# APPROXIMATION THEORY OF TREE TENSOR NETWORKS: TENSORIZED UNIVARIATE FUNCTIONS - PART I 

MAZEN ALI AND ANTHONY NOUY<br>Fraunhofer ITWM, 67663 Kaiserslautern, Germany<br>Centrale Nantes, Nantes Université, LMJL UMR CNRS 6629, France

#### Abstract

We study the approximation of functions by tensor networks (TNs). We show that Lebesgue $L^{p}$-spaces in one dimension can be identified with tensor product spaces of arbitrary order through tensorization. We use this tensor product structure to define subsets of $L^{p}$ of rank-structured functions of finite representation complexity. These subsets are then used to define different approximation classes of tensor networks, associated with different measures of complexity. These approximation classes are shown to be quasi-normed linear spaces. We study some elementary properties and relationships of said spaces.

In part II of this work, we will show that classical smoothness (Besov) spaces are continuously embedded into these approximation classes. We will also show that functions in these approximation classes do not possess any Besov smoothness, unless one restricts the depth of the tensor networks.

The results of this work are both an analysis of the approximation spaces of TNs and a study of the expressivity of a particular type of neural networks (NN) - namely feed-forward sum-product networks with sparse architecture. The input variables of this network result from the tensorization step, interpreted as a particular featuring step which can also be implemented with a neural network with a specific architecture. We point out interesting parallels to recent results on the expressivity of rectified linear unit (ReLU) networks - currently one of the most popular type of NNs.

## 1. Introduction

1.1. Approximation of Functions. We present a new perspective and therewith a new tool for approximating one-dimensional real-valued functions $f: \Omega \rightarrow \mathbb{R}$ on bounded intervals $\Omega \subset \mathbb{R}$. We focus on the one-dimensional setting to keep the presentation comprehensible, but we intend to address the multi-dimensional setting in a forthcoming part III.

The approximation of general functions by simpler "building blocks" has been a central topic in mathematics for centuries with many arising methods: algebraic polynomials, trigonometric polynomials, splines, wavelets or rational functions are among some of the by now established tools. Recently, more sophisticated tools such as tensor networks (TNs) or neural networks (NNs) have proven to be powerful techniques. Approximation methods find application in various areas: signal processing, data compression, pattern recognition, statistical learning, differential equations, uncertainty quantification, and so on. See [5, 6, 8, 10, 22, 23, 33, 34, 36, 37, 40] for examples.

In the 20th century a deep mathematical theory of approximation has been established. It is by now well understood that approximability properties of a function by more standard tools - such as polynomials or splines - are closely related to its smoothness. Moreover, functions that can be approximated with a certain rate can be grouped to form quasi-normed linear spaces. Varying the approximation rate then generates an entire scale of spaces that turn out to be so-called interpolation spaces. See [13, 14] for more details.

In this work, we address the classical question of one-dimensional function approximation but with a new set of tools relying on tensorization of functions and the use of rank-structured tensor formats (or tensor networks). We analyze the resulting approximation classes. We will show in part II [2]

[^0]that many known classical spaces of smoothness are embedded in these newly defined approximation classes. On the other hand, we will also show that these classes are, in a sense, much larger than classical smoothness spaces.
1.2. Neural Networks. Our work was partly motivated by current developments in the field of deep learning. Originally developed in [35, artificial neural networks (NNs) were inspired by models in theoretical neurophysiology of the nervous system that constitutes a brain. The intention behind NNs was to construct a mathematical (and ultimately digital) analogue of a biological neural network. The increase in computational power in recent decades has led to many successful applications of NNs in various fields [44. This in turn has sparked interest in a better mathematical foundation for NNs. One flavor of this research is the analysis of the approximation power of feed-forward NNs. In particular, relevant for this work is the recent paper [24], where the authors analyzed the approximation spaces of deep ReLU and rectified power unit (RePU) networks. In Figure 1, we sketch an example of a feed-forward NN.

Figure 1. Example of an artificial neural network. On the left we have the input nodes marked in red that represent input data to the neural system. The yellow nodes are the neurons that perform some simple operations on the input. The edges between the nodes represent synapses or connections that transfer (after possibly applying an affine linear transformation) the output of one node into the input of another. The final green nodes are the output nodes. In this particular example the number of layers $L$ is three, with two hidden layers.

Mathematically, a feed-forward NN can be represented by a tuple

$$
\Psi=\left(\left[T_{1}, \sigma_{1}\right], \ldots,\left[T_{L}, \sigma_{L}\right]\right)
$$

where $T_{l}: \mathbb{R}^{N_{l-1}} \rightarrow \mathbb{R}^{N_{l}}$ are affine maps; $N_{l}$ is the number of neurons in layer $l$, with $N_{0}$ being the number of inputs and $N_{L}$ the number of outputs; the functions $\sigma_{l}: \mathbb{R}^{l} \rightarrow \mathbb{R}^{l}$ are typically non-linear and represent the operations performed on data inside the neurons. The functions $\sigma_{l}$ are often implemented via a component-wise application of a single non-linear function $\rho: \mathbb{R} \rightarrow \mathbb{R}$ referred to as the activation function. The realization $\mathcal{R}(\Psi)$ of the NN $\Psi$ is the function

$$
\mathcal{R}(\Psi): \mathbb{R}^{N_{0}} \rightarrow \mathbb{R}^{N_{L}}, \quad \mathcal{R}(\Psi):=\sigma_{L} \circ T_{L} \circ \cdots \circ \sigma_{1} \circ T_{1}
$$

Before one can proceed with training (i.e., estimating) a NN, one usually specifies the architecture of the NN: this includes the number of layers $L$, neurons $N_{l}$, connections between the neurons and the nonlinearities $\sigma_{l}$. Only after this, one proceeds with training which entails determining the affine maps $T_{l}$. This is typically done by minimizing some loss or distance functional $\mathcal{J}(\mathcal{R}(\Psi), f)$, where $f: \mathbb{R}^{N_{0}} \rightarrow \mathbb{R}^{N_{L}}$ is the target function that we want to approximate, in some sense. If we set $N_{0}=N_{L}=1$ and, e.g., $\mathcal{J}(\mathcal{R}(\Psi), f)=\|f-\mathcal{R}(\Psi)\|_{p}$, then we are in the classical setting of one-dimensional approximation ${ }^{11}$ (in the $L^{p}$-norm).
1.3. Tensor Networks. Tensor networks have been studied in parallel in different fields, sometimes under different names: e.g., hierarchical tensor formats in numerical analysis, sum-product networks in machine learning, belief networks in bayesian inference. Tensor networks are commonly applied and studied in condensed matter physics, where understanding phenomena in quantum many-body systems has proven to be a challenging problem, to a large extent due to the sheer amount of dependencies that

[^1]cannot be simulated even on the most powerful computers (see [39] for a non-technical introduction). In all these fields, a common challenging problem is the approximation of functions of a very large number of variables. This led to the development of tools tailored to so-called high-dimensional problems.

The mathematical principle behind tensor networks is to use tensor products. For approximating a $d$-variate function $f$, there are several types of tensor formats. The simplest is the so-called $r$-term or $C P$ format, where $f$ is approximated as

$$
\begin{equation*}
f\left(x_{1}, \ldots,, x_{d}\right) \approx \sum_{k=1}^{r} v_{1}^{k}\left(x_{1}\right) \cdots v_{d}^{k}\left(x_{d}\right) \tag{1.1}
\end{equation*}
$$

If each factor $v_{\nu}^{k}$ is encoded with $N$ parameters, the total number of parameters is thus $d N r$, which is linear in the number of variables. The approximation format (1.1) is successful in many applications (chemometrics, inverse problems in signal processing...) but due to a few unfavorable properties (see [25, Chapter 9]), different types of tensor formats are frequently used in numerical approximation. In particular, with the so-called tensor train (TT) format or matrix product state (MPS), the function $f$ is approximated as

$$
\begin{equation*}
f\left(x_{1}, \ldots,, x_{d}\right) \approx \sum_{k_{1}=1}^{r_{1}} \ldots \sum_{k_{d-1}=1}^{r_{d-1}} v_{1}^{k_{1}}\left(x_{1}\right) v_{2}^{k_{1}, k_{2}}\left(x_{2}\right) \ldots v_{d-1}^{k_{d-2}, k_{d-1}}\left(x_{d-1}\right) v_{d}^{k_{d-1}}\left(x_{d}\right) \tag{1.2}
\end{equation*}
$$

The numbers $r_{\nu}$ are referred to as multi-linear ranks or hierarchical ranks. The rank $r_{\nu}$ is related to the classical notion of rank for bi-variate functions, by identifying a $d$-variate function as a function of two complementary groups of variables $\left(x_{1}, \ldots, x_{\nu}\right)$ and $\left(x_{\nu+1}, \ldots, x_{d}\right)$. It corresponds to the socalled $\beta$-rank $r_{\beta}$, with $\beta=\{1, \ldots, \nu\}$. The format in 1.2 is a particular case of tree-based tensor formats, or tree tensor networks [17, 25], the TT format being associated with a linear dimension partition tree. Numerically, such formats have favorable stability properties with robust algorithms (see [20, 22, 38, 42]). Moreover, the corresponding tensor networks and decompositions have a physical interpretation in the context of entangled many-body systems, see [39, 40].

For more general tensor networks, we refer to Figure 2 for graphical representations.

(A) Tensor corresponding to 1.2 with $d=3$.

(B) General Tensor Train (TT) or Matrix Product State (MPS).

(D) General tensor network. Can be seen as an instance of Projected Entangled Pair States (PEPS).
(c) Hierarchical Tucker (HT) or a tree-based format.

Figure 2. Examples of tensor networks. The vertices in Figure 2 represent the lowdimensional functions in the decomposition, such as $v^{1}, \ldots, v^{d}$ in (1.2). The edges between the vertices represent summation over an index (contraction) between two functions, such as summation over $k_{\nu}$ in (1.2). The free edges represent input variables $x_{1}, \ldots, x_{d}$ in (1.2).

The specific choice of a tensor network is sometimes suggested by the problem at hand: e.g., in quantum physics by the entanglement/interaction structure of the quantum system that $f$ is to model - see, e.g., 1, 3, 27, 45].

At first glance, it seems that tensor networks are a tool suited only for approximating high-dimensional functions. However, such formats can be applied in any multi-variate setting and this multi-variate
setting can be enforced even if $d=1$ by a "coarse-graining" of an interval in $\mathbb{R}$ allowing to identify a one-dimensional function with a multi-variate function (or tensor). This identification is the tensorization of functions which is at the core of the approximation tools considered in this work. It was originally applied for matrices in [41 and later coined as quantized tensor format when tensorization is combined with the use of a tensor format.

In high-dimensional approximation, keeping the ranks $r_{\beta}$ small relies on the correct choice of the tensor network that "fits" the interaction structure as hinted above. For the approximation of tensorized functions a different type of structure is required. In [21, 41], it was shown that, if $f$ is vector of evaluations of a polynomial on a grid, then choosing the TT format yields hierarchical ranks that are bounded by the degree of the polynomial. Similar statements were shown for trigonometric polynomials and exponential functions. In [30], this fact was utilized to show that a finite element approximation of two-dimensional functions with singularities, where the coefficient vector was stored in a quantized tensor format, automatically recovers an exponential rate of convergence, analogue to that of $h p$ approximation.

This work can be seen as a consolidation and a deeper analysis of approximation of one-dimensional functions using quantized tensor formats. We first show that Lebesgue spaces of $p$-integrable functions are isometric to tensor product spaces of any order and analyze some basic properties of this identification. We then define and analyze the approximation classes of $L^{p}$ functions that can be approximated by rank-structured functions in the TT format with a certain rate. In Part II [2], we will show direct and (lack of) inverse embeddings.
1.4. Tensor vs. Neural Networks. Recently multiple connections between TNs and NNs have been discovered. In [7], the author exhibits an analogy between the Renormalization Group (RG) - the fundamental physical concept behind TNs - and deep learning, with the scale in RG being akin to depth in NNs. In [32], it was observed that in fact tree tensor networks can be viewed as a specific type of feed-forward NNs with multi-linear functions $\sigma_{l}$, namely sum-product NNs (or arithmetic circuits) [43]. This connection offers intriguing perspectives and it can be exploited both ways: we can use our fundamental understanding of quantum entanglement ${ }^{2}$ to measure and design NNs, see [12, 32]. Or we can use NNs to learn entanglement and augment tensor networks to better represent highly entangled systems, see [11, 31]. Tensor networks also offer a big choice of well studied and robust numerical algorithms.

In this spirit, our work in part II [2] can be seen as a result on the approximation power of a particular type of NN, where the TT format is a feed-forward sum-product NN and a recurrent neural network architecture. When compared to the results of [24] on approximation classes of RePU networks, we will observe in Part II [2] that both tools achieve optimal approximation order for Sobolev spaces. We also show that TNs (using the TT format) achieve optimal approximation order for Besov spaces on the embedding line (corresponding to non-linear approximation). These statements hold for a tensor network of fixed polynomial degree and any smoothness order of the Sobolev/Besov spaces.

On the other hand, TNs are much easier to handle - both analytically and numerically. Moreover, it seems the much simpler architecture of TNs does not sacrifice anything in terms of representing functions of classical smoothness when compared to RePU networks. In particular, both tools are able to recover optimal or close to optimal approximation rates - without being "adapted" to the particular space in question. In other words, all smoothness spaces are included in the same approximation class. This is to be contrasted with more standard approximation tools, such as splines or wavelets, where the approximation class (and thus the approximation method) has to be adapted to the smoothness notion in question. Moreover, both tools will frequently perform better than predicted on specific instances of functions that possess structural features that are not captured by classical smoothness theory ${ }^{3}$.

Of course, this is simply to say that both tools do a good job when it comes to classical notions of smoothness. We still expect that NN approximation classes are very different than those of TNs, in an appropriate sense. We also show in Part II [2] that TNs approximation classes (using the TT format) are not embedded into any Besov space - as was shown in [24] for RePU networks.
1.5. Main Results. First, we show that any $L^{p}$-function $f$ defined on the interval $[0,1)$ can be identified with a tensor. For a given $b \in \mathbb{N}$ (the base) and $d \in \mathbb{N}$ (the level), we first note that any $x \in[0,1)$

[^2]can be uniquely decomposed as
$$
x=\sum_{k=1}^{d} i_{k} b^{-k}+b^{-d} y:=t_{b, d}\left(i_{1}, \ldots, i_{d}, y\right)
$$
where $\left(i_{1}, \ldots, i_{d}\right)$ is the representation of $\left\lfloor b^{d} x\right\rfloor$ in base $b$ and $y=b^{d} x-\left\lfloor b^{d} x\right\rfloor$. This allows to identify a function with a tensor (or multivariate function)
$$
\boldsymbol{f}\left(i_{1}, \ldots, i_{d}, y\right)=f\left(t_{b, d}\left(i_{1}, \ldots, i_{d}, y\right)\right):=T_{b, d} f\left(i_{1}, \ldots, i_{d}, y\right)
$$
and to define different notions of ranks for a univariate function. A function $f$ can be tensorized at different levels $d \in \mathbb{N}$. We analyze the relation between tensorization maps at different levels, and the relation between the ranks of the corresponding tensors of different orders. When looking at $T_{b, d}$ as a map on $L^{p}([0,1))$, a main result is given by Theorem 2.15 and Lemma A. 1 .

Main Result 1.1. For any $0<p \leq \infty, b \in \mathbb{N}(b \geq 2)$ and $d \in \mathbb{N}$, the map $T_{b, d}$ is a linear isometry from $L^{p}([0,1))$ to the algebraic tensor space $\mathbf{V}_{b, d, L^{p}}:=\left(\mathbb{R}^{b}\right)^{\otimes d} \otimes L^{p}([0,1))$, where $\mathbf{V}_{b, d, L^{p}}$ is equipped with a reasonable crossnorm.

For later use in approximation, we introduce the tensor subspace

$$
\mathbf{V}_{b, d, S}:=\left(\mathbb{R}^{b}\right)^{\otimes d} \otimes S
$$

where $S \subset L^{p}([0,1))$ is some finite-dimensional subspace. Then, we can identify $\mathbf{V}_{b, d, S}$ with a finitedimensional subspace of $L^{p}$ as

$$
V_{b, d, S}:=T_{b, d}^{-1}\left(\mathbf{V}_{b, d, S}\right) \subset L^{p}([0,1))
$$

We introduce the crucial assumption that $S$ is closed under $b$-adic dilation, i.e., for any $f \in S$ and any $k \in\{0, \ldots, b-1\}, f\left(b^{-1}(\cdot+k)\right) \in S$. Under this assumption, which is reminiscent of multi-resolution analysis (MRA), we obtain bounds for multilinear ranks that are related to the dimension of $S$. Also, under this assumption on $S$, we obtain the main results given by Propositions 2.23 and 2.24 and Theorem 2.25.

Main Result 1.2. The spaces $V_{b, d, S}$ form a hierarchy of $L^{p}$-subspaces, i.e.

$$
S:=V_{b, 0, S} \subset V_{b, 1, S} \subset V_{b, 2, S} \subset \ldots
$$

and $V_{b, S}:=\bigcup_{d \in \mathbb{N}} V_{b, d, S}$ is a linear space. If we further assume that $S$ contains the constant function one, $V_{b, S}$ is dense in $L^{p}$ for $1 \leq p<\infty$.

For the approximation of multivariate functions (or tensors), we use the set of tensors in the tensor train (TT) format $\mathcal{T} \mathcal{T}_{\boldsymbol{r}}\left(\mathbf{V}_{b, d, S}\right), \boldsymbol{r}=\left(r_{\nu}\right)_{\nu=1}^{d}$, cf. Section 1.3 and Figure 2b. Given a basis $\left\{\varphi_{k}\right\}_{k=1}^{\operatorname{dim} S}$ of $S$, a tensor $\boldsymbol{f}$ in $\mathcal{T} \mathcal{T}_{\boldsymbol{r}}\left(\mathbf{V}_{b, d, S}\right)$ can be written as

$$
\boldsymbol{f}\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k_{1}=1}^{r_{1}} \cdots \sum_{k_{d}=1}^{r_{d}} \sum_{k_{d+1}}^{\operatorname{dim} S} v_{1}^{k_{1}}\left(i_{1}\right) v_{2}^{k_{1}, k_{2}}\left(i_{2}\right) v_{3}^{k_{2}, k_{3}}\left(i_{3}\right) \cdots v_{d}^{k_{d-1}, k_{d}}\left(i_{d}\right) v_{d+1}^{k_{d}, k_{d+1}} \varphi_{k}(y)
$$

where the parameters $\mathbf{v}:=\left(v_{1}, \ldots, v_{d+1}\right)$ form a tensor network (a collection of low-order tensors) with

$$
\mathbf{v}:=\left(v_{1}, \ldots, v_{d+1}\right) \in \mathbb{R}^{b \times r_{1}} \times \mathbb{R}^{b \times r_{1} \times r_{2}} \times \ldots \times \mathbb{R}^{b \times r_{d-1} \times r_{d}} \times \mathbb{R}^{r_{d} \times \operatorname{dim} S}:=\mathcal{P}_{b, d, S, r}
$$

With this we define

$$
\Phi_{b, d, S, \boldsymbol{r}}=T_{b, d}^{-1}\left(\mathcal{T} \mathcal{T}_{\boldsymbol{r}}\left(\mathbf{V}_{b, d, S}\right)\right)=\left\{\mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v}): \mathbf{v} \in \mathcal{P}_{b, d, S, \boldsymbol{r}}\right\}
$$

where $\mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v})$ is the map which associates to a tensor network $\mathbf{v}$ the function $f=T_{b, d} \boldsymbol{f}$ with $\boldsymbol{f}$ defined as above. Then our approximation tool for univariate functions is defined as

$$
\Phi:=\left(\Phi_{n}\right)_{n \in \mathbb{N}}, \quad \Phi_{n}=\left\{\varphi \in \Phi_{b, d, S, \boldsymbol{r}}: d \in \mathbb{N}, \boldsymbol{r} \in \mathbb{N}^{d}, \operatorname{compl}(\varphi) \leq n\right\}
$$

where $\operatorname{compl}(\varphi)$ is some measure of complexity of a function $\varphi$, defined as

$$
\operatorname{compl}(\varphi):=\min \left\{\operatorname{compl}(\mathbf{v}): \mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v})=\varphi, d \in \mathbb{N}, \boldsymbol{r} \in \mathbb{N}^{d}\right\}
$$

where the infimum is taken over all tensor networks $\mathbf{v}$ whose realization is the function $\varphi$. We introduce three different measures of complexity

$$
\begin{aligned}
\operatorname{compl}_{\mathcal{N}}(\mathbf{v}) & :=\sum_{\nu=1}^{d} r_{\nu} \\
\operatorname{compl}_{\mathcal{C}}(\mathbf{v}) & :=b r_{1}+b \sum_{k=2}^{d} r_{k-1} r_{k}+r_{d} \operatorname{dim} S \\
\operatorname{compl}_{\mathcal{S}}(\mathbf{v}) & :=\sum_{\nu=1}^{d+1}\left\|v_{\nu}\right\|_{\ell_{0}}
\end{aligned}
$$

where $\left\|v_{\nu}\right\|_{\ell_{0}}$ is the number of non-zero entries in the tensor $v_{\nu}$. Consequently, this defines three types of subsets

$$
\begin{aligned}
\Phi_{n}^{\mathcal{N}} & :=\left\{\varphi \in \Phi: \operatorname{compl}_{\mathcal{N}}(\varphi) \leq n\right\}, \\
\Phi_{n}^{\mathcal{C}} & :=\left\{\varphi \in \Phi: \operatorname{compl}_{\mathcal{C}}(\varphi) \leq n\right\}, \\
\Phi_{n}^{\mathcal{S}} & :=\left\{\varphi \in \Phi: \operatorname{compl}_{\mathcal{S}}(\varphi) \leq n\right\} .
\end{aligned}
$$

Complexity measures $\operatorname{compl}_{\mathcal{C}}$ and $\operatorname{compl}_{\mathcal{N}}$ are related to the TT-ranks of the tensor $T_{b, d(\varphi)} \varphi$, where $d(\varphi)$ is the minimal $d$ such that $\varphi \in V_{b, d, S}$. The function compl $\mathcal{C}_{\mathcal{C}}$ is a natural measure of complexity which corresponds to the dimension of the parameter space. The function $\operatorname{compl}_{\mathcal{S}}$ is also a natural measure of complexity which counts the number of non-zero parameters. When interpreting a tensor network $\mathbf{v}$ as a sum-product neural network, $\operatorname{compl}_{\mathcal{N}}(\mathbf{v})$ corresponds to the number of neurons, $\operatorname{compl}_{\mathcal{C}}(\mathbf{v})$ to the number of weights, and $\operatorname{compl}_{\mathcal{S}}(\mathbf{v})$ the number of non-zero weights (or connections).

We use $\Phi_{n} \in\left\{\Phi_{n}^{\mathcal{N}}, \Phi_{n}^{\mathcal{C}}, \Phi_{n}^{\mathcal{S}}\right\}$ and the corresponding best approximation error

$$
E_{n}(f)_{p}:=\inf _{\varphi \in \Phi_{n}}\|f-\varphi\|_{p}
$$

for functions $f$ in $L^{p}([0,1))$ to define approximation classes

$$
\left.A_{q}^{\alpha}:=A_{q}^{\alpha}\left(L^{p},\left(\Phi_{n}\right)_{n \in \mathbb{N}}\right)\right):=\left\{f \in L^{p}([0,1)):\|f\|_{A_{q}^{\alpha}}<\infty\right\}
$$

for $\alpha>0$ and $0<q \leq \infty$, where

$$
\|f\|_{A_{q}^{\alpha}}:= \begin{cases}\left(\sum_{n=1}^{\infty}\left[n^{\alpha} E_{n-1}(f)\right]^{q} \frac{1}{n}\right)^{1 / q}, & 0<q<\infty \\ \sup _{n \geq 1}\left[n^{\alpha} E_{n-1}(f)\right], & q=\infty\end{cases}
$$

For the three approximation classes

$$
\begin{aligned}
N_{q}^{\alpha}(X) & :=A_{q}^{\alpha}\left(X,\left(\Phi_{n}^{\mathcal{N}}\right)_{n \in \mathbb{N}}\right) \\
C_{q}^{\alpha}(X) & :=A_{q}^{\alpha}\left(X,\left(\Phi_{n}^{\mathcal{C}}\right)_{n \in \mathbb{N}}\right) \\
S_{q}^{\alpha}(X) & :=A_{q}^{\alpha}\left(X,\left(\Phi_{n}^{\mathcal{S}}\right)_{n \in \mathbb{N}}\right)
\end{aligned}
$$

we obtain the main result of this part I given by Theorems 3.17 and 3.19 .
Main Result 1.3. For any $\alpha>0,0<p \leq \infty$ and $0<q \leq \infty$, the classes $N_{q}^{\alpha}\left(L^{p}\right), C_{q}^{\alpha}\left(L^{p}\right)$ and $S_{q}^{\alpha}\left(L^{p}\right)$ are quasi-normed vector spaces and satisfy the continuous embeddings

$$
C_{q}^{\alpha}\left(L^{p}\right) \hookrightarrow S_{q}^{\alpha}\left(L^{p}\right) \hookrightarrow N_{q}^{\alpha}\left(L^{p}\right) \hookrightarrow C_{q}^{\alpha / 2}\left(L^{p}\right)
$$

1.6. Outline. In Section2, we discuss how one-dimensional functions can be identified with tensors and analyze some basic properties of this identification. In Section 3, we introduce our approximation tool, briefly review general results from approximation theory, and analyze several approximation classes of rank-structured functions. In particular, we show that these classes are quasi-normed linear spaces. We conclude in Section 4 by a brief discussion on how tensorization can be viewed as a particular featuring step and tensor networks as a particular neural network with features as input variables.

## 2. Tensorization of Functions

We begin by introducing how one-dimensional functions can be identified with tensors of arbitrary dimension. We then introduce finite-dimensional subspaces of tensorized functions and show that these form a hierarchy of subspaces that are dense in $L^{p}$. This will be the basis for our approximation tool in Section 3 .

### 2.1. The Tensorization Map. Consider one-dimensional functions on the unit interval

$$
f:[0,1) \rightarrow \mathbb{R}
$$

We tensorize such functions by encoding the input variable $x \in[0,1)$ as follows. Let $b \in \mathbb{N}$ be the base and $d \in \mathbb{N}$ the level. We introduce a uniform partition of $[0,1)$ with $b^{d}$ intervals $\left[x_{i}, x_{i+1}\right)$ with $x_{i}=b^{-d} i, 0 \leq i \leq b^{d}$. An integer $i \in\left\{0, \ldots, b^{d}-1\right\}$ admits a representation $\left(i_{1}, \ldots, i_{d}\right)$ in base $b$ such that

$$
i=\sum_{k=1}^{d} i_{k} b^{d-k}
$$

where $i_{k} \in\{0, \ldots, b-1\}:=I_{b}$. We define a conversion map $t_{b, d}$ from $I_{b}^{d} \times[0,1)$ to $[0,1)$ defined by

$$
t_{b, d}\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k=1}^{d} i_{k} b^{-k}+b^{-d} y
$$

For any $x \in[0,1)$, there exists a unique $\left(i_{1}, \ldots, i_{d}, y\right) \in I_{b}^{d} \times[0,1)$ such that $t_{b, d}\left(i_{1}, \ldots, i_{d}, y\right)=x$, where $\left(i_{1}, \ldots, i_{d}\right)$ is the representation of $\left\lfloor b^{d} x\right\rfloor$ in base $b$ and $y=b^{d} x-\left\lfloor b^{d} x\right\rfloor$. We therefore deduce the following property.

Lemma 2.1. The conversion map $t_{b, d}$ defines a linear bijection from the set $I_{b}^{d} \times[0,1)$ to the interval $[0,1)$, with inverse defined for $x \in[0,1)$ by

$$
t_{b, d}^{-1}(x)=\left(\lfloor b x\rfloor,\left\lfloor b^{2} x\right\rfloor \bmod b, \ldots,\left\lfloor b^{d} x\right\rfloor \bmod b, b^{d} x-\left\lfloor b^{d} x\right\rfloor\right)
$$

Definition 2.2 (Tensorization Map). We define the tensorization map

$$
T_{b, d}: \mathbb{R}^{[0,1)} \rightarrow \mathbb{R}^{I_{b}^{d} \times[0,1)}, \quad f \mapsto f \circ t_{b, d}:=f
$$

which associates to a function $f \in \mathbb{R}^{[0,1)}$ the multivariate function $\boldsymbol{f} \in \mathbb{R}^{I_{b}^{d} \times[0,1)}$ such that

$$
\boldsymbol{f}\left(i_{1}, \ldots, i_{d}, y\right):=f\left(t_{b, d}\left(i_{1}, \ldots, i_{d}, y\right)\right)
$$

From Lemma 2.1, we directly deduce the following property of $T_{b, d}$.
Proposition 2.3. The tensorization map $T_{b, d}$ is a linear bijection from $\mathbb{R}^{[0,1)}$ to $\mathbb{R}^{I_{b}^{d} \times[0,1)}$, with inverse given for $\boldsymbol{f} \in \mathbb{R}^{I_{b}^{d} \times[0,1)}$ by $T_{b, d}^{-1} \boldsymbol{f}=\boldsymbol{f} \circ t_{b, d}^{-1}$.

The space $\mathbb{R}^{I_{b}^{d} \times[0,1)}$ can be identified with the algebraic tensor space

$$
\mathbf{V}_{b, d}:=\mathbb{R}^{I_{b}^{d}} \otimes \mathbb{R}^{[0,1)}=\underbrace{\mathbb{R}^{I_{b}} \otimes \ldots \otimes \mathbb{R}^{I_{b}}}_{d \text { times }} \otimes \mathbb{R}^{[0,1)}=:\left(\mathbb{R}^{I_{b}}\right)^{\otimes d} \otimes \mathbb{R}^{[0,1)}
$$

which is the set of functions $\boldsymbol{f}$ defined on $I_{b}^{d} \times[0,1)$ that admit a representation

$$
\begin{equation*}
\boldsymbol{f}\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k=1}^{r} v_{1}^{k}\left(i_{1}\right) \ldots v_{d}^{k}\left(i_{d}\right) g^{k}(y):=\sum_{k=1}^{r}\left(v_{1}^{k} \otimes \ldots \otimes v_{d}^{k} \otimes g^{k}\right)\left(i_{1}, \ldots, i_{d}, y\right) \tag{2.1}
\end{equation*}
$$

for some $r \in \mathbb{N}$ and for some functions $v_{\nu}^{k} \in \mathbb{R}^{I_{b}}$ and $g^{k} \in \mathbb{R}^{[0,1)}, 1 \leq k \leq r, 1 \leq \nu \leq d$. Letting $\left\{\delta_{j_{\nu}}: j_{\nu} \in I_{b}\right\}$ be the canonical basis of $\mathbb{R}^{I_{b}}$, defined by $\delta_{j_{\nu}}\left(i_{\nu}\right)=\delta_{i_{\nu}, j_{\nu}}$, a function $\boldsymbol{f} \in \mathbb{R}^{I_{b}^{d} \times[0,1)}$ admits the particular representation

$$
\begin{equation*}
\boldsymbol{f}=\sum_{j_{1} \in I_{b}} \ldots \sum_{j_{d} \in I_{b}} \delta_{j_{1}} \otimes \ldots \otimes \delta_{j_{d}} \otimes \boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right) \tag{2.2}
\end{equation*}
$$

The following result provides an interpretation of the above representation.

Lemma 2.4. Let $f \in \mathbb{R}^{[0,1)}$ and $\boldsymbol{f}=T_{b, d} f \in \mathbf{V}_{b, d}$. For $\left(j_{1}, \ldots, j_{d}\right) \in I_{b}^{d}$ and $j=\sum_{k=1}^{d} j_{k} b^{d-k}$, it holds

$$
\begin{equation*}
T_{b, d}\left(f \mathbb{1}_{\left[b^{-d} j, b^{-d}(j+1)\right)}\right)=\delta_{j_{1}} \otimes \ldots \otimes \delta_{j_{d}} \otimes \boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right), \tag{2.3}
\end{equation*}
$$

and

$$
\begin{equation*}
\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)=f\left(b^{-d}(j+\cdot)\right) \tag{2.4}
\end{equation*}
$$

where $f\left(b^{-d}(j+\cdot)\right)$ is the restriction of $f$ to the interval $\left[b^{-d} j, b^{-d}(j+1)\right)$ rescaled to $[0,1)$.
Proof. For $x=t_{b, d}\left(i_{1}, \ldots, i_{d}, y\right)$,

$$
\begin{aligned}
f(x) \mathbb{1}_{\left[b^{-d} j, b^{-d}(j+1)\right)}(x) & =\delta_{j_{1}}\left(i_{1}\right) \ldots \delta_{j_{d}}\left(i_{d}\right) f\left(t_{b, d}\left(i_{1}, \ldots, i_{d}, y\right)\right) \\
& =\delta_{j_{1}}\left(i_{1}\right) \ldots \delta_{j_{d}}\left(i_{d}\right) f\left(t_{b, d}\left(j_{1}, \ldots, j_{d}, y\right)\right) \\
& =\delta_{j_{1}}\left(i_{1}\right) \ldots \delta_{j_{d}}\left(i_{d}\right) \boldsymbol{f}\left(j_{1}, \ldots, j_{d}, y\right) .
\end{aligned}
$$

The property (2.4) simply results from the definition of $\boldsymbol{f}$.
From Lemma 2.4, we deduce that the representation (2.2) corresponds to the decomposition of $f=T_{b, d}^{-1}(\boldsymbol{f})$ as a superposition of functions with disjoint supports,

$$
\begin{equation*}
f(x)=\sum_{j=0}^{b^{d}-1} f_{j}(x), \quad f_{j}(x)=\mathbb{1}_{\left[b^{-d} j, b^{-d}(j+1)\right)}(x) f(x), \tag{2.5}
\end{equation*}
$$

where $f_{j}$ is the function supported on the interval $\left[b^{-d} j, b^{-d}(j+1)\right)$ and equal to $f$ on this interval. Also, Lemma 2.4 yields the following result.

Corollary 2.5. A function $f \in \mathbb{R}^{[0,1)}$ defined by

$$
f(x)= \begin{cases}g\left(b^{d} x-j\right) & \text { for } x \in\left[b^{-d} j, b^{-d}(j+1)\right) \\ 0 & \text { elsewhere }\end{cases}
$$

with $g \in \mathbb{R}^{[0,1)}$ and $0 \leq j<b^{d}$ admits a tensorization $T_{b, d} f=\delta_{j_{1}} \otimes \ldots \otimes \delta_{j_{d}} \otimes g$, which is an elementary tensor.

We now provide a useful result on compositions of tensorization maps for changing the representation level of a function.
Lemma 2.6. Let $\bar{d}, d \in \mathbb{N}$ such that $\bar{d}>d$. For any $\left(i_{1}, \ldots, i_{\bar{d}}, y\right) \in I_{b}^{\bar{d}} \times[0,1)$, it holds

$$
t_{b, \bar{d}}\left(i_{1}, \ldots, i_{\bar{d}}, y\right)=t_{b, d}\left(i_{1}, \ldots, i_{d}, t_{b, \bar{d}-d}\left(i_{d+1}, \ldots, i_{\bar{d}}, y\right)\right),
$$

and the operator $T_{b, \bar{d}} \circ T_{b, d}^{-1}$ from $\mathbf{V}_{b, d}$ to $\mathbf{V}_{b, \bar{d}}$ is such that

$$
T_{b, \bar{d}} \circ T_{b, d}^{-1}=i d_{\{1, \ldots, d\}} \otimes T_{b, \bar{d}-d}
$$

where $i d_{\{1, \ldots, d\}}$ is the identity operator on $\mathbb{R}_{b}^{I_{b}^{d}}$ and $T_{b, \bar{d}-d}$ is the tensorization map from $\mathbb{R}^{[0,1)}$ to $\mathbf{V}_{b, \bar{d}-d}$. Also, the operator $T_{b, d} \circ T_{b, \bar{d}}^{-1}$ from $\mathbf{V}_{b, \bar{d}}$ to $\mathbf{V}_{b, d}$ is such that

$$
T_{b, d} \circ T_{b, \bar{d}}^{-1}=i d_{\{1, \ldots, d\}} \otimes T_{b, \bar{d}-d}^{-1}
$$

Proof. See Appendix A.
For $d=0$, we adopt the conventions that $t_{b, 0}$ is the identity on $[0,1), T_{b, 0}$ is the identity operator on $\mathbb{R}^{[0,1)}$, and $\mathbf{V}_{b, 0}=\mathbb{R}^{[0,1)}$.
2.2. Ranks and Minimal Subspaces. The minimal integer $r$ such that $\boldsymbol{f} \in \mathbf{V}_{b, d}$ admits a representation of the form (2.1) is the canonical tensor rank of $\boldsymbol{f}$ denoted $r(\boldsymbol{f})$. We deduce from the representation (2.2) that

$$
r(\boldsymbol{f}) \leq b^{d} .
$$

Other notions of ranks can be defined from the classical notion of rank by identifying a tensor with a tensor of order two (through unfolding). Letting $V_{\nu}:=\mathbb{R}^{I_{b}}$ for $1 \leq \nu \leq d$, and $V_{d+1}:=\mathbb{R}^{[0,1)}$, we have

$$
\mathbf{V}_{b, d}=\bigotimes_{8^{\nu=1}}^{d+1} V_{\nu}
$$

Then for any $\beta \subset\{1, \ldots, d+1\}$ and its complementary set $\beta^{c}=\{1, \ldots, d+1\} \backslash \beta$, a tensor $\boldsymbol{f} \in \mathbf{V}_{b, d}$ can be identified with an order-two tensor in $\mathbf{V}_{\beta} \otimes \mathbf{V}_{\beta^{c}}$, where $\mathbf{V}_{\gamma}=\bigotimes_{\nu \in \gamma} V_{\nu}$, called the $\beta$-unfolding of $\boldsymbol{f}$. This allows us to define the notion of $\beta$-rank.

Definition 2.7 ( $\beta$-rank). For $\beta \subset\{1, \ldots, d+1\}$, the $\beta$-rank of $\boldsymbol{f} \in \mathbf{V}_{b, d}$, denoted $r_{\beta}(\boldsymbol{f})$, is the minimal integer such that $\boldsymbol{f}$ admits a representation of the form

$$
\begin{equation*}
\boldsymbol{f}=\sum_{k=1}^{r_{\beta}(\boldsymbol{f})} \boldsymbol{v}_{\beta}^{k} \otimes \boldsymbol{v}_{\beta^{c}}^{k} \tag{2.6}
\end{equation*}
$$

where $\boldsymbol{v}_{\beta}^{k} \in \mathbf{V}_{\beta}$ and $\boldsymbol{v}_{\beta^{c}}^{k} \in \mathbf{V}_{\beta^{c}}$.
Since $\mathbf{V}_{b, d}$ is an algebraic tensor space, the $\beta$-rank is finite and we have $r_{\beta}(\boldsymbol{f}) \leq r(\boldsymbol{f})$ (though the $\beta$-rank can be much smaller). Moreover, we have the following straightforward property

$$
r_{\beta}(\boldsymbol{f})=r_{\beta^{c}}(\boldsymbol{f})
$$

and the bound

$$
\begin{equation*}
r_{\beta}(\boldsymbol{f}) \leq \min \left\{\prod_{\nu \in \beta} \operatorname{dim} V_{\nu}, \prod_{\nu \in \beta^{c}} \operatorname{dim} V_{\nu}\right\} \tag{2.7}
\end{equation*}
$$

which can be useful for small $b$ and either very small or very large $\# \beta$.
Representation (2.6) is not unique but the space spanned by the $\boldsymbol{v}_{k}^{\beta}$ is unique and corresponds to the $\beta$-minimal subspace of $\boldsymbol{f}$.

Definition 2.8 ( $\beta$-minimal subspace). For $\beta \subset\{1, \ldots, d+1\}$, the $\beta$-minimal subspace of $\boldsymbol{f}$, denoted $U_{\beta}^{\min }(\boldsymbol{f})$, is the smallest subspace $\mathbf{U}_{\beta} \subset \mathbf{V}_{\beta}$ such that $\boldsymbol{f} \in \mathbf{U}_{\beta} \otimes \mathbf{V}_{\beta^{c}}$, and its dimension is

$$
\operatorname{dim}\left(U_{\beta}^{\min }(\boldsymbol{f})\right)=r_{\beta}(\boldsymbol{f})
$$

We have the following useful characterization of minimal subspaces from partial evaluations of a tensor.

Lemma 2.9. For $\beta \subset\{1, \ldots, d\}$ and $\boldsymbol{f} \in \mathbf{V}_{b, d}$,

$$
U_{\beta^{c}}^{\min }(\boldsymbol{f})=\operatorname{span}\left\{\boldsymbol{f}\left(j_{\beta}, \cdot\right): j_{\beta} \in I_{b}^{\# \beta}\right\} \subset \mathbf{V}_{b, d-\# \beta}
$$

where $\boldsymbol{f}\left(j_{\beta}, \cdot\right) \in \mathbf{V}_{\beta^{c}}=\mathbf{V}_{b, d-\# \beta}$ is a partial evaluation of $\boldsymbol{f}$ along dimensions $\nu \in \beta$.

## Proof. See Appendix A.

Next we define a notion of $(\beta, d)$-rank for univariate functions in $\mathbb{R}^{[0,1)}$.
Definition $2.10\left((\beta, d)\right.$-rank). For a function $f \in \mathbb{R}^{[0,1)}, d \in \mathbb{N}$ and $\beta \subset\{1, \ldots, d+1\}$, we define the $(\beta, d)$-rank of $f$, denoted $r_{\beta, d}(f)$, as the $\beta$-rank of its tensorization in $\mathbf{V}_{b, d}$,

$$
r_{\beta, d}(f)=r_{\beta}\left(T_{b, d} f\right)
$$

In the rest of this work, we will essentially consider subsets $\beta$ of the form $\{1, \ldots, \nu\}$ or $\{\nu+1, \ldots, d+1\}$ for some $\nu \in\{1, \ldots, d\}$. For the corresponding $\beta$-ranks, we will use the shorthand notations

$$
r_{\nu}(\boldsymbol{f}):=r_{\{1, \ldots, \nu\}}(\boldsymbol{f}), \quad r_{\nu, d}(f)=r_{\{1, \ldots, \nu\}, d}(f)
$$

Note that $r_{\nu}(\boldsymbol{f})$ should not be confused with $r_{\{\nu\}}(\boldsymbol{f})$. The ranks $\left(r_{\nu}(\boldsymbol{f})\right)_{1 \leq \nu \leq d}$ of a tensor $\boldsymbol{f} \in \mathbf{V}_{b, d}$ have to satisfy some relations, as seen in the next lemma.

Lemma 2.11 (Ranks Admissibility Conditions). Let $\boldsymbol{f}=\mathbf{V}_{b, d}$. For any set $\beta \subset\{1, \ldots, d+1\}$ and any partition $\beta=\gamma \cup \alpha$, we have

$$
r_{\beta}(\boldsymbol{f}) \leq r_{\gamma}(\boldsymbol{f}) r_{\alpha}(\boldsymbol{f})
$$

and in particular

$$
\begin{equation*}
r_{\nu+1}(\boldsymbol{f}) \leq b r_{\nu}(\boldsymbol{f}) \quad \text { and } \quad r_{\nu}(\boldsymbol{f}) \leq b r_{\nu+1}(\boldsymbol{f}), \quad 1 \leq \nu \leq d-1 \tag{2.8}
\end{equation*}
$$

Proof. See Appendix A.
A function $f$ admits infinitely many tensorizations of different levels. The following result provides a relation between minimal subspaces.

Lemma 2.12. Consider a function $f \in \mathbb{R}^{[0,1)}$ and its tensorization $\boldsymbol{f}^{d}=T_{b, d} f$ at level $d$. For any $1 \leq \nu \leq d$,

$$
T_{b, d-\nu}^{-1}\left(U_{\{\nu+1, \ldots, d+1\}}^{\min }\left(\boldsymbol{f}^{d}\right)\right)=\operatorname{span}\left\{\boldsymbol{f}^{\nu}\left(j_{1}, \ldots, j_{\nu}, \cdot\right):\left(j_{1}, \ldots, j_{\nu}\right) \in I_{b}^{\nu}\right\}=U_{\{\nu+1\}}^{\min }\left(\boldsymbol{f}^{\nu}\right)
$$

where $\boldsymbol{f}^{\nu}=T_{b, \nu} f$ is the tensorization of $f$ at level $\nu$.
Proof. See Appendix A.

For $j=\sum_{k=1}^{\nu} j_{k} b^{\nu-k}$, since $\boldsymbol{f}^{\nu}\left(j_{1}, \ldots, j_{\nu}, \cdot\right)=f\left(b^{-\nu}(j+\cdot)\right)$ is the restriction of $f$ to the interval $\left[b^{-\nu} j, b^{-\nu}(j+1)\right)$ rescaled to $[0,1)$, Lemma 2.12 provides a simple interpretation of minimal subspace $U_{\{\nu+1\}}^{\min }\left(f^{\nu}\right)$ as the linear span of contiguous pieces of $f$ rescaled to $[0,1)$, see the illustration in Figure 3 .

(A) Function $f:[0,1) \rightarrow \mathbb{R}$

(в) Partial evaluations $\boldsymbol{f}^{\nu}\left(j_{1}, j_{2}, \cdot\right)$ for $\left(j_{1}, j_{2}\right) \in\{0,1\}^{2}$.

Figure 3. A function $f:[0,1) \rightarrow \mathbb{R}$ and partial evaluations of $\boldsymbol{f}^{\nu} \in \mathbf{V}_{b, d}$ for $b=d=2$.

Corollary 2.13. Let $f \in \mathbb{R}^{[0,1)}$ and $d \in \mathbb{N}$. For any $1 \leq \nu \leq d$,

$$
r_{\nu, d}(f)=r_{\nu, \nu}(f)
$$

and

$$
r_{\nu, \nu}(f)=\operatorname{dim} \operatorname{span}\left\{f\left(b^{-\nu}(j+\cdot)\right): 0 \leq j \leq b^{\nu}-1\right\}
$$

Proof. It holds

$$
r_{\nu, d}(f)=r_{\{1, \ldots, \nu\}}\left(\boldsymbol{f}^{d}\right)=r_{\{\nu+1, \ldots, d+1\}}\left(\boldsymbol{f}^{d}\right)=\operatorname{dim} U_{\{\nu+1, \ldots, d+1\}}^{\min }\left(\boldsymbol{f}^{d}\right)
$$

and

$$
r_{\nu, \nu}(f)=r_{\{1, \ldots, \nu\}}\left(\boldsymbol{f}^{\nu}\right)=r_{\nu+1}\left(\boldsymbol{f}^{\nu}\right)=\operatorname{dim} U_{\{\nu+1\}}^{\min }\left(\boldsymbol{f}^{\nu}\right)
$$

Lemma 2.12 then implies that $r_{\nu, d}(f)=r_{\nu, \nu}(f)$ and provides the characterization from the linear span of $\boldsymbol{f}^{\nu}\left(j_{1}, \ldots, j_{\nu}, \cdot\right)=f\left(b^{-\nu}(j+\cdot)\right)$, with $j=\sum_{k=1}^{\nu} j_{k} b^{\nu-k}$, which is linearly identified with the restriction $f_{\mid\left[b^{-\nu} j, b^{-\nu}(j+1)\right)}$ shifted and rescaled to $[0,1)$.
2.3. Measures, Lebesgue and Smoothness Spaces. We now look at $T_{b, d}$ as a linear map between spaces of measurable functions, by equipping the interval $[0,1)$ with the Lebesgue measure.

Proposition 2.14. The Lebesgue measure $\lambda$ on $[0,1)$ is the push-forward measure through the map $t_{b, d}$ of the product measure $\mu_{b, d}:=\mu_{b}^{\otimes d} \otimes \lambda$, where $\mu_{b}$ is the uniform probability measure on $I_{b}$. Then the tensorization map $T_{b, d}$ defines a linear isomorphism from the space of measurable functions $\mathbb{R}^{[0,1)}$ to the space of measurable functions $\mathbb{R}^{I_{b}^{d} \times[0,1)}$, where $[0,1)$ is equipped with the Lebesgue measure and $I_{b}^{d} \times[0,1)$ is equipped with the product measure $\mu_{b, d}$.
Proof. See Appendix A.
2.3.1. Lebesgue Spaces. For $0<p \leq \infty$, we consider the Lebesgue space $L^{p}([0,1))$ of functions defined on $[0,1)$ equipped with its standard (quasi-)norm. Then we consider the algebraic tensor space

$$
\mathbf{V}_{b, d, L^{p}}:=\mathbb{R}^{I_{b} \otimes d} \otimes L^{p}([0,1)) \subset \mathbf{V}_{b, d}
$$

which is the space of multivariate functions $\boldsymbol{f}$ on $I_{b}^{d} \times[0,1)$ with partial evaluations $\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right) \in$ $L^{p}([0,1))$. From hereon we frequently abbreviate $L^{p}:=L^{p}([0,1))$.

Theorem 2.15 (Tensorization is an $L^{p}$-Isometry). For any $0<p \leq \infty, T_{b, d}$ is a linear isometry from $L^{p}([0,1))$ to $\mathbf{V}_{b, d, L^{p}}$ equipped with the (quasi-) norm $\|\cdot\|_{p}$ defined by

$$
\|\boldsymbol{f}\|_{p}^{p}=\sum_{j_{1} \in I_{b}} \ldots \sum_{j_{d} \in I_{b}} b^{-d}\left\|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right\|_{p}^{p}
$$

for $p<\infty$, or

$$
\|\boldsymbol{f}\|_{\infty}=\max _{j_{1} \in I_{b}} \ldots \max _{j_{d} \in I_{b}}\left\|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right\|_{\infty}
$$

Proof. The results follows from Proposition 2.14 and by noting that for $\boldsymbol{f}=T_{b, d} f=f \circ t_{b, d}$,

$$
\|f\|_{p}^{p}=\int_{[0,1)}|f(x)|^{p} d \lambda(x)=\int_{I_{b}^{d} \times[0,1)}\left|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, y\right)\right|^{p} d \mu_{b, d}\left(j_{1}, \ldots, j_{d}, y\right)=\|\boldsymbol{f}\|_{p}^{p}
$$

for $p<\infty$, and $\|f\|_{\infty}=\operatorname{ess} \sup _{x}|f(x)|=\operatorname{ess} \sup _{\left(j_{1}, \ldots, j_{d}, y\right)}\left|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, y\right)\right|=\|\boldsymbol{f}\|_{\infty}$.
We denote by $\ell^{p}\left(I_{b}\right)$ the space $\mathbb{R}^{I_{b}}$ equipped with the (quasi-) norm $\|\cdot\|_{\ell^{p}}$ defined for $v=\left(v_{k}\right)_{k \in I_{b}}$ by

$$
\|v\|_{\ell^{p}}^{p}:=b^{-1} \sum_{k=0}^{b-1}\left|v_{k}\right|^{p} \quad(p<\infty), \quad\|v\|_{\ell^{\infty}}:=\max _{0 \leq k \leq b-1}\left|v_{k}\right| .
$$

The space $\mathbf{V}_{b, d, L^{p}}$ can then be identified with the algebraic tensor space

$$
\left(\ell^{p}\left(I_{b}\right)\right)^{\otimes d} \otimes L^{p}([0,1))
$$

and $\|\cdot\|_{p}$ is a crossnorm, i.e., satisfying for an elementary tensor $v^{1} \otimes \ldots \otimes v^{d+1} \in \mathbf{V}_{b, d, L^{p}}$,

$$
\left\|v^{1} \otimes \ldots \otimes v^{d+1}\right\|_{p}=\left\|v^{1}\right\|_{\ell^{p}} \ldots\left\|v^{d}\right\|_{\ell^{p}}\left\|v^{d+1}\right\|_{p}
$$

and even a reasonable crossnorm for $1 \leq p \leq \infty$ (see Lemma A.1 in the appendix). We let $\left\{e_{k}^{p}\right\}_{k \in I_{b}}$ denote the normalized canonical basis of $\ell^{p}\left(I_{b}\right)$, defined by

$$
\begin{equation*}
e_{k}^{p}=b^{1 / p} \delta_{k} \text { for } 0<p<\infty, \quad \text { and } \quad e_{k}^{\infty}=\delta_{k} \text { for } p=\infty \tag{2.9}
\end{equation*}
$$

The tensorization $\boldsymbol{f}=T_{b, d} f$ of a function $f \in L^{p}([0,1))$ admits a representation

$$
\begin{equation*}
\boldsymbol{f}=\sum_{j_{1} \in I_{b}} \ldots \sum_{j_{d} \in I_{b}} e_{j_{1}}^{p} \otimes \ldots \otimes e_{j_{d}}^{p} \otimes f_{j_{1}, \ldots, j_{d}}^{p} \tag{2.10}
\end{equation*}
$$

with $f_{j_{1}, \ldots, j_{d}}^{p}=b^{-d / p} \boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)$ for $p<\infty$ and $f_{j_{1}, \ldots, j_{d}}^{\infty}=\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)$. The crossnorm property implies that

$$
\left\|e_{j_{1}}^{p} \otimes \ldots \otimes e_{j_{d}}^{p} \otimes f_{j_{1}, \ldots, j_{d}}^{p}\right\|_{p}=\left\|f_{j_{1}, \ldots, j_{d}}^{p}\right\|_{p}
$$

so that Theorem 2.15 implies

$$
\|f\|_{p}=\left(\sum_{\left(j_{1}, \ldots, j_{d}\right) \in I_{b}^{d}}\left\|f_{j_{1}, \ldots, j_{d}}^{p}\right\|_{p}^{p}\right)^{1 / p} \quad(p<\infty), \quad\|f\|_{\infty}=\max _{\left(j_{1}, \ldots, j_{d}\right) \in I_{b}^{d}}\left\|f_{j_{1}, \ldots, j_{d}}^{\infty}\right\|_{p}
$$

2.3.2. Sobolev Spaces. Now consider functions $f$ in the Sobolev space $W^{k, p}:=W^{k, p}([0,1))$, equipped with the (quasi-)norm

$$
\|f\|_{W^{k, p}}=\left(\|f\|_{p}^{p}+|f|_{W^{k, p}}^{p}\right)^{1 / p} \quad(p<\infty), \quad\|f\|_{W^{k, \infty}}=\max \left\{\|f\|_{p},|f|_{W^{k, \infty}}\right\}
$$

where $|f|_{W^{k, p}}$ is a (quasi-)semi-norm defined by

$$
|f|_{W^{k, p}}=\left\|D^{k} f\right\|_{p}
$$

with $D^{k} f:=f^{(k)}$ the $k$-th weak derivative of $f$. Since $f$ and its tensorization $\boldsymbol{f}=T_{b, d} f$ are such that $f(x)=\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, b^{d} x-j\right)$ for $x \in\left[b^{d} j, b^{d}(j+1)\right)$ and $j=\sum_{k=1}^{d} b^{d-k} j_{k}$, we deduce that

$$
D^{k} f(x)=b^{k d} \frac{\partial^{k}}{\partial y^{k}} \boldsymbol{f}\left(j_{1}, \ldots, j_{d}, b^{d} x-j\right)
$$

for $x \in\left[b^{d} j, b^{d}(j+1)\right)$, that means that $D^{k}$ can be identified with a rank-one operator over $\mathbf{V}_{b, d, L^{p}}$,

$$
T_{b, d} \circ D^{k} \circ T_{b, d}^{-1}=i d_{\{1, \ldots, d\}} \otimes\left(b^{k d} D^{k}\right)
$$

We deduce from Theorem 2.15 that for $f \in W^{k, p}$,

$$
|f|_{W^{k, p}}=\left\|D^{k} f\right\|_{p}=\left\|T_{b, d}\left(D^{k} f\right)\right\|_{p}=b^{k d}\left\|\left(i d_{\{1, \ldots, d\}} \otimes D^{k}\right) \boldsymbol{f}\right\|_{p}
$$

with

$$
\left(i d_{\{1, \ldots, d\}} \otimes D^{k}\right) \boldsymbol{f}=\sum_{j \in I_{b}^{d}} \delta_{j_{1}} \otimes \ldots \otimes \delta_{j_{d}} \otimes D^{k} \boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)
$$

Then we deduce that if $f \in W^{k, p}, \boldsymbol{f}=T_{b, d} f$ is in the algebraic tensor space

$$
\mathbf{V}_{b, d, W^{k, p}}:=\left(\mathbb{R}^{I_{b}}\right)^{\otimes d} \otimes W^{k, p}
$$

and

$$
|f|_{W^{k, p}}=b^{k d}\left\|\sum_{j_{1} \in I_{b}} \ldots \sum_{j_{d} \in I_{b}} \delta_{j_{1}} \otimes \ldots \otimes \delta_{j_{d}} \otimes D^{k} \boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right\|_{p}
$$

This implies that $T_{b, d} W^{k, p} \subset \mathbf{V}_{b, d, W^{k, p}}$ but $T_{b, d}^{-1}\left(\mathbf{V}_{b, d, W^{k, p}}\right) \not \subset W^{k, p}$. In fact, $T_{b, d}^{-1}\left(\mathbf{V}_{b, d, W^{k, p}}\right)=W^{k, p}\left(\mathcal{P}_{b, d}\right)$, the broken Sobolev space associated with the partition $\mathcal{P}_{b, d}=\left\{\left[b^{d} j, b^{d}(j+1)\right): 0 \leq j \leq b^{d}-1\right\}$. From the above considerations, we deduce

Theorem 2.16. For any $0<p \leq \infty$ and $k \in \mathbb{N}_{0}, T_{b, d}$ is a linear isometry from the broken Sobolev space $W^{k, p}\left(\mathcal{P}_{b, d}\right)$ to $\mathbf{V}_{b, d, W^{k, p}}$ equipped with the (quasi-) norm

$$
\|\boldsymbol{f}\|_{W^{k, p}}=\left(\|\boldsymbol{f}\|_{p}^{p}+|\boldsymbol{f}|_{W^{k, p}}^{p}\right)^{1 / p} \quad(p<\infty), \quad\|\boldsymbol{f}\|_{W^{k, \infty}}=\max \left\{\|\boldsymbol{f}\|_{\infty},|\boldsymbol{f}|_{W^{k, \infty}}\right\}
$$

where $|\cdot|_{W^{k, p}}$ is a (quasi-)semi-norm defined by

$$
|\boldsymbol{f}|_{W^{k, p}}^{p}:=b^{d(k p-1)} \sum_{\left(j_{1}, \ldots, j_{d}\right) \in I_{b}^{d}}\left|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right|_{W^{k, p}}^{p}
$$

for $p<\infty$, and

$$
|\boldsymbol{f}|_{W^{k, \infty}}^{\infty}:=b^{d k} \max _{\left(j_{1}, \ldots, j_{d}\right) \in I_{b}^{d}}\left|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right|_{W^{k, \infty}}
$$

2.3.3. Besov Spaces. Let $f \in L^{p}, 0<p \leq \infty$ and consider the difference operator

$$
\begin{aligned}
\Delta_{h} & : L^{p}([0,1)) \\
\Delta_{h}[f](\cdot) & :=f(\cdot+h)-f(\cdot)
\end{aligned}
$$

For $r=2,3, \ldots$, the $r$-th difference is defined as

$$
\Delta_{h}^{r}:=\Delta_{h} \circ \Delta_{h}^{r-1}
$$

with $\Delta_{h}^{1}:=\Delta_{h}$. The r-th modulus of smoothness is defined as

$$
\begin{equation*}
\omega_{r}(f, t)_{p}:=\sup _{0<h \leq t}\left\|\Delta_{h}^{r}[f]\right\|_{p}, \quad t>0 \tag{2.11}
\end{equation*}
$$

Definition 2.17 (Besov Spaces). For parameters $\alpha>0$ and $0<p, q \leq \infty$, define $r:=\lfloor\alpha\rfloor+1$ and the Besov (quasi-)semi-norm as

$$
|f|_{B_{p, q}^{\alpha}}:= \begin{cases}\left(\int_{0}^{1}\left[t^{-\alpha} \omega_{r}(f, t)_{p}\right]^{q} \frac{\mathrm{~d} t}{t}\right)^{1 / q}, & 0<q<\infty \\ \sup _{0<t \leq 1} t^{-\alpha} \omega_{r}(f, t)_{p}, & q=\infty\end{cases}
$$

The Besov (quasi-)norm is defined as

$$
\|f\|_{B_{p, q}^{\alpha}}:=\|f\|_{p}+|f|_{B_{p, q}^{\alpha}} .
$$

The Besov space is defined as

$$
B_{p, q}^{\alpha}:=\left\{f \in L^{p}:\|f\|_{B_{p, q}^{\alpha}}<\infty\right\} .
$$

As in Section 2.3.2. we would like to compare the Besov space $B_{p, q}^{\alpha}$ with the algebraic tensor space

$$
\mathbf{V}_{b, d, B_{p, q}^{\alpha}}:=\left(\mathbb{R}^{I_{b}}\right)^{\otimes d} \otimes B_{p, q}^{\alpha}
$$

First, we briefly elaborate how the Besov (quasi-)semi-norm scales under affine transformations of the interval. I.e., suppose we are given a function $f:[a, b) \rightarrow \mathbb{R}$ with $-\infty<a<b<\infty$ and a transformed $\bar{f}$ such that

$$
\bar{f}:[\bar{a}, \bar{b}) \rightarrow \mathbb{R}, \quad \bar{x} \mapsto x:=\frac{b-a}{\bar{b}-\bar{a}}(\bar{x}-\bar{a})+a \mapsto f(x)=\bar{f}(\bar{x}),
$$

for $-\infty<\bar{a}<\bar{b}<\infty$. Then,

$$
\begin{aligned}
\Delta_{h}^{r}[\bar{f}]: & {[\bar{a}, \bar{b}-r \bar{h}) \rightarrow \mathbb{R}, } \\
\Delta_{\bar{h}}^{r}[\bar{f}](\bar{x}) & =\sum_{k=0}^{r}\binom{r}{k}(-1)^{r-k} \bar{f}(\bar{x}+k \bar{h})=\sum_{k=0}^{r}\binom{r}{k}(-1)^{r-k} f(x+k h)=\Delta_{h}^{r}[f](x)
\end{aligned}
$$

with

$$
h:=\frac{b-a}{\bar{b}-\bar{a}} \bar{h} .
$$

For $0<p<\infty$, we obtain for the modulus of smoothness

$$
\omega_{r}(\bar{f}, \bar{t})_{p}^{p}=\frac{\bar{b}-\bar{a}}{b-a} \omega_{r}(f, t)_{p}^{p}, \quad t:=\frac{b-a}{\bar{b}-\bar{t}} \bar{t},
$$

and for $p=\infty, \omega_{r}(\bar{f}, \bar{t})_{\infty}=\omega_{r}(f, t)_{\infty}$. Finally, for the Besov (quasi-)semi-norm this implies

$$
\begin{aligned}
& |\bar{f}|_{B_{p, q}^{\alpha}}=\left(\frac{\bar{b}-\bar{a}}{b-a}\right)^{1 / p-\alpha}|f|_{B_{p, q}^{\alpha}}, \quad 0<q \leq \infty, 0<p<\infty, \\
& |\bar{f}|_{B_{p, q}^{\alpha}}=\left(\frac{\bar{b}-\bar{a}}{b-a}\right)^{-\alpha}|f|_{B_{p, q}^{\alpha},}, \quad 0<q \leq \infty, p=\infty .
\end{aligned}
$$

With this scaling at hand, for $p<\infty$, what remains is "adding up" Besov (quasi-)norms of partial evaluations $\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)$. The modulus of smoothness from (2.11) is not suitable for this task. Instead, we can use an equivalent measure of smoothness via the averaged modulus of smoothness (see [14, §5 of Chapter 6 and $\S 5$ of Chapter 12])

$$
\mathrm{w}_{r}(f, t)_{p}^{p}:=\frac{1}{t} \int_{0}^{t}\left\|\Delta_{h}^{r}[f]\right\|_{p}^{p} \mathrm{~d} h, \quad 0<p<\infty
$$

With this definition of Besov norm, we can define a (quasi-)semi-norm

$$
|f|_{B_{p, q}^{\alpha}}=\left(\int_{0}^{1}\left[t^{-\alpha} \mathrm{w}_{r}(f, t)_{p}\right]^{q} \frac{\mathrm{~d} t}{t}\right)^{1 / q}, \quad 0<q<\infty
$$

which is equivalent to the former one and therefore results in the same Besov space $B_{p, q}^{\alpha}$. Expanding the right-hand-side and interchanging the order of integration allows us to add up the contributions to $|f|_{B_{p, q}^{\alpha} \text {. }}$ over the intervals $\left[b^{d} j, b^{d}(j+1)\right)$, provided that $q=p$. However, note that this is not the same as summing over $\left|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right|_{B_{p, q}^{\alpha}}$, since the latter necessarily omits the contributions of $\left|\Delta_{h}^{r}[f]\right|$ across the right boundaries of the intervals $\left[b^{d} j, b^{d}(j+1)\right)$.

Example 2.18. Consider the function

$$
f(x):= \begin{cases}1, & 0 \leq x \leq 1 / 2 \\ 0, & \text { otherwise }\end{cases}
$$

Take $0<\alpha<1$ and $r=1$ in Definition 2.17. The first difference is then

$$
\Delta_{h}[f](x)= \begin{cases}1, & 1 / 2-h<x \leq 1 / 2 \\ 0, & \text { otherwise }\end{cases}
$$

For $0<p<\infty$,

$$
\left\|\Delta_{h}[f]\right\|_{p}^{p}=h
$$

and for $p=\infty$,

$$
\left\|\Delta_{h}[f]\right\|_{\infty}=1
$$

Thus, for the ordinary modulus of smoothness we obtain

$$
\begin{aligned}
\omega_{r}(f, t)_{p} & =t^{1 / p}, \quad 0<p<\infty, \\
\omega_{r}(f, t)_{\infty} & =1 .
\end{aligned}
$$

Inserting this into Definition 2.17, we see that $f \in B_{p, q}^{\alpha}$ if and only if $p \neq \infty$ and $0<\alpha<1 / p$. In this case $0<|f|_{B_{p, q}^{\alpha}}<\infty$.

On the other hand, for $b=2$ and $d=1$, the partial evaluations of the tensorization $T_{2,1} f$ are the constant functions 0 and 1. Thus, any Besov semi-norm of these partial evaluations is 0 and consequently the sum as well. We see that, unlike in Theorem 2.16, even if a function $f$ has Besov regularity, the Besov norm of $f$ is in general not equivalent to the sum of the Besov norms of partial evaluations.

Proposition 2.19. Let $0<p=q \leq \infty$ and $\alpha>0$. Let $B_{p, p}^{\alpha}$ be equipped with the (quasi-)norm associated with the modulus of smoothness when $p=\infty$ or the averaged modulus of smoothness when $p<\infty$. Then, we equip the tensor space $\mathbf{V}_{b, d, B_{p, p}^{\alpha}}$ with the (quasi-)norm

$$
\|\boldsymbol{f}\|_{B_{p, p}^{\alpha}}:=\left(\|\boldsymbol{f}\|_{p}^{p}+|\boldsymbol{f}|_{B_{p, p}^{\alpha}}^{p}\right)^{1 / p} \quad(p<\infty), \quad\|\boldsymbol{f}\|_{B_{\infty, \infty}^{\alpha}}:=\max \left\{\|\boldsymbol{f}\|_{\infty},|\boldsymbol{f}|_{B_{\infty, \infty}^{\alpha}}\right\}
$$

where $|\cdot|_{B_{p, p}^{\alpha}}$ is a (quasi-)semi-norm defined by

$$
|\boldsymbol{f}|_{B_{p, p}^{\alpha}}^{p}:=b^{d(\alpha p-1)} \sum_{\left(j_{1}, \ldots, j_{d}\right) \in I_{b}^{d}}\left|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right|_{B_{p, p}^{\alpha}}^{p},
$$

for $p<\infty$, and

$$
|\boldsymbol{f}|_{B_{\infty, \infty}^{\alpha}}:=b^{d \alpha} \max _{\left(j_{1}, \ldots, j_{d}\right) \in I_{b}^{d}}\left|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right|_{B_{\infty, \infty}^{\alpha}}
$$

Then, $T_{b, d}\left(B_{p, p}^{\alpha}\right) \hookrightarrow \mathbf{V}_{b, d, B_{p, p}^{\alpha}}$ with

$$
|f|_{B_{p, p}^{\alpha}} \geq\left|T_{b, d}(f)\right|_{B_{p, p}^{\alpha}} .
$$

2.4. Tensor Subspaces and Corresponding Function Spaces. For a linear space of functions $S \subset \mathbb{R}^{[0,1)}$, we define the tensor subspace

$$
\mathbf{V}_{b, d, S}:=\left(\mathbb{R}^{I_{b}}\right)^{\otimes d} \otimes S \subset \mathbf{V}_{b, d},
$$

and the corresponding linear subspace of functions in $\mathbb{R}^{[0,1)}$,

$$
V_{b, d, S}=T_{b, d}^{-1}\left(\mathbf{V}_{b, d, S}\right)
$$

In the majority of this work we will be using finite-dimensional subspaces $S$ for approximation. In particular, we will frequently use $S=\mathbb{P}_{m}$ where $\mathbb{P}_{m}$ is the space of polynomials of degree up to $m \in \mathbb{N}_{0}$. In this case we use the shorthand notation

$$
V_{b, d, m}:=V_{b, d, \mathbb{P}_{m}} .
$$

The tensorization $\boldsymbol{f}=T_{b, d}(f)$ of a function $f \in V_{b, d, S}$ admits a representation (2.2) with functions $\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right):=f_{j_{1}, \ldots, j_{d}}$ in $S$. For $x=t_{b, d}\left(j_{1}, \ldots, j_{d}, y\right)$ in the interval $\left[x_{j}, x_{j+1}\right)$, with $j=\sum_{k=1}^{b} j_{k} b^{d-k}$, we have $f(x)=f_{j_{1}, \ldots, j_{d}}(y)=f_{j_{1}, \ldots, j_{d}}\left(b^{d} x-j\right)$. Therefore, the functions $f \in V_{b, d, S}$ have restrictions on intervals $\left[x_{j}, x_{j+1}\right)$ that are obtained by shifting and scaling functions in $S$. In particular, the space
$V_{b, d, m}$ corresponds to the space of piecewise polynomials of degree $m$ over the uniform partition of $[0,1$ ) with $b^{d}$ intervals.

For considering functions with variable levels $d \in \mathbb{N}$, we introduce the set

$$
V_{b, S}:=\bigcup_{d \in \mathbb{N}} V_{b, d, S}
$$

It is straight-forward to see that, in general,

$$
V_{b, d, S} \not \subset V_{b, \bar{d}, S}
$$

for $\bar{d}<d$. E.g., take $S=\mathbb{P}_{m}$ and let $f \in V_{b, d, m}$ be a piece-wise polynomial but discontinuous function. Then, clearly $f$ does not have to be a polynomial over the intervals

$$
\left[k b^{-\bar{d}},(k+1) b^{-\bar{d}}\right), \quad 0 \leq k \leq b^{-\bar{d}}-1
$$

for $\bar{d}<d$. The same holds for the other inclusion, as the following example demonstrates.
Example 2.20. Consider the one-dimensional subspace $S:=\operatorname{span}\{\cos (2 \pi \cdot)\}$. A function $0 \neq f \in V_{b, d, S}$ is thus a piece-wise cosine. Take for simplicity $b=2, d=0$ (i.e., $V_{2,0, S}=S$ ) and $\bar{d}=1$. Then, $f \notin V_{2,1, S}$ due to $\operatorname{span}\{\cos (2 \pi \cdot)\} \not \supset \operatorname{span}\{\cos (\pi \cdot), \cos (\pi+\pi \cdot)\}$, since cosines of different frequencies are linearly independent. The same reasoning can be applied to any $b \geq 2$ and $d, \bar{d} \in \mathbb{N}$ with $d<\bar{d}$.

This motivates the following definition that is reminiscent of multi-resolution analysis (MRA).
Definition 2.21 (Closed under b-adic dilation). We say that a linear space $S$ is closed under b-adic dilation if for any $f \in S$ and any $k \in\{0, \ldots, b-1\}$,

$$
f\left(b^{-1}(\cdot+k)\right) \in S
$$

Lemma 2.22. If $S$ is closed under b-adic dilation, then for all $f \in S$,

$$
f\left(b^{-d}(\cdot+k)\right) \in S
$$

for all $d \in \mathbb{N}$ and $k \in\left\{0, \ldots, b^{d}-1\right\}$.
Proof. See Appendix A.
Important examples of spaces $S$ that satisfy the above property include spaces of polynomials and MRAs. The closedness of $S$ under $b$-adic dilation implies a hierarchy between spaces $V_{b, d, S}$ with different levels, and provides $V_{b, S}$ with a linear space structure.

Proposition 2.23. If $S$ is closed under b-adic dilation, then

$$
S:=V_{b, 0, S} \subset V_{b, 1, S} \subset \ldots \subset V_{b, d, S} \subset \ldots
$$

Proof. See Appendix A.
Proposition 2.24 ( $V_{b, S}$ is a linear space). If $S$ is closed under b-adic dilation, then $V_{b, S}$ is a linear space.

## Proof. See Appendix A.

If $S \subset L^{p}([0,1))$, then $V_{b, S}$ is clearly a subspace of $L^{p}([0,1))$. However, it is not difficult to see that, in general, $V_{b, S}$ is not a closed subspace of $L^{p}([0,1))$. On the other hand, we have the following density result.

Theorem $2.25\left(V_{b, S}\right.$ dense in $\left.L^{p}\right)$. Let $1 \leq p<\infty$. If $S \subset L^{p}([0,1))$ and $S$ contains the constant function one, then $V_{b, S}=\bigcup_{d \in \mathbb{N}} V_{b, d, S}$ is dense in $L^{p}([0,1))$.
Proof. See Appendix A.
Now we provide bounds for ranks of functions in $V_{b, S}$, directly deduced from (2.7).
Lemma 2.26. For $f \in V_{b, d, S}$ and any $\beta \subset\{1, \ldots, d\}$,

$$
r_{\beta, d}(f) \leq \min \left\{b^{\# \beta}, b^{d-\# \beta} \operatorname{dim} S\right\}
$$

In particular, for all $1 \leq \nu \leq d$,

$$
r_{\nu, d}(f) \leq \min \left\{b^{\nu}, b^{d-\nu} \operatorname{dim} S\right\}
$$

In the case where $S$ is closed under $b$-adic dilation, we can obtain sharper bounds for ranks.

Lemma 2.27. Let $S$ be closed under b-adic dilation.
(i) If $f \in S$, then for any $d \in \mathbb{N}, f \in V_{b, d, S}$ and we have

$$
r_{\nu, d}(f) \leq \min \left\{b^{\nu}, \operatorname{dim} S\right\}, \quad 1 \leq \nu \leq d
$$

(ii) If $f \in V_{b, d, S}$, then for any $\bar{d} \geq d, f \in V_{b, \bar{d}, S}$ and we have

$$
\begin{align*}
& r_{\nu, \bar{d}}(f)=r_{\nu, d}(f) \leq \min \left\{b^{\nu}, b^{d-\nu} \operatorname{dim} S\right\}, \quad 1 \leq \nu \leq d, \\
& r_{\nu, \bar{d}}(f) \leq \min \left\{b^{\nu}, \operatorname{dim} S\right\}, \quad d<\nu \leq \bar{d} . \tag{2.12}
\end{align*}
$$

Proof. See Appendix A.
Remark 2.28. Lemma 2.27 shows that the ranks are independent of the representation level of a function $\varphi$, so that we will frequently suppress this dependence and simply note $r_{\nu, d}(\varphi)=r_{\nu}(\varphi)$ for any $d$ such that $\varphi \in V_{b, d, S}$.

We end this section by introducing projection operators based on local projection. Let $\mathcal{I}_{S}$ be a linear projection operator from $L^{p}([0,1))$ to a finite-dimensional space $S$. Then, define the linear operator $\mathcal{I}_{b, d, S}$ on $L^{p}([0,1))$ defined for $f \in L^{p}([0,1))$ by

$$
\begin{equation*}
\left(\mathcal{I}_{b, d, S} f\right)\left(b^{-d}(j+\cdot)\right)=\mathcal{I}_{S}\left(f\left(b^{-d}(j+\cdot)\right)\right), \quad 0 \leq j<b^{d} \tag{2.13}
\end{equation*}
$$

Lemma 2.29 (Local projection). The operator $\mathcal{I}_{b, d, S}$ is a linear operator from $L^{p}([0,1))$ to $V_{b, d, S}$ and satisfies

$$
\begin{equation*}
T_{b, d} \circ \mathcal{I}_{b, d, S} \circ T_{b, d}^{-1}=i d_{\{1, \ldots, d\}} \otimes \mathcal{I}_{S} \tag{2.14}
\end{equation*}
$$

Proof. See Appendix A.
We now provide a result on the ranks of projections.
Lemma 2.30 (Local projection ranks). For any $f \in L^{p}, \mathcal{I}_{b, d, S} f \in V_{b, d, S}$ satisfies

$$
r_{\nu, d}\left(\mathcal{I}_{b, d, S} f\right) \leq r_{\nu, d}(f), \quad 1 \leq \nu \leq d .
$$

Proof. Lemma 2.29 implies that $T_{b, d} \circ \mathcal{I}_{b, d, S} \circ T_{b, d}^{-1}$ is a rank one operator. Since a rank-one operator can not increase $\beta$-ranks, we have for all $1 \leq \nu \leq d$

$$
r_{\nu, d}\left(\mathcal{I}_{b, d, S}(f)\right)=r_{\nu}\left(T_{b, d} \circ \mathcal{I}_{b, d, S} \circ T_{b, d}^{-1} \boldsymbol{f}\right)=r_{\nu}\left(\left(i d_{\{1, \ldots, d\}} \otimes \mathcal{I}_{S}\right) \boldsymbol{f}\right) \leq r_{\nu}(\boldsymbol{f})=r_{\nu, d}(f)
$$

## 3. Tensor Networks and Their Approximation spaces

In this section, we begin by describing particular tensor formats, namely tree tensor networks that will constitute our approximation tool. We then briefly review classical approximation spaces (see [14]). We conclude by introducing different measures of complexity of tree tensor networks and analyze the resulting approximation classes.
3.1. Tree Tensor Networks and The Tensor Train Format. Let $S$ be a finite-dimensional subspace of $\mathbb{R}^{[0,1)}$. A tensor format in the tensor space $\mathbf{V}_{b, d, S}=\left(\mathbb{R}^{I_{b}}\right)^{\otimes d} \otimes S$ is defined as a set of tensors with $\beta$-ranks bounded by some integers $r_{\beta}$, for a certain collection $A$ of subsets $\beta \subset\{1, \ldots, d+1\}$,

$$
\mathcal{T}_{r}^{A}\left(\mathbf{V}_{b, d, S}\right)=\left\{\boldsymbol{f} \in \mathbf{V}_{b, d, S}: r_{\beta}(\boldsymbol{f}) \leq r_{\beta}, \beta \in A\right\} .
$$

When $A$ is a dimension partition tree (or a subset of such a tree), the resulting format is called a hierarchical or tree-based tensor format [17, 26]. A tensor $\boldsymbol{f} \in \mathcal{T}_{r}^{A}\left(\mathbf{V}_{b, d, S}\right)$ in a tree-based tensor format admits a parametrization in terms of a collection of low-order tensors $v_{\beta}, \beta \in A$. Hence, the interpretation as a tree tensor network (see [38, Section 4]).
Remark 3.1. Tree tensor networks are convolutional feedforward neural networks with non-linear feature maps, product pooling, a number of layers equal to the depth of the dimension partition tree and a number of neurons equal to the sum of ranks $r_{\beta}$.

For the most part we will work with the tensor train format with the exception of a few remarks. This format considers the collection of subsets $A=\{\{1\},\{1,2\}, \ldots,\{1, \ldots, d\}\}$, which is a subset of a linear dimension partition tree.

Definition 3.2 (Tensor Train Format). The se $4^{4}$ of tensors in $\mathbf{V}_{b, d}$ in tensor train (TT) format with ranks at most $\boldsymbol{r}:=\left(r_{\nu}\right)_{\nu=1}^{d}$ is defined as

$$
\mathcal{T} \mathcal{T}_{\boldsymbol{r}}\left(\mathbf{V}_{b, d, S}\right):=\left\{\boldsymbol{f} \in \mathbf{V}_{b, d, S}: r_{\nu}(\boldsymbol{f}) \leq r_{\nu}, 1 \leq \nu \leq d\right\}
$$

where we have used the shorthand notation $r_{\nu}(\boldsymbol{f}):=r_{\{1, \ldots, \nu\}}(\boldsymbol{f})$. This defines a set of univariate functions

$$
\Phi_{b, d, S, r}=T_{b, d}^{-1}\left(\mathcal{T} \mathcal{T}_{r}\left(\mathbf{V}_{b, d, S}\right)\right)=\left\{f \in V_{b, d, S}: r_{\nu}(f) \leq r_{\nu}, 1 \leq \nu \leq d\right\}
$$

where $r_{\nu}(f):=r_{\nu, d}(f)$, that we further call the tensor train format for univariate functions.
Letting $\left\{\varphi_{k}\right\}_{k=1}^{\operatorname{dim} S}$ be a basis of $S$, a tensor $\boldsymbol{f} \in \mathcal{T} \mathcal{T}_{r}\left(\mathbf{V}_{b, d, S}\right)$ admits a representation

$$
\begin{equation*}
\boldsymbol{f}\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k_{1}=1}^{r_{1}} \cdots \sum_{k_{d}=1}^{r_{d}} \sum_{k=1}^{\operatorname{dim} S} v_{1}^{k_{1}}\left(i_{1}\right) v_{2}^{k_{1}, k_{2}}\left(i_{2}\right) \cdots v_{d}^{k_{d-1}, k_{d}}\left(i_{d}\right) v_{d+1}^{k_{d}, k} \varphi_{k}(y) \tag{3.1}
\end{equation*}
$$

with parameters $v_{1} \in \mathbb{R}^{b \times r_{1}}, v_{\nu} \in \mathbb{R}^{b \times r_{\nu-1} \times r_{\nu}}, 2 \leq \nu \leq d$, and $v_{d+1} \in \mathbb{R}^{r_{d} \times \operatorname{dim} S}$ forming a tree tensor network

$$
\mathbf{v}=\left(v_{1}, \ldots, v_{d+1}\right) \in \mathcal{P}_{b, d, S, \boldsymbol{r}}:=\mathbb{R}^{b \times r_{1}} \times \mathbb{R}^{b \times r_{1} \times r_{2}} \times \ldots \times \mathbb{R}^{b \times r_{d-1} \times r_{d}} \times \mathbb{R}^{r_{d} \times \operatorname{dim} S}
$$

The format $\mathcal{T} \mathcal{T}_{\boldsymbol{r}}\left(\mathbf{V}_{b, d, S}\right)$ then corresponds to the image of the space of tree tensor networks $\mathcal{P}_{b, d, S, r}$ through the map

$$
R_{b, d, S, \boldsymbol{r}}: \mathcal{P}_{b, d, S, \boldsymbol{r}} \rightarrow \mathcal{T} \mathcal{T}_{\boldsymbol{r}}\left(\mathbf{V}_{b, d, S}\right) \subset \mathbf{V}_{b, d, S}
$$

such that for $\mathbf{v}=\left(v_{1}, \ldots, v_{d+1}\right) \in \mathcal{P}_{b, d, S, \boldsymbol{r}}$, the tensor $\boldsymbol{f}=R_{b, d, S, \boldsymbol{r}}(\mathbf{v})$ is defined by (3.1). The set of functions $\Phi_{b, d, S, r}$ in the tensor train format can be parametrized as follows:

$$
\Phi_{b, d, S, \boldsymbol{r}}=\left\{\varphi=\mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v}): \mathbf{v} \in \mathcal{P}_{b, d, S, \boldsymbol{r}}\right\}, \quad \mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v})=T_{b, d}^{-1} \circ R_{b, d, S, \boldsymbol{r}}
$$

With an abuse of terminology, we call tensor networks both the set of tensors $\mathbf{v}$ and the corresponding function $\varphi=\mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v})$. The representation complexity of $\boldsymbol{f}=R_{b, d, S, \boldsymbol{r}}(\mathbf{v}) \in \mathcal{T} \mathcal{T}_{\boldsymbol{r}}\left(V_{b, d, S}\right)$ is

$$
\begin{equation*}
\mathcal{C}(b, d, S, \boldsymbol{r}):=\operatorname{dim}\left(\mathcal{P}_{b, d, S, \boldsymbol{r}}\right)=b r_{1}+b \sum_{\nu=2}^{d} r_{\nu-1} r_{\nu}+r_{d} \operatorname{dim} S \tag{3.2}
\end{equation*}
$$

Remark 3.3 (Re-Ordering Variables in the TT Format). We chose in Definition 2.2 to order the input variables of the tensorized function $\boldsymbol{f}$ such that $y \in[0,1)$ is in the last position. This specific choice allows the interpretation of partial evaluations of $\{1, \ldots, \nu\}$-unfoldings as contiguous pieces of $f=T_{b, d}^{-1}(\boldsymbol{f})$ (see Lemma 2.12 and the discussion thereafter). Alternatively, we could have chosen the ordering $\left(y, i_{1}, \ldots, i_{d}\right) \mapsto \boldsymbol{f}\left(y, i_{1}, \ldots, i_{d}\right)$, and defined the TT-format and TT-ranks correspondingly. Essentially this is the same as considering a different tensor format, see discussion above. Many of the results of part II [2] remain the same. In particular, the order of magnitude of the rank bounds and therefore the resulting direct and inverse estimates would not change. However, this re-ordering may lead to slightly smaller rank bounds as in Remark 3.9 or slightly larger rank bounds as in [2, Remark 4.6].
3.2. General Approximation Spaces. Approximation spaces have been extensively studied in the second half of the last century. They provide a systematic way of classifying functions that can be approximated with a certain rate. Moreover, they have intriguing connections to smoothness and interpolation spaces (see [13]) and thus provide a complete characterization of approximation properties. We briefly review some fundamentals that we require for the rest of this work. For details we refer to [13, 14].

Let $X$ be a quasi-normed linear space, $\Phi_{n} \subset X$ subsets of $X$ for $n \in \mathbb{N}_{0}$ and $\Phi:=\left(\Phi_{n}\right)_{n \in \mathbb{N}_{0}}$ an approximation tool. Define the best approximation error

$$
E_{n}(f):=E\left(f, \Phi_{n}\right):=\inf _{\varphi \in \Phi_{n}}\|f-\varphi\|_{X}
$$

With this we define approximation classes as

[^3]Definition 3.4 (Approximation Classes). For any $f \in X$ and $\alpha>0$, define the quantity

$$
\|f\|_{A_{q}^{\alpha}}:= \begin{cases}\left(\sum_{n=1}^{\infty}\left[n^{\alpha} E_{n-1}(f)\right]^{q} \frac{1}{n}\right)^{1 / q}, & 0<q<\infty \\ \sup _{n \geq 1}\left[n^{\alpha} E_{n-1}(f)\right], & q=\infty\end{cases}
$$

The approximation classes $A_{q}^{\alpha}$ of $\Phi=\left(\Phi_{n}\right)_{n \in \mathbb{N}_{0}}$ are defined by

$$
A_{q}^{\alpha}:=A_{q}^{\alpha}(X):=A_{q}^{\alpha}(X, \Phi):=\left\{f \in X:\|f\|_{A_{q}^{\alpha}}<\infty\right\} .
$$

These approximation classes have many useful properties if we further assume that $\Phi_{n}$ satisfy the following criteria for any $n \in \mathbb{N}_{0}$.
(P1) $0 \in \Phi_{n}, \Phi_{0}=\{0\}$.
(P2) $\Phi_{n} \subset \Phi_{n+1}$.
(P3) $a \Phi_{n}=\Phi_{n}$ for any $a \in \mathbb{R} \backslash\{0\}$.
(P4) $\Phi_{n}+\Phi_{n} \subset \Phi_{c n}$ for some $c:=c(\Phi)$.
(P5) $\bigcup_{n \in \mathbb{N}_{0}} \Phi_{n}$ is dense in $X$.
(P6) $\Phi_{n}$ is proximinal in $X$, i.e. each $f \in X$ has a best approximation in $\Phi_{n}$.
Additionally, properties (P1) - (P6) will be frequently combined with the so-called direct or Jackson inequality

$$
\begin{equation*}
E_{n}(f) \leq C n^{-r_{\mathrm{J}}}|f|_{Y}, \quad \forall f \in Y, \tag{3.3}
\end{equation*}
$$

for a semi-normed vector space $Y$ and some parameter $r_{\mathrm{J}}>0$, and the inverse or Bernstein inequality

$$
\begin{equation*}
|\varphi|_{Y} \leq C n^{r_{\mathrm{B}}}\|\varphi\|_{X}, \quad \forall \varphi \in \Phi_{n} \tag{3.4}
\end{equation*}
$$

for some parameter $r_{\mathrm{B}}>0$.
The implications of (P1) (P6) about the properties of $A_{q}^{\alpha}$ are as follows

- $(\mathrm{P} 1)+(\mathrm{P} 3)+(\mathrm{P} 4) \Rightarrow A_{q}^{\alpha}$ is a linear space with a quasi-norm.
- (P1) (P3) (P4) $\Rightarrow A_{q}^{\alpha}$ satisfies the direct or Jackson inequality

$$
E_{n}(f) \leq C n^{-r_{J}}\|f\|_{A_{q}^{\alpha}}, \quad \forall f \in A_{q}^{\alpha}
$$

for $r_{\mathrm{J}}=\alpha$.

- (P1) $+(\mathrm{P} 2)+(\mathrm{P} 3)+(\mathrm{P} 4) \Rightarrow A_{q}^{\alpha}$ satisfies the inverse or Bernstein inequality

$$
\|\varphi\|_{A_{q}^{\alpha}} \leq C n^{r_{\mathrm{B}}}\|\varphi\|_{X}, \quad \forall \varphi \in \Phi_{n}
$$

for $r_{\mathrm{B}}=\alpha$.
The other properties (P5) and (P6) are required for characterizing approximation spaces by interpolation spaces, see [14]. Specifically, (P1)-(P4) together with a Jackson estimate as in (3.3) are required to prove so-called direct embeddings: a range of smoothness spaces is continuously embedded into $A_{q}^{\alpha}$. While (P1) -(P6) together with a Bernstein estimate (3.4) are required for inverse embeddings: $A_{q}^{\alpha}$ is continuously embedded into smoothness spaces. We will see in Part II [2] that, in general, for approximation spaces of tensor networks no inverse estimates ${ }^{[5}$ are possible, since these spaces are "too large". Therefore, properties (P5)-(P6) are not essential, while (P5) is typically true for any type of reasonable approximation to ${ }^{\frac{1}{6}}$

We have the continuous embeddings

$$
A_{q}^{\alpha} \hookrightarrow A_{\bar{q}}^{\beta}, \quad \text { if } \alpha>\beta \quad \text { or if } \alpha=\beta \text { and } q \leq \bar{q} .
$$

We will see that, while most properties are easy to satisfy, property (P4) will be the most critical one. In essence (P4) is a restriction on the non-linearity of the sets $\Phi_{n}$, with $c(\Phi)=1$ being satisfied by linear subspaces.

[^4]3.3. Measures of Complexity. We consider as an approximation tool $\Phi$ the collection of tensor networks $\Phi_{b, d, S, r}$ associated with different levels and ranks,
$$
\Phi:=\left(\Phi_{b, d, S, \boldsymbol{r}}\right)_{d \in \mathbb{N}, \boldsymbol{r} \in \mathbb{N}^{d}}
$$
and define the sets of functions $\Phi_{n}$ as
\[

$$
\begin{equation*}
\Phi_{n}:=\left\{\varphi \in \Phi_{b, d, S, \boldsymbol{r}}: d \in \mathbb{N}, \boldsymbol{r} \in \mathbb{N}^{d}, \operatorname{compl}(\varphi) \leq n\right\} \tag{3.5}
\end{equation*}
$$

\]

where $\operatorname{compl}(\varphi)$ is some measure of complexity of a function $\varphi$. The approximation classes of tensor networks depend on the chosen measure of complexity. We propose different measures of complexity and discuss the critical property (P4). A function $\varphi \in \Phi$ may admit representations at different levels. We set

$$
d(\varphi)=\min \left\{d: \varphi \in V_{b, d, S}\right\}
$$

to be the minimal representation level of $\varphi$, and $\boldsymbol{r}(\varphi)=\left(r_{\nu}(\varphi)\right)_{\nu=1}^{d(\varphi)}$ be the corresponding ranks. Measures of complexity may be based on a measure of complexity $\operatorname{compl}(\mathbf{v})$ of tensor networks $\mathbf{v}$ such that $\varphi=\mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v})$. Then, we would define

$$
\begin{equation*}
\Phi_{n}:=\left\{\varphi=\mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v}) \in \Phi_{b, d, S, \boldsymbol{r}}: \mathbf{v} \in \mathcal{P}_{b, d, S, \boldsymbol{r}}, d \in \mathbb{N}, \boldsymbol{r} \in \mathbb{N}^{d}, \operatorname{compl}(\mathbf{v}) \leq n\right\} \tag{3.6}
\end{equation*}
$$

which is equivalent to the definition 3.5 if we let

$$
\begin{equation*}
\operatorname{compl}(\varphi):=\min \left\{\operatorname{compl}(\mathbf{v}): \mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v})=\varphi, d \in \mathbb{N}, \boldsymbol{r} \in \mathbb{N}^{d}\right\} \tag{3.7}
\end{equation*}
$$

where the minimum is taken over all possible representations of $\varphi$.
3.3.1. Complexity Measure: Maximum Rank. In many high-dimensional approximation problems it is common to consider the maximum rank as an indicator of complexity (see, e.g., [4]). By this analogy we consider for $\varphi \in \Phi$,

$$
\begin{equation*}
\operatorname{compl}(\varphi):=b d r_{\max }^{2}(\varphi)+r_{\max }(\varphi) \operatorname{dim} S, \quad r_{\max }(\varphi)=\max \left\{r_{\nu}(\varphi): 1 \leq \nu \leq d(\varphi)\right\} \tag{3.8}
\end{equation*}
$$

This complexity measure does not satisfy (P4).
Proposition $3.5(\mathrm{P} 4)$ not satisfied by the complexity measure based on $\left.r_{\max }\right)$. Let $S$ be closed under badic dilation and assume $\operatorname{dim} S<\infty$. Then, with $\Phi_{n}$ as defined in 3.5 with the measure of complexity (3.8),
(i) There exists no constant $c \in \mathbb{R}$ such that

$$
\Phi_{n}+\Phi_{n} \subset \Phi_{c n}
$$

(ii) There exists a constant $c>1$ such that

$$
\Phi_{n}+\Phi_{n} \subset \Phi_{c n^{2}}
$$

Proof. See Appendix B
3.3.2. Complexity Measure: Sum of Ranks. For a neural network, a natural measure of complexity is the number of neurons. By analogy (see Remark 3.1), we can define a complexity measure equal to the sum of ranks

$$
\begin{equation*}
\operatorname{compl}(\varphi):=\operatorname{compl}_{\mathcal{N}}(\varphi):=\sum_{\nu=1}^{d(\varphi)} r_{\nu}(\varphi) \tag{3.9}
\end{equation*}
$$

and the corresponding set

$$
\begin{equation*}
\Phi_{n}^{\mathcal{N}}:=\left\{\varphi \in \Phi_{b, d, S, \boldsymbol{r}}: d \in \mathbb{N}, \boldsymbol{r} \in \mathbb{N}^{d}, \operatorname{compl}_{\mathcal{N}}(\varphi) \leq n\right\} \tag{3.10}
\end{equation*}
$$

This complexity measure can be equivalently defined by (3.7) with $\operatorname{compl}_{\mathcal{N}}(\mathbf{v})=\sum_{\nu=1}^{d} r_{\nu}$ for $\mathbf{v} \in$ $\mathcal{P}_{b, d, S, \boldsymbol{r}}$.

Lemma 3.6 ( $\Phi_{n}^{\mathcal{N}}$ satisfies (P4)). Let $S$ be closed under b-adic dilation and $\operatorname{dim} S<\infty$. Then, the set $\Phi_{n}^{\mathcal{N}}$ as defined in (3.10 satisfies (P4) with $c=2+\operatorname{dim} S$.
3.3.3. Complexity Measure: Representation Complexity. A straight-forward choice for the complexity measure is the number of parameters required for representing $\varphi$ as in (3.2), i.e.,

$$
\begin{equation*}
\operatorname{compl}(\varphi):=\operatorname{compl}_{\mathcal{C}}(\varphi):=\mathcal{C}(b, d(\varphi), S, \boldsymbol{r}(\varphi))=b r_{1}(\varphi)+b \sum_{k=2}^{d(\varphi)} r_{k-1}(\varphi) r_{k}(\varphi)+r_{d}(\varphi) \operatorname{dim} S, \tag{3.11}
\end{equation*}
$$

and the corresponding set is defined as

$$
\begin{equation*}
\Phi_{n}^{\mathcal{C}}:=\left\{\varphi \in \Phi_{b, d, S, r}: d \in \mathbb{N}, \boldsymbol{r} \in \mathbb{N}^{d}, \operatorname{compl}_{\mathcal{C}}(\varphi) \leq n\right\} \tag{3.12}
\end{equation*}
$$

This complexity measure can be equivalently defined by (3.7) with $\operatorname{compl}_{\mathcal{C}}(\mathbf{v})=\mathcal{C}(b, d, S, \boldsymbol{r})$ for $\mathbf{v} \in$ $\mathcal{P}_{b, d, S, r}$.

Remark 3.7. When interpreting tensor networks as neural networks (see Remark 3.1), the complexity measure compl $\mathcal{C}_{\mathcal{C}}$ is equivalent to the number of weights for a fully connected neural network with $r_{\nu}$ neurons in layer $\nu$.

We can show the set $\Phi_{n}^{\mathcal{C}}$ satisfies (P4) with the help of Lemmas 2.11 and 2.27 .
Lemma 3.8 ( $\Phi_{n}^{\mathcal{C}}$ satisfies (P4)). Let $S$ be closed under b-adic dilation and $\operatorname{dim} S<\infty$. Then, the set $\Phi_{n}^{\mathcal{C}}$ as defined in (3.12) satisfies (P4) with $c=c(b, \operatorname{dim} S)>1$.
Proof. See Appendix B
Remark 3.9 (Re-Ordering Input Variables). In the proof, we have used the property (2.12) from Lemma 2.11. As mentioned in Remark 3.3, we could consider a different ordering of the input variables $\left(y, i_{1}, \ldots, i_{d}\right) \mapsto \boldsymbol{f}\left(y, i_{1}, \ldots, i_{d}\right)$, and the corresponding TT-format. This would change (2.12) to

$$
r_{\nu, \bar{d}}(f)=1, \quad d+1 \leq \nu \leq \bar{d} .
$$

We still require $S$ to be closed under b-adic dilation to ensure $f \in V_{b, \bar{d}, S}$.
Remark 3.10 ( $\ell^{2}$-norm of Ranks). We also considered defining the complexity measure as a $\ell^{2}$-norm of the tuple of ranks

$$
\operatorname{compl}(\varphi):=b \sum_{k=1}^{d(\varphi)} r_{k}(\varphi)^{2}+r_{d}(\varphi) \operatorname{dim} S
$$

This definition satisfies $\left(P_{4}\right)$ as well with analogous results as for the complexity measure compl $_{\mathcal{C}}$ for direct and inverse embeddings. The $\ell^{2}$-norm of ranks is less sensitive to rank-anisotropy than the representation complexity $\operatorname{compl}_{\mathcal{C}}(\varphi)$. Note that both complexity measures reflect the cost of representing a function with tensor networks, not the cost of performing arithmetic operations, where frequently an additional power of $r$ is required (e.g., $\sim r^{3}$ or higher).
3.3.4. Complexity Measure: Sparse Representation Complexity. Finally, for a function $\varphi=\mathcal{R}_{b, d, S, r}(\mathbf{v}) \in$ $\Phi_{b, d, S, r}$, we consider a complexity measure that takes into account the sparsity of the tensors $\mathbf{v}=$ $\left(v_{1}, \ldots, v_{d+1}\right)$,

$$
\begin{equation*}
\operatorname{compl}(\mathbf{v})=\operatorname{compl}_{\mathcal{S}}(\mathbf{v}):=\sum_{\nu=1}^{d+1}\left\|v_{\nu}\right\|_{\ell_{0}} \tag{3.13}
\end{equation*}
$$

where $\left\|v_{\nu}\right\|_{\ell_{0}}$ is the number of non-zero entries in the tensor $v_{\nu}$. By analogy with neural networks (see Remark 3.1), this corresponds to the number of non-zero weights for sparsely connected neural networks. We define the corresponding set as

$$
\begin{equation*}
\Phi_{n}^{\mathcal{S}}:=\left\{\varphi \in \Phi_{b, d, S, r}: d \in \mathbb{N}, \boldsymbol{r} \in \mathbb{N}^{d}, \operatorname{compl}_{\mathcal{S}}(\varphi) \leq n\right\} . \tag{3.14}
\end{equation*}
$$

We can show the set $\Phi_{n}^{\mathcal{S}}$ satisfies (P4). For that, we need the following two lemmas.
Lemma 3.11. Assume $S$ is closed under b-adic dilation and $\operatorname{dim} S<\infty$. Let $\varphi=\mathcal{R}_{b, d, S, r}(\mathbf{v}) \in \Phi_{b, d, S, r}$ with $\boldsymbol{r}=\left(r_{\nu}\right)_{\nu=1}^{d}$. For $\bar{d}>d$, there exists a representation $\varphi=\mathcal{R}_{b, \bar{d}, S, \overline{\boldsymbol{r}}}(\overline{\mathbf{v}}) \in \Phi_{b, \bar{d}, S, \overline{\boldsymbol{r}}}$ with $\overline{\boldsymbol{r}}=\left(\bar{r}_{\nu}\right)_{\nu=1}^{\bar{d}}$ such that $\bar{r}_{\nu}=r_{\nu}$ for $1 \leq \nu \leq d$ and $\bar{r}_{\nu} \leq \max \{\operatorname{dim} S, b\} \operatorname{dim} S$ for $d<\nu \leq \bar{d}$, and

$$
\operatorname{compl}_{\mathcal{S}}(\overline{\mathbf{v}}) \leq b \operatorname{compl}_{\mathcal{S}}(\mathbf{v})+(\bar{d}-d) b^{2}(\operatorname{dim} S)^{3} .
$$

Lemma 3.12 (Sum of Sparse Representations). Let $\varphi_{A}=\mathcal{R}_{b, d, S, \boldsymbol{r}^{A}}\left(\mathbf{v}_{A}\right) \in \Phi_{b, d, S, \boldsymbol{r}^{A}}$ and $\varphi_{B}=$ $\mathcal{R}_{b, d, S, \boldsymbol{r}^{B}}\left(\mathbf{v}_{B}\right) \in \Phi_{b, d, S, \boldsymbol{r}^{B}}$. Then, $\varphi_{A}+\varphi_{B}$ admits a representation $\varphi_{A}+\varphi_{B}=\mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v}) \in \Phi_{b, d, S, \boldsymbol{r}}$ with $r_{\nu}=r_{\nu}^{A}+r_{\nu}^{B}$ for $1 \leq \nu \leq d$, and

$$
\operatorname{compl}_{\mathcal{S}}\left(\varphi_{A}+\varphi_{B}\right) \leq \operatorname{compl}_{\mathcal{S}}(\mathbf{v}) \leq \operatorname{compl}_{\mathcal{S}}\left(\mathbf{v}_{A}\right)+\operatorname{compl}_{\mathcal{S}}\left(\mathbf{v}_{B}\right)
$$

Proof. See Appendix B.
Lemma $3.13\left(\Phi_{n}^{\mathcal{S}}\right.$ satisfies (P4)). Let $S$ be closed under b-adic dilation and $\operatorname{dim} S<\infty$. Then, the set $\Phi_{n}^{\mathcal{S}}$ as defined in (3.14) satisfies (P4) with $c=b+1+b^{2}(\operatorname{dim} S)^{3}$.
Proof. Let $\varphi_{A}, \varphi_{B} \in \Phi_{n}^{\mathcal{S}}$ with $\varphi_{A}=\mathcal{R}_{b, d_{A}, S, \boldsymbol{r}^{A}}\left(\mathbf{v}_{A}\right) \in \Phi_{b, d_{A}, S, \boldsymbol{r}^{A}}$ and $\varphi_{B}=\mathcal{R}_{b, d_{B}, S, \boldsymbol{r}^{B}}\left(\mathbf{v}_{B}\right) \in \Phi_{b, d_{B}, S, \boldsymbol{r}^{B}}$ and w.l.o.g. $d_{A} \leq d_{B}$. From Lemmas 3.11 and 3.12, we know that $\varphi_{A}+\varphi_{B}$ admits a representation $\varphi_{A}+\varphi_{B}=\mathcal{R}_{b, d_{B}, S, \boldsymbol{r}}(\mathbf{v})$ at level $d_{B}$ with

$$
\begin{aligned}
\operatorname{compl}_{\mathcal{S}}(\mathbf{v}) & \leq b \operatorname{compl}_{\mathcal{S}}\left(\mathbf{v}_{A}\right)+\operatorname{compl}_{\mathcal{S}}\left(\mathbf{v}_{B}\right)+\left(d_{B}-d_{A}\right) b^{2}(\operatorname{dim} S)^{3} \\
& \leq\left(b+1+b^{2}(\operatorname{dim} S)^{3}\right) n
\end{aligned}
$$

which ends the proof.
3.3.5. Necessity of (P4). We could consider replacing $n$ with $n^{2}$ in (P4), i.e.,

$$
\begin{equation*}
\Phi_{n}+\Phi_{n} \subset \Phi_{c n^{2}} \tag{3.15}
\end{equation*}
$$

This implies that $A_{q}^{\alpha}$ as defined in Definition 3.4 is no longer a vector space. The statements about Jackson and Bernstein inequalities as well as the relation to interpolation and smoothness spaces is no longer valid as well.

One could try to recover the linearity of $A_{q}^{\alpha}$ by modifying Definition 3.4. In Definition 3.4 we measure algebraic decay of $E_{n}(f)$. Algebraic decay is compatible with (P4) that in turn ensures $A_{q}^{\alpha}$ is a vector space. We could reverse this by asking: what type of decay behavior is "compatible" with 3.15) in the sense that the corresponding approximation class would be a linear space? We can introduce a growth function $\gamma: \mathbb{N} \rightarrow \mathbb{R}^{+}$with $\lim _{n} \gamma(n)=\infty$ and define an approximation class $A_{\infty}^{\gamma}$ of $\Phi=\left(\Phi_{n}\right)_{n \in \mathbb{N}_{0}}$ as

$$
A_{\infty}^{\gamma}:=\left\{f \in X: \sup _{n \geq 1} \gamma(n) E_{n-1}(f)<\infty\right\}
$$

With some elementary computations one can deduce that if the growth function is of the form

$$
\gamma(n):=1+\ln (n)
$$

then (3.15) implies $A_{\infty}^{\gamma}$ is closed under addition. However, functions in $A_{\infty}^{\gamma}$ have too slowly decaying errors for any practical purposes such that we do not intend to analyze this space further.

We could instead ask what form of (P4) would be compatible with a growth function such as

$$
\gamma(n):=\exp \left(a n^{\alpha}\right)
$$

for some $a>0$ and $\alpha>0$, i.e., classes of functions with exponentially decaying errors. In this case we would have to require $c=1$ in (P4), i.e.,

$$
\Phi_{n}+\Phi_{n} \subset \Phi_{n}
$$

in other words, $\Phi_{n}$ is a linear space.
These considerations suggest that preserving (P4) in its original form is necessary to exploit the full potential of classical approximation theory while preserving some flexibility in defining $\Phi_{n}$. Thus, we only consider definitions of $\operatorname{compl}(\cdot)$ that preserve (P4).
3.4. Approximation Spaces of Tensor Networks. We denote by $\Phi_{n}^{\mathcal{N}}, \Phi_{n}^{\mathcal{C}}$ and $\Phi_{n}^{\mathcal{S}}$ the approximation set $\Phi_{n}$ asscociated with the measures of complexity $\operatorname{compl}_{\mathcal{N}}, \operatorname{compl}_{\mathcal{C}}$ and compl $\mathcal{S}_{\mathcal{S}}$ respectively. Then, we define three different families of approximation classes

$$
\begin{align*}
N_{q}^{\alpha}(X) & :=A_{q}^{\alpha}\left(X,\left(\Phi_{n}^{\mathcal{N}}\right)_{n \in \mathbb{N}}\right)  \tag{3.16}\\
C_{q}^{\alpha}(X) & :=A_{q}^{\alpha}\left(X,\left(\Phi_{n}^{\mathcal{C}}\right)_{n \in \mathbb{N}}\right)  \tag{3.17}\\
S_{q}^{\alpha}(X) & :=A_{q}^{\alpha}\left(X,\left(\Phi_{n}^{\mathcal{S}}\right)_{n \in \mathbb{N}}\right) \tag{3.18}
\end{align*}
$$

with $\alpha>0$ and $0<q \leq \infty$. Below, we will show that these approximation classes are in fact approximation spaces and we will then compare these spaces.
3.4.1. Approximation Classes are Approximation Spaces. We proceed with checking if $\Phi_{n}^{\mathcal{N}}, \Phi_{n}^{\mathcal{C}}$ and $\Phi_{n}^{\mathcal{S}}$ satisfy properties (P1) (P6). In particular, satisfying (P1) (P4) will imply that the corresponding approximation classes are quasi-normed Banach spaces. The only property - other than (P4)- that is not obvious, is (P6). This is addressed in the following Lemma for $\Phi_{n}^{\mathcal{N}}$ and $\Phi_{n}^{\mathcal{C}}$.
Lemma 3.14 ( $\Phi_{n}^{\mathcal{N}}$ and $\Phi_{n}^{\mathcal{C}}$ satisfy (P6). Let $1<p<\infty$ and let $S \subset L^{p}$ be a closed subspace. Then, $\Phi_{n}^{\mathcal{N}}$ and $\Phi_{n}^{\mathcal{C}}$ are proximinal in $L^{p}$ for any $n \in \mathbb{N}$. Moreover, if $S$ is finite-dimensional, the above holds for $1 \leq p \leq \infty$.
Proof. See Appendix B
As the following example shows, we cannot in general guarantee (P6) for $\Phi_{n}^{\mathcal{S}}$.
Example 3.15. Suppose $b \geq 3$ and $\operatorname{dim} S \geq 3$. Take two linearly independent vectors $v, w \in \mathbb{R}^{b}$ and $f, g \in S$. For any $N \in \mathbb{N}$, set

$$
\varphi_{N}:=(w+N v) \otimes\left(v+\frac{1}{N} w\right) \otimes f+v \otimes v \otimes(g-N f)
$$

and

$$
\varphi:=v \otimes v \otimes g+v \otimes w \otimes f+w \otimes v \otimes f .
$$

Then, the following holds (see [25, Proposition 9.10 and Remark 12.4]).
(i) For the canonical tensor rank, we have $r\left(\varphi_{N}\right)=2$ for any $N \in \mathbb{N}$ and $r(\varphi)=3$.
(ii) As we will see in Lemma 3.22, $\varphi_{N} \in \Phi_{6 b+2 \operatorname{dim} S}^{\mathcal{S}}$ for any $N \in \mathbb{N}$ and $\varphi \in \Phi_{9 b+3 \operatorname{dim} S}^{\mathcal{S}}$. Moreover, this complexity is minimal for both functions.
(iii) For $N \rightarrow \infty, \varphi_{N} \rightarrow \varphi$ in any norm.

In other words, $E_{6 b+2 \operatorname{dim} S}^{\mathcal{S}}(\varphi)=0$, even though $\varphi \notin \Phi_{6 b+2 \operatorname{dim} S}^{\mathcal{S}}$.
Remark 3.16. (P6) is required for showing that the approximation spaces $A_{q}^{\alpha}$ are continuously embedded into interpolation spaces, see [14, Chapter 7, Theorem 9.3]. Since inverse embeddings for $N_{q}^{\alpha}, C_{q}^{\alpha}$ and $S_{q}^{\alpha}$ hold only in very restricted cases, property (P6) is not essential for our work and the majority of our results. As a side note, (P6) does not hold for ReLU or RePU networks as was discussed in [24].

We now derive the main result of this section.
Theorem 3.17 (Properties of $\Phi_{n}^{\mathcal{N}}, \Phi_{n}^{\mathcal{C}}$ and $\Phi_{n}^{\mathcal{S}}$ ). Let $0<p \leq \infty, S \subset L^{p}$ be a closed subspace that is also closed under $b$-adic dilation and $\operatorname{dim} S<\infty$. Then,
(i) $\Phi_{n}^{\mathcal{N}}$ and $\Phi_{n}^{\mathcal{C}}$ and $\Phi_{n}^{\mathcal{S}}$ satisfy (P1) (P4).
(ii) If $1 \leq p \leq \infty$, then $\Phi_{n}^{\mathcal{N}}$, $\Phi_{n}^{\mathcal{C}}$ additionally satisfy (P6),
(iii) If $1 \leq p<\infty$ and if $S$ contains the constant function one, $\Phi_{n}^{\mathcal{N}}$, $\Phi_{n}^{\mathcal{C}}$ and $\Phi_{n}^{\mathcal{S}}$ additionally satisfy (P5).
Proof. (P1) (P3) are obvious and (P4) follows from Lemmas 3.6, 3.8 and 3.13, that yields (i). (iii) follows from the fact that

$$
\bigcup_{n \in \mathbb{N}} \Phi_{n}=\bigcup_{d \in \mathbb{N}} \bigcup_{\boldsymbol{r} \in \mathbb{N}^{d}} \Phi_{b, d, S, \boldsymbol{r}}=\bigcup_{d \in \mathbb{N}} V_{b, d, S}=V_{b, S},
$$

and from Theorem 2.25. Finally, (ii) follows from Lemma 3.14.
Theorem 3.17 (i) implies that the approximation classes $N_{q}^{\alpha}\left(L^{p}\right), C_{q}^{\alpha}\left(L^{p}\right)$ and $S_{q}^{\alpha}(X)$ are quasinormed vector spaces that satisfy the Jackson and Bernstein inequalities.
3.4.2. Comparing Approximation Spaces. For comparing approximation spaces $N_{q}^{\alpha}\left(L^{p}\right), C_{q}^{\alpha}\left(L^{p}\right)$ and $S_{q}^{\alpha}\left(L^{p}\right)$, we first provide some relations between the sets $\Phi_{n}^{\mathcal{N}}, \Phi_{n}^{\mathcal{C}}$ and $\Phi_{n}^{\mathcal{S}}$.
Proposition 3.18. For any $n \in \mathbb{N}$,

$$
\Phi_{n}^{\mathcal{C}} \subset \Phi_{n}^{\mathcal{S}} \subset \Phi_{n}^{\mathcal{N}} \subset \Phi_{b \operatorname{dim} S+b n^{2}}^{\mathcal{C}}
$$

Proof. See Appendix B
From Proposition 3.18, we obtain ${ }^{7}$

[^5]Theorem 3.19. For any $\alpha>0,0<p \leq \infty$ and $0<q \leq \infty$, the classes $N_{q}^{\alpha}\left(L^{p}\right), C_{q}^{\alpha}\left(L^{p}\right)$ and $S_{q}^{\alpha}\left(L^{p}\right)$ satisfy the continuous embeddings

$$
C_{q}^{\alpha}\left(L^{p}\right) \hookrightarrow S_{q}^{\alpha}\left(L^{p}\right) \hookrightarrow N_{q}^{\alpha}\left(L^{p}\right) \hookrightarrow C_{q}^{\alpha / 2}\left(L^{p}\right) .
$$

3.5. About The Canonical Tensor Format. We conclude by comparing tensor networks with the canonical tensor format

$$
\mathcal{T}_{r}\left(V_{b, d, S}\right)=\left\{\boldsymbol{f} \in \mathbf{V}_{b, d, S}: r(\boldsymbol{f}) \leq r\right\},
$$

which is the set of tensors that admit a representation

$$
\boldsymbol{f}\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k=1}^{r} w_{1}^{k}\left(i_{1}\right) \ldots w_{d}^{k}\left(i_{d}\right) g_{d+1}^{k}(y), \quad g_{d+1}^{k}(y)=\sum_{q=1}^{\operatorname{dim} S} w_{d+1}^{q, k} \varphi_{q}(y)
$$

with $w_{\nu} \in \mathbb{R}^{b \times r}$ for $1 \leq \nu \leq d$ and $w_{d+1} \in \mathbb{R}^{\operatorname{dim} S \times r}$. The canonical tensor format can be interpreted as a shallow sum-product neural network (or arithmetic circuit), see [12].

We let $R_{b, d, S, r}$ be the map from $\left(\mathbb{R}^{b \times r}\right)^{d} \times \mathbb{R}^{\operatorname{dim} S \times r}:=\mathcal{P}_{b, d, S, r}$ to $\mathbf{V}_{b, d, S}$ which associates to a set of tensors $\left(w_{1}, \ldots, w_{d+1}\right)$ the tensor $\boldsymbol{f}=R_{b, d, S, r}\left(w_{1}, \ldots, w_{d+1}\right)$ as defined above. We introduce the sets of functions

$$
\Phi_{b, d, S, r}=T_{b, d}^{-1} \mathcal{T}_{r}\left(V_{b, d, S}\right),
$$

which can be parametrized as follows:

$$
\Phi_{b, d, S, r}=\left\{\varphi=\mathcal{R}_{b, d, S, r}(\mathbf{w}): \mathbf{w} \in \mathcal{P}_{b, d, S, r}\right\}, \quad \mathcal{R}_{b, d, S, r}=T_{b, d}^{-1} \circ R_{b, d, S, r} .
$$

For $\varphi \in V_{b, S}$, we let

$$
r(\varphi)=\min \left\{r(\boldsymbol{f}): \boldsymbol{f} \in \mathbf{V}_{b, d(\varphi), S}, \varphi=T_{b, d}^{-1}(\boldsymbol{f})\right\} .
$$

We introduce as a natural complexity measure the representation complexity

$$
\operatorname{compl}_{\mathcal{R}}(\varphi)=b d(\varphi) r(\varphi)+r(\varphi) \operatorname{dim} S,
$$

define the sets

$$
\Phi_{n}^{\mathcal{R}}=\left\{\varphi \in \Phi_{b, d, S, r}: d \in \mathbb{N}, r \in \mathbb{N}, \operatorname{compl}_{\mathcal{R}}(\varphi) \leq n\right\},
$$

and consider the corresponding approximation classes

$$
R_{q}^{\alpha}\left(L^{p}\right)=A_{q}^{\alpha}\left(L^{p},\left(\Phi_{n}^{\mathcal{R}}\right)_{n \in \mathbb{N}}\right),
$$

with $\alpha>0$ and $0<q \leq \infty$. We start by showing that $\Phi_{n}^{\mathcal{R}}$ satisfies (P1) (P3) and (P5) (under some assumptions), but not (P4).
Lemma 3.20 ( $\Phi_{n}^{\mathcal{R}}$ satisfies (P1) (P3) and (P5)). Let $1 \leq p \leq \infty$ and $S \subset L^{p}$ be a finite-dimensional space. Then $\Phi_{n}^{\mathcal{R}}$ satisfies (P1) (P3). Moreover, if $S$ contains the constant function one, $\Phi_{n}^{\mathcal{R}}$ satisfies (P5) for $1 \leq p<\infty$.
Proof. (P1) (P3) are obvious. (P5) follows from the fact that

$$
\bigcup_{n \in \mathbb{N}} \Phi_{n}^{\mathcal{R}}=\bigcup_{d \in \mathbb{N}} \bigcup_{r \in \mathbb{N}} \Phi_{b, d, S, r}=\bigcup_{d \in \mathbb{N}} V_{b, d, S}=V_{b, S},
$$

and from Theorem 2.25,
Lemma 3.21 ( $\Phi_{n}^{\mathcal{R}}$ does not satisfy (P4). Let $1 \leq p \leq \infty$ and $S \subset L^{p}$ be a finite-dimensional subspace which is closed under b-adic dilation and such that $r\left(T_{b, d}(\varphi)\right)=1$ for any $\varphi \in S$ and $d \in \mathbb{N}$. Then, $\Phi_{n}^{\mathcal{R}}$ satisfies
(i) $\Phi_{n}^{\mathcal{R}}+\Phi_{n}^{\mathcal{R}} \subset \Phi_{3 n^{2}}^{\mathcal{R}}$,
(ii) there exists no constant $c>1$ such that $\Phi_{n}^{\mathcal{R}}+\Phi_{n}^{\mathcal{R}} \subset \Phi_{c n}^{\mathcal{R}}$.

Proof. See Appendix B
Lemma 3.22. For any $n \in \mathbb{N}$, it holds $\Phi_{n}^{\mathcal{R}} \subset \Phi_{n}^{\mathcal{S}}$.
Proof. See Appendix B
Corollary 3.23. For any $\alpha>0$ and $0<q \leq \infty$,

$$
R_{q}^{\alpha}\left(L^{p}\right) \subset S_{q}^{\alpha}\left(L^{p}\right) .
$$

## 4. Tensor Networks as Neural Networks - The Role of Tensorization

The tensorization of functions is a milestone allowing the use of tensor networks for the approximation of multivariate functions. In this section, we interpret tensorization as a non-standard and powerful featuring step which can be encoded in a neural network with a non-classical architecture. Then, we discuss the role of this particular featuring.
4.1. Tensorization as Featuring. When applying $t_{b, d}^{-1}$ to the input variable $x$, we create $d+1$ new variables $\left(i_{1}, \ldots, i_{d}, y\right)$ defined by

$$
i_{\nu}=\sigma\left(b^{\nu} x\right), \quad \sigma(t)=\lfloor t\rfloor \bmod b
$$

$1 \leq \nu \leq d$, and

$$
y=\tilde{\sigma}\left(b^{d} x\right), \quad \tilde{\sigma}(t)=t-\lfloor t\rfloor
$$

see Figure 4 for a graphical representation of functions $\sigma$ and $\tilde{\sigma}$. Then for each $1 \leq \nu \leq d$, we create

Figure 4. Functions $\sigma$ and $\tilde{\sigma}$
$b$ features $\delta_{j_{\nu}}\left(i_{\nu}\right), 0 \leq j_{\nu} \leq b-1$, and we also create $m+1$ features $\varphi_{k}(y)=y^{k}$ from the variable $y$ (or other features for $S$ different from $\mathbb{P}_{m}$ )..$^{6}$ Figure 5 provides an illustration of these features and of products of these features. Finally, tensorization can be seen as a featuring step with a featuring map

$$
\Phi:[0,1) \rightarrow \mathbb{R}^{b^{d}(m+1)}
$$

which maps $x \in[0,1)$ to a $(d+1)$-order tensor

$$
\Phi(x)_{j_{1}, \ldots, j_{d+1}}=\delta_{j_{1}}(\sigma(b x)) \ldots \delta_{j_{d}}\left(\sigma\left(b^{d} x\right)\right) \tilde{\sigma}\left(b^{d} x\right)^{j_{d+1}}
$$

A function $\varphi \in V_{b, d, m}$ is then represented by $\varphi(x)=\sum_{j} \Phi(x)_{j} a_{j}$, where $a$ is a $(d+1)$-order tensor with entries associated with the $b^{d}(m+1)$ features. When considering for $a$ a full tensor (not rankstructured), it results in a linear approximation tool which is equivalent to spline approximation. Note that functions represented on Figures 5 c and 5 d are obtained by summing many features $\Phi(x)_{j_{1}, \ldots, j_{d+1}}$. However, these functions, which have rank-one tensorizations, can be represented with a rank-one tensor $a$ in the feature tensor space, and thus can be encoded with very low complexity within our nonlinear approximation tool.

Increasing $d$ means considering more and more features, and is equivalent to refining the discretisation. At this point, tensorization is an interpretation of a univariate function as a multivariate function, but it is also an alternative way to look at discretization.

[^6]

Figure 5. Representation of some features and their products for $b=2$.
4.2. Encoding Tensorization with a Neural Network. The tensorization step can be encoded as a three-layer feedforward neural network with a single intput $x$ and $b^{d}(m+1)$ outputs corresponding to the entries of $\Phi(x)$. The variables $\left(i_{1}, \ldots, i_{d}, y\right)$ can be seen as the output of a first layer with $d+1$ neurons, which corresponds to the application of a linear map $x \mapsto\left(b, b^{2}, \ldots, b^{d}, b^{d}\right) x$ to the input variable $x$, followed by a component-wise application of the activation function $\sigma$ (for the first $d$ neurons) or $\tilde{\sigma}$ (for the last neuron). Noting that $\delta_{j_{\nu}}\left(i_{\nu}\right)=\mathbb{1}_{[0,1)}\left(i_{\nu}-j_{\nu}\right)$, the variable $\delta_{j_{\nu}}\left(i_{\nu}\right)$ can be seen as the output of a neuron which applies the activation function $t \mapsto \mathbb{1}_{[0,1)}(t)$ to a shift of the input $i_{\nu}$. The variables $y^{k}$ correspond to the ouputs of a classical power unit with input $y$. Therefore, the resulting variables $\delta_{j_{\nu}}\left(i_{\nu}\right)\left(1 \leq \nu \leq d, 0 \leq j_{\nu} \leq b-1\right)$ and $y^{k}(0 \leq k \leq m)$ are the outputs of a second layer with $b d+(m+1)$ neurons, using the activation function $t \mapsto \mathbb{1}_{[0,1)}(t)$ (for the first $b d$ neurons) or classical power activation functions $y \mapsto y^{k}$ for the last $m+1$ neurons. The third layer corresponds to a product pooling layer which creates new variables that are products of $d+1$ variables $\left\{\delta_{j_{1}}\left(i_{1}\right), \ldots, \delta_{j_{d}}\left(i_{d}\right), \varphi_{j_{d+1}}(y)\right\}$.

The approximation tool considered in this work then corresponds to neural networks with three first layers implementing the particular featuring map $\Phi$ followed by a tensor network or sum-product network (with recurrent network architecture). Note that, if instead of using a sum-product network we take a simple linear combination of the outputs of the third layer, we end up with a neural network implementing classical splines with degree $m$ and $b^{d}$ knots.
4.3. The Role of Tensorization. Another featuring (which is rather straight-forward) would have consisted in taking new variables (or features) $x_{j, k}=\left(b^{d} x-j\right)^{k} \mathbb{1}_{I_{j}}(x)=x^{k} \mathbb{1}_{[0,1)}\left(b^{d} x-j\right), 0 \leq k \leq m$, $0 \leq j<b^{d}$, where $I_{j}$ is the interval $\left[b^{d} j, b^{d}(j+1)\right)$. This also leads to $(m+1) b^{d}$ features. This featuring step can be encoded with a two-layer neural network, the first layer with $b^{d}$ neurons implementing affine transformations $x \mapsto b^{d} x-j$ followed by the application of the activation function $t \mapsto t \mathbb{1}_{[0,1)}(t)$, and
a second layer with $b^{d}(m+1)$ neurons that apply classical power activation functions to the outputs of the first layer. When considering a simple linear combination of the outputs of this two-layer neural network, we also end up with classical fixed knot spline approximation.

Both featuring (or tensorization) methods can be encoded with feed-forward neural networks, and both methods lead to a linear feature space corresponding to classical spline approximation. One may ask what is the interest of using the very specific feature map $\Phi$ ? In fact, the use of the particular feature map $\Phi$, which is related to multi-resolution analysis, allows to further exploit sparsity or low-rankness of the tensor when approximating functions from smoothness spaces, and probably other classes of functions. It is well known that the approximation class of splines of degree $m \geq r-1$ is the Sobolev space $W^{r, p}$. Therefore, whatever the featuring used, the approximation class of the resulting linear approximation tool (taking linear combinations of the features) is the Sobolev space $W^{m+1, p}$. We will see in Part II [2] that (near-)optimal performance is achieved by the proposed approximation tool for a large range of smoothness spaces for any fixed $m$ (including $m=0$ ), at the price of letting $d$ grow (or equivalently the depth of the tensor networks) to capture higher regularity of functions. When working with a fixed $m$, exploiting low-rank structures will then be crucial.

This reveals that the power of the approximation tool considered in this work comes from the combination of a particular featuring step (the tensorization step) and the use of tensor networks.

## Appendix A. Proofs for Section 2

Proof of Lemma 2.6. We have

$$
t_{b, \bar{d}}\left(i_{1}, \ldots, i_{\bar{d}}, y\right)=\sum_{k=1}^{\bar{d}} i_{k} b^{-k}+b^{-\bar{d}} y=\sum_{k=1}^{d} i_{k} b^{-k}+\sum_{k=1}^{\bar{d}-d} i_{k+d} b^{-k-d}+b^{-\bar{d}} y=\sum_{k=1}^{d} i_{k} b^{-k}+b^{-d} z,
$$

with $z=\sum_{k=1}^{\bar{d}-d} i_{k+d} b^{-k}+b^{-(\bar{d}-d)} y=t_{b, \bar{d}-d}\left(i_{d+1}, \ldots, i_{\bar{d}}, y\right)$, which proves the first statement. Then consider an elementary tensor $\boldsymbol{v}=v_{1} \otimes \ldots \otimes v_{d} \otimes g \in \mathbf{V}_{b, d}$, with $v_{k} \in \mathbb{R}^{I_{b}}$ and $g \in \mathbb{R}^{[0,1)}$. We have

$$
\begin{aligned}
T_{b, \bar{d}} \circ T_{b, d}^{-1} \boldsymbol{v}\left(i_{1}, \ldots, i_{\bar{d}}, y\right) & =\boldsymbol{v}\left(t_{b, d}^{-1} \circ t_{b, \bar{d}}\left(i_{1}, \ldots, i_{\bar{d}}, y\right)\right) \\
& =\boldsymbol{v}\left(i_{1}, \ldots, i_{d}, t_{b, \bar{d}-d}\left(i_{d+1}, \ldots, i_{\bar{d}}, y\right)\right) \\
& =v_{1}\left(i_{1}\right) \ldots v_{d}\left(i_{d}\right) g\left(t_{b, \bar{d}-d}\left(i_{d+1}, \ldots, i_{\bar{d}}, y\right)\right) \\
& =v_{1}\left(i_{1}\right) \ldots v_{d}\left(i_{d}\right) T_{b, \bar{d}-d} g\left(i_{d+1}, \ldots, i_{\bar{d}}, y\right) \\
& =\left(v_{1} \otimes \ldots \otimes v_{d} \otimes\left(T_{b, \bar{d}-d} g\right)\right)\left(i_{d+1}, \ldots, i_{\bar{d}}, y\right),
\end{aligned}
$$

which proves the second property. The last property simply follows from $T_{b, d} \circ T_{b, \bar{d}}^{-1}=\left(T_{b, \bar{d}} \circ T_{b, d}^{-1}\right)^{-1}=$ $\left(i d_{\{1, \ldots, d\}} \otimes T_{b, \bar{d}-d}\right)^{-1}=i d_{\{1, \ldots, d\}} \otimes T_{b, \bar{d}-d}^{-1}$.

Proof of Lemma 2.9. $\boldsymbol{f}$ is identified with a tensor in $\mathbf{V}_{\beta} \otimes \mathbf{V}_{\beta^{c}}$ with $\mathbf{V}_{\beta} \in\left(\mathbb{R}^{I_{b}}\right)^{\otimes \# \beta}$ and $\mathbf{V}_{\beta^{c}}=\mathbf{V}_{b, d-\# \beta}$. We have $U_{\beta^{c}}^{\min }(\boldsymbol{f})=\left\{\left(\boldsymbol{\varphi}_{\beta} \otimes i d_{\beta^{c}}\right) \boldsymbol{f}: \boldsymbol{\varphi}_{\beta} \in\left(\mathbf{V}_{\beta}\right)^{\prime}\right\}$ with $\left(\mathbf{V}_{\beta}\right)^{\prime}$ the algebraic dual of $\mathbf{V}_{\beta}$ (see [15, Corollary 2.19]). Then for any basis $\left\{\boldsymbol{\varphi}_{\beta}^{j_{\beta}}: j_{\beta} \in I_{b}^{\# \beta}\right\}$ of $\left(\mathbf{V}_{\beta}\right)^{\prime}$, we have $U_{\beta^{c}}^{\min }(\boldsymbol{f})=\operatorname{span}\left\{\left(\boldsymbol{\varphi}_{\beta}^{j_{\beta}} \otimes i d_{\beta^{c}}\right) \boldsymbol{f}: j_{\beta} \in I_{b}^{\# \beta}\right\}$. We conclude by introducing the particular basis $\varphi_{\beta}^{j_{\beta}}=\delta_{j_{\beta}}$, with $\delta_{j_{\beta}}=\otimes_{\nu \in \beta} \delta_{j_{\nu}} \in \mathbb{R}_{b}^{I_{b}{ }^{\# \beta}}$, and by noting that $\left(\delta_{j_{\beta}} \otimes i d_{\beta^{c}}\right) \boldsymbol{f}=\boldsymbol{f}\left(j_{\beta}, \cdot\right) \in \mathbf{V}_{\beta^{c}}$.
Proof of Lemma 2.11. For any set $\beta \subset\{1, \ldots, d+1\}$ and any partition $\beta=\gamma \cup \alpha$, the minimal subspaces from Definition 2.8 satisfy the hierarchy property (see [25, Corollary 6.18]) $U_{\beta}^{\min }(\boldsymbol{f}) \subset U_{\gamma}^{\min }(\boldsymbol{f}) \otimes$ $U_{\alpha}^{\min }(\boldsymbol{f})$, from which we deduce that $r_{\beta}(\boldsymbol{f}) \leq r_{\gamma}(\boldsymbol{f}) r_{\alpha}(\boldsymbol{f})$. Then for $1 \leq \nu \leq d-1$, by considering $\gamma=$ $\{1, \ldots, \nu\}$ and $\alpha=\{\nu+1\}$, we obtain $r_{\nu+1}(\boldsymbol{f}) \leq r_{\nu}(\boldsymbol{f}) r_{\{\nu+1\}}(\boldsymbol{f})$, where $r_{\{\nu+1\}}(\boldsymbol{f})=\operatorname{dim} U_{\{\nu+1\}}^{\min }(\boldsymbol{f}) \leq b$, which yields the first inequality. By considering $\gamma=\{\nu+1\}$ and $\alpha=\{\nu+2, \ldots, d+1\}$, we obtain $r_{\nu}(\boldsymbol{f})=r_{\{\nu+1, \ldots, d+1\}}(\boldsymbol{f}) \leq r_{\{\nu+1\}}(\boldsymbol{f}) r_{\{\nu+2, \ldots, d+1\}}(\boldsymbol{f})=r_{\{\nu+1\}}(\boldsymbol{f}) r_{\nu+1}(\boldsymbol{f}) \leq b r_{\nu+1}(\boldsymbol{f})$, that is the second inequality.

Proof of Lemma 2.12. We have from Lemma 2.9 that

$$
T_{b, d-\nu}^{-1}\left(U_{\{\nu+1, \ldots, d+1\}}^{\min }\left(f^{d}\right)\right)=\operatorname{span}\left\{T_{b, d-\nu}^{-1}\left(f^{d}\left(j_{1}, \ldots, j_{\nu}, \cdot\right)\right):\left(j_{1}, \ldots, j_{\nu}\right) \in I_{b}^{\nu}\right\}
$$

where $\boldsymbol{f}^{d}\left(j_{1}, \ldots, j_{\nu}, \cdot\right) \in \mathbf{V}_{b, d-\nu}$ is a partial evaluation of $\boldsymbol{f}^{d}$ along the first $\nu$ dimensions. We note that

$$
\begin{aligned}
T_{b, d-\nu}^{-1}\left(\boldsymbol{f}^{d}\left(j_{1}, \ldots, j_{\nu}, \cdot\right)\right) & =\left(\left(i d_{\{1, \ldots, \nu\}} \otimes T_{b, d-\nu}^{-1}\right) \boldsymbol{f}^{d}\right)\left(j_{1}, \ldots, j_{\nu}, \cdot\right) \\
& =\left(T_{b, \nu} \circ T_{b, d}^{-1} \boldsymbol{f}^{d}\right)\left(j_{1}, \ldots, j_{\nu}, \cdot\right)=\boldsymbol{f}^{\nu}\left(j_{1}, \ldots, j_{\nu}, \cdot\right),
\end{aligned}
$$

where the second equality results from Lemma 2.6. The result then follows from Lemma 2.9 again.
Proof of Proposition 2.14. Subsets of the form $J \times A$, with $A$ a Borel set of $[0,1)$ and $J=\times_{k=1}^{d} J_{k}$ with $J_{k} \subset I_{b}, 1 \leq k \leq d$, form a generating system of the Borel $\sigma$-algebra of $I_{b}^{d} \times[0,1)$. The image of such a set $J \times A$ through $t_{b, d}$ is $\bigcup_{j \in J} A_{j}$, where $A_{j_{1}, \ldots, j_{d}}=b^{-d}(j+A)$ with $j=\sum_{k=1}^{d} j_{k} b^{d-k}$. Then
$\lambda\left(t_{b, d}(J \times A)\right)=\lambda\left(\bigcup_{j \in J} A_{j}\right)=\# J b^{-d} \lambda(A)=\# J_{1} \ldots \# J_{d} b^{-d} \lambda(A)=\mu_{b}\left(J_{1}\right) \ldots \mu_{b}\left(J_{d}\right) \lambda(A)=\mu_{b, d}(J \times A)$.
Then, we conclude on $T_{b, d}$ by noting that it is a linear bijection (Proposition 2.3) which preserves measurability.
Lemma A.1. Let $S$ be a closed subspace of $L^{p}, 1 \leq p \leq \infty$. The norm $\|\cdot\|_{p}$ is a reasonable crossnorm on $\left(\ell^{p}\left(I_{b}\right)^{\otimes d} \otimes S\right.$.
Proof. Let $v_{k} \in \ell^{p}\left(I_{b}\right), 1 \leq k \leq d$, and $g \in S$. For $p<\infty$, we have

$$
\left\|v_{1} \otimes \ldots \otimes v_{d} \otimes g\right\|_{p}^{p}=\sum_{i_{1} \in I_{b}} \ldots \sum_{i_{d} \in I_{b}}\left|v_{1}\left(i_{1}\right)\right|^{p} \ldots\left|v_{d}\left(i_{d}\right)\right|^{p} b^{-d} \int_{0}^{1}|g(y)|^{p} d y=\left\|v_{1}\right\|_{\ell^{p}}^{p} \ldots\left\|v_{d}\right\|_{\ell^{p}}^{p}\|g\|_{p}^{p},
$$

and for $p=\infty$,

$$
\left\|v_{1} \otimes \ldots \otimes v_{d} \otimes g\right\|_{\infty}=\max _{i_{1} \in I_{b}}\left|v_{1}\left(i_{1}\right)\right| \ldots \max _{i_{d} \in I_{b}}\left|v_{d}\left(i_{d}\right)\right| \underset{y}{\operatorname{ess} \sup }|g(y)|=\left\|v_{1}\right\| \ell_{\ell \infty} \ldots\left\|v_{d}\right\|_{\ell_{\infty}}\|g\|_{\infty},
$$

which proves that $\|\cdot\|_{p}$ is a crossnorm. Then, consider the dual norm $\|\varphi\|_{p}^{*}=\sup _{\|f\| \leq 1}|\varphi(\boldsymbol{f})|$ over the algebraic tensor space $\left(\ell^{p}\left(I_{b}\right)^{*}\right)^{\otimes d} \otimes S^{*}$, where $V^{*}$ stands for the continuous dual of a space $V$. For $(v, \psi) \in \ell^{p}\left(I_{b}\right) \times \ell^{p}\left(I_{b}\right)^{*}$, we consider the duality pairing $\psi(v)=b^{-1} \sum_{k=0}^{b-1} \psi_{k} v_{k}$, such that $\ell^{p}\left(I_{b}\right)^{*}=$ $\ell^{q}\left(I_{b}\right)$ with $1 / p+1 / q=1$. Consider $\phi \in S^{*}$ and $\varphi_{\nu} \in \ell^{p}\left(I_{b}\right)^{*}, 1 \leq \nu \leq d$. To prove that $\|\cdot\|_{p}$ is a reasonable crossnorm, we have to prove that

$$
\left\|\varphi_{1} \otimes \ldots \otimes \varphi_{d} \otimes \phi\right\|_{p}^{*} \leq\left\|\varphi_{1}\right\|_{\ell q} \ldots\left\|\varphi_{d}\right\|_{\ell q}\|\phi\|_{p}^{*},
$$

with $\|\phi\|_{p}^{*}=\sup _{f \in S,\|f\|_{p} \leq 1} \phi(f)$. Let $\varphi=\varphi_{1} \otimes \ldots \otimes \varphi_{d} \in\left(\ell^{p}\left(I_{b}\right)^{*}\right)^{\otimes d}=\ell^{q}\left(I_{b}^{d}\right)$. For $j \in I_{b}^{d}$, we let $\delta_{j}=\delta_{j_{1}} \otimes \ldots \otimes \delta_{j_{d}} \in \ell^{p}\left(I_{b}^{d}\right)$. Any $\boldsymbol{f} \in V_{b, d, S}$ admits a representation $\boldsymbol{f}=\sum_{j \in I_{b}^{d}} \delta_{j} \otimes g_{j}$ where $g_{j}=\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right) \in L^{p}$, and

$$
\left|\left(\varphi_{1} \otimes \ldots \otimes \varphi_{d} \otimes \phi\right)(\boldsymbol{f})\right|=\mid \varphi\left(\sum_{j \in I_{b}^{d}} \delta_{j} \phi\left(g_{j}\right)|=|\varphi(\mathbf{v})|\right.
$$

where $\mathbf{v} \in \ell^{p}\left(I_{b}^{d}\right)$ is a tensor with entries $\mathbf{v}(j)=\phi\left(g_{j}\right)$. Also,

$$
|\varphi(\mathbf{v})| \leq\|\varphi\|_{\ell^{p}}^{*}\|\mathbf{v}\|_{\ell^{p}} \leq\|\varphi\|_{\ell^{q}}\|\phi\|_{p}^{*}\|\mathbf{w}\|_{\ell^{p}},
$$

where $\mathbf{w} \in \ell^{p}\left(I_{b}^{d}\right)$ is a tensor with entries $\mathbf{w}(j)=\left\|g_{j}\right\|_{p}=\left\|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right\|_{p}$. From Theorem 2.15, we have $\|\mathbf{w}\|_{\ell \infty}=\max _{j \in I_{b}^{d}}\left\|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right\|_{\infty}=\|\boldsymbol{f}\|_{\infty}$, and for $p<\infty$

$$
\|\mathbf{w}\|_{\ell^{p}}^{p}=b^{-d} \sum_{j \in I_{b}^{d}}|\mathbf{w}(j)|^{p}=b^{-d} \sum_{j \in I_{b}^{d}}\left\|\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right\|_{p}^{p}=\|\boldsymbol{f}\|_{p}^{p} .
$$

Therefore, $\left|\left(\varphi_{1} \otimes \ldots \otimes \varphi_{d} \otimes \phi\right)(\boldsymbol{f})\right| \leq\|\varphi\|_{\ell q}\|\phi\|_{p}^{*}\|\boldsymbol{f}\|_{p}$. We conclude by noting that $\|\cdot\|_{\ell^{q}}$ is a crossnorm on $\ell^{q}\left(I_{b}^{d}\right)=\ell^{q}\left(I_{b}\right)^{\otimes d}$, so that $\|\varphi\|_{\ell^{q}\left(I_{b}^{d}\right)}=\left\|\varphi_{1}\right\|_{\ell^{q}} \ldots\left\|\varphi_{d}\right\|_{\ell^{q}}$.
Proof of Lemma 2.22. By definition, the result is true for $d=1$. The result is then proved by induction. Assume that for all $f \in S, f\left(b^{-d}(\cdot+k)\right) \in S$ for all $k \in\left\{0, \ldots, b^{d}-1\right\}$. Then for $f \in S$, consider the function $f\left(b^{-d-1}(\cdot+k)\right)$ with $k \in\left\{0, \ldots, b^{d+1}-1\right\}$. We can write $k=b k^{\prime \prime}+k^{\prime}$ for some $k^{\prime} \in\{0, \ldots, b-1\}$ and $k^{\prime \prime} \in\left\{0, \ldots, b^{d}-1\right\}$. Then for any $x \in[0,1)$,

$$
f\left(b^{-d-1}(x+k)\right)=f\left(b^{-d}\left(b^{-1}\left(x+k^{\prime}\right)+k^{\prime \prime}\right)\right)=g\left(b^{-1}\left(x+k^{\prime}\right)\right)
$$

for some $g \in S$, and $g\left(b^{-1}\left(x+k^{\prime}\right)\right)=h(x)$ for some $h \in S$. Therefore $f\left(b^{-d-1}(\cdot+k)\right)=h(\cdot) \in S$, which ends the proof.
Proof of Proposition 2.23. For $f \in S$, we have $\left(T_{b, 1} f\right)\left(i_{1}, \cdot\right)=f\left(b^{-1}\left(\cdot+i_{1}\right)\right)$. Then from Lemma 2.22, we have $\left(T_{b, 1} f\right)\left(i_{1}, \cdot\right) \in S$, which implies $f \in V_{b, 1, S}$. Now assume $f \in V_{b, d, S}$ for $d \in \mathbb{N}$, i.e. $T_{b, d} f=$ $\boldsymbol{f}^{d} \in \mathbf{V}_{b, d, S}$. Then $\boldsymbol{f}^{d}\left(i_{1}, \ldots, i_{d}, \cdot\right) \in S$ and from Lemma 2.22, $\boldsymbol{f}^{d}\left(i_{1}, \ldots, i_{d}, b^{-1}\left(i_{d+1}+\cdot\right)\right) \in S$. Then using Lemma 2.6, we have that $\boldsymbol{f}^{d}\left(i_{1}, \ldots, i_{d}, b^{-1}\left(i_{d+1}+\cdot\right)\right)=f \circ t_{b, d}\left(i_{1}, \ldots, i_{d}, t_{b, 1}\left(i_{d+1}, \cdot\right)\right)=f \circ$ $t_{b, d+1}\left(i_{1}, \ldots, i_{d+1}, \cdot\right)$, which implies that $\left(T_{b, d+1} f\right)\left(i_{1}, \ldots, i_{d+1}, \cdot\right) \in S$, and therefore $f \in V_{b, d+1, S}$.

Proof of Proposition 2.24. Since $0 \in V_{b, d, S}$ for any $d$, we have $0 \in V_{b, S}$. For $f_{1}, f_{2} \in V_{b, S}$, there exists $d_{1}, d_{2} \in \mathbb{N}$ such that $f_{1} \in V_{b, d_{1}, S}$ and $f_{2} \in V_{b, d_{2}, S}$. Letting $d=\max \left\{d_{1}, d_{2}\right\}$, we have from Proposition 2.23] that $f_{1}, f_{2} \in V_{b, d, S}$, and therefore $c f_{1}+f_{2} \in V_{b, d, S} \subset V_{b, S}$ for all $c \in \mathbb{R}$, which ends the proof.
Proof of Theorem 2.25. The set of simple functions over $[0,1)$ is dense in $L^{p}([0,1))$ for $1 \leq p<\infty$ (see, e.g., [9, Lemma 4.2.1]). Then, it remains to prove that $V_{b, S}$ is dense in the set of simple functions over $[0,1)$. Consider a simple function $f=\sum_{i=0}^{n-1} a_{i} \mathbb{1}_{\left[x_{i}, x_{i+1}\right)} \neq 0$, with $0=x_{0}<x_{1}<\ldots<x_{n}=1$, and $\|f\|_{p}^{p}=\sum_{i=0}^{n-1}\left|a_{i}\right|^{p}\left(x_{i+1}-x_{i}\right)$. Let $x_{i}^{d}=b^{-d}\left\lfloor b^{d} x_{i}\right\rfloor, 0 \leq i \leq n$, and consider the function $f_{d}=$ $\sum_{i=0}^{n-1} a_{i} \mathbb{1}_{\left[x_{i}^{d}, x_{i+1}^{d}\right)}$ which is such that $f_{d} \in V_{b, d, S}$. Then, noting that $x_{0}^{d}=x_{0}=0$ and $x_{n}^{d}=x_{n}=1$, it holds

$$
f-f_{d}=\sum_{i=0}^{n-1} a_{i}\left(\mathbb{1}_{\left[x_{i}, x_{i+1}\right)}-\mathbb{1}_{\left[x_{i}^{d}, x_{i+1}^{d}\right]}\right)=\sum_{i=0}^{n-1} a_{i}\left(\mathbb{1}_{\left[x_{i+1}^{d}, x_{i+1}\right)}-\mathbb{1}_{\left[x_{i}^{d}, x_{i}\right)}\right)=\sum_{i=0}^{n-2}\left(a_{i}-a_{i+1}\right) \mathbb{1}_{\left[x_{i+1}^{d}, x_{i+1}\right)} .
$$

Then, noting that $0 \leq x_{i}-x_{i}^{d} \leq b^{-d}$ for all $0<i<n$, we have

$$
\left\|f-f_{d}\right\|_{p}^{p}=\sum_{i=0}^{n-2}\left|a_{i}-a_{i+1}\right|^{p}\left(x_{i+1}-x_{i+1}^{d}\right) \leq 2^{p} b^{-d} \sum_{i=0}^{n-1}\left|a_{i}\right|^{p}=2^{p} b^{-d}\|f\|_{p}^{p}\left(\min _{0 \leq i \leq n-1}\left(x_{i+1}-x_{i}\right)\right)^{-1},
$$

so that $\left\|f-f_{d}\right\|_{p} \rightarrow 0$ as $d \rightarrow \infty$, which ends the proof.
Proof of Lemma 2.27. (i) If $f \in S$, from Proposition 2.23, we have $f \in V_{b, \nu, S}$ for any $\nu$, so that $r_{\nu, \nu}(f) \leq \operatorname{dim} S$. Then, using Corollary 2.13, we have $r_{\nu, d}(f)=r_{\nu, \nu}(f) \leq \operatorname{dim} S$. The other bound $r_{\nu, d}(f) \leq b^{\nu}$ results from Lemma 2.26.
(ii) The fact that $f \in V_{b, \bar{d}, S}$ follows from Proposition 2.23. Then, from Corollary 2.13, we have that $r_{\nu, \bar{d}}(f)=r_{\nu, \nu}(f)$ for all $1 \leq \nu \leq \bar{d}$. For $1 \leq \nu \leq d$, Corollary 2.13 also implies $r_{\nu, \nu}(f)=r_{\nu, d}(f)$ and we obtain the desired inequality from Lemma 2.26 . For $\nu>d$, we note that $r_{\nu, \nu}(f)=\operatorname{dim} U_{\{\nu+1\}}^{\min }\left(T_{b, \nu} f\right)$. From Proposition 2.23, we know that $T_{b, \nu} f \in V_{b, \nu, S}$ for $\nu \geq d$, so that $U_{\{\nu+1\}}^{\min }\left(T_{b, \nu} f\right) \subset S$ and $r_{\nu, \nu}(f) \leq$ $\operatorname{dim}(S)$. The other bound $r_{\nu, \bar{d}}(f) \leq b^{\nu}$ results from Lemma 2.26 .

Proof of Lemma 2.29, Let $\left\{\phi_{l}\right\}_{1 \leq l \leq \operatorname{dim} S}$ be a basis of $S$, such that for $g \in L^{p}, \mathcal{I}_{S}(g)=\sum_{l=1}^{\operatorname{dim} S} \phi_{l} \sigma_{l}(g)$, with $\sigma_{l}$ a linear map from $L^{p}$ to $\mathbb{R}$. For $f \in L^{p}$, and $x \in\left[b^{-d} j, b^{-d}(j+1)\right)$,

$$
\mathcal{I}_{b, d, S} f(x)=\sum_{l=1}^{\operatorname{dim} S} \phi_{l}\left(b^{d} x-j\right) \sigma_{l}\left(f\left(b^{-d}(j+\cdot)\right) .\right.
$$

We have $f\left(b^{-d}(j+\cdot)=\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right.$, with $j=\sum_{k=1}^{d} b^{d-k} j_{k}$ and $\boldsymbol{f}=T_{b, d} f$, so that

$$
T_{b, d}\left(\mathcal{I}_{b, d, S} f\right)\left(j_{1}, \ldots, j_{d}, y\right)=\sum_{l=1}^{\operatorname{dim} S} \phi_{l}(y) \sigma_{l}\left(\boldsymbol{f}\left(j_{1}, \ldots, j_{d}, \cdot\right)\right)
$$

For $\boldsymbol{f}=\varphi_{1} \otimes \ldots \varphi_{d} \otimes g$, using the linearity of $\sigma_{l}$, we then have

$$
T_{b, d}\left(\mathcal{I}_{b, d, S}\left(T_{b, d}^{-1} \boldsymbol{f}\right)\right)\left(j_{1}, \ldots, j_{d}, y\right)=\varphi_{1}\left(j_{1}\right) \ldots \varphi_{d}\left(j_{d}\right)\left(\sum_{l=1}^{\operatorname{dim} S} \phi_{l}(y) \sigma_{l}(g)\right)=\varphi_{1}\left(j_{1}\right) \ldots \varphi_{d}\left(j_{d}\right) \mathcal{I}_{S}(g)(y),
$$

which proves (2.14).

## Appendix B. Proofs for Section 3

Proof of Proposition 3.5. (ii). Let $\varphi_{A}, \varphi_{B} \in \Phi_{n}$ with $\varphi_{A} \in V_{b, d_{A}, S}, \varphi_{B} \in V_{b, d_{B}, S}$ and w.l.o.g. $d_{B} \geq d_{A}$. Set $r_{A}:=r_{\max }\left(\varphi_{A}\right)$ and $r_{B}:=r_{\max }\left(\varphi_{B}\right)$. Then,

$$
\begin{aligned}
\operatorname{compl}\left(\varphi_{A}+\varphi_{B}\right) & \leq b d_{A}\left(\max \left(r_{A}, \operatorname{dim} S\right)+r_{B}\right)^{2}+\left(\max \left(r_{A}, \operatorname{dim} S\right)+r_{B}\right) \operatorname{dim} S \\
& \leq 2 b d_{A} r_{B}^{2}+4 b d_{A} r_{A}^{2}+4 b d_{A}(\operatorname{dim} S)^{2}+r_{A} \operatorname{dim} S+r_{B} \operatorname{dim} S+(\operatorname{dim} S)^{2} \\
& \leq\left[4+4(\operatorname{dim} S)^{2}+\operatorname{dim} S\right] n+4 n^{2} \leq\left[8+4(\operatorname{dim} S)^{2}+\operatorname{dim} S\right] n^{2}
\end{aligned}
$$

(i). Let $W_{0}$ denote the principal Branch of the Lambert $W$ function. Take $n \in \mathbb{N}$ large enough such that

$$
d_{A}:=\left\lfloor\frac{1}{\ln (b)} W_{0}\left[n \frac{\ln (b)}{2 \max \{b, \operatorname{dim} S\}}\right]\right\rfloor \geq 2, \quad d_{A}:=\left\lfloor\frac{n-\operatorname{dim} S}{b}\right\rfloor \geq 2
$$

Pick a full-rank function $\varphi_{A} \in V_{b, d_{A}, S}$ such that $r_{A}^{2}:=r_{\max }^{2}\left(\varphi_{A}\right)=b^{2\left\lfloor\frac{d_{A}}{2}\right\rfloor}$. Then,

$$
\operatorname{compl}\left(\varphi_{A}\right) \leq b d_{A} b^{d_{A}}+b^{\frac{d_{A}}{2}} \operatorname{dim} S \leq 2 \max \{b, \operatorname{dim} S\} d_{A} b^{d_{A}} \leq n,
$$

by the choice of $d_{A}$ and the properties of the Lambert $W$ function.
Pick any $\varphi_{B} \in V_{b, d_{B}, S}$ with $r_{B}:=r_{\max }\left(\varphi_{B}\right)=1$ and $d_{B}=d_{A}$, so that $\operatorname{compl}\left(\varphi_{B}\right)=b d_{B}+\operatorname{dim} S \leq n$. Then, $\varphi_{A}, \varphi_{B} \in \Phi_{n}$. On the other hand, $r_{A} \geq r_{B}$ and from [29] we can estimate the Lambert $W$ function from below as

$$
W_{0}\left[n \frac{\ln (b)}{2 \max \{b, \operatorname{dim} S\}}\right] \geq \ln \left[n \frac{\ln (b)}{2 \max \{b, \operatorname{dim} S\}}\right]-\ln \ln \left[n \frac{\ln (b)}{2 \max \{b, \operatorname{dim} S\}}\right]
$$

Then

$$
\begin{aligned}
\operatorname{compl}\left(\varphi_{A}+\varphi_{B}\right) & \geq b d_{A} r_{A}^{2}+r_{A} \operatorname{dim} S \\
& \geq b\left(\frac{n-\operatorname{dim} S}{b}-1\right)\left(b^{\frac{1}{\ln (b)} W_{0}\left[n \frac{\ln (b)}{2 \max \{b, \operatorname{dim} S\}}\right]-1}\right) \\
& =\left(\frac{n-\operatorname{dim} S}{b}-1\right)\left(n \frac{\ln (b)}{2 \max \{b, \operatorname{dim} S\}}\right)\left[\ln \left(n \frac{\ln (b)}{2 \max \{b, \operatorname{dim} S\}}\right)\right]^{-1},
\end{aligned}
$$

The leading term in the latter expression is

$$
\frac{\ln (b)}{2 b \max \{b, \operatorname{dim} S\}} n^{2}\left[\ln \left(n \frac{\ln (b)}{2 \max \{b, \operatorname{dim} S\}}\right)\right]^{-1}
$$

This cannot be bounded by $c n$ for any $c>0$ and thus (i) follows.
Proof of Lemma 3.6. Let $\varphi_{A}, \varphi_{B} \in \Phi_{n}^{\mathcal{N}}$ with $d_{A}:=d\left(\varphi_{A}\right), d_{B}:=d\left(\varphi_{B}\right), \boldsymbol{r}^{A}:=\boldsymbol{r}^{A}\left(\varphi_{A}\right), \boldsymbol{r}^{B}:=\boldsymbol{r}^{B}\left(\varphi_{B}\right)$ and w.l.o.g. $d_{A} \leq d_{B}$. Then using Lemma 2.27,

$$
\begin{aligned}
\operatorname{compl}_{\mathcal{N}}\left(\varphi_{A}+\varphi_{B}\right) & \leq \sum_{\nu=1}^{d_{B}}\left(r_{\nu}^{A}+r_{\nu}^{B}\right) \leq \sum_{\nu=1}^{d_{A}} r_{\nu}^{A}+\left(d_{B}-d_{A}\right) \operatorname{dim} S+\sum_{\nu=1}^{d_{B}} r_{\nu}^{B} \\
& \leq \operatorname{compl}_{\mathcal{N}}\left(\varphi_{A}\right)+\operatorname{compl}_{\mathcal{N}}\left(\varphi_{B}\right)(1+\operatorname{dim} S) \leq(2+\operatorname{dim} S) n .
\end{aligned}
$$

Proof of Lemma 3.8. Let $\varphi_{A}, \varphi_{B} \in \Phi_{n}^{\mathcal{C}}$ with $d_{A}:=d\left(\varphi_{A}\right), d_{B}:=d\left(\varphi_{B}\right), \boldsymbol{r}^{A}:=\boldsymbol{r}^{A}\left(\varphi_{A}\right), \boldsymbol{r}^{B}:=\boldsymbol{r}^{B}\left(\varphi_{B}\right)$ and w.l.o.g. $d_{A} \leq d_{B}$. Then

$$
\left.\begin{array}{rl} 
& \operatorname{compl}_{\mathcal{C}}\left(\varphi_{A}+\varphi_{B}\right) \leq b\left(r_{1}^{A}+r_{1}^{B}\right)
\end{array}\right)+\sum_{k=2}^{d_{B}} b\left(r_{k-1}^{A}+r_{k-1}^{B}\right)\left(r_{k}^{A}+r_{k}^{B}\right)+\left(r_{d_{B}}^{A}+r_{d_{B}}^{B}\right) \operatorname{dim} S .
$$

Since $\varphi_{A}, \varphi_{B} \in \Phi_{n}^{\mathcal{C}}$, we have $N_{1}=\operatorname{compl}_{\mathcal{C}}\left(\varphi_{A}\right) \leq n$ and $N_{2}=\operatorname{compl}_{\mathcal{C}}\left(\varphi_{B}\right) \leq n$. Then, using Lemma 2.11, we have

$$
\begin{aligned}
N_{3} & \leq b\left(\sum_{k=2}^{d_{A}}\left(r_{k-1}^{A}\right)^{2}\right)^{1 / 2}\left(\sum_{k=2}^{d_{A}}\left(r_{k}^{B}\right)^{2}\right)^{1 / 2}+b\left(\sum_{k=2}^{d_{A}}\left(r_{k-1}^{B}\right)^{2}\right)^{1 / 2}\left(\sum_{k=2}^{d_{A}}\left(r_{k}^{A}\right)^{2}\right)^{1 / 2} \\
& \left.\leq b\left(\sum_{k=2}^{d_{A}} b r_{k-1}^{A} r_{k}^{A}\right)^{1 / 2}\left(\sum_{k=2}^{d_{A}} b r_{k-1}^{B} r_{k}^{B}\right)^{2}\right)^{1 / 2}+b\left(\sum_{k=2}^{d_{A}} b r_{k-1}^{B} r_{k}^{B}\right)^{1 / 2}\left(\sum_{k=2}^{d_{A}} b r_{k-1}^{A} r_{k}^{A}\right)^{1 / 2}
\end{aligned}
$$

$$
\leq 2 b \operatorname{compl}_{\mathcal{C}}\left(\varphi_{A}\right)^{1 / 2} \operatorname{compl}_{\mathcal{C}}\left(\varphi_{B}\right)^{1 / 2} \leq 2 b n .
$$

If $d_{A}=d_{B}$, we have $N_{4}=N_{5}=N_{6}=0$. If $d_{A}<d_{B}$, using Lemma 2.27, we have

$$
\begin{aligned}
& N_{4} \leq(\operatorname{dim} S)^{2} b\left(d_{B}-d_{A}\right) \leq(\operatorname{dim} S)^{2} \operatorname{compl}_{\mathcal{C}}\left(\varphi_{B}\right) \leq n(\operatorname{dim} S)^{2}, \\
& N_{5} \leq(\operatorname{dim} S)^{2} \leq(\operatorname{dim} S) \operatorname{compl}_{\mathcal{C}}\left(\varphi_{A}\right) \leq n \operatorname{dim} S, \\
& N_{6} \leq(\operatorname{dim} S)\left(\sum_{k=d_{A}+1}^{d_{B}} b r_{k}^{B}+b r_{k-1}^{B}\right) \leq 2(\operatorname{dim} S) \operatorname{compl}_{\mathcal{C}}\left(\varphi_{B}\right) \leq 2 n \operatorname{dim} S .
\end{aligned}
$$

Thus, putting all together

$$
\operatorname{compl}_{\mathcal{C}}\left(\varphi_{A}+\varphi_{B}\right) \leq\left[(\operatorname{dim} S)^{2}+3 \operatorname{dim} S+2 b+2\right] n,
$$

and (P4) is satisfied with $c:=(\operatorname{dim} S)^{2}+3 \operatorname{dim} S+2 b+2$.

Proof of Lemma 3.11. We have the representation

$$
T_{b, d}(\varphi)\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k_{1}=1}^{r_{1}} \cdots \sum_{k_{d}=1}^{r_{d}} \sum_{q=1}^{\operatorname{dim} S} v_{1}^{k_{1}}\left(i_{1}\right) \cdots v_{d}^{k_{d-1}, k_{d}}\left(i_{d}\right) v_{d+1}^{k_{d, q}} \varphi_{q}(y) .
$$

Then, from Lemma 2.6,

$$
\begin{aligned}
& T_{b, \bar{d}}(\varphi)\left(i_{1}, \ldots, i_{\bar{d}}, y\right) \\
& =\sum_{k_{1}=1}^{r_{1}} \cdots \sum_{k_{d}=1}^{r_{d}} \sum_{q=1}^{\operatorname{dim} S} v_{1}^{k_{1}}\left(i_{1}\right) \cdots v_{d}^{k_{d-1}, k_{d}}\left(i_{d}\right) v_{d+1}^{k_{d, q}, T_{b, \bar{d}-d}\left(\varphi_{q}\right)\left(i_{d+1}, \ldots, i_{\bar{d}}, y\right)} \\
& =\sum_{k_{1}=1}^{r_{1}} \cdots \sum_{k_{d}=1}^{r_{d}} \sum_{q=1}^{\operatorname{dim} S} \sum_{j_{d+1}=1}^{b} v_{1}^{k_{1}}\left(i_{1}\right) \cdots v_{d}^{k_{d-1}, k_{d}}\left(i_{d}\right) \underbrace{v_{d d,}^{k_{d}, \delta_{j_{d+1}}}\left(i_{d+1}\right)}_{\bar{v}_{d+1}^{k_{d+1}\left(q, j_{d+1}\right)}\left(i_{d+1}\right)} T_{b, \bar{d}-d}\left(\varphi_{q}\right)\left(j_{d+1}, i_{d+2}, \ldots, i_{\bar{d}}, y\right),
\end{aligned}
$$

where $\bar{v}_{d+1} \in \mathbb{R}^{b \times r_{d} \times(b \operatorname{dim} S)}$. Since $S$ is closed under $b$-adic dilation, we know from Lemma 2.27 that $r_{\nu}\left(\varphi_{q}\right) \leq \operatorname{dim} S$ for all $\nu \in \mathbb{N}$. Let $l=\bar{d}-d$ and first assume $l \geq 2$. Then, $T_{b, \bar{d}-d}\left(\varphi_{q}\right)$ admits a representation

$$
\begin{aligned}
& T_{b, \bar{d}-d}\left(\varphi_{q}\right)\left(j_{d+1}, i_{d+2}, \ldots, i_{\bar{d}}, y\right) \\
& =\sum_{\alpha_{1}=1}^{\operatorname{dim} S} \cdots \sum_{\alpha_{l}=1}^{\operatorname{dim} S} \sum_{p=1}^{\operatorname{dim} S} w_{1}^{q, \alpha_{1}}\left(j_{d+1}\right) w_{2}^{q, \alpha_{1}, \alpha_{2}}\left(i_{d+2}\right) \ldots w_{l}^{q, \alpha_{l-1}, \alpha_{l}}\left(i_{\bar{d}}\right) w_{l+1}^{q, \alpha_{l}, p} \varphi_{p}(y) \\
& =\sum_{\alpha_{2}=1}^{\operatorname{dim} S} \cdots \sum_{\alpha_{l}=1}^{\operatorname{dim} S} \sum_{p=1}^{\operatorname{dim} S} w_{1,2}^{q, \alpha_{2}}\left(j_{d+1}, i_{d+2}\right) \ldots w_{l}^{q, \alpha_{l-1}, \alpha_{l}}\left(i_{\bar{d}}\right) w_{l+1}^{q, \alpha_{l}, p} \varphi_{p}(y)
\end{aligned}
$$

with $w_{1,2}^{q, \alpha_{2}}\left(j_{d+1}, i_{d+2}\right)=\sum_{\alpha_{1}=1}^{\operatorname{dim} S} w_{1}^{q, \alpha_{1}}\left(j_{d+1}\right) w_{2}^{q, \alpha_{1}, \alpha_{2}}\left(i_{d+2}\right)$. Then,

$$
\begin{aligned}
& T_{b, \bar{d}-d}\left(\varphi_{q}\right)\left(j_{d+1}, i_{d+2}, \ldots, i_{\bar{d}}, y\right) \\
& =\sum_{\alpha_{2}, q_{2}=1}^{\operatorname{dim} S} \ldots \sum_{\alpha_{l}, q_{l}=1}^{\operatorname{dim} S} \sum_{p=1}^{\operatorname{dim} S} \underbrace{\delta_{d,}}_{\bar{v}_{d+2}^{\left(q, j_{d+1}\right),\left(q_{2}, \alpha_{2}\right)}{ }_{\left(i_{d+2}\right)}^{\delta_{q, q_{2}} w_{1,2}^{q, \alpha_{2}}\left(j_{d+1}, i_{d+2}\right)}} \ldots \underbrace{\delta_{q_{l-1}, q_{l}} w_{l}^{q_{l-1}, \alpha_{l-1}, \alpha_{l}}\left(i_{\bar{d}}\right)}_{\bar{v}_{\bar{d}}^{\left(q_{l-1}, \alpha_{l-1}\right),\left(q_{l}, \alpha_{l}\right)}\left(i_{\bar{d}}\right)} \underbrace{w_{l+1}^{q_{l}, \alpha_{l}, p}}_{\bar{v}_{\bar{d}+1}^{\left(q_{l}, \alpha_{l}\right), p}} \varphi_{p}(y)
\end{aligned}
$$

with $\bar{v}_{d+2} \in \mathbb{R}^{b \times(b \operatorname{dim} S) \times(\operatorname{dim} S)^{2}}, \bar{v}_{\nu} \in \mathbb{R}^{b \times(\operatorname{dim} S)^{2} \times(\operatorname{dim} S)^{2}}$ for $d+3 \leq \nu \leq \bar{d}$, and $\bar{v}_{\bar{d}+1} \in \mathbb{R}^{(\operatorname{dim} S)^{2} \times \operatorname{dim} S}$. Then, we have $\varphi \in \mathcal{R}_{b, \bar{d}, S, \overline{\mathbf{r}}}(\overline{\mathbf{v}})$ with $\overline{\mathbf{v}}=\left(\bar{v}_{1}, \ldots, v_{d}, \bar{v}_{d+1}, \ldots, \bar{v}_{\bar{d}+1}\right)$, with $\bar{v}_{\nu}$ defined above for $\nu>d$, and $\bar{r}_{\nu}=r_{\nu}$ for $\nu \leq d, \bar{r}_{d+1}=b \operatorname{dim} S$, and $\bar{r}_{\nu}=(\operatorname{dim} S)^{2}$ for $d+1<\nu \leq \bar{d}$. From the definition of $\bar{v}_{\nu}$, we easily deduce that $\left\|\bar{v}_{d+1}\right\|_{\ell_{0}}=b\left\|v_{d+1}\right\|_{\ell_{0}},\left\|\bar{v}_{d+2}\right\|_{\ell_{0}} \leq b^{2}(\operatorname{dim} S)^{2},\left\|\bar{v}_{\nu}\right\|_{\ell_{0}} \leq b(\operatorname{dim} S)^{3}$ for $d+3 \leq \nu \leq \bar{d}$, and $\left\|\bar{v}_{\bar{d}+1}\right\|_{\ell_{0}} \leq(\operatorname{dim} S)^{3}$. Then, for $l=\bar{d}-d \geq 2$, we obtain

$$
\operatorname{compl}_{\mathcal{S}}(\overline{\mathbf{v}})=\sum_{\nu=1}^{d+1}\left\|\bar{v}_{\nu}\right\|_{\ell_{0}}+\sum_{\nu=d+2}^{\bar{d}+1}\left\|\bar{v}_{\nu}\right\|_{\ell_{0}} \leq b \operatorname{compl}_{\mathcal{S}}(\mathbf{v})+b^{2}(\operatorname{dim} S)^{2}+b(\operatorname{dim} S)^{3}(\bar{d}-d-2)+(\operatorname{dim} S)^{3} .
$$

For $l=1$, we have a representation

$$
T_{b, \bar{d}-d}\left(\varphi_{q}\right)\left(j_{d+1}, y\right)=\sum_{p=1}^{\operatorname{dim} S} \bar{v}_{d+2}^{\left(q, j_{d+1}\right), p} \varphi_{p}(y)
$$

with $\bar{v}_{d+2} \in \mathbb{R}^{(b \operatorname{dim} S) \times \operatorname{dim} S}$ such that $\bar{v}_{d+2}^{\left(q, j_{d+1}\right), p}=\sum_{\alpha_{1}=1}^{\operatorname{dim}^{2} S} w_{1}^{q, \alpha_{1}}\left(j_{d+1}\right) \varphi_{2}^{q, \alpha_{1}, p}$. Then, for $l=1, \varphi \in$ $\mathcal{R}_{b, \bar{d}, S, \overline{\boldsymbol{r}}}(\overline{\mathbf{v}})$ with $\overline{\mathbf{v}}=\left(\bar{v}_{1}, \ldots, v_{d}, \bar{v}_{d+1}, \bar{v}_{\bar{d}+2}\right)$, and

$$
\operatorname{compl}_{\mathcal{S}}(\overline{\mathbf{v}}) \leq b \operatorname{compl}_{\mathcal{S}}(\mathbf{v})+b(\operatorname{dim} S)^{2}=b \operatorname{compl}_{\mathcal{S}}(\mathbf{v})+b(\operatorname{dim} S)^{2}(\bar{d}-d) .
$$

For any $l \geq 1$, we then deduce

$$
\operatorname{compl}_{\mathcal{S}}(\overline{\mathbf{v}}) \leq b \operatorname{compl}_{\mathcal{S}}(\mathbf{v})+b^{2}(\operatorname{dim} S)^{3}(\bar{d}-d)
$$

Proof of Lemma 3.12. $\varphi_{A}$ and $\varphi_{B}$ admit representations

$$
T_{b, d}\left(\varphi_{C}\right)\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k_{1}=1}^{r_{1}^{C}} \cdots \sum_{k_{d}=1}^{r_{d}^{C}} \sum_{q=1}^{\operatorname{dim} S} v_{1}^{C, k_{1}}\left(i_{1}\right) \cdots v_{d}^{C, k_{d-1}, k_{d}}\left(i_{d}\right) v_{d+1}^{C, k_{d}, q} \varphi_{q}(y)
$$

with $C=A$ or $B$. Then, $\varphi_{A}+\varphi_{B}$ admit the representation

$$
T_{b, d}\left(\varphi_{A}+\varphi_{B}\right)\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k_{1}=1}^{r_{1}^{A}+r_{1}^{B}} \cdots \sum_{k_{d}=1}^{r_{d}^{A}+r_{d}^{B}} \sum_{q=1}^{\operatorname{dim} S} v_{1}^{k_{1}}\left(i_{1}\right) \cdots v_{d}^{k_{d-1}, k_{d}}\left(i_{d}\right) v_{d+1}^{k_{d, q}} \varphi_{q}(y),
$$

with $v_{1}^{k_{1}}=v_{1}^{A, k_{1}}$ if $1 \leq k_{1} \leq r_{1}^{A}$ and $v_{1}^{k_{1}}=v_{1}^{B, k_{1}}$ if $r_{1}^{A}<k_{1} \leq r_{1}^{A}+r_{1}^{B}$,

$$
v_{\nu}^{k_{\nu-1}, k_{\nu}}= \begin{cases}v^{A, k_{\nu-1}, k_{\nu}} & \text { if } 1 \leq k_{\nu-1}, k_{\nu} \leq r_{1}^{A} \\ v^{B, k_{\nu-1}, k_{\nu}} & \text { if } r_{1}^{A}<k_{\nu-1}, k_{\nu} \leq r_{1}^{A}+r_{1}^{B} \\ 0 & \text { elsewhere },\end{cases}
$$

and $v_{d+1}^{k_{d}, q}=v_{d+1}^{A, k_{d}, q}$ if $1 \leq k_{d} \leq r_{1}^{A}$ and $v_{d+1}^{k_{d, q}}=v_{d+1}^{B, k_{d}, q}$ if $r_{1}^{A}<k_{d} \leq r_{1}^{A}+r_{1}^{B}$. From the above, we deduce that $\left\|v^{C}\right\|_{\ell_{0}} \leq\left\|v^{A}\right\|_{\ell_{0}}+\left\|v^{B}\right\|_{\ell_{0}}$, so that

$$
\operatorname{compl}_{\mathcal{S}}(\mathbf{v})=\sum_{\nu=1}^{d+1}\left\|v^{C}\right\|_{\ell_{0}} \leq \operatorname{compl}_{\mathcal{S}}(\mathbf{v}) \leq \operatorname{compl}_{\mathcal{S}}\left(\mathbf{v}_{A}\right)+\operatorname{compl}_{\mathcal{S}}\left(\mathbf{v}_{B}\right)
$$

Proof of Lemma 3.14. The norm defined in Theorem 2.15 is a reasonable crossnorm (see Lemma A.1) and thus, in particular, not weaker than the injective norm on $V_{b, d, S}$. Thus, by [25, Lemma 8.6] $\mathcal{T} \mathcal{T}_{r}\left(V_{b, d, S}\right)$ for $\boldsymbol{r} \in \mathbb{N}^{d}$ is a weakly closed subset of $L^{p}$. Moreover, the set $\Phi_{n}$, with either $\Phi_{n}=\Phi_{n}^{\mathcal{N}}$ or $\Phi_{n}^{\mathcal{C}}$, is a finite union of the sets $\mathcal{T} \mathcal{T}_{r}\left(V_{b, d, S}\right)$ for different $d \in \mathbb{N}$ and $\boldsymbol{r} \in \mathbb{N}^{d}$. Since finite unions of closed sets (in the weak topology) are closed, it follows that $\Phi_{n}$ is weakly closed in $L^{p}$, and a fortiori, $\Phi_{n}$ is also closed in the strong topology. Since $L^{p}$ is reflexive for $1<p<\infty$ and $\Phi_{n}$ is weakly closed, $\Phi_{n}$ is proximinal in $L^{p}$ (see [25, Theorem 4.28]).

Now consider that $S$ is finite-dimensional. There exists $d$ such that $\Phi_{n} \subset V_{b, d, S}$ and $V_{b, d, S}$ is finitedimensional. Since $\Phi_{n}$ is a closed subset of a finite-dimensional space $V_{b, d, S}$, it is proximinal in $L^{p}$ for any $1 \leq p \leq \infty$.

Proof of Proposition 3.18. Consider a function $0 \neq \varphi \in V_{b, S}$ and let $d=d(\varphi)$ and $\boldsymbol{r}=\boldsymbol{r}(\varphi)$. We have

$$
\operatorname{compl}_{\mathcal{N}}(\varphi)=\sum_{\nu=1}^{d} r_{\nu} \leq b r_{1}+\sum_{r_{\nu}=2}^{d} b r_{\nu-1} r_{\nu}+b \operatorname{dim} S=\operatorname{compl}_{\mathcal{C}}(\varphi),
$$

which implies $\Phi_{n}^{\mathcal{C}} \subset \Phi_{n}^{\mathcal{N}}$. Also

$$
\begin{aligned}
\operatorname{compl}_{\mathcal{C}}(\varphi) & \leq b r_{1}+b\left(\sum_{\nu=1}^{d-1} r_{\nu}^{2}\right)^{1 / 2}\left(\sum_{\nu=2}^{d} r_{\nu}^{2}\right)^{1 / 2}+b \operatorname{dim} S \leq b r_{1}+b\left(\sum_{\nu=1}^{d-1} r_{\nu}\right)\left(\sum_{\nu=2}^{d} r_{\nu}\right)+b \operatorname{dim} S \\
& \leq b\left(\sum_{\nu=1}^{d} r_{\nu}\right)^{2}+b \operatorname{dim} S=b \operatorname{compl}_{\mathcal{N}}(\varphi)^{2}+b \operatorname{dim} S
\end{aligned}
$$

which yields $\Phi_{n}^{\mathcal{N}} \subset \Phi_{b \operatorname{dim} S+b n^{2}}^{\mathcal{C}}$. Also, we clearly have $\operatorname{compl}_{\mathcal{S}}(\varphi) \leq \operatorname{compl}_{\mathcal{C}}(\varphi)$, which implies $\Phi_{n}^{\mathcal{C}} \subset$ $\Phi_{n}^{\mathcal{S}}$. Now consider any tensor network $\mathbf{v} \in \mathcal{P}_{b, d, S, \boldsymbol{r}}$ such that $\varphi=\mathcal{R}_{b, d, S, \boldsymbol{r}}(\mathbf{v})$, with $d(\varphi) \leq d$ and $\boldsymbol{r}(\varphi) \leq \boldsymbol{r}$. We have that $r_{1}(\varphi) \leq \operatorname{dim}\left\{v_{1}^{k_{1}}(\cdot) \in \mathbb{R}^{b}: 1 \leq k_{1} \leq r_{1}\right\} \leq\left\|v_{1}\right\|_{\ell_{0}}$ and for $2 \leq \nu \leq d$, $r_{\nu}(\varphi) \leq \operatorname{dim}\left\{v_{\nu}^{; k_{\nu}}(\cdot) \in \mathbb{R}^{b \times r_{\nu-1}}: 1 \leq k_{\nu} \leq r_{\nu}\right\} \leq\left\|v_{\nu}\right\|_{\ell^{0}}$. Therefore

$$
\operatorname{compl}_{\mathcal{N}}(\varphi)=\sum_{\nu=1}^{d} r_{\nu}(\varphi) \leq \sum_{\nu=1}^{d}\left\|v_{\nu}\right\|_{\ell_{0}} \leq \operatorname{compl}_{\mathcal{S}}(\mathbf{v}) .
$$

The inequality being true for any tensor network $\mathbf{v}$ such that $\varphi=\mathcal{R}_{b, d, S, r}(\mathbf{v})$, we deduce $\operatorname{compl}_{\mathcal{N}}(\varphi) \leq$ $\operatorname{compl}_{\mathcal{S}}(\varphi)$, which yields $\Phi_{n}^{\mathcal{S}} \subset \Phi_{n}^{\mathcal{N}}$.

Proof of Lemma 3.21. (i). Consider $\varphi_{A}, \varphi_{B} \in \Phi_{n}^{\mathcal{R}}$, and let $d_{A}=d\left(\varphi_{A}\right), d_{B}=d\left(\varphi_{B}\right), r_{A}=r\left(\varphi_{A}\right)$ and $r_{B}=r\left(\varphi_{B}\right)$. Assume w.l.o.g. that $d_{A} \leq d_{B}$. The function $\varphi_{A}$ admits a representation

$$
T_{b, d_{A}} \varphi_{A}\left(i_{1}, \ldots, i_{d_{A}}, y\right)=\sum_{k=1}^{r_{A}} w_{1}^{A, k}\left(i_{1}\right) \ldots w_{d}^{A, k}\left(i_{d}\right) w_{d+1}^{A, k}(y),
$$

and

$$
T_{b, d_{B}} \varphi_{A}\left(i_{1}, \ldots, i_{d_{B}}, y\right)=\sum_{k=1}^{r_{A}} w_{1}^{A, k}\left(i_{1}\right) \ldots w_{d}^{A, k}\left(i_{d}\right) T_{b, d_{B}}\left(w_{d+1}^{A, k}\right)(y) .
$$

From the assumption on $S$, we have $T_{b, d_{B}}\left(w_{d+1}^{A, k}\right)$ of rank 1 , so that $r\left(T_{b, d_{B}} \varphi_{A}\right) \leq r_{A}$. We easily deduce that $r\left(\varphi_{A}+\varphi_{B}\right) \leq r_{A}+r_{B}$ and $\operatorname{compl}_{\mathcal{R}}\left(\varphi_{A}+\varphi_{B}\right) \leq b d_{B}\left(r_{A}+r_{B}\right)+\left(r_{A}+r_{B}\right) b \operatorname{dim} S \leq 2 n+b r_{A}\left(d_{B}-d_{A}\right) \leq$ $2 n+n^{2} \leq 3 n^{2}$.
(ii). The proof idea is analogous to Proposition 3.5 we take a rank-one tensor $\varphi_{B} \in \Phi_{n}^{\mathcal{R}}$ such that $d_{B} \sim n$ and a full-rank tensor $\varphi_{A} \in \Phi_{n}^{\mathcal{R}}$ with $d_{A}<d_{B}$ such that $r_{A} \sim b^{d_{A}} \sim n$. Then, as in Proposition 3.5, $\operatorname{compl}_{\mathcal{R}}\left(\varphi_{A}+\varphi_{B}\right) \sim n^{2}$.
Proof of Lemma 3.22. Let $\varphi \in \Phi_{n}^{\mathcal{R}}, d=d(\varphi), r=r(\varphi)$. The function $\varphi$ admits a representation

$$
T_{b, d} \varphi\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k=1}^{r} \sum_{q=1}^{\operatorname{dim} S} w_{1}^{k}\left(i_{1}\right) \ldots w_{d}^{k}\left(i_{d}\right) w_{d+1}^{q, k} \varphi_{q}(y) .
$$

Letting $v_{1}=w_{1}, v_{d+1}=w_{d+1}$ and $v_{\nu} \in \mathbb{R}^{b \times r \times r}$ such that $v_{\nu}^{k_{\nu-1}, k_{\nu}}=\delta_{k_{\nu-1}, k_{\nu}} w_{\nu}^{k_{\nu}}$ for $2 \leq \nu \leq d$, and letting $r=(r, \ldots, r) \in \mathbb{N}^{d}$, we have

$$
T_{b, d} \varphi\left(i_{1}, \ldots, i_{d}, y\right)=\sum_{k_{1}=1}^{r} \ldots \sum_{k_{d}=1}^{r} \sum_{q=1}^{\operatorname{dim} S} v_{1}^{k}\left(i_{1}\right) \ldots w_{d}^{k_{d-1}, k_{d}}\left(i_{d}\right) w_{d+1}^{q, k_{d}} \varphi_{q}(y)
$$

which proves that $T_{b, d} \varphi \in \Phi_{b, d, S, r}$ with

$$
\operatorname{compl}_{\mathcal{S}}(\varphi)=\sum_{\nu=1}^{d+1}\left\|v_{\nu}\right\|_{\ell_{0}}=\sum_{\nu=1}^{d+1}\left\|w_{\nu}\right\|_{\ell_{0}} \leq b r d+r \operatorname{dim} S=\operatorname{compl}_{\mathcal{R}}(\varphi) \leq n
$$

that is $\varphi \in \Phi_{n}^{\mathcal{S}}$.
