

On a linearized Mullins-Sekerka/Stokes system for two-phase flows

Helmut Abels* and Andreas Marquardt†

March 14, 2024

Abstract

We study a linearized Mullins-Sekerka/Stokes system in a bounded domain with various boundary conditions. This system plays an important role to prove the convergence of a Stokes/Cahn-Hilliard system to its sharp interface limit, which is a Stokes/Mullins-Sekerka system, and to prove solvability of the latter system locally in time. We prove solvability of the linearized system in suitable L^2 -Sobolev spaces with the aid of a maximal regularity result for non-autonomous abstract linear evolution equations.

Key words: Two-phase flow, sharp interface limit, Cahn-Hilliard equation, Free boundary problems, Mullins-Sekerka equation,

1 Introduction

We study the following linearized Mullins-Sekerka/Stokes system

$$\begin{aligned} D_{t,\Gamma}h + \mathbf{b} \cdot \nabla_{\Gamma}h - bh + \tfrac{1}{2}X_0^*((\mathbf{v}^+ + \mathbf{v}^-) \cdot \mathbf{n}_{\Gamma_t}) + \tfrac{1}{2}X_0^*([\partial_{\mathbf{n}_{\Gamma_t}}\mu]) &= g \quad \text{on } \Sigma \times (0, T), \\ h(., 0) &= h_0 \quad \text{in } \Sigma, \end{aligned}$$

where for every $t \in [0, T]$, the functions $\mathbf{v}^{\pm} = \mathbf{v}^{\pm}(x, t)$, $p^{\pm} = p^{\pm}(x, t)$ and $\mu^{\pm} = \mu^{\pm}(x, t)$ for $(x, t) \in \Omega_T^{\pm}$ with $\mathbf{v}^{\pm} \in H^2(\Omega^{\pm}(t))^d$, $p^{\pm} \in H^1(\Omega^{\pm}(t))$ and $\mu^{\pm} \in H^2(\Omega^{\pm}(t))$

*Fakultät für Mathematik, Universität Regensburg, 93040 Regensburg, Germany helmut.abels@ur.de

†Fakultät für Mathematik, Universität Regensburg, 93040 Regensburg, Germany

are the unique solutions to

$$\Delta\mu^\pm = a_1 \quad \text{in } \Omega^\pm(t), \quad (1)$$

$$\mu^\pm = X_0^{*,-1}(\sigma\Delta_\Gamma h \pm a_2 h) + a_3 \quad \text{on } \Gamma_t, \quad (2)$$

$$\mathbf{n} \cdot \nabla \mu^- = a_4 \quad \text{on } \Gamma_{\mu,1}, \quad (3)$$

$$\mu^- = a_4 \quad \text{on } \Gamma_{\mu,2}, \quad (4)$$

$$-\Delta \mathbf{v}^\pm + \nabla p^\pm = \mathbf{a}_1 \quad \text{in } \Omega^\pm(t), \quad (5)$$

$$\operatorname{div} \mathbf{v}^\pm = 0 \quad \text{in } \Omega^\pm(t), \quad (6)$$

$$[\mathbf{v}] = \mathbf{a}_2 \quad \text{on } \Gamma_t, \quad (7)$$

$$[2D_s \mathbf{v} - p\mathbf{I}] \mathbf{n}_{\Gamma_t} = X_0^{*,-1}(\mathbf{a}_3 h + \mathbf{a}_4 \Delta_\Gamma h + a_5 \nabla_\Gamma h + \mathbf{a}_5) \quad \text{on } \Gamma_t, \quad (8)$$

$$B_j(\mathbf{v}^-, p^-) = \mathbf{a}_6 \quad \text{on } \Gamma_{S,j}, j = 1, 2, 3. \quad (9)$$

Here $\Omega \subseteq \mathbb{R}^d$, $d = 2, 3$, is a bounded domain with smooth boundary, which is the disjoint union of $\Omega^+(t)$, $\Omega^-(t)$ and Γ_t , where $\Gamma_t = \partial\Omega^+(t)$ is a smoothly evolving $(d-1)$ -dimensional orientable hypersurface. We assume that $\Gamma_t \subseteq \Omega$ for all $t \in (0, T)$, i.e., there is no boundary contact and contact angle. Moreover, Γ_t is given for $t \in [0, T]$ as well as a_1, \dots, a_4 , $\mathbf{a}_1, \dots, \mathbf{a}_6$ are given for some $T > 0$, $\sigma > 0$ is the surface tension constant and $D_s \mathbf{v} = \frac{1}{2}(\nabla \mathbf{v} + \nabla \mathbf{v}^T)$. Furthermore,

$$[g](p, t) := \lim_{h \searrow 0} [g^+(p + \mathbf{n}_{\Gamma_t}(p)h, t) - g^-(p - \mathbf{n}_{\Gamma_t}(p)h, t)] \quad \text{for } p \in \Gamma_t$$

for suitable functions g^\pm and $X_0: \Sigma \times [0, T] \rightarrow \Gamma := \bigcup_{t \in [0, T]} \Gamma_t \times \{t\}$ is a suitable diffeomorphism, which is described in Section 2 below. For $a: \Sigma \times [0, T] \rightarrow \mathbb{R}^N$, $N \in \mathbb{N}$, we define $X_0^{*,-1}a: \Gamma \rightarrow \mathbb{R}^N$ by

$$(X_0^{*,-1}a)(p, t) = a(X_0^{-1}(p, t)) \quad \text{for all } (p, t) \in \Gamma$$

and for $b: \Gamma \rightarrow \mathbb{R}^N$, $N \in \mathbb{N}$, we define $X_0^*b: \Sigma \times [0, T] \rightarrow \mathbb{R}^N$ by

$$(X_0^*b)(s, t) = b(X_0(s, t)) \quad \text{for all } (s, t) \in \Sigma \times [0, T].$$

This system arises in the construction of approximate solutions in the proof of convergence of a Stokes/Cahn-Hilliard system to its sharp interface limit, which is a Stokes/Mullins-Sekerka system, cf. [2]-[3]. Here $\mathbf{v}^\pm: \bigcup_{t \in [0, T]} \Omega^\pm(t) \times \{t\} \rightarrow \mathbb{R}^d$ and $p^\pm: \bigcup_{t \in [0, T]} \Omega^\pm(t) \times \{t\} \rightarrow \mathbb{R}$ are the velocity and pressure incompressible viscous Newtonian fluids filling the domains $\Omega^\pm(t)$ at time t , which are separated by the (fluid) interface Γ_t . Furthermore, $h: \Sigma \times [0, T] \rightarrow \mathbb{R}$ is a linearized height function that describes the evolution of the interface at a certain order and $\mu^\pm: \bigcup_{t \in [0, T]} \Omega^\pm(t) \times \{t\} \rightarrow \mathbb{R}$ is a linearized chemical potential related to the fluids in $\Omega^\pm(t)$. If one neglects the terms related to \mathbf{v}^\pm, p^\pm , a similar linearized system arises in the study of the sharp interface limit of the Cahn-Hilliard equation, cf. [6]. Moreover, similar systems arise in the construction of strong solutions for a Navier-Stokes/Mullins-Sekerka system locally in time, cf. [4].

We consider different kinds of boundary conditions for \mathbf{v}^- and μ^- simultaneously. More precisely, we assume that

$$\partial\Omega = \Gamma_{\mu,1} \cup \Gamma_{\mu,2} = \Gamma_{S,1} \cup \Gamma_{S,2} \cup \Gamma_{S,3},$$

where $\Gamma_{\mu,1}, \Gamma_{\mu,2}$ and $\Gamma_{S,1}, \Gamma_{S,2}, \Gamma_{S,3}$ are disjoint and closed. Moreover, we have

$$\begin{aligned} B_1(\mathbf{v}^-, p^-) &= \mathbf{v}^- && \text{on } \Gamma_{S,1} \\ (B_2(\mathbf{v}^-, p^-))_{\tau} &= ((2D_s \mathbf{v}^- - p^-) \mathbf{n}_{\partial\Omega})_{\tau} + \alpha_2 \mathbf{v}_{\tau}^- && \text{on } \Gamma_{S,2} \\ \mathbf{n}_{\partial\Omega} \cdot B_2(\mathbf{v}^-, p^-) &= \mathbf{n}_{\partial\Omega} \cdot \mathbf{v}^- && \text{on } \Gamma_{S,2} \\ B_3(\mathbf{v}^-, p^-) &= (2D_s \mathbf{v}^- - p^-) \mathbf{n}_{\partial\Omega} + \alpha_3 \mathbf{v}^- && \text{on } \Gamma_{S,3}, \end{aligned}$$

where $\mathbf{n}_{\partial\Omega}$ denotes the exterior normal on $\partial\Omega$. To avoid a non-trivial kernel in the following we assume that one of the following cases holds true:

$$|\Gamma_{S,1}| + \alpha_2 |\Gamma_{S,2}| + \alpha_3 |\Gamma_{S,3}| > 0$$

Then Korn's inequality yields

$$\|\mathbf{v}\|_{H^1(\Omega)} \leq C \left(\|D_s \mathbf{v}\|_{L^2(\Omega)} + \alpha_2 \|\mathbf{v}_{\tau}\|_{L^2(\Gamma_{S,2})} + \alpha_3 \|\mathbf{v}\|_{L^2(\Gamma_{S,3})} \right) \quad (10)$$

for all $\mathbf{v} \in H^1(\Omega)^d$ with $\mathbf{v}|_{\Gamma_{S,1}} = 0$, $\mathbf{n}_{\partial\Omega} \cdot \mathbf{v}|_{\Gamma_{S,2}} = 0$, cf. [5, Corollary 5.9].

The structure of this contribution is as follows: In Section 2 we summarize some preliminaries on the parametrization of the interface Γ_t and non-autonomous evolution equations. In Section 3 we present and prove our main results on existence and smoothness of solutions to the linearized Mullins-Sekerka system. Finally, in the appendix we prove an auxiliary result on the existence of a pressure.

The results of this paper are extensions of results in the second author's PhD Thesis.

2 Preliminaries

2.1 Notation

Throughout this manuscript we denote by $\xi \in C^\infty(\mathbb{R})$ a cut-off function such that

$$\xi(s) = 1 \text{ if } |s| \leq \delta, \xi(s) = 0 \text{ if } |s| > 2\delta, \text{ and } 0 \geq s\xi'(s) \geq -4 \text{ if } \delta \leq |s| \leq 2\delta. \quad (11)$$

2.2 Coordinates

We parametrize $(\Gamma_t)_{t \in [0, T_0]}$ with the aid of a family of smooth diffeomorphisms $X_0: \Sigma \times [0, T_0] \rightarrow \Gamma = \bigcup_{t \in [0, T_0]} \Gamma_t \times \{t\}$. Here either $\Sigma \subseteq \mathbb{R}^d$ is a smooth $(d-1)$ -dimensional compact, orientable manifold without boundary, where $d \geq 2$ is allowed, or $d = 2$ and

$\Sigma = \mathbb{T}^1$. We have included the latter case to cover the setting in [1, 2, 3]. Moreover, $\mathbf{n}_{\Gamma_t}(x)$ denotes the exterior normal of Γ_t in x with respect to $\Omega^-(t)$ and we denote

$$\mathbf{n}(s, t) := \mathbf{n}_{\Gamma_t}((X_0(s, t))_1) \quad \text{for all } s \in \Sigma, t \in [0, T_0],$$

where $(X_0(s, t))_1 \in \mathbb{R}^d$ denote the spatial components of $X_0(s, t)$. In the following we will need a tubular neighborhood of Γ_t : For $\delta > 0$ sufficiently small, the orthogonal projection $P_{\Gamma_t}(x)$ of all

$$x \in \Gamma_t(3\delta) = \{y \in \Omega : \text{dist}(y, \Gamma_t) < 3\delta\}$$

is well-defined and smooth. Moreover, we choose δ so small that $\text{dist}(\partial\Omega, \Gamma_t) > 3\delta$ for every $t \in [0, T_0]$. Every $x \in \Gamma_t(3\delta)$ has a unique representation

$$x = P_{\Gamma_t}(x) + r\mathbf{n}_{\Gamma_t}(P_{\Gamma_t}(x))$$

where $r = \text{sdist}(\Gamma_t, x)$. Here

$$d_{\Gamma}(x, t) := \text{sdist}(\Gamma_t, x) = \begin{cases} \text{dist}(\Omega^-(t), x) & \text{if } x \notin \Omega^-(t), \\ -\text{dist}(\Omega^+(t), x) & \text{if } x \in \Omega^-(t). \end{cases}$$

For the following we define for $\delta' \in (0, 3\delta]$

$$\Gamma(\delta') = \bigcup_{t \in [0, T_0]} \Gamma_t(\delta') \times \{t\}.$$

We introduce new coordinates in $\Gamma(3\delta)$ which we denote by

$$X : (-3\delta, 3\delta) \times \Sigma \times [0, T_0] \mapsto \Gamma(3\delta) \text{ by } X(r, s, t) := X_0(s, t) + r\mathbf{n}(s, t),$$

where

$$r = \text{sdist}(\Gamma_t, x), \quad s = (X_0^{-1}(P_{\Gamma_t}(x), t))_1 =: S(x, t),$$

where $(X_0^{-1}(P_{\Gamma_t}(x), t))_1$ denote the components in Σ of $X_0^{-1}(P_{\Gamma_t}(x), t)$.

In the case that h is twice continuously differentiable with respect to s and continuously differentiable with respect to t , we introduce the notations

$$\begin{aligned} D_{t,\Gamma}h(s, t) &:= \partial_t (h(S(x, t), t))|_{x=X_0(s, t)}, & \nabla_{\Gamma}h(s, t) &:= \nabla (h(S(x, t), t))|_{x=X_0(s, t)}, \\ \Delta_{\Gamma}h(s, t) &:= \Delta (h(S(x, t), t))|_{x=X_0(s, t)}, \end{aligned}$$

where ∇ and Δ act with respect to x . We note that in the case that $d = 2$ and $\Sigma = \mathbb{T}^1$ we have

$$\begin{aligned} D_{t,\Gamma}h(s, t) &= (\partial_t + \partial_t S(X_0(s, t)) \cdot \partial_s) h(s, t), \\ \nabla_{\Gamma}h(s, t) &= \nabla S(X_0(s, t)) \partial_s h(s, t), \\ \Delta_{\Gamma}h(s, t) &= \Delta S(X_0(s, t)) \partial_s h(s, t) + |\nabla S(X_0(s, t))|^2 \partial_s^2 h(s, t). \end{aligned}$$

as in [1, 2, 3].

2.3 Maximal Regularity for Non-autonomous Equations

In order to prove our main result we use of the theory of maximal regularity for non-autonomous abstract evolution equations. Therefore, we give a short overview of the basic definitions and results which we will use. These are taken from [7] and all the proofs of the statements can be found in that article.

In this subsection let X and D be two Banach spaces such that D is continuously and densely embedded in X .

Definition 2.1 (L^p -maximal regularity). *Let $p \in (1, \infty)$.*

1. *Let $A \in \mathcal{L}(D, X)$. Then A has L^p -maximal regularity and we write $A \in \mathcal{MR}_p$ if for some bounded interval $(t_1, t_2) \subset \mathbb{R}$ and all $f \in L^p(t_1, t_2; X)$ there exists a unique $u \in W^{1,p}(t_1, t_2; X) \cap L^p(t_1, t_2; D)$ such that*

$$\begin{aligned} \partial_t u + Au &= f \quad \text{a.e. on } (t_1, t_2), \\ u(t_1) &= 0. \end{aligned}$$

2. *Let $T > 0$ and $A : [0, T] \rightarrow \mathcal{L}(D, X)$ be a bounded and strongly measurable function. Then A has L^p -maximal regularity and we write $A \in \mathcal{MR}_p(0, T)$ if for all $f \in L^p(0, T; X)$ there exists a unique $u \in W^{1,p}(0, T; X) \cap L^p(0, T; D)$ such that*

$$\begin{aligned} \partial_t u + A(t)u &= f \quad \text{a.e. on } (0, T), \\ u(0) &= 0. \end{aligned}$$

It can be shown that if $A \in \mathcal{MR}_p$ for some $p \in (1, \infty)$ then $A \in \mathcal{MR}_p$ for all $p \in (1, \infty)$. Hence, we often simply write $A \in \mathcal{MR}$.

Definition 2.2 (Relative Continuity).

We say that $A : [0, T] \rightarrow \mathcal{L}(D, X)$ is relatively continuous if for each $t \in [0, T]$ and all $\epsilon > 0$ there exist $\delta > 0$, $\eta \geq 0$ such that for all $x \in D$ and for all $s \in [0, T]$ with $|s - t| \leq \delta$ the inequality

$$\|A(t)x - A(s)x\|_X \leq \epsilon \|x\|_D + \eta \|x\|_X$$

holds.

Theorem 2.3. *Let $T > 0$ and $A : [0, T] \rightarrow \mathcal{L}(D, X)$ be a strongly measurable and relatively continuous function. If $A(t) \in \mathcal{MR}$ for all $t \in [0, T]$, then $A \in \mathcal{MR}_p(0, t)$ for every $0 < t \leq T$ and every $p \in (1, \infty)$.*

Proof. See [7, Theorem 2.7]. □

A very important tool for proving maximal regularity properties of differential operators are perturbation techniques. Employing these can often help to show maximal regularity for a variety of operators by separating them into a main part (for which maximal regularity can be readily shown) and a perturbation.

In the following we give a perturbation result which is key to many results in the next chapter.

Definition 2.4 (Relatively Close).

Let Y be a Banach space such that

$$D \hookrightarrow Y \hookrightarrow X.$$

We say Y is close to X compared with D , if for each $\epsilon > 0$ there exists $\eta \geq 0$ such that

$$\|x\|_Y \leq \epsilon \|x\|_D + \eta \|x\|_X \quad \text{for all } x \in D.$$

Proposition 1. *Let Y be as in Definition 2.4 and let the inclusion $D \hookrightarrow Y$ be compact. Then Y is close to X compared with D .*

Proof. See [7, Example 2.9 (d)]. □

Theorem 2.5. *Let $T > 0$ and Y be a Banach space that is close to X compared with D . Furthermore, let $A: [0, T] \rightarrow \mathcal{L}(D, X)$ be relatively continuous and $B: [0, T] \rightarrow \mathcal{L}(Y, X)$ be strongly measurable and bounded. If $A(t) \in \mathcal{MR}$ for every $t \in [0, T]$ then $A + B \in \mathcal{MR}_p(0, T)$.*

Proof. See [7, Theorem 2.11]. □

3 Main Results

3.1 Parabolic Equations on Evolving Surfaces

We introduce the space

$$X_T = L^2(0, T; H^{\frac{7}{2}}(\Sigma)) \cap H^1(0, T; H^{\frac{1}{2}}(\Sigma)) \quad (12)$$

for $T \in (0, \infty)$, where we equip X_T with the norm

$$\|h\|_{X_T} = \|h\|_{L^2(0, T; H^{\frac{7}{2}}(\Sigma))} + \|h\|_{H^1(0, T; H^{\frac{1}{2}}(\Sigma))} + \|h|_{t=0}\|_{H^2(\Sigma)}.$$

Theorem 3.1. *Let $T \in (0, T_0]$. Let $\mathbf{b}: \Sigma \times [0, T] \rightarrow \mathbb{R}^d$ and $b_1, b_2: \Sigma \times [0, T] \rightarrow \mathbb{R}$ be smooth given functions. For every $g \in L^2(0, T; H^{\frac{1}{2}}(\Sigma))$ and $h_0 \in H^2(\Sigma)$, there is a unique solution $h \in X_T$ of*

$$\begin{aligned} D_{t,\Gamma} h + \mathbf{b} \cdot \nabla_\Gamma h - b_1 h + X_0^*([\partial_{\mathbf{n}_\Gamma} \mu]) &= g && \text{on } \Sigma \times (0, T), \\ h(\cdot, 0) &= h_0 && \text{on } \Sigma, \end{aligned} \quad (13)$$

where $\mu|_{\Omega^\pm(t)} \in H^2(\Omega^\pm(t))$, for $t \in [0, T]$, is determined by

$$\Delta\mu^\pm = 0 \quad \text{in } \Omega^\pm(t), \quad (14a)$$

$$\mu^\pm = X_0^{*, -1}(\sigma\Delta_\Gamma h \pm b_2 h) \quad \text{on } \Gamma_t, \quad (14b)$$

$$\mathbf{n}_{\partial\Omega} \cdot \nabla\mu^- = 0 \quad \text{on } \Gamma_{\mu,1}, \quad (14c)$$

$$\mu^- = 0 \quad \text{on } \Gamma_{\mu,2}. \quad (14d)$$

Furthermore, the estimates

$$\sum_{\pm} \|\mu^\pm\|_{L^2(0,T;H^2(\Omega^\pm(t))) \cap L^6(0,T;H^1(\Omega^\pm(t)))} \leq C \|h\|_{X_T}, \quad (15)$$

hold for some constant $C > 0$ independent of μ and h .

Proof. We may write (13) in abstract form as

$$\begin{aligned} \partial_t h + \mathcal{A}(t)h &= g & \text{in } \Sigma \times [0, T], \\ h(., 0) &= h_0 & \text{in } \Sigma, \end{aligned}$$

where $\mathcal{A}(t): H^{\frac{7}{2}}(\Sigma) \rightarrow H^{\frac{1}{2}}(\Sigma)$ depends on $t \in [0, T]$. Now we fix $t_0 \in [0, T]$ and analyze the operator $\mathcal{A}(t_0)$, where we replace t with the fixed t_0 in all time dependent coefficients.

In order to understand this operator we define

$$\mathfrak{D}_{t_0}: H^{\frac{7}{2}}(\Sigma) \rightarrow H^{\frac{3}{2}}(\Gamma_{t_0}): h \mapsto (X_0^{*, -1}(\sigma\Delta_\Gamma h))(., t_0),$$

$$S_{t_0}^N: H^{\frac{3}{2}}(\Gamma_{t_0}) \rightarrow H^2(\Omega^+(t_0)) \times H^2(\Omega^-(t_0)): f \mapsto (\Delta_N)^{-1}f,$$

$$B_{t_0}: H^2(\Omega^+(t_0)) \times H^2(\Omega^-(t_0)) \rightarrow H^{\frac{1}{2}}(\Sigma): (\mu^+, \mu^-) \mapsto (X_0^*([\nabla\mu \cdot \mathbf{n}_{\Gamma_{t_0}}]))(., t_0),$$

where $(\Delta_N)^{-1}f$ is the unique solution (μ_N^+, μ_N^-) to

$$\Delta\mu_N^\pm = 0 \quad \text{in } \Omega^\pm(t_0), \quad (16a)$$

$$\mu_N^\pm = f \quad \text{on } \Gamma_{t_0}, \quad (16b)$$

$$\nabla\mu_N^- \cdot \mathbf{n}_{\partial\Omega} = 0 \quad \text{on } \partial\Omega. \quad (16c)$$

In the literature the concatenation $B_{t_0} \circ S_{t_0}^N$ is often referred to as the *Dirichlet-to-Neumann* operator and $A_0(t_0) := B_{t_0} \circ S_{t_0}^N \circ \mathfrak{D}_{t_0}$ is called the *Mullins-Sekerka* operator. It can be shown that

$$A_0: [0, T] \rightarrow \mathcal{L}(H^{\frac{7}{2}}(\Sigma), H^{\frac{1}{2}}(\Sigma))$$

has L^p -maximal regularity, i.e., $A_0 \in \mathcal{MR}_p(0, T)$. We will not prove this in detail but just give a short sketch describing the essential ideas: first, a reference surface $\tilde{\Sigma} \subset\subset \Omega$ is fixed such that Γ_t can be expressed as a graph over $\tilde{\Sigma}$ for t in some time interval $[\tilde{t}, \tilde{t} + \epsilon] \subset [0, T]$. e.g. one may choose $\tilde{\Sigma} := \Gamma_0$ and then determine $\epsilon_0 > 0$

such that Γ_t may be written as graph over Γ_0 for all $t \in [0, \epsilon_0]$, which is possible since Γ is a smoothly evolving hypersurface. Next, a Hanzawa transformation is applied, enabling us to consider (16c) as a system on fixed domains Ω^\pm and $\tilde{\Sigma}$, but with time dependent coefficients (see e.g. [4, Chapter 2.2] or and [12, Chapter 4]). Here, Ω^+ , Ω^- and $\tilde{\Sigma}$ denote disjoint sets such that $\partial\Omega^+ = \tilde{\Sigma}$ and $\Omega = \Omega^+ \cup \Omega^- \cup \tilde{\Sigma}$ holds and we assume in the following that $t_0 \in [0, \epsilon_0]$. To be more specific, the Hanzawa transformation results in a system of the form

$$\begin{aligned} a(x, t, \nabla_x) \bar{\mu}^\pm &= 0 && \text{in } \Omega^\pm, \\ \bar{\mu}^\pm &= \tilde{f} && \text{on } \tilde{\Sigma}, \\ \nabla \bar{\mu}^- \cdot \mathbf{n}_{\partial\Omega} &= 0 && \text{on } \partial\Omega, \end{aligned}$$

where a is the transformed Laplacian, depending smoothly on t and \tilde{f} is the transformation of f . Applying the Hanzawa transformation (and the diffeomorphism X_0) also to the operators \mathfrak{D}_{t_0} and B_{t_0} , we end up with a transformed operator $\tilde{A}_0(t_0) \in \mathcal{L}(H^{\frac{7}{2}}(\Sigma), H^{\frac{1}{2}}(\Sigma))$ and [11, Corollary 6.6.5] implies that $\tilde{A}_0(t_0)$ has L^p -maximal regularity. As all involved differential operators and coefficients depend smoothly on t , it is possible to show that $\tilde{A}_0: [0, \epsilon_0] \rightarrow \mathcal{L}(H^{\frac{7}{2}}(\Sigma), H^{\frac{1}{2}}(\Sigma))$ is relatively continuous. Therefore Theorem 2.3 implies $\tilde{A}_0 \in \mathcal{MR}_p(0, \epsilon_0)$ and, transforming back, also $A_0 \in \mathcal{MR}_p(0, \epsilon_0)$. Repeating this procedure with a new reference surface $\Sigma := \Gamma_{\epsilon_0}$ and iteratively continuing the argumentation, we end up with $A_0 \in \mathcal{MR}_p(0, T)$.

We proceed by showing that $\mathcal{A}(t_0) = A_0(t_0) + \mathcal{B}(t_0)$ holds for some lower order perturbation \mathcal{B} . We introduce

$$S_{t_0}^{DN}: H^{\frac{3}{2}}(\Gamma_{t_0}) \rightarrow H^2(\Omega^+(t_0)) \times H^2(\Omega^-(t_0)): f \mapsto (\Delta_{DN})^{-1}f,$$

where $(\mu_{DN}^+, \mu_{DN}^-) := (\Delta_{DN})^{-1}f$ is the unique solution to (16), replacing $\nabla \mu_N^- \cdot \mathbf{n}_{\partial\Omega} = 0$ on $\Gamma_{\mu,2}$ by $\mu_D^- = 0$ on $\Gamma_{\mu,2}$. Moreover, we write $S_{t_0}^\Delta := S_{t_0}^{DN} - S_{t_0}^N$ and observe that the equality

$$B_{t_0} \circ S_{t_0}^{DN} \circ \mathfrak{D}_{t_0} = A_0(t_0) + \mathcal{B}_0(t_0) \quad (17)$$

is satisfied, where $\mathcal{B}_0(t_0) := B_{t_0} \circ S_{t_0}^\Delta \circ \mathfrak{D}_{t_0}$. Let $f \in H^{\frac{3}{2}}(\Gamma_{t_0})$ be fixed, $(\mu_{DN}^+, \mu_{DN}^-) := S_{t_0}^{DN}f$, $(\mu_N^+, \mu_N^-) := S_{t_0}^Nf$ and $\tilde{\mu}^\pm := \mu_{DN}^\pm - \mu_N^\pm$, implying $(\tilde{\mu}^+, \tilde{\mu}^-) = S_{t_0}^\Delta f$. Then $\tilde{\mu}^\pm \in H^2(\Omega^\pm(t_0))$ solves

$$\begin{aligned} \Delta \tilde{\mu}^\pm &= 0 && \text{in } \Omega^\pm(t_0), \\ \tilde{\mu}^\pm &= 0 && \text{on } \Gamma_{t_0}, \\ \mathbf{n}_{\partial\Omega} \cdot \nabla \tilde{\mu}^- &= 0 && \text{on } \Gamma_{\mu,1} \\ \tilde{\mu}^- &= \mu_N^- && \text{on } \Gamma_{\mu,2} \end{aligned}$$

and elliptic regularity theory implies

$$\|\tilde{\mu}^-\|_{H^2(\Omega^-(t_0))} \leq C \|\mu_N^-\|_{H^{\frac{3}{2}}(\Gamma_{\mu,2})} \quad (18)$$

and $\tilde{\mu}^+ \equiv 0$ in $\Omega^+(t_0)$. For the further argumentation, we show

$$\|\mu_N^-\|_{H^{\frac{3}{2}}(\partial\Omega)} \leq C\|\mu_N^-\|_{H^{\frac{1}{2}}(\Gamma_{t_0})}. \quad (19)$$

To this end let $\gamma(x) := \xi(4d_{\mathbf{B}}(x))$ for all $x \in \Omega$, where ξ is a cut-off function satisfying (11). In particular $\text{supp}\gamma \cap \Gamma_t = \emptyset$ for all $t \in [0, T_0]$ by our assumptions and $\gamma \equiv 1$ in $\partial\Omega(\frac{\delta}{4})$. Denoting $\hat{\mu} := \gamma\mu_N^- \in H^2(\Omega^-(t_0))$, we compute using $\Delta\mu_N^- = 0$ in $\Omega^-(t_0)$ that $\hat{\mu}$ is a solution to

$$\begin{aligned} \Delta\hat{\mu} &= 2\nabla\gamma \cdot \nabla\mu_N^- + (\Delta\gamma)\mu_N^- && \text{in } \Omega^-(t_0), \\ \hat{\mu} &= 0 && \text{on } \Gamma_{t_0}, \\ \nabla\hat{\mu} \cdot \mathbf{n}_{\partial\Omega} &= 0 && \text{on } \partial\Omega, \end{aligned}$$

which, again regarding elliptic regularity theory, implies $\|\hat{\mu}\|_{H^2(\Omega^-(t_0))} \leq C\|\mu_N^-\|_{H^1(\Omega^-(t_0))}$. This is essential in view of (19) as it leads to

$$\begin{aligned} \|\mu_N^-\|_{H^{\frac{3}{2}}(\partial\Omega)} &= \|\hat{\mu}\|_{H^{\frac{3}{2}}(\partial\Omega)} \leq C\|\hat{\mu}\|_{H^2(\Omega^-(t_0))} \\ &\leq C\|\mu_N^-\|_{H^1(\Omega^-(t_0))} \leq \tilde{C}\|\mu_N^-\|_{H^{\frac{1}{2}}(\Gamma_{t_0})}, \end{aligned}$$

where we used the continuity of the trace operator $\text{tr}: H^2(\Omega^-(t_0)) \rightarrow H^{\frac{3}{2}}(\partial\Omega^-(t_0))$ in the first inequality (cf. [10, Theorem 3.37]) and standard estimates for elliptic equations in the second and third inequality.

Let now $h \in H^{\frac{7}{2}}(\Sigma)$ and $(\tilde{\mu}^+, \tilde{\mu}^-) := S_{t_0}^\Delta \circ \mathfrak{D}_{t_0} h$. Our prior considerations enable us to estimate

$$\begin{aligned} \|B_{t_0} \circ S_{t_0}^\Delta \circ \mathfrak{D}_{t_0} h\|_{H^{\frac{1}{2}}(\Sigma)} &\leq C\|\tilde{\mu}^-\|_{H^2(\Omega^-(t_0))} \leq C\|\mu_N^-\|_{H^{\frac{3}{2}}(\partial\Omega)} \\ &\leq C\|\mu_N^-\|_{H^{\frac{1}{2}}(\Gamma_{t_0})} \leq C\|\sigma\Delta_\Gamma h\|_{H^{\frac{1}{2}}(\Sigma)} \leq C\|h\|_{H^{\frac{5}{2}}(\Sigma)}, \end{aligned}$$

where we employed the continuity of the trace in the first line, (18) in the second, (19) in the third and the definition of μ_N^- in the fourth. As $H^{\frac{7}{2}}(\Sigma)$ is dense in $H^{\frac{5}{2}}(\Sigma)$, we may extend $\mathcal{B}_0(t_0)$ to an operator

$$\mathcal{B}_0(t_0): H^{\frac{5}{2}}(\Sigma) \rightarrow H^{\frac{1}{2}}(\Sigma), \quad (20)$$

which shows in regard to (17) that we may view $B_{t_0} \circ S_{t_0}^\Delta \circ \mathfrak{D}_{t_0}$ as a lower order perturbation of $A_0(t_0)$.

Next we take care of the term involving b_2 in (14b). For this we consider the operator

$$\mathcal{B}_1(t_0): H^{\frac{7}{2}}(\Sigma) \rightarrow H^{\frac{1}{2}}(\Sigma): h \mapsto X_0^*([\partial_{\mathbf{n}_{\Gamma_{t_0}}} \mu_1]),$$

where $\mu_1^\pm \in H^2(\Omega^\pm(t_0))$ is the solution to

$$\begin{aligned} \Delta\mu_1^\pm &= 0 && \text{in } \Omega^\pm(t_0), \\ \mu_1^\pm &= \pm b_2 h && \text{on } \Gamma_{t_0}, \\ \mathbf{n}_{\partial\Omega} \cdot \nabla\mu_1^- &= 0 && \text{on } \Gamma_{\mu,1}, \\ \mu_1^- &= 0 && \text{on } \Gamma_{\mu,2}. \end{aligned}$$

We estimate

$$\begin{aligned}\|\mathcal{B}_1(t_0)h\|_{H^{\frac{1}{2}}(\Sigma)} &\leq C\|[\partial_{\mathbf{n}_{\Gamma_{t_0}}}\mu_1]\|_{H^{\frac{1}{2}}(\Gamma_{t_0})} \\ &\leq C(\|\mu_1^+\|_{H^2(\Omega^+(t_0))} + \|\mu_1^-\|_{H^2(\Omega^-(t_0))}) \leq C\|h\|_{H^{\frac{3}{2}}(\Sigma)},\end{aligned}\quad (21)$$

where $C > 0$ can be chosen independent of h and $t_0 \in [0, T]$. Here we again employed the continuity of the trace operator and elliptic theory.

Defining

$$\mathcal{B}(t_0): H^{\frac{7}{2}}(\Sigma) \rightarrow H^{\frac{1}{2}}(\Sigma): h \mapsto \mathcal{B}(t_0)h := \tilde{\mathbf{b}}(\cdot, t_0) \cdot \nabla_{\Gamma} h - b_1(\cdot, t_0)h + (\mathcal{B}_0(t_0) + \mathcal{B}_1(t_0))h,$$

where $\tilde{\mathbf{b}}$ is chosen such that $\partial_t h + \tilde{\mathbf{b}} \cdot \nabla_{\Gamma} h = D_{t,\Gamma} h + \mathbf{b} \cdot \nabla_{\Gamma} h$, and using (21) and (20), we find that

$$\|\mathcal{B}(t_0)h\|_{H^{\frac{1}{2}}(\Sigma)} \leq C\|h\|_{H^{\frac{5}{2}}(\Sigma)}.$$

Thus, we can extend $\mathcal{B}(t_0)$ to a bounded operator $\mathcal{B}(t_0): H^{\frac{5}{2}}(\Sigma) \rightarrow H^{\frac{1}{2}}(\Sigma)$. Since $H^{\frac{5}{2}}(\Sigma)$ is close to $H^{\frac{1}{2}}(\Sigma)$ compared to $H^{\frac{7}{2}}(\Sigma)$ as the embedding $H^{\frac{7}{2}}(\Sigma) \hookrightarrow H^{\frac{5}{2}}(\Sigma)$ is compact, we get due to Theorem 2.5, that $\mathcal{A} = A_0 + \mathcal{B}$ has L^p -maximal regularity for all $t \in [0, T]$.

By elliptic theory

$$\|\mu^{\pm}\|_{H^1(\Omega^{\pm}(t))} \leq C\|X_0^{*,-1}(\sigma\Delta_{\Gamma}h + b_2h)\|_{H^{\frac{1}{2}}(\Gamma_t)} \leq C\|h\|_{H^{\frac{5}{2}}(\Sigma)}$$

for almost all $t \in [0, T]$ and thus

$$\|\mu^{\pm}\|_{L^6(0,T;H^1(\Omega^{\pm}(t)))} \leq C\|h\|_{L^6(0,T;H^{\frac{5}{2}}(\Sigma))} \leq C\|h\|_{X_T}.$$

□

Theorem 3.2. *Let $T \in (0, T_0]$ and $t \in [0, T]$. For every $\mathbf{f} \in L^2(\Omega)^d$, $\mathbf{s} \in H^{\frac{3}{2}}(\Gamma_t)^d$, $\mathbf{a} \in H^{\frac{1}{2}}(\Gamma_t)^d$ and $\mathbf{g}: \partial\Omega \rightarrow \mathbb{R}^d$ such that $\mathbf{g}|_{\Gamma_{S,1}} \in H^{\frac{3}{2}}(\Gamma_{S,1})^d$, $\mathbf{n}_{\partial\Omega} \cdot \mathbf{g}|_{\Gamma_{S,2}} \in H^{\frac{3}{2}}(\Gamma_{S,2})$, $(I - \mathbf{n}_{\partial\Omega} \otimes \mathbf{n}_{\partial\Omega})\mathbf{g}|_{\Gamma_{S,2}} \in H^{\frac{1}{2}}(\Gamma_{S,2})^d$, $\mathbf{g}|_{\Gamma_{S,3}} \in H^{\frac{1}{2}}(\Gamma_{S,3})^d$ satisfying the compatibility condition*

$$\int_{\Gamma_t} \mathbf{n}_{\Gamma_t} \cdot \mathbf{s} d\mathcal{H}^{d-1} + \int_{\partial\Omega} \mathbf{n}_{\partial\Omega} \cdot \mathbf{g} d\mathcal{H}^{d-1} = 0 \quad \text{if } \Gamma_{S,3} = \emptyset \quad (22)$$

the system

$$-\Delta \mathbf{v}^{\pm} + \nabla p^{\pm} = \mathbf{f} \quad \text{in } \Omega^{\pm}(t), \quad (23)$$

$$\operatorname{div} \mathbf{v}^{\pm} = 0 \quad \text{in } \Omega^{\pm}(t), \quad (24)$$

$$B_j(\mathbf{v}^-, p^-) = \mathbf{g}|_{\Gamma_{S,j}} =: \mathbf{g}_j \quad \text{on } \Gamma_{S,j}, j = 1, 2, 3, \quad (25)$$

$$[\mathbf{v}] = \mathbf{s} \quad \text{on } \Gamma_t, \quad (26)$$

$$[2D_s \mathbf{v} - p\mathbf{I}] \mathbf{n}_{\Gamma_t} = \mathbf{a} \quad \text{on } \Gamma_t \quad (27)$$

has a unique solution $(\mathbf{v}^\pm, p^\pm) \in H^2(\Omega^\pm(t))^d \times H^1(\Omega^\pm(t))$ satisfying $\int_\Omega p \, dx = 0$ if $\Gamma_{S,3} = \emptyset$. Moreover, there is a constant $C > 0$ independent of $t \in [0, T_0]$ such that

$$\begin{aligned} \|(\mathbf{v}, p)\|_{H^2(\Omega^\pm(t)) \times H^1(\Omega^\pm(t))} &\leq C \left(\|\mathbf{f}\|_{L^2(\Omega)} + \|\mathbf{s}\|_{H^{\frac{3}{2}}(\Gamma_t)} + \|\mathbf{a}\|_{H^{\frac{1}{2}}(\Gamma_t)} \right. \\ &\quad \left. + \|\mathbf{g}_1\|_{H^{\frac{3}{2}}(\Gamma_{S,1})} + \|\mathbf{g}_{2,\mathbf{n}}\|_{H^{\frac{3}{2}}(\Gamma_{S,2})} + \|\mathbf{g}_{2,\boldsymbol{\tau}}\|_{H^{\frac{1}{2}}(\Gamma_{S,2})} + \|\mathbf{g}_3\|_{H^{\frac{1}{2}}(\Gamma_{S,3})} \right) \end{aligned} \quad (28)$$

holds.

Proof. We can assume for simplicity that $\mathbf{g} = 0$ on $\Gamma_{S,1}$ and $\mathbf{n}_{\partial\Omega} \cdot \mathbf{g} = 0$ on $\Gamma_{S,2}$. Otherwise we subtract a suitable extension of \mathbf{g} . As a first step, we reduce the system (23)–(27) to the case $\mathbf{s} = 0$. Elliptic theory implies that the equation

$$\begin{aligned} \Delta q &= 0 && \text{in } \Omega^-(t), \\ \nabla q \cdot \mathbf{n}_{\Gamma_t} &= \mathbf{s} \cdot \mathbf{n}_{\Gamma_t} && \text{on } \Gamma_t, \\ \mathbf{n}_{\partial\Omega} \cdot \nabla q &= \mathbf{n}_{\partial\Omega} \cdot \mathbf{g}_2 && \text{on } \Gamma_{S,1} \cup \Gamma_{S,2}, \\ q &= 0 && \text{on } \Gamma_{S,3} \end{aligned}$$

has a unique solution $q \in H^3(\Omega^-(t))$ with $\int_{\Omega^-(t)} q \, dx = 0$ if $\Gamma_{S,3} = \emptyset$ since $\mathbf{s} \in H^{\frac{3}{2}}(\Gamma_t)^d$ and $\mathbf{n}_{\partial\Omega} \cdot \mathbf{g}_2 \in H^{\frac{3}{2}}(\Gamma_{S,1} \cup \Gamma_{S,2})$. Here, if $\Gamma_{S,3} = \emptyset$, the necessary compatibility condition is satisfied because of (22). Moreover, we have the estimate

$$\|q\|_{H^3(\Omega^-(t))} \leq C \left(\|\mathbf{s}\|_{H^{\frac{3}{2}}(\Gamma_t)} + \|\mathbf{n}_{\partial\Omega} \cdot \mathbf{g}_2\|_{H^{\frac{3}{2}}(\Gamma_{S,1} \cup \Gamma_{S,2})} \right).$$

Regarding the tangential part of \mathbf{s} , we may solve the stationary Stokes system

$$\begin{aligned} -\Delta \mathbf{w} + \nabla \tilde{p} &= 0 && \text{in } \Omega^-(t), \\ \operatorname{div} \mathbf{w} &= 0 && \text{in } \Omega^-(t), \\ \mathbf{w} &= (I - \mathbf{n}_{\Gamma_t} \otimes \mathbf{n}_{\Gamma_t})(\mathbf{s} - \nabla q) && \text{on } \Gamma_t, \\ \mathbf{w} &= 0 && \text{on } \partial\Omega. \end{aligned}$$

We may find a solution $(\mathbf{w}, \tilde{p}) \in H^2(\Omega^-(t))^d \times H^1(\Omega^-(t))$ (made unique by the normalization $\int_{\Omega^-(t)} \tilde{p} \, dx = 0$) and also get the estimate

$$\|\mathbf{w}\|_{H^2(\Omega^-(t))} + \|\tilde{p}\|_{H^1(\Omega^-(t))} \leq C \left(\|\mathbf{s}\|_{H^{\frac{3}{2}}(\Gamma_t)} + \|\mathbf{n}_{\partial\Omega} \cdot \mathbf{g}_2\|_{H^{\frac{3}{2}}(\Gamma_{S,1} \cup \Gamma_{S,2})} \right).$$

Thus, defining $\tilde{\mathbf{w}} := \mathbf{w} + \nabla q$, the couple $(\tilde{\mathbf{w}}, \tilde{p})$ solves

$$\begin{aligned} -\Delta \tilde{\mathbf{w}} + \nabla \tilde{p} &= 0 && \text{in } \Omega^-(t), \\ \operatorname{div} \tilde{\mathbf{w}} &= 0 && \text{in } \Omega^-(t), \\ \tilde{\mathbf{w}} &= \mathbf{s} && \text{on } \Gamma_t, \\ \tilde{\mathbf{w}} &= 0 && \text{on } \partial\Omega, \end{aligned}$$

and may be estimated by \mathbf{s} in strong norms. Next, let

$$\tilde{\mathbf{g}} := \mathbf{g}_j + B_j(\tilde{\mathbf{w}}, \tilde{p}) \quad \text{on } \Gamma_{S,j}, j = 1, 2, 3$$

and $\tilde{\mathbf{a}} := \mathbf{a} - (2D_s \tilde{\mathbf{w}} - \tilde{p} \mathbf{I}) \mathbf{n}_{\Gamma_t} \in H^{\frac{1}{2}}(\Gamma_t)^d$, where the regularity is due to the properties of the trace operator. Then, for every strong solution $(\hat{\mathbf{v}}^\pm, \hat{p}^\pm)$ of (23)-(27), with $\mathbf{s} \equiv 0$ and \mathbf{g}, \mathbf{a} substituted by $\tilde{\mathbf{g}}, \tilde{\mathbf{a}}$, the functions

$$(\mathbf{v}^+, p^+) := (\hat{\mathbf{v}}^+, \hat{p}^+) \quad \text{and} \quad (\mathbf{v}^-, p^-) := (\hat{\mathbf{v}}^- - \tilde{\mathbf{w}}, \hat{p}^- - \tilde{p})$$

are solutions to the original system (23)-(27). So, we will consider $\mathbf{s} \equiv 0$ in the following and show existence of strong solutions in that case.

As a starting point, we construct a solution $(\mathbf{v}, p) \in V(\Omega) \times L^2(\Omega)$ to the weak formulation

$$\begin{aligned} & \int_{\Omega} 2D_s \mathbf{v} : D_s \boldsymbol{\psi} \, dx - \int_{\Omega} p \operatorname{div} \boldsymbol{\psi} \, dx + \int_{\Gamma_{S,2}} \alpha_2 \mathbf{v} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) + \int_{\Gamma_{S,3}} \alpha_3 \mathbf{v} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) \\ &= \int_{\Omega} \mathbf{f} \cdot \boldsymbol{\psi} \, dx + \int_{\Gamma_t} \mathbf{a} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) - \int_{\partial\Omega} \mathbf{g} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s), \end{aligned} \quad (29)$$

for all $\boldsymbol{\psi} \in H^1(\Omega)^d$ with $\boldsymbol{\psi}|_{\Gamma_{S,1}} = 0$, $\mathbf{n} \cdot \boldsymbol{\psi}|_{\Gamma_{S,2}} = 0$, where

$$V(\Omega) = \{\mathbf{u} \in H^1(\Omega)^d : \operatorname{div} \mathbf{u} = 0, \mathbf{u}|_{\Gamma_{S,1}} = 0, \mathbf{n} \cdot \mathbf{u}|_{\Gamma_{S,2}} = 0\}.$$

Considering first $\boldsymbol{\psi} \in V(\Omega)$ and the right hand side as a functional $\mathbf{F} \in (V(\Omega))'$, the Lemma of Lax-Milgram implies the existence of a unique $\mathbf{v} \in V(\Omega)$ solving (29) for all $\boldsymbol{\psi} \in V(\Omega)$, where the coercivity of the involved bilinear form is a consequence of (10).

Next consider the functional

$$\begin{aligned} F(\boldsymbol{\psi}) := & - \int_{\Omega} 2D_s \mathbf{v} : D_s \boldsymbol{\psi} \, dx - \int_{\Gamma_{S,2}} \alpha_2 \mathbf{v} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) - \int_{\Gamma_{S,3}} \alpha_3 \mathbf{v} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) \\ & + \int_{\Omega} \mathbf{f} \cdot \boldsymbol{\psi} \, dx + \int_{\Gamma_t} \mathbf{a} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) - \int_{\partial\Omega} \mathbf{g} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s), \end{aligned}$$

for all $\boldsymbol{\psi} \in H^1(\Omega)^d$ with $\boldsymbol{\psi}|_{\Gamma_{S,1}} = 0$, $\mathbf{n} \cdot \boldsymbol{\psi}|_{\Gamma_{S,2}} = 0$. Then F vanishes on $V(\Omega)$ and by Lemma A.1 in Appendix A there is a unique $p \in L^2(\Omega)$ with $\int_{\Omega} p \, dx = 0$ if $\Gamma_{S,3} = \emptyset$ such that

$$F(\boldsymbol{\psi}) = - \int_{\Omega} p \operatorname{div} \boldsymbol{\psi} \, dx \quad \text{for all } \boldsymbol{\psi} \in H^1(\Omega)^d \text{ with } \boldsymbol{\psi}|_{\Gamma_{S,1}} = 0, \mathbf{n} \cdot \boldsymbol{\psi}|_{\Gamma_{S,2}} = 0.$$

Hence (\mathbf{v}, p) solve (29). Moreover, we obtain the estimate

$$\|(\mathbf{v}, p)\|_{H^1(\Omega) \times L^2(\Omega)} \leq C \left(\|\mathbf{f}\|_{L^2(\Omega)} + \|\mathbf{a}\|_{H^{\frac{1}{2}}(\Gamma_t)} + \|\mathbf{g}\|_{H^{\frac{1}{2}}(\partial\Omega)} \right). \quad (30)$$

We now show higher regularity of (\mathbf{v}, p) by localization.

Let $\eta^\pm \in C^\infty(\overline{\Omega})$ be a partition of unity of Ω , such that the inclusions $\Omega^+(t) \cup \Gamma_t(\delta) \subset \{x \in \Omega \mid \eta^+(x) = 1\}$ and $\partial\Omega(\delta) \subset \{x \in \Omega \mid \eta^-(x) = 1\}$ hold. We choose η^\pm such that $\{x \in \Omega : \eta^\pm(x) = 1\}$ has smooth boundary and define $U^\pm := \text{supp}(\eta^\pm)$, $\partial U_0^- := \partial U^- \setminus \partial\Omega$ and

$$\dot{U} := \{x \in \Omega \mid \eta^+(x) \in (0, 1)\} = \{x \in \Omega \mid \eta^-(x) \in (0, 1)\}.$$

Moreover, we set $\dot{p}^- := p\eta^-$ and $\tilde{\mathbf{v}}^- := \mathbf{v}\eta^-$ in Ω and we correct the divergence of $\tilde{\mathbf{v}}^-$ with the help of the Bogovskii-operator: Let $\varphi \in C_c^\infty(\Omega)$ with $\text{supp}(\varphi) \subset U^+ \setminus \dot{U}$ and $\int_\Omega \varphi \, dx = 1$ and set

$$\hat{g} := \text{div}(\tilde{\mathbf{v}}^-) - \varphi \int_{U^+} \text{div}(\tilde{\mathbf{v}}^-) \, dx$$

in U^+ . As $\mathbf{v} \in V(\Omega)$, we have $\text{div}(\tilde{\mathbf{v}}^-) = \mathbf{v} \cdot \nabla \eta^-$ and thus $\hat{g} \in H_0^1(U^+)$, $\int_{U^+} \hat{g} \, dx = 0$. Consequently, [9, Theorem III.3.3] implies that there is $\hat{\mathbf{v}}^- \in H_0^2(U^+)$, which we extend onto Ω by 0, satisfying

$$\begin{aligned} \text{div} \hat{\mathbf{v}}^- &= \hat{g} \text{ in } U^+, \\ \|\hat{\mathbf{v}}^-\|_{H^2(\Omega)} &\leq C \|\mathbf{v}\|_{H^1(\Omega)}. \end{aligned} \quad (31)$$

Therefore, $\dot{\mathbf{v}}^- := \tilde{\mathbf{v}}^- - \hat{\mathbf{v}}^-$ fulfills $\text{div} \dot{\mathbf{v}}^- = 0$ in U^- since $\varphi \equiv 0$ in that domain. Let now

$$\boldsymbol{\psi} \in \{\mathbf{w} \in H^1(U^-)^d : \mathbf{w} = 0 \text{ on } \partial U_0^-, \mathbf{w}|_{\Gamma_{S,1}} = 0, \mathbf{n} \cdot \mathbf{w}|_{\Gamma_{S,2}} = 0\},$$

then

$$\begin{aligned} & \int_{U^-} 2D_s \dot{\mathbf{v}}^- : D_s \boldsymbol{\psi} - \dot{p}^- \text{div} \boldsymbol{\psi} \, dx + \int_{\Gamma_{S,2}} \alpha_2 \mathbf{v} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) + \int_{\Gamma_{S,3}} \alpha_3 \mathbf{v} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) \\ &= \int_{U^-} 2D_s \tilde{\mathbf{v}}^- : D_s \boldsymbol{\psi} - p \text{div}(\boldsymbol{\psi} \eta^-) + (p \nabla \eta^-) \cdot \boldsymbol{\psi} \, dx + \int_{\Gamma_{S,2}} \alpha_2 \mathbf{v} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) \\ & \quad + \int_{\Gamma_{S,3}} \alpha_3 \mathbf{v} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) - \int_{U^-} 2D_s \hat{\mathbf{v}}^- : D_s \boldsymbol{\psi} \, dx \\ &= \int_{U^-} \mathbf{f} \cdot \boldsymbol{\psi} \eta^- \, dx - \int_{\partial\Omega} \mathbf{g} \cdot \boldsymbol{\psi} \, d\mathcal{H}^{d-1}(s) + (p \nabla \eta^-) \cdot \boldsymbol{\psi} \, dx \\ & \quad + \int_{U^-} 2 \text{div}(D_s \hat{\mathbf{v}}^-) \cdot \boldsymbol{\psi} + (2D_s \mathbf{v} \nabla \eta^- - \text{div}(\mathbf{v} \otimes \nabla \eta^- + \nabla \eta^- \otimes \mathbf{v})) \cdot \boldsymbol{\psi} \, dx, \end{aligned}$$

where we used the definition of $\dot{\mathbf{v}}^-$ and \dot{p}^- in the first equality and integration by parts together with $\hat{\mathbf{v}}^- \in H_0^2(U^+)$ and $\nabla \eta^- = 0$ on U^- in the second equality. Additionally, we employed the fact that (\mathbf{v}, p) is the weak solution to (29). Hence,

$(\dot{\mathbf{v}}^-, \dot{p}^-)$ are a weak solution to the system

$$\begin{aligned} -\Delta \dot{\mathbf{v}}^- + \nabla \dot{p}^- &= \tilde{\mathbf{f}} && \text{in } U^-, \\ \operatorname{div} \dot{\mathbf{v}}^- &= 0 && \text{in } U^-, \\ \dot{\mathbf{v}}^- &= \hat{\mathbf{v}}^- && \text{on } \partial U_0^-, \\ B_j(\mathbf{v}^-, \dot{p}^-) &= \mathbf{g} && \text{on } \Gamma_{S,j}, j = 1, 2, 3, \end{aligned} \quad (32)$$

where

$$\tilde{\mathbf{f}} := \mathbf{f}\eta^- + p\nabla\eta^- + 2\operatorname{div}(D_s\hat{\mathbf{v}}) + 2D_s\mathbf{v}\nabla\eta^- - \operatorname{div}(\mathbf{v} \otimes \nabla\eta^- + \nabla\eta^- \otimes \mathbf{v}) \in L^2(U^-)$$

and $\hat{\mathbf{v}}^- \in H^{\frac{3}{2}}(\partial U_0^-)$ by the properties of the trace operator. Writing

$$\tilde{\mathbf{g}} := \begin{cases} \mathbf{g} & \text{on } \Gamma_{S,1}, \\ \alpha_j \dot{\mathbf{v}}^- + \mathbf{g} & \text{on } \Gamma_{S,j}, j = 2, 3, \end{cases}$$

using localization techniques and results for strong solutions of the stationary Stokes equation in one phase with inhomogeneous do-nothing boundary condition (cf. Theorem 3.1 in [14]), with Dirichlet boundary condition (cf. [9]) and slip-boundary conditions (cf. Solonnikov and Ščadilov [15, Theorem 2]), we find that $(\dot{\mathbf{v}}^-, \dot{p}^-) \in H^2(U^-) \times H^1(U^-)$. Moreover, regarding (31), (30) and the definition of $\tilde{\mathbf{f}}$, we get

$$\|(\dot{\mathbf{v}}^-, \dot{p}^-)\|_{H^2(U^-) \times H^1(U^-)} \leq C \left(\|\mathbf{f}\|_{L^2(\Omega)} + \|\mathbf{a}\|_{H^{\frac{1}{2}}(\Gamma_t)} + \|\mathbf{g}\|_{H^{\frac{1}{2}}(\partial\Omega)} \right).$$

Analogously, we define $\tilde{\mathbf{v}}^+ := \mathbf{v}\eta^+$ and $\hat{\mathbf{v}}^+ \in H_0^2(\dot{U})$ as a solution to $\operatorname{div} \hat{\mathbf{v}}^+ = \operatorname{div} \tilde{\mathbf{v}}^+$. Here, we do not need to correct the mean value, since

$$\int_{\dot{U}} \operatorname{div} \tilde{\mathbf{v}}^+ dx = \int_{\partial \dot{U}} \mathbf{v} \cdot \mathbf{n}_{\partial \dot{U}} \eta^+ d\mathcal{H}^{d-1}(s) = - \int_{\{\eta^+=1\}} \operatorname{div} \mathbf{v} dx = 0.$$

We set $\dot{\mathbf{v}}^+ := \tilde{\mathbf{v}}^+ - \hat{\mathbf{v}}^+$ and $\dot{p}^+ := p\eta^+$ and get after similar calculations as before that $(\dot{\mathbf{v}}^+, \dot{p}^+)$ is a weak solution to the two phase stationary Stokes system

$$-\Delta \dot{\mathbf{v}}^+ + \nabla \dot{p}^+ = \hat{\mathbf{f}} \quad \text{in } U^+, \quad (33)$$

$$\operatorname{div} \dot{\mathbf{v}}^+ = 0 \quad \text{in } U^+, \quad (34)$$

$$\dot{\mathbf{v}}^+ = 0 \quad \text{on } \partial U^+, \quad (35)$$

$$[\dot{\mathbf{v}}^+] = 0 \quad \text{on } \Gamma_t, \quad (36)$$

$$[2D_s \dot{\mathbf{v}}^+ - \dot{p}^+ \mathbf{I}] \mathbf{n}_{\Gamma_t} = \mathbf{a} \quad \text{on } \Gamma_t, \quad (37)$$

where $\hat{\mathbf{f}} \in L^2(U^+)$. Then [13, Theorem 1.1] implies $\dot{\mathbf{v}}^+|_{\Omega^+(t)} \in H^2(\Omega^+(t))$ and $\dot{\mathbf{v}}^+|_{U^+ \setminus \Omega^+(t)} \in H^2(U^+ \setminus \Omega^+(t))$, and also that the pressure satisfies $\dot{p}^+|_{\Omega^+(t)} \in H^1(\Omega^+(t))$ and $\dot{p}^+|_{U^+ \setminus \Omega^+(t)} \in H^1(U^+ \setminus \Omega^+(t))$ with estimates in the associated norms. In particular, $\mathbf{v} = \dot{\mathbf{v}}^+$ in $\Omega^+(t)$ and $\mathbf{v} = \dot{\mathbf{v}}^+ + \dot{\mathbf{v}}^- + \hat{\mathbf{v}}^+ + \hat{\mathbf{v}}^-$ in $\Omega^-(t)$, yielding the desired regularity and (28). To show that $C > 0$ may be chosen independently of $t \in [0, T_0]$, one may make use of extension arguments, see e.g. the proof of [1, Lemma 2.10]. \square

Theorem 3.3. *Let $T \in (0, T_0]$. Let $\mathbf{b}: \Sigma \times [0, T] \rightarrow \mathbb{R}^d$, $b: \Sigma \times [0, T] \rightarrow \mathbb{R}$, $a_1: \Omega \times [0, T] \rightarrow \mathbb{R}$, $a_2, a_3, a_5: \Gamma \rightarrow \mathbb{R}$, $a_4: \partial\Omega \times [0, T] \rightarrow \mathbb{R}$, $\mathbf{a}_1: \Omega \times [0, T] \rightarrow \mathbb{R}^d$, $\mathbf{a}_2, \mathbf{a}_3, \mathbf{a}_4, \mathbf{a}_5: \Gamma \rightarrow \mathbb{R}^d$ and $\mathbf{a}_6: \partial\Omega \times [0, T] \rightarrow \mathbb{R}^d$ be smooth given functions such that*

$$\int_{\Gamma_t} \mathbf{n}_{\Gamma_t} \cdot \mathbf{a}_2 d\mathcal{H}^{d-1} + \int_{\partial\Omega} \mathbf{n}_{\partial\Omega} \cdot \mathbf{a}_6 d\mathcal{H}^{d-1} = 0 \quad \text{if } \Gamma_{S,3} = \emptyset.$$

For every $g \in L^2(0, T; H^{\frac{1}{2}}(\Sigma))$ and $h_0 \in H^2(\Sigma)$ there exists a unique solution $h \in X_T$ of

$$\begin{aligned} D_{t,\Gamma} h + \mathbf{b} \cdot \nabla_{\Gamma} h - bh + \frac{1}{2} X_0^*((\mathbf{v}^+ + \mathbf{v}^-) \cdot \mathbf{n}_{\Gamma_t}) + \frac{1}{2} X_0^*([\partial_{\mathbf{n}_{\Gamma_t}} \mu]) &= g \quad \text{in } \Sigma \times (0, T), \\ h(., 0) &= h_0 \quad \text{in } \Sigma, \end{aligned}$$

where for every $t \in [0, T]$, the functions $\mathbf{v}^{\pm} = \mathbf{v}^{\pm}(x, t)$, $p^{\pm} = p^{\pm}(x, t)$ and $\mu^{\pm} = \mu^{\pm}(x, t)$ for $(x, t) \in \Omega_T^{\pm}$ with $\mathbf{v}^{\pm} \in H^2(\Omega^{\pm}(t))$, $p^{\pm} \in H^1(\Omega^{\pm}(t))$ and $\mu^{\pm} \in H^2(\Omega^{\pm}(t))$ are the unique solutions to

$$\Delta \mu^{\pm} = a_1 \quad \text{in } \Omega^{\pm}(t), \quad (38)$$

$$\mu^{\pm} = X_0^{*, -1}(\sigma \Delta_{\Gamma} h \pm a_2 h) + a_3 \quad \text{on } \Gamma_t, \quad (39)$$

$$\mathbf{n}_{\partial\Omega} \cdot \nabla \mu^{-} = a_4 \quad \text{on } \Gamma_{\mu,1}, \quad (40)$$

$$\mu^{-} = a_4 \quad \text{on } \Gamma_{\mu,2}, \quad (41)$$

$$-\Delta \mathbf{v}^{\pm} + \nabla p^{\pm} = \mathbf{a}_1 \quad \text{in } \Omega^{\pm}(t), \quad (42)$$

$$\operatorname{div} \mathbf{v}^{\pm} = 0 \quad \text{in } \Omega^{\pm}(t), \quad (43)$$

$$[\mathbf{v}] = \mathbf{a}_2 \quad \text{on } \Gamma_t, \quad (44)$$

$$[2D_s \mathbf{v} - p\mathbf{I}] \mathbf{n}_{\Gamma_t} = X_0^{*, -1}(\mathbf{a}_3 h + \mathbf{a}_4 \Delta_{\Gamma} h + \mathbf{a}_5 \nabla_{\Gamma} h + \mathbf{a}_5) \quad \text{on } \Gamma_t, \quad (45)$$

$$B_j(\mathbf{v}^-, p^-) = \mathbf{a}_6 \quad \text{on } \Gamma_{S,j}, j = 1, 2, 3. \quad (46)$$

Moreover, if g , h_0 and b , \mathbf{b} , a_i , and \mathbf{a}_j are smooth on their respective domains for $i \in \{1, \dots, 5\}$, $j \in \{1, \dots, 6\}$, then h is smooth and p^{\pm} , \mathbf{v}^{\pm} and μ^{\pm} are smooth on $\Omega^{\pm}(t)$.

Proof. We show this by a perturbation argument. First of all note that we may without loss of generality assume that $a_1, a_3, a_4, \mathbf{a}_1, \mathbf{a}_2, \mathbf{a}_5, \mathbf{a}_6 = 0$ on their respective domains. The above system may be reduced to this case by solving

$$\begin{aligned} \Delta \hat{\mu}^{\pm} &= a_1 && \text{in } \Omega^{\pm}(t), \\ \hat{\mu}^{\pm} &= a_3 && \text{on } \Gamma_t, \\ \mathbf{n} \cdot \nabla \hat{\mu}^{-} &= a_4 && \text{on } \Gamma_{\mu,1}, \\ \hat{\mu}^{-} &= a_4 && \text{on } \Gamma_{\mu,2} \end{aligned}$$

with the help of standard elliptic theory and

$$\begin{aligned}
-\Delta \hat{\mathbf{v}}^\pm + \nabla \hat{p}^\pm &= \mathbf{a}_1 && \text{in } \Omega^\pm(t), \\
\operatorname{div} \hat{\mathbf{v}}^\pm &= 0 && \text{in } \Omega^\pm(t), \\
[\hat{\mathbf{v}}] &= \mathbf{a}_2 && \text{on } \Gamma_t, \\
[2D_s \hat{\mathbf{v}} - p] \mathbf{n} &= \mathbf{a}_5 && \text{on } \Gamma_t, \\
B_j(\hat{\mathbf{v}}^-, \hat{p}^-) &= \mathbf{a}_6 && \text{on } \Gamma_{S,j}, j = 1, 2, 3,
\end{aligned}$$

with the help of Theorem 3.2 and setting

$$\hat{g} = g - \frac{1}{2} X_0^* ([\partial_{\mathbf{n}_{\Gamma_t}} \hat{\mu}] + (\hat{\mathbf{v}}^+ + \hat{\mathbf{v}}^-) \cdot \mathbf{n}_{\Gamma_t}).$$

Now let $t \in [0, T]$, $h \in H^{\frac{7}{2}}(\Sigma)$ and let $\mathbf{v}_h^\pm \in H^2(\Omega^\pm(t))^d$, $p_h^\pm \in H^1(\Omega^\pm(t))$ be the solution to (42)–(46). Multiplying (42) by \mathbf{v}_h^\pm and integrating in $\Omega^\pm(t)$ together with integration by parts and the consideration of the boundary values (45) and (46) allows us to deduce

$$\begin{aligned}
&\int_{\Omega^+(t)} 2|D_s \mathbf{v}_h^+|^2 dx + \int_{\Omega^-(t)} 2|D_s \mathbf{v}_h^-|^2 dx + \sum_{j=2,3} \int_{\Gamma_{S,j}} \alpha_j |\mathbf{v}_h^-|^2 d\mathcal{H}^{d-1}(s) \\
&= \int_{\Gamma_t} X_0^{*,-1} (\mathbf{a}_3 h + \mathbf{a}_4 \Delta_\Gamma h + a_5 \nabla_\Gamma h) \cdot \mathbf{v}_h^- d\mathcal{H}^{d-1}(s).
\end{aligned} \tag{47}$$

Hence, by [5, Corollary 5.8] and the continuity of the trace we find

$$\|\mathbf{v}_h^-\|_{H^1(\Omega^-(t))} \leq C \|h\|_{H^2(\Sigma)} \tag{48}$$

for C independent of h and t . [5, Corollary 5.8], also implies

$$\int_{\Omega^+(t)} 2|D_s \mathbf{v}_h^+|^2 dx + \int_{\Gamma_t} |\mathbf{v}_h^+|^2 d\mathcal{H}^{d-1}(s) \geq C \|\mathbf{v}_h^+\|_{H^1(\Omega^+(t))}^2,$$

leading to

$$\|\mathbf{v}_h^+\|_{H^1(\Omega^-(t))} \leq C \|h\|_{H^2(\Sigma)} \tag{49}$$

due to $\mathbf{v}_h^+ = \mathbf{v}_h^-$ on Γ_t , (48) and (47). Defining

$$\mathcal{B}(t) : H^{\frac{7}{2}}(\Sigma) \rightarrow H^{\frac{1}{2}}(\Sigma) : h \mapsto \mathcal{B}(t)h = \frac{1}{2} X_0^* ((\mathbf{v}_h^+ + \mathbf{v}_h^-) \cdot \mathbf{n}_{\Gamma_t}),$$

we may use (48) and (49) to confirm

$$\|\mathcal{B}(t)h\|_{H^{\frac{1}{2}}(\Sigma)} \leq C \|h\|_{H^2(\Sigma)}$$

for $C > 0$ independent of h and t . As $H^{\frac{7}{2}}(\Sigma)$ is dense in $H^2(\Sigma)$ we can extend $\mathcal{B}(t)$ to an operator $\mathcal{B}(t) : H^2(\Sigma) \rightarrow H^{\frac{1}{2}}(\Sigma)$ and $H^2(\Sigma)$ is close to $H^{\frac{1}{2}}(\Sigma)$ compared with $H^{\frac{7}{2}}(\Sigma)$.

The existence of a unique solution $h \in X_T$ with the properties stated in the theorem is now a consequence of Theorem 2.5. Higher regularity may be shown by localization and e.g. the usage of difference quotients. \square

A Existence of a Pressure

Lemma A.1. *Let $F \in \{\boldsymbol{\psi} \in H^1(\Omega)^d : \boldsymbol{\psi}|_{\Gamma_{S,1}} = 0, \mathbf{n}_{\partial\Omega} \cdot \boldsymbol{\psi}|_{\Gamma_{S,2}} = 0\} \rightarrow \mathbb{R}$ be linear and bounded such that*

$$F(\boldsymbol{\psi}) = 0 \quad \text{for all } \boldsymbol{\psi} \in V(\Omega) = \{\boldsymbol{\psi} \in H^1(\Omega)^d : \operatorname{div} \boldsymbol{\psi} = 0, \boldsymbol{\psi}|_{\Gamma_{S,1}} = 0, \mathbf{n}_{\partial\Omega} \cdot \boldsymbol{\psi}|_{\Gamma_{S,2}} = 0\}.$$

Then there is a unique $p \in L^2(\Omega)$ with $\int_{\Omega} p \, dx = 0$ if $\Gamma_{S,3} = \emptyset$ such that

$$F(\boldsymbol{\psi}) = - \int_{\Omega} p \operatorname{div} \boldsymbol{\psi} \, dx \quad \text{for all } \boldsymbol{\psi} \in H^1(\Omega)^d \text{ with } \boldsymbol{\psi}|_{\Gamma_{S,1}} = 0, \mathbf{n}_{\partial\Omega} \cdot \boldsymbol{\psi}|_{\Gamma_{S,2}} = 0.$$

Proof. We will apply the closed range theorem. To this end let

$$\begin{aligned} X &= \{\boldsymbol{\psi} \in H^1(\Omega)^d : \boldsymbol{\psi}|_{\Gamma_{S,1}} = 0, \mathbf{n}_{\partial\Omega} \cdot \boldsymbol{\psi}|_{\Gamma_{S,2}} = 0\}, \\ Y &= \left\{ g \in L^2(\Omega) : \int_{\Omega} g(x) \, dx = 0 \text{ if } \Gamma_{S,3} = \emptyset \right\} \end{aligned}$$

and consider

$$T : X \rightarrow Y : \boldsymbol{\psi} \mapsto -\operatorname{div} \boldsymbol{\psi}.$$

Then T is onto, which can be seen as follows: Let $g \in Y$.

If $\Gamma_{S,3} \neq \emptyset$, then there is a unique solution $q \in H^1(\Omega)$ of

$$\begin{aligned} \Delta q &= g && \text{in } \Omega, \\ q|_{\Gamma_{S,3}} &= 0 && \text{on } \Gamma_{S,3}, \\ \mathbf{n}_{\partial\Omega} \cdot \nabla q|_{\Gamma_{S,1} \cup \Gamma_{S,2}} &= 0 && \text{on } \Gamma_{S,1} \cup \Gamma_{S,2}. \end{aligned}$$

Moreover, using the solvability of the stationary Stokes equation with non-homogenous Dirichlet boundary conditions, we find some $\mathbf{w} \in H^1(\Omega)^d$ with $\operatorname{div} \mathbf{w} = 0$ and

$$\mathbf{w}|_{\Gamma_{S,1}} = \nabla q|_{\Gamma_{S,1} \cup \Gamma_{S,2}}, \quad \mathbf{w}|_{\Gamma_{S,3}} = 0.$$

Then $\boldsymbol{\psi} = \mathbf{w} - \nabla q \in X$ with $-\operatorname{div} \boldsymbol{\psi} = g$.

If $\Gamma_{S,3} = \emptyset$, we have $\int_{\Omega} g(x) \, dx = 0$ and can use the well-known Bogovskii operator to obtain some $\boldsymbol{\psi} \in H_0^1(\Omega)$ with $-\operatorname{div} \boldsymbol{\psi} = g$.

Now the closed range theorem implies that $T' : Y' \rightarrow X'$ is injective and

$$\mathcal{R}(T') = \mathcal{N}(T)^\circ = \{F \in X' : F(\boldsymbol{\psi}) = 0 \text{ for all } \boldsymbol{\psi} \in V(\Omega)\}.$$

This proves the statement of the lemma. □
