g(f)| + 2(n - 1)|\text{grad}_g(f)|^4_g
\]

and using the classical Bochner formula, we obtain:

\[
\langle \text{Ric}^d, df \otimes df \rangle_g = \frac{1}{2}|\Delta^g(f)|^2_g - |\text{Hess}^g(f)|^2_g - n\text{Hess}^g(f)(\text{grad}_g(f), \text{grad}_g(f)) - |\text{grad}_g(f)|^2_g|\Delta^g(f)| + 2(n - 1)|\text{grad}_g(f)|^4_g
\]

and we can state:
Proposition 3.8. Let \((M, g)\) be a compact \(n\)-dimensional pseudo-Riemannian manifold, \(f\) a smooth function on \(M\) such that \(|\text{grad}_g(f)|_g\) is constant. Then:

\[
\text{vol}(M) = \frac{1}{2(n-1)|\text{grad}_g(f)|_g^4} \left\{ \int_M |\text{Hess}^g(f)|_g^2 d\mu_g + \int_M \text{grad}_g(f)(\Delta^g(f))d\mu_g + \int_M \langle \text{Ric}^d, df \otimes df \rangle_g d\mu_g \right\}.
\]

Also, the Bochner formula can be written in terms of \(\text{Ric}^d\) and \(\text{Hess}^d(f)\) as follows:

\[
\frac{1}{2} \Delta^g(|\text{grad}_g(f)|_g^2) = |\text{Hess}^d(f)|_g^2 + \text{Ric}^d(\text{grad}_g(f), \text{grad}_g(f)) + \text{grad}_g(f)(\Delta^d(f)) - 3(n+2)|\text{grad}_g(f)|_g^4 - 3|\text{grad}_g(f)|_g^2 \Delta^g(f) + \frac{n-4}{2} \text{grad}_g(f)(|\text{grad}_g(f)|_g^2) = |\text{Hess}^d(f)|_g^2 + \text{Ric}^d(\text{grad}_g(f), \text{grad}_g(f)) + \text{grad}_g(f)(\Delta^d(f)) - 3|\text{grad}_g(f)|_g^2 \Delta^d(f) - \frac{n+8}{2} \text{grad}_g(f)(|\text{grad}_g(f)|_g^2)
\]

and we can state:

Proposition 3.9. Let \((M, g)\) be a compact \(n\)-dimensional pseudo-Riemannian manifold, \(f\) a smooth function on \(M\) such that \(|\text{grad}_g(f)|_g\) is constant. Then:

\[
\text{vol}(M) = \frac{1}{3(n+2)|\text{grad}_g(f)|_g^4} \left\{ \int_M |\text{Hess}^d(f)|_g^2 d\mu_g + \int_M \text{grad}_g(f)(\Delta^d(f))d\mu_g + \int_M \text{Ric}^d(\text{grad}_g(f), \text{grad}_g(f))d\mu_g \right\}.
\]

Remark 3.10. Notice that, under the same hypotheses, we have:

\[
\int_M |\text{Hess}^g(f)|_g^2 d\mu_g + \int_M \text{grad}_g(f)(\Delta^g(f))d\mu_g + \int_M \text{Ric}^g(\text{grad}_g(f), \text{grad}_g(f))d\mu_g = 0.
\]

Proposition 3.11. Let \((M, g)\) be a compact \(n\)-dimensional pseudo-Riemannian manifold, \(f\) a smooth function on \(M\) such that \(|\text{grad}_g(f)|_g\) is constant. If \((\nabla^g, Q^d, \text{grad}_g(f), \lambda)\) is a gradient almost soliton, then:

\[
\text{vol}(M) = \frac{1}{2(n-1)|\text{grad}_g(f)|_g^4} \left\{ \int_M |\text{Hess}^g(f)|_g^2 d\mu_g + |\text{grad}_g(f)|_g^2 \int_M \lambda d\mu_g + n \int_M \text{grad}_g(f)(\lambda)d\mu_g - \int_M \text{grad}_g(f)(\text{scal}^g(\nabla^g))d\mu_g \right\}.
\]
Proof. Indeed, $\nabla^g \text{grad}_g(f) + Q^df = \lambda I$ implies

$$\text{Hess}^g(f) + \text{Ric}^df = \lambda g.$$  

Then:

$$\langle \text{Ric}^df, df \otimes df \rangle_g = \lambda |\text{grad}_g(f)|_g^2 - \frac{1}{2} \text{grad}_g(f)(|\text{grad}_g(f)|_g^2).$$

Also, replacing $\text{Ric}^df$ from (5) in (6) and taking the trace w.r.t. $g$, we get:

$$\Delta^g(f) + \text{scal}^g \text{grad}^g(f) + (n-1)(n-2)|\text{grad}_g(f)|_g^2 = n\lambda.$$  

Applying $\text{grad}_g(f)$ to the previous relation and using Proposition 3.8, we obtain the conclusion.

Remark 3.12. Under the same hypotheses:

i) if $\lambda = 2(n-1)|\text{grad}_g(f)|_g^2$, then

$$\text{vol}(M) = \frac{1}{(n-1)(n+2)|\text{grad}_g(f)|_g^2} \int_M \text{scal}^g \text{grad}^g(f) \, d\mu_g;$$

moreover, if $\text{scal}^g \text{grad}^g(f)$ is constant, then $\text{scal}^g \text{grad}^g(f) = (n-1)(n+2)|\text{grad}_g(f)|_g^2 \geq 0$ provided $|\text{grad}_g(f)|_g^2 \geq 0$ and $f$ is a harmonic function for $\Delta^g$;

ii) if $\lambda$ is a constant and $\lambda \neq 2(n-1)|\text{grad}_g(f)|_g^2$, then

$$\text{vol}(M) = \frac{1}{\{2(n-1)|\text{grad}_g(f)|_g^2 - \lambda\}|\text{grad}_g(f)|_g^2} \left\{ \int_M |\text{Hess}^g(f)|_g^2 \, d\mu_g - \int_M \text{grad}_g(f) \text{scal}^g \text{grad}^g(f) \, d\mu_g \right\};$$

moreover, if $f$ is a harmonic function for $\Delta^g$, then

$$\text{vol}(M) = \frac{1}{\{2(n-1)|\text{grad}_g(f)|_g^2 - \lambda\}|\text{grad}_g(f)|_g^2} \int_M |\text{Hess}^g(f)|_g^2 \, d\mu_g,$$

hence, in the Riemannian case, $\lambda < 2(n-1)|\text{grad}_g(f)|_g^2$, therefore

$$\text{scal}^g \text{grad}^g(f) < (n-1)(n+2)|\text{grad}_g(f)|_g^2.$$

Proposition 3.13. Let $(M, g)$ be an $n$-dimensional pseudo-Riemannian manifold and $f$ a smooth function on $M$. If $(\nabla^g, Q^df, \text{grad}_g(f), \lambda)$ is a gradient almost soliton, then:

$$(n-1)^2 |\text{Hess}^g(f)|_g^2 + \frac{(n-1)(n-2)^2}{n} |\text{grad}_g(f)|_g^4 - \frac{(n-1)^2}{n} (\Delta^g(f))^2 +$$
Gradient solitons in statistical manifolds

\[ + \frac{2(n-1)(n-2)}{n} \left| \text{grad}_g(f) \right|^2_g \Delta^g(f) - 2(n-1)(n-2) \text{Hess}^g(f)(\text{grad}_g(f), \text{grad}_g(f)) \leq \]

\[ \leq \left| \text{Ric}^g \right|^2_g \leq \]

\[ \leq (n-1)^2 \left| \text{Hess}^g(f) \right|^2_g - \frac{(n-1)(n-2)^2}{n} \left| \text{grad}_g(f) \right|^4_g + \frac{1}{n} (\text{scal}^g(\nabla^g))^2 + \]

\[ + \frac{2(n-2)}{n} \left| \text{grad}_g(f) \right|^2_g \text{scal}^g(\nabla^g) - 2(n-2) \text{Ric}^g(\text{grad}_g(f), \text{grad}_g(f)). \]

PROOF. Compute \[ |\text{Hess}^g(f)|^2_g \] from

\[ (1-n) \text{Hess}^g(f) = \{ \lambda - n|\text{grad}_g(f)|^2_g - \Delta^g(f) \} g - (n-2) df \otimes df - \text{Ric}^g \]

and \[ |\text{Ric}^g|^2_g \] from

\[ \text{Ric}^g = \{ \lambda - n|\text{grad}_g(f)|^2_g - \Delta^g(f) \} g - (n-2) df \otimes df + (n-1) \text{Hess}^g(f). \]

Remark that the conditions to exist a solution (in \( \lambda \)) give precisely the double inequality from the conclusion. \( \square \)

**Proposition 3.14.** Let \((M,g)\) be a compact \(n\)-dimensional pseudo-Riemannian manifold, \(f\) a smooth function on \(M\) such that \(|\text{grad}_g(f)|_g\) is constant. If \((\nabla^d f, Q^g, \text{grad}_g(f), \lambda)\) is a gradient soliton, then:

\[
\text{vol}(M) = \frac{1}{\lambda |\text{grad}_g(f)|^2_g} \{- \int_M |\text{Hess}^g(f)|^2_g d\mu_g + \int_M \text{grad}_g(f)(\text{scal}^g(\nabla^g)) d\mu_g \}.
\]

PROOF. Indeed, \(\nabla^d f \text{grad}_g(f) + Q^g = \lambda I\) implies

(7) \[ \text{Hess}^d(f) + \text{Ric}^g = \lambda g. \]

Also:

\[ (\text{Ric}^d, df \otimes df)_g = \text{Ric}^g(\text{grad}_g(f), \text{grad}_g(f)) + \{n|\text{grad}_g(f)|^2_g + \Delta^g(f)\}|\text{grad}_g(f)|^2_g + \]

\[ + (n-2)|\text{grad}_g(f)|^4_g \]

and replacing \(\text{Hess}^d(f)\) from (4) in (7) and taking the trace w.r.t. \(g\), we get:

\[ \Delta^g(f) + \text{scal}^g(\nabla^g) + (n+2)|\text{grad}_g(f)|^2_g = n\lambda. \]

Applying \(\text{grad}_g(f)\) to the previous relation and using Proposition 3.8 we obtain the conclusion. \( \square \)
Proposition 3.15. Let $(M, g)$ be an $n$-dimensional pseudo-Riemannian manifold and $f$ a smooth function on $M$. If $(\nabla^g, Q^g, \text{grad}_g(f), \lambda)$ is a gradient almost soliton, then:

$$|	ext{Hess}^g(f)|^2_g + \frac{4(n-1)}{n} |\text{grad}_g(f)|^4_g - \frac{1}{n} (\Delta^g(f))^2 - \frac{4}{n} |\text{grad}_g(f)|^2_g \lambda^g(f) + 4 \text{Hess}^g(f)(\text{grad}_g(f), \text{grad}_g(f)) \leq \leq |	ext{Ric}^g|_g^2 \leq$$

$$\leq |\text{Hess}^g(f)|^2_g - \frac{4(n-1)}{n} |\text{grad}_g(f)|^4_g + \frac{1}{n} (\text{scal}^g_{(g,\nabla^g)})^2 + \frac{4}{n} |\text{grad}_g(f)|^2_g \text{scal}^g_{(g,\nabla^g)} - 4 \text{Ric}^g(\text{grad}_g(f), \text{grad}_g(f)).$$

Proof. Compute $|\text{Hess}^g(f)|^2_g$ from

$$\text{Hess}^g(f) = (\lambda - |\text{grad}_g(f)|^2_g)g - 2df \otimes df - \text{Ric}^g$$

and $|\text{Ric}^g|_g^2$ from

$$\text{Ric}^g = (\lambda - |\text{grad}_g(f)|^2_g)g - 2df \otimes df - \text{Hess}^g(f).$$

Remark that the conditions to exist a solution (in $\lambda$) give precisely the double inequality from the conclusion. \qed

Remark 3.16. If $|\text{grad}_g(f)|_g = 1$, then the double equality from the previous Proposition implies

$$\text{Ric}^g(\text{grad}_g(f), \text{grad}_g(f)) = \frac{1}{4n} \{(\text{scal}^g_{(g,\nabla^g)}) + 2\}^2 + (\Delta^g(f) + 2)^2 - 8n\}.$$ 

In this case, from the soliton equation (7), we get

$$\text{Ric}^g(\text{grad}_g(f), \text{grad}_g(f)) = \lambda - 3$$

and

$$\Delta^g(f) = n\lambda - (n + 2) - \text{scal}^g_{(g,\nabla^g)}.$$ 

Replacing the last two expressions in the first one and asking for the equation of order two in $\lambda$ to have solution, we get $n^2 (\text{scal}^g_{(g,\nabla^g)})^2 \leq 0$, hence the manifold is of zero scalar curvature. Moreover, if $f$ is a harmonic function for $\Delta^g$, then $\lambda = \frac{n+2}{n}$ and $\text{Ric}^g(\text{grad}_g(f), \text{grad}_g(f)) = -\frac{2(n-1)}{n} < 0$.

Remark that Petersen [33] called $f$ a distance function if it is a solution of the Hamilton-Jacobi equation $|\text{grad}_g(f)|_g^2 = 1$, which he uses in his book.
