CURIOUS CONVERGENT SERIES OF INTEGERS WITH MISSING DIGITS

MELVYN B. NATHANSON

Abstract. A classical theorem of Kempner states that the sum of the reciprocals of positive integers with missing decimal digits converges. This result is extended to much larger families of “missing digits” sets of positive integers with both convergent and divergent harmonic series.

1. Kempner’s theorem

“It is well known that the series
\[ \sum_{n=1}^{\infty} \frac{1}{n} = 1 + \frac{1}{2} + \frac{1}{3} + \cdots \]
diverges. The object of this Note is to prove that if the denominators do not include all natural numbers 1, 2, 3, …, but only those which do not contain any figure 9, the series converges. The method of proof holds unchanged if, instead of 9, any other figure 1, 2, …, 8 is excluded, but not for the figure 0.”

A harmonic series is a series of the form \( \sum_{a \in A} 1/a \), where \( A \) is a set of positive integers. Mathematicians have long been interested in the convergence or divergence of harmonic series. Let \( c \in \{1, 2, \ldots, 9\} \), and let \( A_{10}(c) \) be the set of positive integers in which the digit \( c \) does not occur in the usual decimal representation. Kempner [6] proved in 1914 that \( \sum_{a \in A_{10}(c)} 1/a \) converges. He called this “a curious convergent series.” More generally, for every integer \( g \geq 2 \), every positive integer \( n \) has a unique \( g \)-adic representation of the form \( n = \sum_{i=0}^{k} c_i g^i \), with digits \( c_i \in \{0, 1, 2, \ldots, g-1\} \) for \( i = 0, 1, \ldots, k \) and \( c_k \neq 0 \). If \( A_g(c) \) is the set of integers whose \( g \)-adic representation contains no digit \( c \), then the infinite series \( \sum_{a \in A_g(c)} 1/a \) converges.

Kempner’s theorem has been studied and extended by Baillie [1], Farhi [2], Gordon [3], Irwin [4], Lubeck-Ponomarenko [5], Schmelzer and Baillie [6], and Wadhwa [11, 12]. It is Theorem 144 in Hardy and Wright [4].

The \( g \)-adic representation is a special case of a more general method to represent the positive integers. A \( G \)-adic sequence is a strictly increasing sequence of positive integers \( G = (g_i)_{i=0}^{\infty} \) such that \( g_0 = 1 \) and \( g_i \) divides \( g_{i+1} \) for all \( i \geq 0 \). The integer
\[ d_i = \frac{g_{i+1}}{g_i} \]
satisfies \( d_i \geq 2 \) and
\[
g_{k+1} = g_k d_k = d_0 d_1 d_2 \cdots d_k
\]
for all \( k \geq 0 \). Every positive integer \( n \) has a unique representation in the form
\[
n = \sum_{i=0}^{k} c_i g_i
\]
where \( c_i \in \{0, 1, \ldots, d_i - 1\} \) for all \( i = 0, 1, \ldots, k \) and \( c_k \neq 0 \). We call (2) the \( \mathcal{G} \)-adic representation of \( n \). This is equivalent to deBruijn’s additive system (Nathanson [8, 9]).

Harmonic series constructed from sets of positive integers with missing \( \mathcal{G} \)-adic digits do not necessarily converge. In Theorem 1 we construct sets of integers with missing \( \mathcal{G} \)-adic digits whose harmonic series converge, and also sets of integers with missing \( \mathcal{G} \)-adic digits whose harmonic series diverge.

2. \( \mathcal{G} \)-adic representations with bounded quotients

Lemma 1. Let \( \mathcal{G} = (g_i)_{i=0}^{\infty} \) be a \( \mathcal{G} \)-adic sequence with quotients \( d_i = g_{i+1}/g_i \). Let \( I \) be a set of nonnegative integers, and, for all \( i \in I \), let \( U_i \) be a nonempty proper subset of \([0, d_i - 1]\). For all \( k \geq 0 \), let \( A_k \) be the set of integers \( n \in [g_k, g_{k+1} - 1] \) whose \( \mathcal{G} \)-adic representation \( n = \sum_{i=0}^{k} c_i g_i \) satisfies the following missing digits condition:
\[
c_i \in [0, d_i - 1] \setminus U_i \quad \text{for all } i \in I \cap [0, k].
\]
The set \( A_k \) satisfies:

(a) \( A_k = \emptyset \) if and only if \( k \in I \) and \( U_k = [1, d_k - 1] \).
(b) If \( k \notin I \) or if \( k \in I \) and \( U_k \neq [1, d_k - 1] \), then
\[
|A_k| \leq \prod_{i=0}^{k} (d_i - |U_i|) \prod_{i=0}^{k} d_i \leq 2|A_k|.
\]

Proof. If \( n \in [g_k, g_{k+1} - 1] \), then \( n \) has the \( \mathcal{G} \)-adic representation
\[
n = \sum_{i=0}^{k-1} c_i g_i + c_k g_k
\]
with \( c_k \neq 0 \), and so \( c_k \in [1, d_k - 1] \). It follows that \( A_k = \emptyset \) if and only if \( k \in I \) and \([0, d_k - 1] \setminus U_k = \{0\}\) if and only if \( k \in I \) and \( U_k = [1, d_k - 1] \).

For \( A_k \neq \emptyset \), there are three cases.

(i) If \( k \in I \) and \( 0 \in U_k \), then
\[
|A_k| = \prod_{i=0}^{k} (d_i - |U_i|) \prod_{i=0}^{k} d_i.
\]

(ii) If \( k \in I \) and \( 0 \notin U_k \subseteq [1, d_k - 1] \), then \( |U_k| \leq d_k - 2 \) and so
\[
d_k - |U_k| \leq 2(d_k - |U_k| - 1).
\]
We obtain

\[ |A_k| = (d_k - |U_k| - 1) \prod_{i=0}^{k-1} (d_i - |U_i|) \prod_{i \in I} d_i \]

\[ < \prod_{i \in I} (d_i - |U_i|) \prod_{i \in I} d_i \]

\[ \leq 2(d_k - |U_k| - 1) \prod_{i=0}^{k-1} (d_i - |U_i|) \prod_{i \notin I} d_i \]

\[ = 2|A_k|. \]

(iii) If \( k \notin I \), then (because \( d_k \geq 2 \) implies \( d_k \leq 2(d_k - 1) \))

\[ |A_k| = (d_k - 1) \prod_{i=0}^{k-1} (d_i - |U_i|) \prod_{i \notin I} d_i < \prod_{i=0}^{k-1} (d_i - |U_i|) \prod_{i \notin I} d_i \]

\[ \leq 2(d_k - 1) \prod_{i=0}^{k-1} (d_i - |U_i|) \prod_{i \notin I} d_i \]

\[ = 2|A_k|. \]

This completes the proof. \( \square \)

Let \( A \) be a set of positive integers, and let \( A(n) \) be the number of elements \( a \in A \) with \( a \leq n \). The upper asymptotic density of the set \( A \) is \( d(U)(A) = \limsup_{n \to \infty} A(n)/n \). If \( \lim_{n \to \infty} A(n)/n \) exists, then \( d(A) = \lim_{n \to \infty} A(n)/n \) is called the density of the set \( A \). We have \( d(U)(A) = 0 \) if and only if \( d(A) = 0 \).

**Lemma 2.** Let \( A \) be a set of positive integers. If \( \sum_{a \in A} 1/a < \infty \), then \( d(A) = 0 \).

**Proof.** We show that \( d(U)(A) > 0 \) implies \( \sum_{a \in A} 1/a = \infty \).

If \( d(U)(A) = \limsup_{n \to \infty} A(n)/n = \alpha > 0 \), then, for every \( \varepsilon > 0 \), we have

\[ \frac{A(n)}{n} < \alpha + \varepsilon \quad \text{for all integers } n \geq N(\varepsilon) \]

and

\[ \frac{A(n_i)}{n_i} > \alpha - \varepsilon \quad \text{for infinitely many integers } n_i. \]

Let \( \varepsilon < \alpha/3 \). There is a sequence of positive integers \( (n_i)_{i=0}^{\infty} \) satisfying inequality (4) such that \( n_0 \geq N(\varepsilon) \) and \( n_i > 2n_{i-1} \) for all \( i \geq 1 \). We have

\[ A(n_i) - A(n_{i-1}) > (\alpha - \varepsilon)n_i - (\alpha + \varepsilon)n_{i-1} \]

\[ > (\alpha - \varepsilon)n_i - \frac{(\alpha + \varepsilon)n_i}{2} \]

\[ = n_i \left( \frac{\alpha - 3\varepsilon}{2} \right) \]
and so
\[ \sum_{a \in A_{n_1 < a \leq n_i}} \frac{1}{a} \geq \frac{A(n_i) - A(n_{i-1})}{n_i} > \frac{\alpha - 3\varepsilon}{2} > 0. \]

It follows that
\[ \sum_{1 \leq a \leq n_k} \frac{1}{a} \geq \sum_{i=1}^{k} \sum_{n_{i-1} < a \leq n_i} \frac{1}{a} > k \left( \frac{\alpha - 3\varepsilon}{2} \right) \]
and so the infinite series \( \sum_{a \in A} 1/a \) implies \( d(A) = 0 \). This completes the proof.

The converse of Lemma 2 is false. The set of prime numbers has density zero, but the sum of the reciprocals of the primes diverges.

**Theorem 1.** Let \( G = (g_i)_{i=0}^{\infty} \) be a \( G \)-adic sequence with bounded quotients, that is,
\[ d_i = g_{i+1} - g_i \leq d \quad \text{for all } i = 0, 1, 2, \ldots \]

Let \( n = \sum_{i=0}^{k} c_i g_i \) be the \( G \)-adic representation of the positive integer \( n \).

Let \( I \) be a set of nonnegative integers, and, for all \( i \in I \), let \( U_i \) be a nonempty proper subset of \([0, d_i - 1]\). Let \( A \) be the set of positive integers \( n \) such that \( c_i \in [0, d_i - 1] \setminus U_i \) for all \( i \in I \).

If
\[ I(k) \geq \frac{(1 + \delta) \log k}{\log(d/(d-1))} \]
for some \( \delta > 0 \) and all \( k \geq k_0 = k_0(\delta) \), then the set \( A \) has density zero and the harmonic series \( \sum_{a \in A} 1/a \) converges.

If
\[ I(k) \leq \frac{(1 - \delta) \log k}{\log d} \]
for some \( \delta > 0 \) and all \( k \geq k_1 = k_1(\delta) \), then the harmonic series \( \sum_{a \in A} 1/a \) diverges.

Kempner’s theorem is the special case \( g_i = 10^i \), \( d_i = 10 \), and \( U_i = \{9\} \) for all \( i \in I = N_0 \).

**Proof.** For all \( k \in N_0 \), the sets
\[ A_k = A \cap [g_k, g_{k+1} - 1] \]
are pairwise disjoint, and \( A = \bigcup_{k=0}^{\infty} A_k \).

For all \( i \in I \), we have
\[ 1 \leq |U_i| \leq d_i - 1 \]
and
\[ \frac{1}{d_i} \leq \frac{1}{d} \leq \frac{d_i - |U_i|}{d_i} = 1 - \frac{|U_i|}{d_i} \leq 1 - \frac{1}{d} < 1. \]

Let \( I(k) \) satisfy inequality (6). We obtain
\[ (1 - \frac{1}{d})^{I(k)} \leq \left( \frac{d - 1}{d} \right)^{\frac{(1+\delta) \log k}{\log(d/(d-1))}} = \frac{1}{k^{1+\delta}}. \]
If \( a \in A_k \), then \( a \geq g_k = d_0d_1 \cdots d_{k-1} \). By Lemma 1,
\[
\sum_{a \in A_k} \frac{1}{a} \geq \sum_{k=k_0}^{\infty} \frac{1}{A_k g_k} \leq \sum_{k=k_0}^{\infty} \frac{|A_k|}{g_k}.
\]

By Lemma 2, the set \( A \) has density zero.

Let \( I(k) \geq \frac{(1 + \delta) \log k}{\log d} \) satisfy inequality (7). We obtain
\[
(9) \quad \left( \frac{1}{d} \right)^{I(k)} \geq \left( \frac{1}{d} \right)^{\frac{(1 - \delta) \log k}{\log d}} = \frac{1}{k^{1 - \delta}}.
\]

Thus, the harmonic series diverges. This completes the proof. \( \square \)

Corollary 1. Let \( I \) be a set of nonnegative integers, and let \((v_i)_{i \in I}\) be a sequence of 0s and 1s. Let \( A \) be the set of integers \( n \) such that, if \( n \in [2^k, 2^{k+1} - 1] \) has the 2-adic representation \( n = \sum_{i=0}^{k} c_i 2^i \), then \( c_i = v_i \) for all \( i \in I \cap [0, k] \). If \( I(k) \geq (1 + \delta) \log_2 k \)
\[
I(k) \geq (1 + \delta) \log_2 k
\]
for some $\delta > 0$ and all $k \geq k_0(\delta)$, then the harmonic series $\sum_{a \in A} 1/a$ converges. If
\[
I(k) \leq (1 - \delta) \log_2 k
\]
for some $\delta > 0$ and all $k \geq k_1(\delta)$, then the harmonic series $\sum_{a \in A} 1/a$ diverges.

Proof. For all $i \in I$, let $u_i = 1 - v_i$ and $U_i = \{u_i\}$. Apply Theorem 1. □

It is an open problem to determine the convergence or divergence of $\sum_{a \in A} 1/a$ if $I(k) \sim \log_2 k$.

3. $G$-adic representations with unbounded quotients

Theorem 1 shows that harmonic series constructed from sequences of integers with missing $G$-adic digits do not always converge. It follows from Theorem 1 that if $\sum_{a \in A} 1/a$ diverges and if
\[
I(k) \geq (\log k)^{1+\delta}
\]
for some $\delta > 0$ and all $k \geq k_0(\delta)$, then the sequence $G$ has unbounded quotients, that is,
\[
\limsup d_i = \infty.
\]

Recall the following inequality, proved by induction: If $0 \leq x_i < 1$ for $i = 1, \ldots, n$, then
\[
\prod_{i=1}^{n} (1 - x_i) \geq 1 - \sum_{i=1}^{n} x_i.
\]

\[\text{(10)}\]

**Theorem 2.** Let $G = (g_i)_{i=0}^{\infty}$ be a $G$-adic sequence with unbounded quotients, and let $n = \sum_{i=0}^{k} c_i g_i$ be the $G$-adic representation of the positive integer $n$. Let $I$ be an infinite set of nonnegative integers, and, for all $i \in I$, let $U_i$ be a nonempty proper subset of $[0, d_i - 1]$. Let $A$ be the set of positive integers whose $G$-adic representations satisfy the missing digits condition
\[
c_i \in [0, d_i - 1] \setminus U_i \quad \text{for all } i \in I \cap [0, k].
\]

Let $A_k = A \cap [g_k, g_{k+1} - 1]$. If $A_k \neq \emptyset$ for only finitely many $k$, then the set $A$ is finite and its harmonic series converges. If $A_k \neq \emptyset$ for infinitely many $k$, and if
\[
\sum_{i \in I} \frac{|U_i|}{d_i} < \infty
\]
then the harmonic series $\sum_{a \in A} 1/a$ diverges.

For example, the “missing digits” set constructed from $G = (g_i)_{i=0}^{\infty}$ with $g_i = 2^{i+1}/2$ and $d_i = 2^i$ and with $I = \mathbb{N}_0$ and $U_i = \{0\}$ for all $i \in I$ has a divergent harmonic series.

Proof. Inequalities (10) and (11) imply the convergence of the infinite product
\[
\prod_{i \in I} \left(1 - \frac{|U_i|}{d_i}\right)
\]
and so there exists $\delta > 0$ such that
\[
\prod_{i \in I} \left(1 - \frac{|U_i|}{d_i}\right) > \delta
\]
for all $k \in \mathbb{N}_0$.

Let $A_k \neq \emptyset$ for infinitely many $k$. Using the notation of Theorem 1, we have

\[
\sum_{a \in A} \frac{1}{a} = \sum_{k=0}^{\infty} \frac{1}{a_{k+1}} \geq \sum_{k=0}^{\infty} \frac{|A_k|}{\prod_{i=0}^{k} (d_i - |U_i|) \prod_{i \in I} d_i}
\]

\[
= \frac{1}{2} \sum_{k=0}^{\infty} \sum_{A_k \neq \emptyset} \frac{1}{\prod_{i=0}^{k} d_i \prod_{i \in I} (d_i - |U_i|) \prod_{i \in I} d_i}
\]

and so the harmonic series diverges. This completes the proof. \[\Box\]
