Model-Driven Deep Learning for Massive MU-MIMO with Finite-Alphabet Precoding

Hengtao He, *Student Member, IEEE*, Mengjiao Zhang, Shi Jin, *Senior Member, IEEE*, Chao-Kai Wen, *Member, IEEE*, and Geoffrey Ye Li, *Fellow, IEEE*

Abstract—Massive multiuser multiple-input multiple-output (MU-MIMO) has been the mainstream technology in fifthgeneration wireless systems. To reduce high hardware costs and power consumption in massive MU-MIMO, low-resolution digital-to-analog converters (DAC) for each antenna and radio frequency (RF) chain in downlink transmission is used, which brings challenges for precoding design. To circumvent these obstacles, we develop a model-driven deep learning (DL) network for massive MU-MIMO with finite-alphabet precoding in this article. The architecture of the network is specially designed by unfolding an iterative algorithm. Compared with the traditional state-of-the-art techniques, the proposed DL-based precoder shows significant advantages in performance, complexity, and robustness to channel estimation error under Rayleigh fading channel.

Index Terms—Deep learning, Model-driven, Massive MIMO, Finite-alphabet, Neural network, precoding

I. INTRODUCTION

Massive multiuser multiple-input multiple-output (MU-MIMO) wireless systems, where the base station (BS) is equipped with several hundreds of antenna elements, have significant improvements in spectral efficiency, energy efficiency and reliability [1]. Increasing the number of RF chains at the BS could, however, result in significant increases in hardware costs and power consumption. Therefore, practical massive MU-MIMO systems may require low-cost and power-efficient hardware components at the BS. Specifically, in downlink transmissions, equipping low-resolution digital-to-analog converters (DACs) can greatly reduce the cost and power consumption [2] but directly limits the degree of freedom for the output signals and brings challenges into precoder design.

To address the issues, many efficient quantized precoding schemes have been proposed [3]–[6]. By using biconvex relaxation, an one-bit precoding algorithm for massive MU-MIMO systems is developed in [3], which outperforms the zero-forcing (ZF) precoder directly followed by quantization, but still with high complexity. To reduce the complexity, a computationally-efficient one-bit beamforming algorithm referred to as C2PO, and its VLSI architectures are proposed in [4]. Aside from one-bit DACs, a universal algorithm for a downlink massive MU-MIMO system with finite-alphabet precoding in [5] includes low-resolution DACs and phase-shifter-based architecture, which presents excellent performance and can be implemented with low computational complexity.

Recently, deep learning (DL) has been applied to physical layer communications [7]–[9], such as channel state information (CSI) feedback [10], channel estimation [11] and precoder design [12], [13]. However, most existing DL-based precoders focus on data-driven approaches, which consider the precoder as a black box and train it by using a huge volume of data. By contrary, model-driven DL approaches [7] significantly reduce required volume of data for training and converge fast.

A neural-network optimized precoder in [14], named NNO-C2PO, recently has been proposed for one-bit precoding. The NNO-C2PO is obtained by unfolding the biConvex one-bit PrecOding (C2PO) algorithm and optimizing several manual parameters. Unfolding iterative algorithm into neural network has first been proposed for sparse signal recovery [15] and become a promising model-driven DL technique for wireless communications [7], [16]. Inspired by these works, we unfold the iterative discrete estimation (IDE2) [5] precoder into a neural network and add some adjustable parameters to learn the step size and damping factor to develop a model-driven DL approach for massive MU-MIMO with finite-alphabet precoding.

Notations—For any matrix A, A^T , A^H , and tr(A) denote the transpose, conjugated transpose, and trace of A, respectively. In addition, I is the identity matrix, 0 is the zero matrix. A proper complex Gaussian with mean μ and covariance Θ can be described by the probability density function,

$$\mathcal{N}_{\mathbb{C}}(\mathbf{z}; \boldsymbol{\mu}, \boldsymbol{\Theta}) = \frac{1}{\det(\pi \boldsymbol{\Theta})} e^{-(\mathbf{z} - \boldsymbol{\mu})^H \boldsymbol{\Theta}^{-1}(\mathbf{z} - \boldsymbol{\mu})}.$$

II. SYSTEM MODEL AND PROBLEM FORMULATION

In this section, we will first present the massive MU-MIMO downlink system model. Then, the finite-alphabet precoding is formulated as an integer programming problem.

Fig. 1. The diagram of massive MU-MIMO downlink system with low-resolution DACs. The BS uses a finite-alphabet precoder and N antennas to serve K users.

A. System Model

Consider downlink transmission of a narrow-band massive MU-MIMO system illustrated as Fig. 1, where a BS equipped with N antennas serves K single-antenna users. In the figure, $\mathbf{s} \in \mathbb{C}^K$ is the required transmitted constellation points for K users. We assume $\mathbb{E}\{\mathbf{s}\mathbf{s}^H\} = \mathbf{I}$ for the transmitted symbol vector. The received signal of all users $\mathbf{y} = [y_1, y_2, \dots, y_K] \in \mathbb{C}^K$ can be obtained by

$$\mathbf{y} = \mathbf{H}\mathbf{x} + \mathbf{n},\tag{1}$$

where $\mathbf{x} = [x_1, x_2, \dots, x_N] \in \mathbb{C}^N$ is the precoded signal transmitted from the BS and carries transmitted information for different users. $\mathbf{n} \sim \mathcal{N}_{\mathbb{C}}(0, \sigma^2 \mathbf{I}_{N_{\mathrm{r}}})$ is the additive white Gaussian noise (AWGN) vector and $\mathbf{H} \in \mathbb{C}^{N \times K}$ is the downlink MIMO channel matrix. We assume the entries of channel \mathbf{H} are independent circularly-symmetric complex Gaussian random variables with unit variance, i.e., $h_{i,j} \sim \mathcal{N}_{\mathbb{C}}(0,1)$. In downlink transmission, the precoded vector \mathbf{x} should satisfy the average power constraint

$$\frac{1}{N}\mathbb{E}\{\|\mathbf{x}\|_2^2\} \le P_t,\tag{2}$$

where P_t is the transmit power of each antenna.

Each user is assumed to be able to rescale the received signal by a precoding factor β to obtain the estimated constellation points \hat{s}_k for $k=1,\ldots,K$, i.e., $\hat{s}_k=\beta y_k$, that is, $\hat{\mathbf{s}}=[\hat{s}_1,\hat{s}_2,\ldots,\hat{s}_k]^T=\beta\mathbf{y}=\beta\mathbf{H}\mathbf{x}+\beta\mathbf{n}$. The precoding factor β is determined by the precoder. We consider that the zero-forcing (ZF) precoder is used, the precoding factor β is accordingly obtained by power constraint in (2) and given by $\beta=\sqrt{\frac{\text{tr}((\mathbf{H}\mathbf{H}^H)^{-1})}{NP_t}}$ [3], [5]. As a result, the MSE of the estimation error between the rescaled received signal $\beta\mathbf{y}$ and the transmitted symbol vector \mathbf{s} can be written as

$$\mathbb{E}_{\mathbf{s}}\left\{\|\mathbf{s} - \beta \mathbf{y}\|_{2}^{2}\right\} = \mathbb{E}_{\mathbf{s}}\left\{\|\mathbf{s} - \beta \mathbf{H} \mathbf{x}\|_{2}^{2}\right\} + \beta^{2} K \sigma^{2},\tag{3}$$

where the metric for interuser interference (IUI) is defined by IUI = $\mathbb{E}_{\mathbf{s}} \{ \|\mathbf{s} - \beta \mathbf{H} \mathbf{x}\|_{2}^{2} \}$. The MSE in (3) measures the performance of the precoder and can be used as the loss function for DL network.

B. Problem Formulation

If the ZF precoder is used at the BS, the IUI can achieve zero if the BS is with infinite-resolution DACs and high-linearity power amplifiers [5]. In practical setting, each antenna is equipped with a low-cost constrained RF chain, including low-resolution DACs, low-resolution analog phase shift to reduce the cost and power consumption.

Algorithm 1: IDE2 algorithm

Inputs: s, $\tilde{\mathbf{H}} = \beta \mathbf{H}$

Initial: t = 0, $\mathbf{x}_{d}^{1} = \mathbf{0}$, $\alpha = 0.95$

while t < T do

$$\mathbf{W}_{\mathbf{u}} = [\operatorname{diag}(\tilde{\mathbf{H}}^{H}\tilde{\mathbf{H}})]^{-1}\tilde{\mathbf{H}}^{H}$$
 (5)

$$\mathbf{r}^{t} = \mathbf{x}_{d}^{t} + \gamma^{t} \mathbf{W}_{u} (\mathbf{s} - \tilde{\mathbf{H}} \mathbf{x}_{d}^{t})$$
 (6)

$$\mathbf{x}^{t+1} = \Pi_{\mathcal{X}}(\mathbf{r}^t) \tag{7}$$

$$\mathbf{x}_{d}^{t+1} = \alpha \mathbf{x}_{d}^{t} + (1 - \alpha)\mathbf{x}^{t+1} \tag{8}$$

 $t \leftarrow t + 1$

Output $\mathbf{x} = \mathbf{x}^{t+1}$

In this article, we assume each entry of the vector \mathbf{x} is restricted to a finite-alphabet set $\chi = \{\chi_0, \dots, \chi_{M-1}\}$, where $M = |\chi|$. Such finite-alphabet set, including QAM and PSK symbols, can relax the perfect hardware requirement [2]–[5]. However, it brings several challenges in precoder design, especially obtaining zero IUI becomes difficult in general. The goal of finite-alphabet precoding is to design a precoder $\mathcal{P}(\mathbf{s}, \mathbf{H})$ that minimizes the MSE between the rescaled received signal $\beta \mathbf{y}$ and the transmitted symbol vector \mathbf{s} under the power constraint (2), which is given by

$$\min_{\mathbf{x},\beta} \quad \mathbb{E}_{\mathbf{s}} \{ \|\mathbf{s} - \beta \mathbf{H} \mathbf{x}\|_{2}^{2} \}$$
s.t. $\mathbf{x} \in \chi^{N}, \beta > 0$ (4)

The problem of (4) is related to an integer programming problem, which is always NP-hard. Several iterative approaches have been proposed for finite-alphabet precoding, including SQUID [3], C2PO [4], IDE2 [5], and NNO-C2PO [14]. In the next section, we will introduce the IDE2 precoder as a representative algorithm and improve it by DL.

III. IDE2-NET

After introducing the IDE2 precoding in [5], we propose IDE2-Net by unfolding the IDE2 precoder for finite-alphabet precoding. Then, we present the network architecture and elaborate the learnable variables and computational complexity of the IDE2-Net.

A. IDE2 Precoder

The IDE2 preocder has been proposed to achieve finitealphabet precoding for massive MIMO systems. The iterative

Fig. 2. The diagram of IDE2-Net precoder. The network consists of T cascade layers and each layer has the same structure and contains the linear estimator \mathbf{W}_{u} , nonlinear estimator Π_{χ} , trainable variables γ^t and α^t .

procedure is illustrated in Algorithm 1. The IDE2 precoder is with low-complexity and is mainly composed of two parts, linear estimator (6) and nonlinear estimator (7). Specifically, given the prior information of \mathbf{x}_d^t on

$$\mathbb{E}\{\mathbf{x}\} = \mathbf{x}_{d}^{t} \quad \text{and} \quad \mathbb{E}\{(\mathbf{x} - \mathbf{x}_{d}^{t})(\mathbf{x} - \mathbf{x}_{d}^{t})^{H}\} = \frac{1}{\mu}\mathbf{I}, \tag{9}$$

the linear estimator in (6) is an accurate approximation in massive MIMO systems for the optimal linear minimum meansquared error (LMMSE) estimator

$$\mathbf{r}^{t} = \mathbf{x}_{d}^{t} + \mathbf{W} \left(\mathbf{s} - \tilde{\mathbf{H}} \mathbf{x}_{d}^{t} \right), \tag{10}$$

where

$$\mathbf{W} = \left(\tilde{\mathbf{H}}^H \tilde{\mathbf{H}} + \mu \mathbf{I}\right)^{-1} \tilde{\mathbf{H}}^H, \tag{11}$$

and $\tilde{\mathbf{H}} = \beta \mathbf{H}$. From the perspective of estimation theory, the LMMSE estimator in (10) is biased in each iteration. It can be revised as an unbiased version by replacing \mathbf{W} with $\mathbf{W}_{\mathrm{u}} = \mathbf{D}\mathbf{W}$, where \mathbf{D} is a diagonal matrix and the diagonal elements of $\mathbf{W}_{\mathrm{u}}\tilde{\mathbf{H}} = \mathbf{D}(\tilde{\mathbf{H}}^H\tilde{\mathbf{H}} + \mu \mathbf{I})^{-1}\tilde{\mathbf{H}}^H\tilde{\mathbf{H}}$ are 1. Therefore, \mathbf{D} is given by

$$\mathbf{D} = [\operatorname{diag}(\mathbf{W}\tilde{\mathbf{H}})]^{-1}. \tag{12}$$

In massive MIMO systems, the complexity for computing the LMMSE matrix (11) is very high. Fortunately, it can be addressed by using an approximation for the matrix inversion, which is given by

$$\left(\tilde{\mathbf{H}}^H \tilde{\mathbf{H}} + \mu \mathbf{I}\right)^{-1} \approx \frac{1}{\mu} \mathbf{I}.$$
 (13)

Consequently, we obtain

$$\mathbf{W}_{\mathbf{u}} \approx [\operatorname{diag}(\tilde{\mathbf{H}}^{H}\tilde{\mathbf{H}})]^{-1}\tilde{\mathbf{H}}^{H}.$$
 (14)

Thus, the linear estimator can be derived as (6). As the BS is equipped with low-resolution DACs, the output of the linear estimator \mathbf{r}^t should be projected onto finite-precoding set χ . The nonlinear estimator can be denoted by

$$\mathbf{x}^{t+1} = \Pi_{\mathcal{V}}(\mathbf{r}^t). \tag{15}$$

In each iteration, Π_{χ} generates \mathbf{x}^{t+1} exactly from the discrete point set χ , which is clearly different from \mathbf{r}^{t} . Therefore,

a damping factor α should be introduced to help the algorithm to be convergent as follows,

$$\mathbf{x}_{d}^{t+1} = \alpha \mathbf{x}_{d}^{t} + (1 - \alpha) \mathbf{x}^{t+1}. \tag{16}$$

The three equations in (6)-(8) are executed iteratively until convergence.

B. Network Architecture

We propose a model-driven-DL-based precoder, named IDE2-Net, for massive MU-MIMO with finite-alphabet precoding. As Fig. 2 illustrated, the structure of the IDE2-Net is obtained by unfolding the IDE2 precoder and adding several trainable parameters. The input of the IDE2-Net is the signal vector \mathbf{s} , and the channel matrix, $\tilde{\mathbf{H}}$, and the final output is $\mathbf{x}^{\text{out}} = \Pi_{\chi} \left(\mathbf{x}_{\text{d}}^{T+1} \right)$. The IDE2-Net consists of T cascade layers, where each has the same architecture but is with different trainable parameters. For the t-th layer of the IDE2-Net, the calculative process is performed as follows

$$\mathbf{W}_{\mathrm{n}} = [\operatorname{diag}(\tilde{\mathbf{H}}^{H}\tilde{\mathbf{H}})]^{-1}\tilde{\mathbf{H}}^{H}, \tag{17}$$

$$\mathbf{r}^t = \mathbf{x}_d^t + \gamma^t \mathbf{W}_{\mathbf{u}} (\mathbf{s} - \tilde{\mathbf{H}} \mathbf{x}_d^t), \tag{18}$$

$$\mathbf{x}^{t+1} = \Pi_{\mathcal{V}}(\mathbf{r}^t),\tag{19}$$

$$\mathbf{x}_{d}^{t+1} = \alpha^{t} \mathbf{x}_{d}^{t} + (1 - \alpha^{t}) \mathbf{x}^{t+1}, \tag{20}$$

where $\theta^t = \{\gamma^t, \alpha^t\}$ are learnable variables in each layer. When $\gamma^t = 1$ and $\alpha^t = 0.95$ for each layer, the IDE2-Net is reduced to the IDE2 precoder.

In Section III-A, we have introduced the principle of the IDE2 precoder. In fact, IDE2 appears nearly similar to the classical projected gradient descent algorithm with the objective function as illustrated in (4). The update for each iteration can be described as the following form

$$\mathbf{x}_{d}^{t+1} = \Pi_{\chi} (\mathbf{x}_{d}^{t} + \lambda \tilde{\mathbf{H}} (\mathbf{s} - \tilde{\mathbf{H}} \mathbf{x}_{d}^{t})), \tag{21}$$

where the step size λ is always set to be sufficiently small to ensure convergence. Different from the classical projected gradient algorithm with a constant step size λ , the IDE2 precoder uses a vector form step size, $[\operatorname{diag}(\tilde{\mathbf{H}}^H\tilde{\mathbf{H}})]^{-1}$, that makes the linear estimator in (6) unbiased. By contrary, the step size in (21) is λ , which makes each update in a biased manner. The step size in the IDE2 precoder is obtained by

TABLE I Complexity analysis of different precoders

Algorithm	Multiplications	Learnable Variables
IDE2	O(2NK+N)	0
IDE2-Net	O(2NK+N)	2
C2PO	$O(N^2K + NK)$	0
NNO-C2PO	$O(N^2K + NK)$	2
SQUID	O(2NK+N)	0

an approximation in a large system and is not the optimal one. Therefore, we will optimize the step size by tuning the parameter γ^t with DL. Furthermore, we have found that the damping factor α is important in IDE2 precoder in [5] and $\alpha=0.95$ is selected based on a trade-off between stability and speed of convergence. The optimized α depends on SNR and modulated symbols. Therefore, optimizing α through DL is an efficient approach.

C. Complexity Analysis

Here, we compare the computational complexity of the proposed IDE2-Net and other prior state-of-the-art methods, including SQUID [3], IDE2 [5], C2PO [4], NNO-C2PO [14] in terms of the number of multiplication operations and learnable variables in each iteration, and summarize the corresponding results in Table I. The complexity of the IDE2, IDE-Net2 and SQUID is O(2NK + N), which is much lower than that of C2PO and NNO-C2PO. Furthermore, the number of trainable variables of the IDE2-Net is only determined by the number of layers T and is independent of the number of antennas N and users K. This is a very attractive feature for massive MIMO systems. The few trainable variables can improve the stability and convergence speed of the IDE2-Net in the training process.

IV. NUMERICAL RESULTS

In this section, we provide numerical results to show the performance of the proposed model-driven-DL-based precoder. First, we elaborate the implementation details and parameter settings. Then, the bit error-rate (BER) performance under i.i.d. Rayleigh MIMO channels¹ with perfect CSI is provided. The robustness of IDE2-Net to channel estimation error is also investigated.

A. Implementation Details

IDE2-Net is implemented by utilizing Tensorflow in our simulation by using a PC with GPU NVIDIA GeForce GTX 1080 Ti. The SNR is defined as

$$SNR = \frac{NP_t}{\sigma^2},$$
 (22)

including the array gain and can be regarded as the received SNR for each user. We consider the extreme case that the BS is equipped with one-bit DACs. As existing deep learning APIs are mostly devoted to process the real-valued data, we consider equivalent real-valued representation for the system model (1). The code will be available at https://github.com/hehengtao/IDE2-Net.

Fig. 3. Convergence analysis of IDE2-Net, IDE2, and NNO-C2PO precoder for a massive MU-MIMO system with N = 128 and K = 16 in a Rayleigh-fading channel with SNR = 14 dB.

The training data consists of a number of randomly generated pairs $\mathbf{d}^{(i)} \triangleq (\mathbf{s}^{(i)}, \mathbf{H}^{(i)})$. For each pair $\mathbf{d}^{(i)}$, the channel \mathbf{H} is randomly generated from the i.i.d. MIMO channel model. The data $\mathbf{s}^{(i)}$ is generated from the 16-QAM modulation symbol with M being the modulation order. We train the network with 1,000 epochs. At each epoch, the training set contains 5,000 different samples $\mathbf{d}^{(i)}$, and 1,000 different validation samples. The network is trained using the stochastic gradient descent (SGD) optimizer. The learning rate is set to be 0.1 initially, and has 10-fold decrease for every 200 epochs, afterwards keeps 0.0001 for the remaining epochs. The batch size is set to 100. We use the cost function defined as

$$Loss(\boldsymbol{\theta}) = \mathbb{E}_{\mathbf{s}} \left\{ \|\mathbf{s} - \beta \mathbf{H} \mathbf{x}^{\text{out}}\|_{2}^{2} \right\}$$
 (23)

where \mathbf{x}^{out} is the final output of the IDE2-Net. The nonlinear estimator Π_{χ} in each layer is not differentiable. We adopt the identity function in the backward pass, known as the straight-through estimator in [18] to decouple the forward-propagation and backpropagation. Then, all remaining operations in the IDE2-Net have well-defined gradients and can be differentiated automatically.

B. BER Performance

First, we analyze the convergence of the IDE2-Net, IDE2 and NNO-C2PO precoders. Fig. 3 illustrates the BER performance versus the number of iterations (layers). From the figure, the IDE2-Net has faster convergence speed than IDE2 and NNO-C2PO algorithms, which demonstrates the learnable variables can significantly accelerate convergence of the IDE2 algorithm. The reason is the IDE2-Net can learn the optimal parameters $\theta = \{\gamma^t, \alpha^t\}_{t=1}^T$ involved in the step size and damping factors from the data.

Fig. 4 compares the BER performance of the IDE2-Net, IDE2 [5], NNO-C2PO [14], SQUID, SDRr, and SDR1 precoders in [3] with different numbers of iterations *T*. The NNO-C2PO is the state-of-the-art DL-based precoder. Except for SDRr, the IDE2-Net outperforms other precoders in terms of BER performance. However, the high complexity of SDRr precoder prevents its use for massive MU-MIMO systems with hundreds of antennas. Furthermore, compared with the IDE2 precoder, the IDE2-Net has significantly performance

¹In this paper, we consider conventional Rayleigh MIMO channel, which is often used in [3]–[6]. The practical impairments considered in [17] can be investigated in our future work.

Fig. 4. BER performance of several precoders with different number of iterations for a massive MU-MIMO system with N = 128 and K = 16 in a Rayleigh-fading channel.

improvement for different numbers of iterations. However, the performance gain is decreased with the increase of the layers. This is because the IDE2-Net and IDE2 precoder will have similar performance when the number of layers is adequate.

C. Robustness to Channel Estimation Error

In aforementioned sections, we have assumed that the BS has perfect CSI. Then, we investigate the robustness of the IDE2-Net to channel estimation error in this section. We assume the noisy channel is given by

$$\hat{\mathbf{H}} = \sqrt{1 - \epsilon} \mathbf{H} + \sqrt{\epsilon} \mathbf{E},\tag{24}$$

where $\epsilon \in [0, 1]$ and **E** has $\mathcal{N}_{\mathbb{C}}(0, 1)$ entries. The value of $\epsilon = 0$, $\epsilon \in (0, 1)$, and $\epsilon = 1$ correspond to cases with perfect CSI, partial CSI, or no CSI, respectively. We consider the IDE2-Net and NNO-C2PO are with T = 20 layers and SNR = 14 dB. The IDE2-Net and NNO-C2PO are trained with perfect CSI and deployed with imperfect CSI.

Fig. 5 demonstrates the robustness of different precoders to channel estimation error. As the figure illustrated, the robustness of IDE2-Net to channel estimation error is better than IDE2 precoder, and similar to NNO-C2PO, SQUID, and SDR1, which demonstrates the learnable variables can improve the robustness.

V. CONCLUSION

We have developed a model-driven DL network for massive MU-MIMO with finite-alphabet precoding, named IDE2-Net. The IDE2-Net inherits the superiority of the iterative precoder and DL technique and presents excellent performance. The network has lower complexity than other precoding algorithms and only few adjustable parameters are required to be optimized. Simulation results demonstrate that significant performance gain can be obtained by learning corresponding optimal parameters from the data to improve the BER performance, accelerating convergence and enhancing robustness to channel estimation error with Rayleigh fading channel.
