#### Abstract

Quantum entanglement, induced by spatial noncommutativity, is investigated for an anisotropic harmonic oscillator. Exact solutions for the system are obtained after the model is re-expressed in terms of canonical variables, by performing a particular Bopp's shift to the noncommuting degrees of freedom. Employing Simon's separability criterion, we find that the states of the system are entangled provided a unique function of the (mass and frequency) parameters obeys an inequality. Entanglement of Formation for this system is also computed and its relation to the degree of anisotropy is discussed. It is worth mentioning that, even in a noncommutative space, entanglement is generated only if the harmonic oscillator is anisotropic. Interestingly, the Entanglement of Formation saturates for higher values of the deformation parameter $\theta$, that quantifies spatial noncommutativity.

[^0]
## 1 Introduction

The celebrated ideas of quantum computers, quantum cryptography, and quantum teleportation have emerged from quantum information science that deals with manipulation of individual quanta of information. Entanglement has assumed the role of a key resource in quantum communication and computation and it is exploited as protocols to perform tasks that are supposedly intractable with classical information processing. Entanglement lies at the heart of most of the counter intuitive features of quantum mechanics, such as non-local correlations between space like separated entangled partners (for a review see [1]) and related phenomena. In spite of Einstein's worry about the "spooky action at a distance", it has been experimentally confirmed [2, 3] that quantum physics predicts correlations that violate Bell's inequality. However, as it turns out, quantum entanglement has found remarkable physical applications in the fields like quantum computation, quantum optics, condensed matter physics and many more 4] 5]. Connections between quantum gravity and quantum information theory in the $A d S / C F T$ correspondence, in particular relation between geometrical structure of the dual spacetime and entanglement structure of the conformal field theory have emerged in recent times (for review see [7]). Another topical and exciting area is entanglement entropy [8] and its application in the issue of black hole entropy (for a review see [9]).

In the present article we will consider a novel form of entanglement generation - Noncommutativity induced entanglement. Earlier works in this area can be found in [10], [11], 12]. In fact the work by Bastos et. al. [12] is very significant in this context and we will return to its relevance in connection to the present work in section 6, Conclusion. Noncommutative (NC) extension of quantum mechanics and quantum field theory have generated a large amount of interest in diverse physics communities (for reviews see [13]). Historically NC extension was first introduced by Snyder [14] to ameliorate short distance singularities in quantum field theories but it was not successful in this context (although for other reasons Snyder's form of Noncommutativity has also become of interest in recent times ([15])). Another form of NC extension induces a minimal length and is exploited in phenomenological model building for quantum gravity [16, 17] and in addressing certain conceptual inconsistencies in black hole physics [18. The more recent wave of interest was created by the work of Seiberg and Witten [19] who revealed that in certain low energy limits, the theory of open strings attached to $D$-Branes, can be described as an effective field theory residing in an NC space. Interestingly, this form NC extension actually mimics the well known Landau problem of planar charged particle dynamics in a strong uniform background magnetic field in normal direction. This last form of noncommutativity will be directly relevant to our work. Some of
the earliest applications of noncommutative geometry in explicit quantum mechanical problems appeared in [20], [21], [22]. Formal aspects of noncommutative quantum mechanics appeared in [23], [24], [25]. In the context of gravitational physics, neutrons in the presence of an external gravitational field with noncommutativity were studied in [26]. Novel effects, induced by noncommutativity, were considered in quantum cosmology [27], [28] and in black hole physics [29]. Aspects of noncommutative geometry were discussed in 30 ] in the context of string theory and in [31, 32, 33, 34, 35, 36, 37] in quantum field theory.

Let us come to our main subject matter: entanglement and in particular Gaussian Entanglement (GE). Entanglement is manifested through nonlocal correlations between two (or more) quantum states such that it is impossible to describe the states individually. Operationally this trait implies the presence of global states of a composite system that are not expressible as products of states of the individual subsystems. Quantum information can appear in discrete and continuous forms. Initial studies on entanglement were concentrated on finite-dimensional quantum systems of which the simplest and most well-known example of discrete quantum information is the quantum bit or "qubit," a quantum system with two distinguishable states. However, quantum information can also be encoded in a continuous variable quantum system where it has an infinite dimensional Hilbert space spanned by observables with continuous eigenspectra. It has been realized that the latter approach, where information carriers are continuous variables (rather than discrete qubits) constitutes an extremely powerful alternative framework for quantum information processing (for reviews see [38, 39]). Continuous variable systems have led to the advances in resource states preparation, fault tolerant quantum computation as well as analysis of topological order, cryptography and machine learning in the theoretical domain.

Gaussian states bear a special significance as continuous variable states: (i) Even though being infinite-dimensional systems they are characterized by a finite number of parameters.
(ii) A simple algebraic formalism can be used to manipulate them analytically.
(iii) Any quantum information process depends on combination of Gaussian states, Gaussian operations, and Gaussian measurements.
(iv) The physical states and algebraic operations can be realized and controlled in the laboratory utilizing standard techniques of quantum optics such as beam splitters, phase shifters, squeezers and other efficient detection systems.

Gaussian states can be formed in a variety of physical systems that include light field modes [40, 41, 42, cold atoms [43], excitons in photonic cavities 44]. GE between two Gaussian modes are readily generated, for
example, in case of two output beams of a parametric down converter sent through optical fibers [45] or in atomic ensembles interacting with light [46]. Apart from that, Gaussian states find applications in realizations of quantum key distributions [47], teleportation [48] and electromagnetically induced transparency [49]. Technique has also been developed to quantify GE theoretically [50, 52, 53, 54, 55]. In this perspective, it is indeed worthwhile to study alternative ways of generating GE. The present work discusses a novel possibility: inducing entanglement by introduction of an additional structure in phase-space manifold, i.e, the spatial noncommutativity.

In the present paper we investigate GE in an anisotropic Harmonic Oscillator (HO) in NC space. Let us briefly outline the flowchart of our work. We start by writing down the Hamiltonian for the two-dimensional anisotropic HO in NC coordinates and momenta. Subsequently we exploit Bopp's shift method to rewrite the Hamiltonian in canonical variables where it is easy to see that indeed the noncommutativity is capable of generating GE. For computation of the entanglement entropy, we exploit a simple relation, derived by Rendell and Rajagopal [50. This requires exact solution for the NC anisotropic HO model which we derive following the framework used in Ref. [51]. Finally we compute the GE for our model. Interestingly, under certain approximations, our model can be identified with a planar HO in external magnetic field, perpendicular to the plane where the noncommutativity of the space generates an effective magnetic field.

Previously in the literature, separability criterion of oscillator systems has been discussed in terms of the covariance matrix [56]. However in this paper, we take a step ahead and provide a quantitative measure for such entanglement as well as analyze Simon's separability condition for our system. It turns out that the solutions of the anisotropic HO in NC space are not separable, thus implying that the system is entangled. It is also observed that this entanglement has an upper-bound in high deformation region and it increases with the deformation parameter asymptotically to this value.

Noncommutativity induced entanglement entropy for an isotropic two dimensional HO was studied in Ref. [57]. There are nontrivial differences in the formalism adopted: In Ref. [57] the authors have worked in a Wigner function framework with NC degrees of freedom whereas we have utilized the well established Bopp's shift method to convert the NC variables to canonical ones and have directly computed the von Neumann entanglement entropy for a most general form of anisotropic two dimensional HO. We will compare and contrast our results later.

The sections are arranged in the following way: In Section 2, we shall present a brief review of the work done so far on the entanglement properties of HO and state the main results that are useful in the present study. Mathematical details are provided in Appendix A. In Section 3, we shall introduce our model and discuss in an intuitive manner why we expect en-
tanglement to be present in the system. Further, we shall also obtain the exact solutions for the anisotropic HO in NC space. The rationalization procedure for the Hamiltonian is interesting but quite involved. The details can be found in Appendix B. Section 4 is devoted to the study of GE properties of our model. It contains our major result comprising of the measure of GE. We discuss our results graphically. In Section 5 we make a summary of the work and discuss our results.

## 2 Entanglement properties of pure twomode Gaussian state

In this section we shall discuss the entanglement properties of pure two mode Gaussian states. In particular the entanglement criterion and entanglement of formation for pure two mode Gaussian states will be considered. (Earlier works and references can be found for example in [58].) For the special case of two mode Gaussian state the separability criteria is both necessary and sufficient condition for entanglement. In order to obtain the entanglement criteria and entanglement of formation, the coefficients of the quadrature components of the wave function will be used [50].

A two-mode Gaussian state is said to be entangled if we have a nontrivial cross term in the exponential, as for example :

$$
\begin{equation*}
\psi=N_{0} \exp \left\{\left[-\frac{1}{2}\left(\alpha x_{1}^{2}+\beta x_{2}^{2}+2 \gamma x_{1} x_{2}\right)\right]\right\}, \quad \gamma \neq 0 \tag{1}
\end{equation*}
$$

where $\alpha, \beta$ and $\gamma$-s are in general complex numbers. Let us write them as $\alpha=\alpha_{1}+i \alpha_{2}, \beta=\beta_{1}+i \beta_{2}, \gamma=\gamma_{1}+i \gamma_{2}$. From the normalization of these states we also have $\left|N_{0}\right|^{2}=\Delta / \pi$ where $\Delta^{2}=\alpha_{1} \beta_{1}-\gamma_{1}^{2}>0$ (For details, see appendix A). In addition, we also have $\alpha_{1}>0$ to ensure that $\psi \in L^{2}$. In Ref. 50 the authors have demonstrated that if the vacuum state consists of a non-trivial cross term in the exponential (such as $\gamma x_{1} x_{2}$ in (1) above), the state will be entangled. Consider the state in Eq. (1), we define:

$$
\begin{align*}
A & =\left(\begin{array}{cc}
\left\langle x_{1}^{2}\right\rangle & \left\langle\left\{x_{1}, p_{1}\right\}\right\rangle \\
\left\langle\left\{x_{1}, p_{1}\right\}\right\rangle & \left\langle p_{1}^{2}\right\rangle
\end{array}\right), \quad B=\left(\begin{array}{cc}
\left\langle x_{2}^{2}\right\rangle & \left\langle\left\{x_{2}, p_{2}\right\}\right\rangle \\
\left\langle\left\{x_{2}, p_{2}\right\}\right\rangle & \left\langle p_{2}^{2}\right\rangle
\end{array}\right),  \tag{2}\\
C & =\left(\begin{array}{cc}
\left\langle x_{1} x_{2}\right\rangle & \left\langle x_{1} p_{2}\right\rangle \\
\left\langle p_{1} x_{2}\right\rangle & \left\langle p_{1} p_{2}\right\rangle
\end{array}\right), \quad J=\left(\begin{array}{cc}
0 & 1 \\
-1 & 0
\end{array}\right) . \tag{3}
\end{align*}
$$

The elements of the matrices are calculated for the Gaussian state in Eq. (1). (Details are given in Appendix A). Let us define the quantity [50]:

$$
\begin{equation*}
E_{S}=\operatorname{det} A \operatorname{det} B+\left(\frac{1}{4}-|\operatorname{det} C|\right)^{2}-\operatorname{Tr}-\frac{1}{4}(\operatorname{det} A+\operatorname{det} B) \tag{4}
\end{equation*}
$$

where $\operatorname{Tr}=\operatorname{tr}\left(A J C J B J C^{T} J\right)$. With this, Simon's seperability criterion [52] is stated as,

$$
\begin{equation*}
E_{S} \geq 0 \tag{5}
\end{equation*}
$$

This is a necessary and sufficient condition for bipartite Gaussian states to be separable; otherwise for $E_{S}<0$, the state is entangled. For the state in Eq. (1), $E_{S}$ is calculated to be (using the results in Appendix A) 50:

$$
\begin{equation*}
E_{S}=-\frac{1}{4} \frac{\gamma_{1}^{2}+\gamma_{2}^{2}}{\Delta^{2}} \tag{6}
\end{equation*}
$$

where $\Delta^{2}=\alpha_{1} \beta_{1}-\gamma_{1}^{2}>0$. We can immediately see that for all non-zero $\gamma$, $E_{S}<0$ implying that the state will be entangled.

To quantify this entanglement, we pick an entropy measure which reduces to Von-Neumann entropy for a pure state: The Entanglement of Formation $E_{F}$. The mathematical definition and its physical interpretation has been discussed in the Appendix A. Here, we only give its form which is relevant for the state in Eq. (1) [50]:

$$
\begin{equation*}
E_{F}=(\Omega+1 / 2) \ln (\Omega+1 / 2)-(\Omega-1 / 2) \ln (\Omega-1 / 2) \tag{7}
\end{equation*}
$$

where $\Omega$ is defined by the relation $\Omega^{2}=1 / 4-E_{S}$. We see that for $E_{S}=0$ i.e. for the separable case $E_{F}$ is also zero as is expected.

In this paper, we are primarily interested in the induced Gaussian entanglement produced by the noncommutativity of the space. We have considered a particular anisotropic HO in two dimensional NC space. We shall discuss about how the entanglement depends on the degree of anisotropy. The entanglement of the system is also quantified in terms of the deformation parameter $\theta$ and it has been shown that the entanglement vanishes if the deformation of the space is trivial. Moreover, we restate the separability criterion of the ground state of such a system. We will be using the results shown above.

## 3 Anisotropic harmonic oscillator in two dimensional NC space

In two dimension the NC extension of the quantum mechanics may be realized by a simple modification of the commutation relation among the selfadjoin position ( $X_{i}, i=1,2$ ) and momentum ( $P_{i}, i=1,2$ ) operators, such that they satisfy the following commutation relations:

$$
\begin{equation*}
\left[X_{i}, X_{j}\right]=i \epsilon_{i j} \theta, \quad\left[X_{i}, P_{j}\right]=i \delta_{i j}, \quad\left[P_{i}, P_{j}\right]=0, \quad i, j=1,2, \tag{8}
\end{equation*}
$$

with anti symmetric matrix $\epsilon_{i j}, \epsilon_{12}=1$. In this noncommutating space we consider an anisotropic oscillator represented by the following Hamiltonian:

$$
\begin{equation*}
H=\frac{P_{1}^{2}}{2 m_{1}}+\frac{P_{2}^{2}}{2 m_{2}}+\alpha_{1} X_{1}^{2}+\alpha_{2} X_{2}^{2}, \quad \alpha_{1} \neq \alpha_{2}, \quad \alpha_{1}, \alpha_{2}>0 \tag{9}
\end{equation*}
$$

The purpose of the present section is to find exact solution for this system in the two dimensional NC space. It should be noted that the solution of isotropic HO in arbitrary dimension in NC space has been considered previously in the literature [59]. The interesting property of the extended Heisenberg algebra of the type considered in Eq. (8) is that through a linear transformation, popularly known as Bopp's shift, it can be related to the standard Heisenberg algebra:

$$
\begin{equation*}
\left[x_{i}, x_{j}\right]=0, \quad\left[x_{i}, p_{j}\right]=i \delta_{i j}, \quad\left[p_{i}, p_{j}\right]=0, \quad i, j=1,2 \tag{10}
\end{equation*}
$$

For our present purpose we consider the following Bopp's shift:

$$
\begin{equation*}
X_{1}=x_{1}-\frac{\theta}{2} p_{2}, \quad X_{2}=x_{2}+\frac{\theta}{2} p_{1}, \quad P_{1}=p_{1}, \quad P_{2}=p_{2} \tag{11}
\end{equation*}
$$

Obviously the transformation of Eq. (11) is not unitary as it changes the symplectic structure. This transformation enables us to convert the Hamiltonian in the NC space into a modified Hamiltonian in the commutative space having an explicit dependence on the deformation parameter $\theta$. The states of the system are then wave functions on the ordinary Hilbert space. The dynamics of the system is now governed by the Schrodinger equation with the NC parameter $\theta$-dependent Hamiltonian.

In the present case, we cast the the Bopp shifted Hamiltonian in the following form,

$$
\begin{equation*}
H=\frac{p_{1}^{2}}{2 M_{1}}+\frac{p_{2}^{2}}{2 M_{2}}+\frac{1}{2} M_{1} \omega_{1}^{2} x_{1}^{2}+\frac{1}{2} M_{2} \omega_{2}^{2} x_{2}^{2}-\theta\left(\alpha_{1} x_{1} p_{2}-\alpha_{2} x_{2} p_{1}\right) \tag{12}
\end{equation*}
$$

where

$$
\begin{equation*}
\frac{1}{M_{1}}=\left(\frac{1}{m_{1}}+\frac{\alpha_{2} \theta^{2}}{2}\right), \frac{1}{M_{2}}=\left(\frac{1}{m_{2}}+\frac{\alpha_{1} \theta^{2}}{2}\right) ; \frac{1}{2} M_{i} \omega_{i}^{2}=\alpha_{i}, i=1,2 \tag{13}
\end{equation*}
$$

Let us make an important observation in connection to [57]. If the HO was isotropic, (as considered in [57]), then in (12) the NC induced $\theta$-term is actually $\theta L_{3}$, that is angular momentum component in the 3 -direction.

Since $L_{3}$ commutes with the isotropic HO, the $\theta L_{3}$-term will not make any changes in the isotropic HO wavefunctions and so, there will be no GE for isotropic HO in presence of noncommutativity of the space. We will show later that the explicit result for entanglement also corroborate this. However this result is in contradiction to [57] where GE appears even for NC isotropic HO.

It is noteworthy that the introduction of noncommutativity modifies the mass parameters 60]. In general, the form of the Hamiltonian of Eq. (12) depends on the map (11) 61]. It should be pointed out that modifications in mass parameters and its effect on the equivalence principle was considered previously in 60]. Furthermore it is important to note that although the Hamiltonian depends on the particular map chosen, the physical predictions involving eigenvalues, expectation values, probabilities do not depend on the map, as proved in [24]. The Hamiltonian of Eq. 12] can also be written in the following form:

$$
\begin{align*}
H & =\frac{1}{2 M_{1}}\left(p_{1}+\theta M_{1} \alpha_{2} x_{2}\right)^{2}+\frac{1}{2 M_{2}}\left(p_{2}-\theta M_{2} \alpha_{1} x_{1}\right)^{2} \\
& +\frac{1}{2}\left(M_{1} \omega_{1}^{2}-M_{2} \theta^{2} \alpha_{1}^{2}\right) x_{1}^{2}+\frac{1}{2}\left(M_{2} \omega_{2}^{2}-M_{1} \theta^{2} \alpha_{2}^{2}\right) x_{2}^{2} \tag{14}
\end{align*}
$$

For $m_{1}=m_{2}, \alpha_{1}=\alpha_{2}$, i.e for an isotropic HO in the NC space (see Eq. (12)), this Hamiltonian has the interpretation of a particle moving in a two dimensional plane ( $\mathrm{x}, \mathrm{y}$ ) in a perpendicular magnetic field with a strength proportional to the noncommutating parameter $\theta$. It is interesting to note that in this case, the effect of taking $\theta=0$, is equivalent to switching off the magnetic field.

In order to solve the Hamiltonian of Eq. (12), it is convenient to express it in the following form [51]:

$$
\begin{equation*}
H=\frac{1}{2} X^{T} \mathcal{H} X, \quad X=\left(x_{1}, p_{1}, x_{2}, p_{2}\right)^{T} \tag{15}
\end{equation*}
$$

where the column matrix $X$ satisfies the commutator relations

$$
\begin{equation*}
\left[X_{\alpha}, X_{\beta}\right]=-\left(\Sigma_{y}\right)_{\alpha \beta} \tag{16}
\end{equation*}
$$

where $\Sigma_{y}=\operatorname{diag}\left(\sigma_{y}, \sigma_{y}\right), \sigma_{y}$ being the Pauli matrix, and $\mathcal{H}$ is the following symmetric matrix

$$
\mathcal{H}=\left(\begin{array}{cccc}
M_{1} \omega_{1}^{2} & 0 & 0 & -\theta \alpha_{1}  \tag{17}\\
0 & \frac{1}{M_{1}} & \theta \alpha_{2} & 0 \\
0 & \theta \alpha_{2} & M_{2} \omega_{2}^{2} & 0 \\
-\theta \alpha_{1} & 0 & 0 & \frac{1}{M_{2}}
\end{array}\right)
$$

The idea is to diagonalized the Hamiltonian $H$ of Eq. (12) such that it can be expressed as a sum of two one dimensional harmonic oscillators. This diagonalization must be done without affecting the symplectic structure of the system reflected in the Eq. (16), i.e. the linear transformation that diagonalized $\mathcal{H}$ must preserve the relation (16). In the following procedure, we shall express the Hamiltonian into a form expressed in terms of raising and lowering operators [51]. It should be noted here that the Hamiltonian $H$ and $X$ satisfy the following commutation relation

$$
\begin{equation*}
[i H, X]=\Omega X \tag{18}
\end{equation*}
$$

where

$$
\begin{equation*}
\Omega=i \Sigma_{y} \mathcal{H} \tag{19}
\end{equation*}
$$

having the explicit form

$$
\Omega=\left(\begin{array}{cccc}
0 & \frac{1}{M_{1}} & \theta \alpha_{2} & 0  \tag{20}\\
-M_{1} \omega_{1}^{2} & 0 & 0 & \theta \alpha_{1} \\
-\theta \alpha_{1} & 0 & 0 & \frac{1}{M_{2}} \\
0 & -\theta \alpha_{2} & -M_{2} \omega_{2}^{2} & 0
\end{array}\right)
$$

It should be noted that for $\theta \alpha_{1}=\theta \alpha_{2}=\omega_{B}$ and $M_{1}=M_{2}$, the matrix $\Omega$ reduces to the form considered in the Ref. 51] for the case of isotropic oscillator. Now the next step is to diagonalized the matrix $\Omega$. Rest of the calculations are quite involved and we relegate these to Appendix B.

The diagonal Hamiltonian is given by,

$$
\begin{equation*}
H=\sigma_{1}\left(a_{1}^{\dagger} a_{1}+\frac{1}{2}\right)+\sigma_{2}\left(a_{2}^{\dagger} a_{2}+\frac{1}{2}\right) \tag{21}
\end{equation*}
$$

where

$$
\begin{equation*}
\sigma_{1}=\left(\frac{b+\sqrt{D}}{2}\right)^{\frac{1}{2}}, \quad \sigma_{2}=\left(\frac{b-\sqrt{D}}{2}\right)^{\frac{1}{2}} \tag{22}
\end{equation*}
$$

with $\sigma_{1}>\sigma_{2}$. Explicit expressions for $b, D$ are given in Appendix B.

Clearly the Hamiltonian of Eq. (12) is expressed as a sum of two decoupled one dimensional HOs. This Hamiltonian has the same form as considered in Ref. [51. However, in this case the expressions for $\sigma_{1}$ and $\sigma_{2}$ are different which incorporate the effect of anisotropic nature of the system. The energy levels are readily obtained as

$$
\begin{equation*}
E_{n_{1}, n_{2}}=\sigma_{1}\left(n_{1}+\frac{1}{2}\right)+\sigma_{2}\left(n_{2}+\frac{1}{2}\right), \quad n_{1}, n_{2}=0,1,2,3, \ldots \ldots \tag{23}
\end{equation*}
$$

which is the sum of the energy of two one dimensional harmonic oscillators.
The energy eigenfunctions for the system in coordinate representation are straightforward to obtain. In particular the ground state is given by

$$
\begin{equation*}
\psi_{00}=N_{0} \exp \left\{\left[-\frac{1}{2}\left(\Lambda_{11} x_{1}^{2}+\Lambda_{22} x_{2}^{2}+\left(\Lambda_{12}+\Lambda_{21}\right) x_{1} x_{2}\right)\right]\right\} \tag{24}
\end{equation*}
$$

The remaining task is is to compute the entanglement. Explicit expressions of $\Lambda_{i j}$ and some steps of computation are provided in Appendix B.

## 4 Entanglement for the anisotropic oscillator in NC space

After obtaining the exact solution for the ground state wave function of the anisotropic oscillator in NC space, we are now in the position to study the entanglement properties of the system. As we have already emphasized in Section 2. Eq. (6), the $x_{1} x_{2}$-term in Eq. (24) is a signature of entanglement.

In order to quantify the entanglement of the system we shall calculate the quantity $E_{S}$, described in section 2 (see Eq. (6)), which takes the following form in the present case:

$$
\begin{equation*}
E_{S}=-\frac{1}{4} \frac{\left[\operatorname{Im}\left(\Lambda_{12}\right)\right]^{2}}{\left(\Lambda_{11} \Lambda_{22}\right)} \tag{25}
\end{equation*}
$$

with the Simon's Separability criterion [52]:

$$
\begin{equation*}
E_{S} \geq 0 \tag{26}
\end{equation*}
$$

From the expression of $\Lambda_{12}$ given in Appendix B, we see that $\Lambda_{12}$ vanishes for $\theta=0$ showing that GE is induced by noncommutativity of the space. One of the main feature is that this entanglement also depends on the degree of the anisotropy. Furthermore, the important point is that for $m_{1}=m_{2}$ and $\alpha_{1}=\alpha_{2}$, the off diagonal terms $\Lambda_{i j}, i \neq j$ vanish which again shows that for isotropic case there is no entanglement.

Therefore, the necessary and sufficient condition for entanglement is to have a negative $E_{S}[62][63$. In our present case, Eq. (25) takes the following form:

$$
\begin{equation*}
E_{S}=-\frac{\theta^{2}}{8} \sqrt{\alpha_{1} m_{2} \alpha_{2} m_{1}} \frac{\left(\sqrt{\alpha_{1} m_{2}}-\sqrt{\alpha_{2} m_{1}}\right)^{2}}{\left[2 \theta^{2} \alpha_{1} m_{2} \alpha_{2} m_{1}+\left(\sqrt{\alpha_{1} m_{2}}+\sqrt{\alpha_{2} m_{1}}\right)^{2}\right]} . \tag{27}
\end{equation*}
$$

It is evident from the above expression that $E_{S}$ can never be positive. However, it can be zero. This situation arises when either $\theta=0$ or $\frac{\alpha_{1}}{m_{1}}-\frac{\alpha_{2}}{m_{2}}=0$. For $\theta=0$ i.e. in the absence of deformation, the system of harmonic oscillators is defined on the usual commutative space and as expected there is no entanglement in this case:
$\psi_{00}\left(x_{1}, x_{2}\right) \sim \exp \left[-1 / 2\left(\Lambda_{11} x_{1}^{2}+\Lambda_{22} x_{2}^{2}\right)\right]=\exp \left[-1 / 2 \Lambda_{11} x_{1}^{2}\right] \otimes \exp \left[-1 / 2 \Lambda_{22} x_{2}^{2}\right]$.
Furthermore, $E_{s}$ can be zero for NC anisotropic HO provided the condition $\frac{\alpha_{1}}{m_{1}}=\frac{\alpha_{2}}{m_{2}}$ is satisfied. Again we reaffirm that $E_{s}$ vanishes for isotropic HO even for non-zero $\theta$.

We can consider two special cases:
(i) $\alpha_{1}=\alpha_{2}=\alpha$. In this case

$$
\begin{equation*}
E_{S}^{(i)}=-\frac{\theta^{2} \alpha m_{1} m_{2}}{8 \sqrt{m_{1} m_{2}}} \frac{\left(\sqrt{m_{1}}-\sqrt{m_{2}}\right)^{2}}{\left[2 \theta^{2} \alpha m_{1} m_{2}+\left(\sqrt{m_{1}}+\sqrt{m_{2}}\right)^{2}\right]} \tag{28}
\end{equation*}
$$

(ii) $m_{1}=m_{2}=m$. In this case

$$
\begin{equation*}
E_{S}^{(i i)}=-\frac{\theta^{2} m \alpha_{1} \alpha_{2}}{8 \sqrt{\alpha_{1} \alpha_{2}}} \frac{\left(\sqrt{\alpha_{1}}-\sqrt{\alpha_{2}}\right)^{2}}{\left[2 \theta^{2} m \alpha_{1} \alpha_{2}+\left(\sqrt{\alpha_{1}}+\sqrt{\alpha_{2}}\right)^{2}\right]} \tag{29}
\end{equation*}
$$

Note that case (i) can be identified with a system of anisotropic oscillator $\left(m_{1} \neq m_{2}\right)$ placed in a magnetic field, perpendicular to the oscillator plane. On the other hand, case (ii) corresponds to a conventional anisotropic oscillator $\left(\alpha_{1} \neq \alpha_{2}\right)$. The former case (i) might be amenable to experimental verification. Also it is interesting to note the symmetry between (28) and (29) under the interchange of mass and frequency parameters.

For the non-trivial deformation case, the separability criterion, therefore, boils down to

$$
\begin{equation*}
\frac{\alpha_{1}}{m_{1}}=\frac{\alpha_{2}}{m_{2}} \tag{30}
\end{equation*}
$$

We can crosscheck the validity of this criterion for isotropic harmonic oscillators with equal masses. The above mentioned system will be separable as the Hamiltonian for this case can be written as:

$$
\begin{equation*}
H=H_{0}-\theta \alpha L_{3} \tag{31}
\end{equation*}
$$

Figure 1: $E_{F}$ (ordinate) vs $\theta$ (abcissa) for $m_{1}=m_{2}=$ $1, \alpha_{1}=5$ and $\alpha_{2}=10$

Figure 2: $\quad E_{F}$ (ordinate) vs $r$ (abcissa) for $m_{1}=m_{2}=1, \theta=1$ and $\alpha_{1} \alpha_{2}=2$
where,

$$
\begin{equation*}
H_{0}=\frac{1}{2}\left(\frac{1}{m}+\frac{\alpha \theta^{2}}{2}\right)\left(p_{1}^{2}+p_{2}^{2}\right)+\alpha\left(x_{1}^{2}+x_{2}^{2}\right) \tag{32}
\end{equation*}
$$

and,

$$
\begin{equation*}
L_{3}=x_{1} p_{2}-x_{2} p_{1} . \tag{33}
\end{equation*}
$$

As $L_{3}$ commutes with $H_{0}$ hence H shares same eigenstates with $H_{0}$ which are separable. This can be easily verified from our separability criterion.

Let us now plot the variation of $E_{F}$ of Eq. (7) with increasing deformation $\theta$ and increasing ratio $r=\frac{\alpha_{1} / m_{1}}{\alpha_{2} / m_{2}}$. Note that $r$ can be considered as a generalized measure of anisotropy, that is $r=1$ trivially for isotropic case $m_{1}=m_{2}, \alpha_{1}=\alpha_{2}$. However, $r$ can be unity for anisotropic case as well provided $\alpha_{1} / m_{1}=\alpha_{2} / m_{2}$. Fig. 1 and Fig. 2 describe the variation of the function $E_{F}$ with $\theta$ and $r$ respectively. For the plot $\theta$ vs $E_{F}$, we have taken unit mass for both oscillators and $\alpha_{1}=5, \alpha_{2}=10$, i.e., $r=0.5$. In the 2 nd figure we have plotted r vs $E_{S}$ where, we have fixed $m_{1}, m_{2}$ and $\theta$ to unity and an additional criterion of $\alpha_{1} \alpha_{2}=2$ without loss of generality.

We see that the function increases rapidly for lower values of $\theta$, and saturates asymptotically for high $\theta$. The bound is derived straightforwardly by taking the limit of $\theta$ going to infinity in (27) for $E_{S}$ :

$$
\begin{equation*}
\lim _{\theta \rightarrow \infty} E_{S}(\theta)=-\frac{1}{16} \frac{1}{\sqrt{\alpha_{1} m_{2} \alpha_{2} m_{1}}}\left(\sqrt{\alpha_{1} m_{2}}-\sqrt{\alpha_{2} m_{1}}\right)^{2} \tag{34}
\end{equation*}
$$

Now as $\Omega$ is related to $E_{S}$ by the equation $\Omega^{2}=1 / 4-E_{S}$, hence the bound on $\Omega$ can be obtained by simply putting the limiting value of $E_{S}$ in the equation:

$$
\begin{equation*}
\lim _{\theta \rightarrow \infty} \Omega=\Omega_{0}=\frac{1}{4}\left(\alpha_{1} m_{2} \alpha_{2} m_{1}\right)^{-1 / 4}\left(\sqrt{\alpha_{1} m_{2}}+\sqrt{\alpha_{2} m_{1}}\right) \tag{35}
\end{equation*}
$$

Hence, the bound on $E_{F}$ is given by:

$$
\begin{equation*}
E_{F}<\left(\Omega_{0}+1 / 2\right) \ln \left(\Omega_{0}+1 / 2\right)-\left(\Omega_{0}-1 / 2\right) \ln \left(\Omega_{0}-1 / 2\right) . \tag{36}
\end{equation*}
$$

On the other hand, $r$ being the measure of anisotropy, it is important to find the profile of $E_{S}$ against $r$. The plot of $r$ versus $E_{F}$ has two regions $r<1$ and $r>1$. As we converge to the point $r=1$, we see that it vanishes which is exactly what we prescribe as the separability criterion, but away from the point $r=1$, where the degree of anisotropy is non-trivial, the entanglement increases rapidly. It is clear from (35) that the measure of the entanglement is symmetric to the interchange of the oscillators.

## 5 Conclusion

In this paper we have studied in detail the entanglement property of a two dimensional anisotropic harmonic oscillator, where the entanglement is induced by spatial noncommutativity. We follow the procedure of Bopp's shift, a transformation that reduces the noncommutative model to one comprising of canonical variables. An additional interaction term, dependent up on the noncommutativity parameter $\theta$, is generated. This all important term is responsible for the entanglement. The essential role of anisotropy is emphasized throughout the paper and we have also pointed out the mismatch between our results and that of [57]. Since the two computational schemes of [57] and the present one are inherently different, the choice between the two procedures can only be settled through experiments.

As an intermediate step we have obtained exact solutions for the energy eigenvalues and eigenfunctions of a planar anisotropic oscillator, which is a new result in the context of NC geometry induced physics. The nontrivial entanglement is established by considering Simon's separability criterion. We have shown dependence of Entanglement of Fomation upon the noncommutative deformation $\theta$ and also upon the anisotropy parameter $r$. We have clearly established that the entanglement is zero for vanishing noncommutative deformation, $\theta=0$. However, anisotropy plays an essential role for generating entanglement since in noncommutative deformed case for an isotropic oscillator, the eigenfunctions of the deformed and undeformed oscillator are the same which shows the there can be no entanglement for an isotropic oscillator, even for nonzero noncommutativity.

Finally, we briefly discuss areas where the results, derived in this paper, can be tested experimentally. The anisotropic oscillator model has a wide range of applications. For instance, it can describe motion of an electron in an anisotropic metal lattice [65]. In the presence of external electromagnetic fields, these model might play a role in semiconductor physics. Diamagnetic properties of small metallic particles are mapped to these models [66].

An empirical polarizable force field, based on the classical Drude oscillator model, is another area of application [67]. Furthermore, in the recently developed theory of magneto-optical phenomena, anisotropic oscillator models have played significant roles [68]. Probing entanglement properties in these experimentally realizable systems can give new insights.

Let us conclude our work with a cautionary note with a mention of certain features of our framework that can be improved. Note that we have performed our analysis in terms of canonical variables $x, p$ obeying canonical commutation relations, even though the original model was posited in terms of $X, P$ degrees of freedom that satisfy the non-canonical (or noncommutative) commutation relations. Also, in this context, recall that the structure of the noncommutative Hamiltonian is identical to the canonical one, with the variables $x, p$ replaced by $X, P$. Indeed, in all instances [20, 21, 22, 23] of noncommutative extension of quantum mechanics in perturbative framework this starting point is an assumption since we do not really know of any typical dynamical model explicitly in noncommutative space. Recall that in a similar vein, in noncommutative generalization of a quantum field theory as well the basic model is that of a known canonical field theory model with products of field variables (at a same spacetime point) replaced by the so called $*$-product (or Groenwald-Moller product) [19, 13, 31, 32, 33, 34, 35, 36, 37]. For want of a better option, in all examples of noncommutative quantum mechanical or field theory models, the next step is to express the noncommutative models in terms of canonical degrees of freedom, through Darboux map in quantum mechanics (as done in here and in other works) or through canonical fields in a field theory by expanding the $*$-product (and incorporating the Seiberg-Witten map for gauge theories [19, 13, 33. This procedure allows us to exploit standard computational techniques on the Hamiltonian (in quantum mechanics) or Lagrangian (in quantum field theory) that receive additional terms induced by noncommutativity through the Darboux map (in quantum mechanics) or *-product (in quantum field theory). Thus the final results are generically computed in a canonical framework in terms of canonical variables. Precisely this scheme has been followed in our work. A notable work, relevant to the present paper, is by Bastos et. al. in [12], where also Darboux map is used to convert the noncommutative model to an extended model in terms of canonical variables in a Wigner function approach but importantly, it is shown that the final result can be reexpressed in terms of noncommutative variables and also the final results are independent of the Darboux map. However, we have done our analysis in a different framework, and indeed, it would be nice if in our case also similar procedure can be adapted. This is an interesting open question that we wish to pursue in near future.

Another point is the dependency of our results on the specific Darboux map. We have exploited the simplest and most direct form of map that
has been used by others in numerous occasions. We admit that one can use more elaborate maps that can change the numerical results but it is quite obvious that the take home message of our paper, that entanglement can be generated through noncommutativity, will remain intact. Only experimental verification can fix a specific choice of the map. Furthermore, apart from numerical difference in the final result of entanglement measure, more complicated Darboux maps can introduce qualitative changes in the final result, but it is expected that those will involve corrections involving higher orders of the noncommutative parameter $\theta$. So far our results are exact with the entanglement measure appearing in 27 in $O\left(\theta^{2}\right)$ and corrections to still higher orders in $\theta$ may not be significant for small $\theta$ in a perturbative framework.

Acknowledgement: We thank the Reviewers for their insightful comments that have helped us to improve the paper in a significant way.

## 6 Appendix A

Normalization of the state in Eq. (1) produces the criterion that $\alpha_{1} \beta_{1}-\gamma_{1}^{2}$ and $\alpha_{1}$ must be positive:

$$
\begin{align*}
|\psi|^{2} & =\left|N_{0}\right|^{2} \int \exp \left[-\left(\alpha_{1} q_{1}^{2}+\beta_{1} q_{2}^{2}+2 \gamma_{1} q_{1} q_{2}\right)\right] d q_{1} d q_{2} \\
& =\left|N_{0}\right|^{2} \int \sqrt{\frac{\pi}{\alpha_{1}}} \exp \left[-\left(\beta_{1}-\frac{\gamma_{1}^{2}}{\alpha_{1}}\right) q_{2}^{2}\right] d q_{2} \\
& =\left|N_{0}\right|^{2} \sqrt{\frac{\pi}{\alpha_{1}}} \sqrt{\frac{\pi}{\beta_{1}-\frac{\gamma_{1}^{2}}{\alpha_{1}}}}  \tag{37}\\
& =\left|N_{0}\right|^{2} \frac{\pi}{\sqrt{\alpha_{1} \beta_{1}-\gamma_{1}^{2}}} .
\end{align*}
$$

This should equal to unity. Hence, we have $\left|N_{0}\right|^{2}=\frac{\sqrt{\alpha_{1} \beta_{1}-\gamma_{1}^{2}}}{\pi}=\frac{\Delta}{\pi}$. As the Gaussian Integral must be convergent, therefore $\alpha_{1} \beta_{1}-\gamma_{1}^{2}$ must be greater than zero. So, we have a real $\left|N_{0}\right|^{2}$.

Now, the matrices A, B and C are defined in Eq.(2) and in Eq.(3) and the entries are calculated for the state in (1) [50]:

$$
\begin{align*}
& \left\langle x_{1}^{2}\right\rangle=\frac{\beta_{1}}{2 \Delta^{2}} ; \quad\left\langle x_{2}^{2}\right\rangle=\frac{\alpha_{1}}{2 \Delta^{2}} ; \quad\left\langle x_{1} x_{2}\right\rangle=-\frac{\gamma_{1}}{2 \Delta^{2}}  \tag{38}\\
& \left\langle p_{1}^{2}\right\rangle=\frac{\beta_{1}|\alpha|^{2}-\alpha_{1}\left(\gamma_{1}^{2}-\gamma_{2}^{2}\right)-2 \alpha_{2} \gamma_{1} \gamma_{2}}{2 \Delta^{2}}  \tag{39}\\
& \left\langle p_{2}^{2}\right\rangle=\frac{\alpha_{1}|\beta|^{2}-\beta_{1}\left(\gamma_{1}^{2}-\gamma_{2}^{2}\right)-2 \beta_{2} \gamma_{1} \gamma_{2}}{2 \Delta^{2}} \tag{40}
\end{align*}
$$

$$
\begin{gather*}
\left\langle p_{1} p_{2}\right\rangle=\frac{\left(\alpha_{1} \gamma_{1}+\alpha_{2} \gamma_{2}\right) \Delta^{2}+\left(\alpha_{1} \beta_{2}-\gamma_{1} \gamma_{2}\right)\left(\alpha_{1} \gamma_{2}-\alpha_{2} \gamma_{1}\right)}{2 \alpha_{1} \Delta^{2}}  \tag{41}\\
\left\langle\left\{x_{1}, p_{1}\right\}\right\rangle=\frac{\gamma_{1} \gamma_{2}-\alpha_{2} \beta_{1}}{2 \Delta^{2}} ;\left\langle\left\{x_{2}, p_{2}\right\}\right\rangle=\frac{\gamma_{1} \gamma_{2}-\alpha_{1} \beta_{2}}{2 \Delta^{2}} ;  \tag{42}\\
\left\langle x_{1} p_{2}\right\rangle=\frac{\gamma_{1} \beta_{2}-\gamma_{2} \beta_{1}}{2 \Delta^{2}} ;\left\langle x_{2} p_{1}\right\rangle=\frac{\gamma_{1} \alpha_{2}-\gamma_{2} \alpha_{1}}{2 \Delta^{2}} \tag{43}
\end{gather*}
$$

From these relations we can calculate the determinants of $\mathrm{A}, \mathrm{B}$ and C in terms of the quadrature coefficients:

$$
\begin{gather*}
\operatorname{det} A=\left\langle x_{1}^{2}\right\rangle\left\langle p_{1}^{2}\right\rangle-\left\langle\left\{x_{1}, p_{1}\right\}\right\rangle^{2}  \tag{44}\\
=\operatorname{det} B=\left\langle x_{2}^{2}\right\rangle\left\langle p_{2}^{2}\right\rangle-\left\langle\left\{x_{2}, p_{2}\right\}\right\rangle^{2}  \tag{45}\\
=\frac{1}{4}+\frac{1}{4} \frac{\gamma_{1}^{2}+\gamma_{2}^{2}}{\Delta^{2}}  \tag{46}\\
\operatorname{det} C=-\frac{1}{4} \frac{\gamma_{1}^{2}+\gamma_{2}^{2}}{\Delta^{2}} . \tag{47}
\end{gather*}
$$

In this paper, we quantified the entanglement using the Entanglement of Formation. If we have $n$ number of Bell states and if by local operations and classical communication (LOCC) we can produce only $m$ number of the given state $|\psi\rangle$ from those Bell states then the entanglement of formation corresponds to the ratio $\mathrm{n} / \mathrm{m}[64]$. Mathematically it can be defined as [50]:

$$
\begin{equation*}
E_{F}(\rho)=i n f\left[\sum_{K} p_{K} E_{v n}\left(\psi_{K}\right)\right] \tag{48}
\end{equation*}
$$

for all possible decomposition $\rho=\sum_{K} p_{K}\left|\psi_{K}\right\rangle\left\langle\psi_{K}\right|$. $E_{v n}$ refers to the VonNeumann entropy of the state which can be considered as the quantum mechanical analogue of Shannon entropy. Shannon entropy of X quantifies the amount of uncertainty about X before we learn its value 64. For an entangled state, we will always have a decreased entropy as a measurement of one of its subsystem can give information about the other subsystem therefore decreasing its uncertainty[64]. However, this formula is rarely used as there are difficulties in optimization involved in finding the infimum 50. Fortunately, in this case, it can be derived in a simpler form which is mentioned in Eq. (7).

## 7 Appendix B

In this section we shall consider the diagonalization of the matrix $\Omega$ considered in Eq. 20) and will present the necessary steps to arrive at the

Eq. 21. To diagonalize $\Omega$, note that it is not a symmetric matrix. The characteristic polynomial for this matrix is given by

$$
\begin{equation*}
\operatorname{det}\{(\lambda I-\Omega)\}=\lambda^{4}+b \lambda^{2}+c=0 \tag{49}
\end{equation*}
$$

where

$$
\begin{equation*}
b=\omega_{1}^{2}+\omega_{2}^{2}+2 \theta^{2} \alpha_{1} \alpha_{2}, \quad c=\left(\omega_{2}^{2}-\theta^{2} \frac{M_{1}}{M_{2}} \alpha_{2}^{2}\right)\left(\omega_{1}^{2}-\theta^{2} \frac{M_{2}}{M_{1}} \alpha_{1}^{2}\right) \tag{50}
\end{equation*}
$$

From Eq. (13), it can easily be checked that $c>0$ and $D \equiv b^{2}-4 c \geq 0$ with $\sqrt{D}<b$. Therefore, both roots for $\lambda^{2}$ are real and negative, implying that the above characteristic equation has four pure imaginary roots:

$$
\begin{equation*}
\left\{\lambda_{1}, \lambda_{2}, \lambda_{3}, \lambda_{4}\right\}=\left\{-i \sigma_{1}, i \sigma_{1},-i \sigma_{2}, i \sigma_{2}\right\} \tag{51}
\end{equation*}
$$

where

$$
\begin{equation*}
\sigma_{1}=\left(\frac{b+\sqrt{D}}{2}\right)^{\frac{1}{2}}, \quad \sigma_{2}=\left(\frac{b-\sqrt{D}}{2}\right)^{\frac{1}{2}} \tag{52}
\end{equation*}
$$

with $\sigma_{1}>\sigma_{2}$. Since the matrix $\Omega$ is not symmetric the left and right eigenvectors are different. The two left eigenvectors corresponding to the eigenvalues $-i \sigma_{i}(i=1,2)$ are given by

$$
\begin{equation*}
u_{i} \Omega=-i \sigma_{i} u_{i}, \quad i=1,2 \tag{53}
\end{equation*}
$$

and the other two are $u_{i}^{*}$ corresponding to the eigenvalues $i \sigma_{i}(i=1,2)$. In the explicit form the left eigenvectors are

$$
u_{i}=\frac{1}{k_{i}}\left(\begin{array}{c}
-i M_{1} M_{2} \sigma_{i}\left(\sigma_{i}^{2}-\omega_{2}^{2}-\theta^{2} \alpha_{1} \alpha_{2}\right)  \tag{54}\\
M_{2}\left(\sigma_{i}^{2}-\omega_{2}^{2}\right)+\theta^{2} M_{1} \alpha_{2}^{2} \\
\theta M_{1} M_{2} \alpha_{2}\left(\sigma_{i}^{2}-\theta^{2} \alpha_{1} \alpha_{2}\right)+\theta M_{2}^{2} \alpha_{1} \omega_{2}^{2} \\
i \theta \sigma_{i}\left(M_{1} \alpha_{2}+M_{2} \alpha_{1}\right)
\end{array}\right)^{T}, \quad i=1,2
$$

where $k_{i}$ 's are the normalization constants. The right eigenvectors are $v_{i}, i=1,2$ (corresponding to the eigenvalues $-i \sigma_{i}, i=1,2$ ) and $v_{i}^{*}, i=1,2$ (corresponding to the eigenvalues $-i \sigma_{i}, i=1,2$ ) satisfying the equation

$$
\begin{equation*}
\Omega v_{i}=-i \sigma_{i} v_{i}, \quad i=1,2 \tag{55}
\end{equation*}
$$

From Eqs. (53) and (55), it is easy to check that

$$
\begin{equation*}
u_{i}^{*} v_{j}=u_{i} v_{j}^{*}, \forall i, j=1,2 \tag{56}
\end{equation*}
$$

and by appropriately choosing the normalization constant, we have

$$
\begin{equation*}
u_{i} v_{j}=u_{i}^{*} v_{j}^{*}=\delta_{i j}, \forall i, j=1,2 \tag{57}
\end{equation*}
$$

Using Eqs. (18) and 53, 55, the relation between the left and right eigenvectors may be expressed as [51]

$$
\begin{equation*}
v_{i}=-\Sigma_{y} u_{i}^{\dagger}, \quad i=1,2 \tag{58}
\end{equation*}
$$

We define a $4 \times 4$ row matrix

$$
\begin{equation*}
Q=\left(v_{1}, v_{1}^{*}, v_{2}, v_{2}^{*}\right) \tag{59}
\end{equation*}
$$

The inverse is given by

$$
\begin{equation*}
Q^{-1}=\left(u_{1}^{T}, u_{1}^{* T}, u_{2}^{T}, u_{2}^{* T}\right)^{T} \tag{60}
\end{equation*}
$$

and

$$
\begin{equation*}
Q^{-1} \Omega Q=\operatorname{diag} \quad\left(-i \sigma_{1}, i \sigma_{1},-i \sigma_{2}, i \sigma_{2}\right) \tag{61}
\end{equation*}
$$

Another important relation is

$$
\begin{equation*}
Q^{\dagger}=-\Sigma_{z} Q^{-1} \Sigma_{y}, \quad \Sigma_{z}=\quad \operatorname{diag} \quad\left(\sigma_{z}, \sigma_{z}\right) \tag{62}
\end{equation*}
$$

Where, $\sigma_{x}, \sigma_{y}$ and $\sigma_{z}$ are the Pauli matrices.
We now define the raising and lowering operators by the relations

$$
\begin{equation*}
a_{i}=u_{i} X, \quad a_{i}^{\dagger}=u_{i}^{*} X, \quad\left[a_{i}, a_{j}^{\dagger}\right]=\delta_{i j}, \quad i, j=1,2 \tag{63}
\end{equation*}
$$

We define

$$
\begin{equation*}
A=\left(a_{1}, a_{1}^{\dagger}, a_{2}, a_{2}^{\dagger}\right) \tag{64}
\end{equation*}
$$

which can be written as

$$
\begin{equation*}
A=Q^{-1} X \tag{65}
\end{equation*}
$$

Now using relations (15), (19) and (62), it is easy to show that

$$
\begin{equation*}
H=\frac{1}{2} A^{\dagger} \Sigma A, \quad \Sigma=\quad \operatorname{diag} \quad\left(\sigma_{1}, \sigma_{1}, \sigma_{2}, \sigma_{2}\right) \tag{66}
\end{equation*}
$$

which written in the explicit form yields the Hamiltonian of Eq. (21).
Now, we shall work out the wave functions for the system described by the Hamiltonian of Eq. 12 . This may be expressed as:

$$
\begin{equation*}
\left|n_{1} n_{2}\right\rangle=\frac{1}{\sqrt{n_{1}!n_{2}!}}\left(a_{1}^{\dagger}\right)^{n_{1}}\left(a_{2}^{\dagger}\right)^{n_{2}}|00\rangle, \quad n_{1}, n_{2}=0,1,2,3, \ldots . \tag{67}
\end{equation*}
$$

where the ground state $|00\rangle$ is given by

$$
\begin{equation*}
a_{1}|00\rangle=a_{2}|00\rangle=0 \tag{68}
\end{equation*}
$$

Next, we shall determine this ground state wave function $\psi_{00}$ in the coordinate space representation where

$$
\begin{equation*}
\psi_{00}=\left\langle x_{1} x_{2} \mid n_{1} n_{2}\right\rangle \tag{69}
\end{equation*}
$$

and the other excited states can be obtained by using Eq. 67). In the coordinate space representation, Eq. (68) takes the following form:

$$
\begin{equation*}
\left(\xi_{i j} x_{j}-i \eta_{i j} \partial_{j}\right) \psi_{00}=0 \tag{70}
\end{equation*}
$$

where

$$
\xi=\left(\begin{array}{ll}
u_{11} & u_{13}  \tag{71}\\
u_{21} & u_{23}
\end{array}\right), \quad \eta=\left(\begin{array}{ll}
u_{12} & u_{14} \\
u_{22} & u_{24}
\end{array}\right)
$$

with $u_{i \beta}(i=1,2 ; \beta=1,2,3,4)$ is the $\beta$-th component of $u_{i}$. In order to solve Eq. (70), we choose the trial solution $\psi_{00}=N_{0} \exp \left\{\left(-S\left(x_{1}, x_{2}\right)\right)\right\}$, where $N_{0}$ is the normalization constant and $S=\frac{1}{2} x_{i} \Lambda_{i j} x_{j}$. Substituting this into Eq. 70, we get

$$
\begin{equation*}
\Lambda=i \eta^{-1} \xi \tag{72}
\end{equation*}
$$

This can easily be solved with the following expression for the components of the matrix $\Lambda$ :

$$
\begin{equation*}
\Lambda_{11}=\frac{M_{1} M_{2} \sigma_{1} \sigma_{2}\left(\sigma_{1}+\sigma_{2}\right)}{\left[M_{2}\left(\omega_{2}^{2}+\sigma_{1} \sigma_{2}\right)-\theta^{2} M_{1} \alpha_{2}^{2}\right]} \tag{73}
\end{equation*}
$$

$$
\begin{align*}
\Lambda_{22} & =\frac{M_{2}\left(M_{2} \omega_{2}^{2}-M_{1} \theta^{2} \alpha_{2}^{2}\right)\left(\sigma_{1}+\sigma_{2}\right)}{\left[M_{2}\left(\omega_{2}^{2}+\sigma_{1} \sigma_{2}\right)-\theta^{2} M_{1} \alpha_{2}^{2}\right]}  \tag{74}\\
\Lambda_{12} & =\Lambda_{21}=\frac{i M_{2}\left(\theta^{3} M_{1} \alpha_{2}^{2} \alpha_{1}-\theta M_{2} \alpha_{1} \omega_{2}^{2}+\theta M_{1} \alpha_{2} \sigma_{1} \sigma_{2}\right)}{\left[M_{2}\left(\omega_{2}^{2}+\sigma_{1} \sigma_{2}\right)-\theta^{2} M_{1} \alpha_{2}^{2}\right]} \tag{75}
\end{align*}
$$

All these expressions reduce to the form as obtained in the Ref. [51] for the case $M_{1}=M_{2}$ and $\theta \alpha_{1}=\theta \alpha_{2}=\omega_{B}$.
