The black hole (BH) information paradox has been a central problem in fundamental physics, posing a question lying between macroscopic BH physics and microscopic descriptions of a BH. In recent years, quantum information theory has shed new light on the problem, where based on the information scrambling and entanglement, a microscopic process of how information leaks out from a quantum BH has been clarified. However, micro-macro correspondence in the information paradox has been yet to be revealed. Here, we study the information leakage from a quantum BH with symmetry and reveal two novel micro-macro relations. In particular, we show that symmetry induces a delay in the onset of leakage and information remnant that lingers for. The delay turns out to be closely related to thermodynamic properties of the BH, bridging the information problem to BH thermodynamics, while the information remnant is dominated by symmetry-breaking of the BH. Our analysis thus paves the way to the unified understanding of microscopic and macroscopic descriptions of quantum BHs through the information leakage problem.

In this paper, we provide short and long versions. The short version aims to overview our main results: it starts with a brief introduction and explains all the key ideas and important results, but no technical details. In contrast, the long version covers all in detail and is written in a self-contained manner.
Part I

Short version of the paper

Introduction

A black hole (BH) is one of the most peculiar objects in the universe. While macroscopic properties of BHs can be fairly understood by general relativity, finding microscopic descriptions of BHs has been a central problem in fundamental physics as it will unlock the unified theory of quantum gravity. A significant step was made by the discovery of Hawking radiation \cite{1,2}: due to a quantum effect, a quantum BH emits thermal radiation and eventually evaporates, unveiling the close similarity between BHs and thermodynamics. This discovery however accelerates the question about the micro-macro relations of quantum BHs since it is not clear whether the information in a quantum BH, i.e. the microscopic description, is carried away by the radiation.

Despite the fact that information is unlikely to be carried away in classical cases due to the no-hair theorem \cite{3–5}, recent developments of the holographic principle indicate that information in a BH should be preserved in the whole process and will leak out as they evaporate, showing a gap between our macroscopic and microscopic understandings of BHs. This question is known as the information paradox. Fully clarifying microscopic details of the information leakage, and relating them to macroscopic properties, are crucial towards further development of fundamental physics.

A novel approach was proposed from the theory of quantum information \cite{6}. The theory offers the way of dealing with quantum information in a BH in an operational manner. Based on a quantum mechanical model of BHs, it was shown that complex internal dynamics of quantum BHs, called scrambling \cite{7,8}, leads to extremely quick leakage of information, providing a hint to the detailed process of information leakage from a microscopic perspective. The result has spiked a number of novel research topics aiming to understand quantum information of BHs \cite{7–27}, which has largely contributed to the progress not only of fundamental physics but also of a wide range of theoretical physics, even indicating a possible duality between quantum BHs and quantum chaos.

The micro-macro correspondence in the information leakage problem is however yet to be clarified. The analysis based on scrambling predicts instant leakage of full information, in which there are few quantitative parameters to be connected with macroscopic properties of the BH. Thus, to obtain a deeper insight, it is of great importance to push forward quantum information theoretic approach, so that the information leakage can be understood also in terms of macroscopic BH physics.

In this paper, we study the information leakage when a BH has symmetry, which is mostly the case in realistic situations. Symmetry induces richer macroscopic BH physics, but at the same time, prevents the dynamic of the BH from being fully scrambling, which results in deviations from the case without symmetry. By developing a novel approach of quantum information that enables us to simultaneously deal with quantum information and symmetry, we fully clarify the deviations and unveil two relations between information leakage and macroscopic properties of the BH associated with the symmetry and BH thermodynamics.

A model of information leakage problem

Our analysis is based on a quantum mechanical BH model \cite{6}. To capture the information-theoretic nature, we consider a BH $B_{\text{in}}$ containing $N$-qubit information, where $N := S_{\text{BH}}$ shall be interpreted as the Bekenstein-Hawking entropy. A qubit is the basic unit of quantum information and is represented by a spin-1/2 particle (see Methods for our notations).

We consider two types of initial states of the BH. One is a “pure” BH, where $B_{\text{in}}$ is in a pure...
FIG. 1: Diagram of the BH information problem based on the quantum mechanical BH model: the blue lines represent trajectories of qubits, and the yellow wavy lines indicate that they may be entangled. The initial BH $B_{\text{in}}$ is composed of $N = S_{\text{BH}}$ qubits in a state $\xi_{\text{in}}^{B_{\text{in}}}$ with $S_{\text{BH}}$ being the Bekenstein-Hawking entropy. At time $T_1$, Alice throws a $k$-qubit quantum system $A$, which is maximally entangled with the reference $R$, into the BH $B_{\text{in}}$. The state $\xi_{\text{in}}^{B_{\text{in}}}$ of the initial BH $B_{\text{in}}$ is purified to be $|\xi\rangle_{B_{\text{in}}B_{\text{rad}}}$ by the past Hawking radiation $B_{\text{rad}}$ emitted before $T_1$. The internal scrambling dynamics and the radiation gradually take place, as indicated in the figure by green boxes and purple lines, respectively. Each $U_i$ is internal unitary time-evolution acting on $N + k - i + 1$ qubits. By time $T_2$, $\ell$ qubits ($S_{\text{rad}}$) are carried away from the BH by the radiation, making the BH $S = AB_{\text{in}}$ shrink to $S_{\text{in}}$ of $N + k - \ell$ qubits. We denote the dynamics of the BH from $T_1$ to $T_2$ by $L_{S \rightarrow S_{\text{in}}S_{\text{rad}}}$. Bob collects all the radiation $S_{\text{rad}}$ and tries to recover the information source $A$ by applying a quantum operation $D$, where he may additionally make use of the past radiation $B_{\text{rad}}$. We assume that Bob knows the initial state $|\xi\rangle$ and the dynamics $L$ of the BH.

Quantum Information and Symmetry
In this paper, we particularly consider uncharged rotating BHs, known as Kerr BHs, where the symmetry axis is assumed to be the $Z$-axis without loss of generality. The conserved quantity is then the $Z$-component of angular momentum, which we denote by the $Z$-axis AM for short. Note that the symmetry at the level of quantum gravity has been argued to be weakly violated [30, 31].
However, to be consistent with the BHs predicted by general relativity, the violation should be weak. We hence assume, as a first approximation, that the BH has exact symmetry.

The effect of symmetry is not only on the conserved quantity, but also on the information in the BH, where we can define symmetry-invariant information. Let $\mathcal{H}^A$ be the Hilbert space of $A$. In terms of the $Z$-axis symmetry, $\mathcal{H}^A$ is decomposed into subspaces $\bigoplus_m \mathcal{H}^A_m$ labeled by the $Z$-axis AM $\kappa$. We assume that $R$ also has a decomposition $\mathcal{H}_{\kappa}^R = \bigoplus_m \mathcal{H}_{\kappa}^R$ and that $AR$ is initially prepared in a maximally entangled state $\Phi^{AR}$ compatible with this decomposition. Using the projection $\Pi_{\kappa}^R$ onto $\mathcal{H}_{\kappa}^R$, we define

$$\Phi_{\text{diag}}^{AR} = \sum_i p_i \Phi_{i \kappa}^{AR},$$

with $p_i$ being $\text{Tr}[(I^A \otimes \Pi_{\kappa}^R) \Phi^{AR}]$ and $\Phi_{i \kappa}^{AR}$ being $(I^A \otimes \Pi_{\kappa}^R) \Phi^{AR} (I^A \otimes \Pi_{\kappa}^R)/p_i$. Since $\Phi_{\text{diag}}^{AR}$ is invariant under the axial rotation of $A$, we refer to the information in $\Phi_{\text{diag}}^{AR}$ as symmetry-invariant.

We now introduce two errors in recovering information from the radiation. One is $\Delta_{\text{int}}(\xi : \mathcal{L})$ for the symmetry-invariant information in $\Phi_{\text{diag}}^{AR}$, and the other is $\Delta_{\text{tot}}(\xi : \mathcal{L})$ for the total information in $\Phi^{AR}$ (see Methods). Both depend on the state $\xi^{B_{\text{in}}}$ of the initial BH $B_{\text{in}}$ as well as the dynamics $\mathcal{L}$ of the BH, and take a value between 0 and 1.

**Black holes without symmetry**

When the BH has no symmetry, the dynamics $\mathcal{L}$ fully scrambles all information. This is formulated by choosing each unitary $U_i$ in $\mathcal{L}$ at random. In this case, the recovery error $\Delta_{\text{tot}}$ typically satisfies \cite{6, 32}

$$\log_2[\Delta_{\text{tot}}(\xi : \mathcal{L})] \leq k + \frac{1 - e}{2} N - \ell,$$

where $e := H_{\text{min}}(B_{\text{in}})\xi / \max_\rho H_{\text{min}}(B_{\text{in}})\rho$ is the entanglement entropy ratio of $\xi^{B_{\text{in}}}$ to the maximum value in terms of the min-entropy \cite{33} (see Methods for the definition). The entanglement entropy ratio $e$ takes the values between 0 and 1 and is large when the initial BH $B_{\text{in}}$ and the past radiation $B_{\text{rad}}$ are strongly entangled.

In particular, $\Delta_{\text{tot}}(\xi : \mathcal{L}) \leq 2^{N/2 + k - \ell}$ for the pure BH, and $\Delta_{\text{tot}}(\xi : \mathcal{L}) \leq 2^{k - \ell}$ for the mixed BH after the Page time \cite{28}, where $\xi^{B_{\text{in}}B_{\text{rad}}}$ is a maximally entangled state. Since the latter does not depend on $N$, no matter how large the initial mixed BH is, the $k$-qubit information leaks out when a little more than $k$ qubits are evaporated.

The mechanism behind this is decoupling \cite{32, 34, 36} caused by the fully scrambling dynamics $\mathcal{L}$, in the sense that $\mathcal{L}^{S \rightarrow S_{\text{in}}} (\psi^{SR}) \approx \pi^{S_{\text{in}}} \otimes \pi^R$, where $\psi^{SR} := \Phi^{AR} \otimes \xi^{B_{\text{in}}}$. This guarantees that information is encoded into good codewords, enabling the retrieval of information from the radiation $S_{\text{rad}}$.

**Dynamics of Kerr Black Hole and Recovery Errors**

Unlike the dynamics of the BH without symmetry, the dynamics $\mathcal{L}_{\text{Kerr}}$ of the Kerr BH is restricted by the axial symmetry: each unitary $U_i$ therein should be in the form of $U_i = \bigoplus_m U_i^{(m)}$, where $U_i^{(m)}$ is scrambles only the subspace with a fixed $Z$-axis AM, labelled by $m$, of the BH of $N+k-i+1$ qubits. Due to this restriction, $\mathcal{L}_{\text{Kerr}}$ never fully changes the AM, and no full decoupling occurs. The absence of full decoupling was also pointed out in Ref. \cite{14}.

Although no full decoupling occurs in the Kerr BH, the dynamics $\mathcal{L}_{\text{Kerr}}$ can still scramble each subspace with a fixed $Z$-axis AM, making $S_{\text{in}}$ and $R$ partially decoupled. This is made rigorous by the partial decoupling theorem \cite{37}. The technique centers on constructing a fictitious quantum state $\Gamma^{S^{*}ER}$ on a system $S^{*}ER$, where $E$ is a copy of the remaining Kerr BH $S_{\text{in}}$, and $S^{*}$ is an
extension of $S$. The state $\Gamma_{SR}^{*}$ is constructed from $\xi^{Bin}$, the symmetry of the BH, and the channel-state duality \([38, 39]\) of the evaporation process.

The key quantity is the conditional min-entropy $H_{\text{min}}(S^{*}|ER)_{\Gamma}$ of $\Gamma$: the dynamics $L_{\text{Kerr}}$ typically transforms the initial state $\Psi^{SR}$ to $L_{\text{Kerr}}^{S \rightarrow S_{\text{in}}}(\Psi^{SR})$ such that

$$
\log \left( \| L_{\text{Kerr}}^{S \rightarrow S_{\text{in}}}(\Psi^{SR}) - \sum_{m} q_{m} \tau_{m}^{S_{\text{in}}} \otimes \Psi_{m}^{R} \|_{1} \right) \leq -\frac{H_{\text{min}}(S^{*}|ER)_{\Gamma}}{2}.
$$

Here, $\| \cdot \|_{1}$ is the trace norm, $m$ runs over all the labels of $Z$-axis AM in $S$, and the probability distribution $\{q_{m}\}$ and the quantum states $\tau_{m}^{S_{\text{in}}}$ and $\Psi_{m}^{R}$ can be explicitly obtained (see Methods).

Thus, when $H_{\text{min}}(S^{*}|ER)_{\Gamma} \gg 1$, the remaining BH $S_{\text{in}}$ and the reference $R$ are correlated only through the value $m$ of the AM, but no quantum correlation is left.

Based on this partial decoupling, we can obtain upper bounds on $\Delta_{\text{inv}}$ and $\Delta_{\text{tot}}$, which however turn out not to be tight. This is due to the well-known fact that the conditional min-entropy is sensitive to the events that happen so rarely that we can practically ignore. By ignoring the rare events occurring with probability $\omega$, the fictitious state $\Gamma$ can be modified to a subnormalized one $\tilde{\Gamma}$. Noticing that ignoring the rare events results in additional error $\omega$, we arrive at

$$
\Delta_{\text{inv}}(\xi : L_{\text{Kerr}}) \leq 2 \Theta_{\xi},
$$

$$
\Delta_{\text{tot}}(\xi : L_{\text{Kerr}}) \leq 2 \Theta_{\xi} + \eta_{\xi},
$$

where $\Theta_{\xi} = 2^{-\frac{1}{2}H_{\text{min}}(S^{*}|ER)_{\xi} + w}$, and $\eta_{\xi} \in [0, 2]$ is explicitly given (see Methods). Both $\Theta_{\xi}$ and $\eta_{\xi}$ depend on $N$, $k$, and $\ell$.

**Numerical Evaluations of Recovery Errors**

Using Inequalities (4) and (5), $\Delta_{\text{inv}}$ and $\Delta_{\text{tot}}$ are numerically plotted in Figure 2 for the pure Kerr BH and Figure 3 for the mixed Kerr BH. In both cases, we chose the state $\xi$ of the initial BH $B_{\text{in}}$ such that its $Z$-axis AM is $L$ on average with fluctuation $\delta L$ (see Methods).

The $\Delta_{\text{inv}}$ starts decreasing after a certain amount of evaporation and, thereafter, continues dropping exponentially quickly. Let $\ell_{\Delta}(L, \delta L)$ be the number of evaporated qubits needed to achieve $\Delta_{\text{inv}} \leq \Delta$. Compared to the trivial case ($L = \delta L = 0$), $\ell_{\Delta}(L, \delta L) \geq \ell_{\Delta}(0, 0)$ for any $\Delta > 0$, implying that the non-trivial Kerr BH has a delay of information leakage. The delay ranges from negligibly small to macroscopically large values, depending on $L$ and $\delta L$, even for the mixed BH. Hence, even from the mixed BH, the information does not necessarily leak out quickly.

The $\Delta_{\text{tot}}$ also starts decreasing nearly at the same timing as $\Delta_{\text{inv}}$. However, soon after, the dropping becomes much slower and the error remains at a non-negligible value. This implies that a part of the information necessary for decoding the whole information remains in the interior of the BH until the complete evaporation. We call the residual information information remnant, which is by definition not symmetry-invariant.

**Delay of Leakage and Cramping of Entanglement**

The origin of the delay in information leakage may be ascribed to the nearly maximal entanglement generated by the scrambling dynamics \([28, 29, 41]\). To clarify this point, we first consider the BH without symmetry, whose fully scrambling dynamics generates high entanglement between $S_{\text{rad}}$ and $S_{\text{in}}$. This implies that the marginal states in each subsystem tend to spread widely, letting the marginal state in the smaller subsystem be so mixed that no trace of the initial state remains. In contrast, the spread in the large subsystem needs to be “cramped” at the dimension of the smaller one, because any bipartite pure state should have an equal size in the two subsystems \([42]\).

The cramping in the larger subsystem is crucial in the information recovery: when more than half of the qubits are evaporated from a pure BH, $S_{\text{rad}}$ is the larger one and the cramping sets in.
The mixed BH sees the onset much earlier since it is already on the verge of cramping initially, thanks to entanglement with past radiation $B_{\text{rad}}$. To represent this property in a semiquantitative way, we introduce a degree of cramping in $S_{\text{rad}}$ as $C := H(B_{\text{in}}) + \log(\dim S_{\text{rad}}^n / \dim \bar{S}_{\text{rad}}^n)$. When $C > k$, the $k$-qubit information shall have no significant overlap in $\bar{S}_{\text{rad}}^n$, and shall be recoverable from the radiation $S_{\text{rad}}$. It corresponds to $\ell > k + N/2$ for the pure BH and $\ell > k$ for the mixed BH, which agrees well with Inequality (2).

Let us apply the same argument to the Kerr BH. For simplicity, we consider an initial Kerr BH $B_{\text{in}}$ with a fixed $Z$-axis AM $L$ with $\delta L = 0$. The number of up-spins in $B_{\text{in}}$ is $L/h + N/2$, where $h$ is the Plank constant. Due to the conservation of AM, the subspace $\bar{S}_{\text{rad}}^n$ with $n$ up-spins in $S_{\text{rad}}$ is entangled only with $H_{w}^n$ satisfying $n + n' \approx L/h + (N + k)/2$. This leads to a cramping condition for each value of $n$ as

$$H(B_{\text{in}}) + \log \left[ \frac{\dim S_{\text{rad}}^n}{\dim \bar{S}_{\text{rad}}^n} \right] > k,$$

which should be fulfilled by all probable values of $n$ for the information to be recoverable. If the condition is not satisfied for certain $n$, the information in the corresponding subspace is counted as recovery error.

As an estimate of $\ell_{\Delta}(L, 0)$, we consider the number $\ell_c(L)$ of qubits to be evaporated such that Inequality (6) holds for all $n$ with $|\delta n| \leq c\sqrt{\delta n^2}$ ($\delta n := n - \langle n \rangle$). The $c$ is a parameter related to the recovery error since taking a larger $c$ means that we require Inequality (6) for a wider range of $n$, resulting in less error. By assuming $1 \ll k \ll N$, dimensions in Inequality (6) are well approximated using $s(\lambda) := -(1/2 - \lambda) \log[1/2 - \lambda] - (1/2 + \lambda) \log[1/2 + \lambda]$, where $\lambda := L/(hN)$ is the $Z$-axis AM ratio of the initial Kerr BH $B_{\text{in}}$. We also denote the initial degree of cramping

![Recovery Errors from the radiation emitted by the pure Kerr BH](image)
FIG. 3: Recovery Errors from the radiation emitted by the mixed Kerr BH: upper bounds on $\Delta_{\text{inv}}(\xi : L_{\text{Kerr}})$ (dashed lines) and those on $\Delta_{\text{tot}}(\xi : L_{\text{Kerr}})$ (filled markers) for the mixed Kerr BH, which is initially highly entangled with the past radiation, are plotted. We consider a family of specific entangled states with various $Z$-axis AM $L$ and fluctuation $\delta L$. The figures (i) - (iv) show the bounds for $|L| = 0, N/8, N/4, 3N/8$, respectively, where $\pm L$ leads to the same result as explained in the caption of Figure 2, while $\delta L$ is chosen to be $0.1\sqrt{N}$ (red), $0.5\sqrt{N}$ (blue), $0.9\sqrt{N}$ (green), and $0.3N$ (brown). The $\Delta_{\text{inv}}$ for $(L, \delta L) = (0, 0)$ is also plotted by a yellow dash-dotted line for comparison. The size $N$ of the initial Kerr BH is set to 500, and the size $k$ of the quantum information source to 5. Similarly to the pure Kerr BH, we observe that both $\Delta_{\text{inv}}(\xi : L_{\text{Kerr}})$ and $\Delta_{\text{tot}}(\xi : L_{\text{Kerr}})$ start decreasing at almost same timing, and that only $\Delta_{\text{tot}}$ stops decreasing soon after, except the one for $\delta L = 0.3N$. The significant difference from the pure Kerr BH is that the timing at which the errors start decreasing can be much earlier. It indeed ranges widely from $O(k)$ to $O(N)$ depending on the $Z$-axis AM $L$ and its fluctuation $\delta L$ of the initial Kerr BH. The details are discussed in the main text.

before radiation is emitted by $C_{\text{ini}} \approx H(B_{\text{in}})\xi - (N + k)s(\lambda) < 0$. We can then show (see Methods)

$$\ell_c(L) \approx \ell_0(L) + c\ell_\text{fl}(L), \quad (7)$$

where

$$\ell_0(L) = -\frac{C_{\text{ini}}}{2s(\lambda)} + \frac{k}{2s(\lambda)}, \quad (8)$$

$$\ell_\text{fl}(L) = \frac{|s(\lambda)|}{s(\lambda)} \sqrt{\frac{\ell_0(L)}{|s''(\lambda)|} \left(1 - \frac{\ell_0(L)}{N + k}\right)}. \quad (9)$$

In Figure 4, we compare $\ell_\Delta(L, 0)$ computed from the partial decoupling argument, and $\ell_c(L)$ from the cramping argument. Since they are numerically shown to coincide very well, we conclude that $\ell_c(L)$ based on the cramping argument provides a good estimate of the number of qubits that should be evaporated for the information to become recoverable from the radiation.

In Equation (7), we have decomposed $\ell_c(L)$ into two terms. The first term, $\ell_0(L)$, represents a delay originated from an information theoretic reason: noting that evaporation of a qubit with entropy $s(\lambda)$ increases the degree of cramping by $2s(\lambda)$, $\ell_0(L)$ qubits should be necessarily evaporated for the radiation to typically have sufficiently large space to store information of $k$ qubits. Hence, we refer to $\ell_0(L)$ as an information-theoretic delay. Note that the information-theoretical delay also depends on the entanglement between the initial Kerr BH $B_{\text{in}}$ and the past Harking radiation $B_{\text{out}}$, quantified by the entanglement entropy $H(B_{\text{in}})\xi$.

It is the second term $\ell_\text{fl}(L)$ that is a non-trivial consequence of the symmetry of the Kerr BH. It stems from the fluctuation of the $Z$-axis AM in the radiation, making the cramping condition...
is the Boltzmann constant. We then have \( \omega \) allowing us to rewrite Equation (9) as follows:

\[
\delta \ell_c(\lambda) = \delta \ell_c(\lambda N) - \delta t_c(0),
\]

of the Z-axis AM ratio \( \lambda = L/(\hbar N) \) of the initial Kerr BH \( B_{in} \). The upper and lower figures show the delays for the pure and mixed Kerr BHs, respectively. The size \( N \) of the initial Kerr BH \( B_{in} \) is set to 300, and the size \( k \) of the quantum information source \( A \) is fixed to 3. In both figures, \( \delta \ell_\Delta(\lambda) \) is computed for \( \Delta = 0.005 \) (red plots), 0.05 (blue plots), and 0.5 (green plots), while \( \delta \ell_c(\lambda) \) is computed for \( c = 3.4 \) (red dashed line), 2.6 (blue dashed line), and 1.6 (green dashed line) for the pure BH, and 10.8 (red dashed line), 8.7 (blue dashed line), and 6.2 (green dashed line) for the mixed BH. In both pure and mixed Kerr BHs, they nearly coincide, indicating that the cramping argument provides good estimations.

\[ \delta \ell_c(\lambda) = \delta \ell_c(\lambda N) - \delta t_c(0), \]

harder to be fulfilled. We hence call \( \ell_\beta(L) \) a fluctuational delay. Note also that, when the Z-axis AM \( L \) of the initial Kerr BH is small, the delay of information leakage is simply proportional to \( \ell_\beta(L) \) because the delay is given by \( \delta \ell_c(\lambda) = \ell_c(\lambda(N+k)) - \ell_c(0) \), and \( \ell_\beta(L) = \ell_\beta(0) \approx \ell_\beta(0) \) and \( \ell_\beta(0) = 0 \) for small \( L \).

**Delay and BH Thermodynamics**

The fluctuational delay \( \ell_\beta(L) \) can be further rewritten in terms of thermodynamic quantities of the Kerr BH.

The Hamiltonian of the Kerr BH should be symmetric but sufficiently random for the dynamics to be scrambling in each subspace with a fixed Z-axis AM. To focus on the thermodynamics properties that do not strongly rely on such randomness, we especially consider the Kerr BH with temperature \( T \) sufficiently higher than the energy scale of the Hamiltonian, so that the thermodynamic entropy \( S(\lambda, L, T) \) of the Kerr BH is independent of \( T \), and the free energy \( F(T, \lambda, L) \) is approximately given by \( -TS(\lambda, L) \).

We then define an intensive state function \( \omega := -\left( \frac{\partial F}{\partial L} \right)_{T,N} \) conjugate to the Z-axis AM \( L \) in \( B_{in} \), and the coefficient of thermal “expansion” of \( L \), \( \alpha := -\left( \frac{1}{T} \frac{\partial L}{\partial T} \right)_{\omega,N} \), which is the sensitivity of the Z-axis AM to temperature. The state function \( \omega(T, \lambda) \) corresponds to the angular velocity of the Kerr BH.

In our particular model, the thermodynamic entropy \( S(\lambda, L) \) is given by \( k_B s(\lambda) N \), where \( k_B \) is the Boltzmann constant. We then have \( \omega(T, \lambda) = k_B T s'(\lambda)/\hbar \) and \( \alpha(T, \lambda) = -s'(\lambda)/(s''(\lambda) \lambda T) \), allowing us to rewrite Equation (9) as follows:

\[
L_\beta \approx \frac{L}{S(\lambda, L)} \sqrt{k_B |\omega(T, \lambda) \alpha(T, \lambda)|} \left( 1 - \frac{L_0}{L} \right) L_0,
\]

where \( L_\beta := \hbar \lambda \ell_\beta(L) \) and \( L_0 := \hbar \lambda \ell_0(L) \) are approximately the Z-axis AM corresponding to the fluctuational delay \( \ell_\beta(L) \) and the information-theoretic delay \( \ell_0(L) \), respectively. Note that \( \omega(T, \lambda) \alpha(T, \lambda) \) is independent of the temperature \( T \), and so is \( L_\beta \).

Equation (10) shows that, after radiating \( L_0 \) of the Z-axis AM to fulfill the information-theoretic requirement, the Kerr BH must further radiate an extra amount \( L_\beta \) of the Z-axis AM to release the
Information Remnant and Symmetry-Breaking

We finally study the information remnant characterized by $\eta_\xi(N, k, \ell)$, which is plotted in Figure 5 for various fluctuations $\delta L$ of the initial Kerr BH. We also provide a Q function of $\xi_B$ in (see Methods) that visualizes how $Z$-symmetric the state is. By comparing them, we observe that, when $\eta_\xi$ is small, the $Z$-axial symmetry in $\xi_B$ is strongly broken.

We can analytically elaborate this relation based on the fact that, for the whole information in $\Phi_A$ to be recoverable from the radiation $S_{\text{rad}}$, classical information about the $Z$-axis AM in $R$ should not be inferred from the remaining BH $S_{\text{in}}$. By elaborating this, we can obtain a lower bound on $\eta_\xi$ in terms of a degree $\zeta(S_{\text{in}})$ of symmetry-breaking in $S_{\text{in}}$. Using a purification $|\Psi\rangle_{S_{\text{in}}S_{\text{in}}'}$ of $\Psi_{S_{\text{in}}}$, where $S_{\text{in}}' = RB_{\text{rad}}S_{\text{rad}}$, and denoting by $L_Z$ the $Z$-axis AM operator in $S_{\text{in}}$, we
define \( \zeta(S_{\text{in}}) \) by \( | \langle \Psi | e^{i\delta L_Z} \otimes I | \Psi \rangle |^2 = 1 - \zeta(S_{\text{in}})(\delta \theta)^2/2 + O((\delta \theta)^3) \). It turns out that \( \zeta(S_{\text{in}}) \) is equal to twice the variance of the Z-axis AM in \( S_{\text{in}} \). We then obtain

\[
\eta_\xi \gtrsim \sqrt{\frac{2}{3} \langle |\delta \kappa| \rangle} \left( 1 - \frac{\ell}{N + k} \right) \frac{1}{\sqrt{\zeta(S_{\text{in}})}},
\]

where \( \langle |\delta \kappa| \rangle \) is the mean absolute deviation of the Z-axis AM in \( R \) (see Methods for details). Hence, when information remnant is small, \( \zeta(S_{\text{in}}) \) should be necessarily large, implying that the Z-axial symmetry in \( S_{\text{in}} \) should be broken strongly.

When \( \sqrt{\ell} \ll \delta L \), the degree of symmetry-breaking in \( S_{\text{in}} \) should be inherited from that of the initial Kerr BH \( B_{\text{in}} \). This is because the degree of symmetry-breaking is related to the fluctuation of the Z-axis AM, and the evaporation of \( \ell \) qubits increases the fluctuation only by \( O(\sqrt{\ell}) \), which is less dominant than \( \delta L \) when \( \sqrt{\ell} \ll \delta L \). Thus, we conclude that \( \eta_\xi \gtrsim \zeta(B_{\text{in}})^{-1/2} \). On the other hand, when \( \sqrt{\ell} \gg \delta L \), the fluctuation due to the evaporation dominates, so that \( \eta_\xi \gtrsim \ell^{-1/2} \).

This clarifies yet another micro-macro correspondence of a quantum Kerr BH. Since the symmetry-breaking often leads to rich physics such as thermal and quantum phase transitions, Equation (11) further opens the possibility to connecting the information remnant to quantum many-body phenomena, which will accelerate the exploration of the duality between quantum gravity and strongly-correlated quantum many-body physics.

**Summary and Discussions**

We have fully clarified how information is carried away from a quantum Kerr BH, based on a novel quantum information-theoretic approach. We have then revealed two micro-macro relations of the Kerr BH in the information leakage problem. One is between the delay of information leakage and BH thermodynamics, and the other is the information remnant and the symmetry-breaking. Both reveal non-trivial interplays between quantum information, symmetry of the BH, and macroscopic BH physics, providing a deep insight into the symmetry and information at the level of quantum gravity.

As a future problem, it is important to explore further consequences of the interplays, which will be the key to unlock the theory of quantum gravity. It is also important to take the weak violation of symmetry into account. Since the violation of the exact symmetry will result in deviations from our analysis, we can quantify the degree of symmetry violation by evaluating such deviations, which will open an operational approach to understanding symmetry in quantum gravity.

**Methods**

**Notations**

We here introduce important notations. We explicitly write the relevant systems in the super-script, such as \( \mathcal{H}^S \) for the Hilbert space of \( S \), \( X^{SR} \) for an operator on \( SR \), \( \mathcal{E}^{C \rightarrow D} \) for a superoperator from a system \( C \) to \( D \), and so on. A reduced operator on \( S \) of \( \rho^{SR} \) is denoted by \( \rho^S \), that is, \( \rho^S = \text{Tr}_R[\rho^{SR}] \). We also use a similar notation for superoperators, that is, for a given superoperator \( \mathcal{E}^{C \rightarrow DF} \), \( \mathcal{E}^{C \rightarrow D} := \text{Tr}_F \circ \mathcal{E}^{C \rightarrow DF} \). Furthermore, as the identity operator \( I \) acts trivially, we often denote \( (M^S \otimes I^R)\rho^{SR}(M^{S^\dagger} \otimes I^R) \) simply by \( M^S \rho^{SR} M^{S^\dagger} \).

The infidelity between two quantum states \( \rho \) and \( \sigma \) is defined by \( 1 - F(\rho, \sigma) \), where \( F(\rho, \sigma) := \| \sqrt{\rho} \sqrt{\sigma} \|_1^2 \) is the fidelity, and \( \| X \|_1 := \text{Tr} \sqrt{X X^\dagger} \) is the trace norm. We define the recovery errors
\[ \Delta_{inv} \text{ and } \Delta_{tot} \text{ by} \]
\[ \Delta_{inv} := \inf_D \left[ 1 - F(\Phi_{\text{diag}}^{AR}, \hat{\Phi}_{AR}) \right], \]
\[ \Delta_{tot} := \inf_D \left[ 1 - F(\Phi_{AR}^{'}, \hat{\Phi}_{AR}) \right], \]
\[ \text{respectively. Here, the state } \hat{\Phi}_{AR} \text{ is the final state of the whole process given by} \]
\[ \hat{\Phi}_{AR} := D^{S_{\text{rad}}B_{\text{rad}} \rightarrow A} \circ \mathcal{A}^{B_{\text{in}} \rightarrow S_{\text{rad}}} (\Phi_{AR} \otimes \xi_{B_{\text{in}}B_{\text{rad}}}), \]
\[ \text{where the infimum is taken over all possible quantum operations } D^{S_{\text{rad}}B_{\text{rad}} \rightarrow A}, i.e. \text{ completely-positive and trace-preserving maps, applied by Bob onto the radiation } S_{\text{rad}} \text{ and the past radiation } B_{\text{rad}}. \]

In our analysis, the min-entropy and conditional min-entropy play important roles, which are defined by
\[ H_{\text{min}}(A)_\rho = \sup \{ \lambda \in \mathbb{R} | 2^{-\lambda} I^A \geq \rho^A \}, \]
\[ H_{\text{min}}(A|B)_\rho = \sup \{ \lambda \in \mathbb{R} | 2^{-\lambda} I^A \otimes \sigma^B \geq \rho^{AB} \}, \]
\[ \text{respectively. The first supremum in the conditional min-entropy is taken over all normalized states } \sigma^B. \text{ See Ref. [33] for a comprehensive introduction of the entropies.} \]

We label each subspace with a fixed Z-axis AM by the number of up-spins, which is a nonnegative integer. For instance, the Hilbert spaces \( \mathcal{H}^A, \mathcal{H}^{B_{\text{in}}}, \text{ and } \mathcal{H}^S = \mathcal{H}^A \otimes \mathcal{H}^{B_{\text{in}}} \) are decomposed due to the symmetry as
\[ \mathcal{H}^A = \bigoplus_{k=0}^N \mathcal{H}_k^A, \mathcal{H}^{B_{\text{in}}} = \bigoplus_{\mu=0}^N \mathcal{H}_\mu^{B_{\text{in}}}, \text{ and } \mathcal{H}^S = \bigoplus_{m=0}^{N+k} \mathcal{H}_m^S, \]
\[ \text{respectively. The projection operator onto each subspace is denoted by } \Pi_k^A, \Pi_{\mu}^{B_{\text{in}}}, \text{ and } \Pi_m^S. \]

**Construction of \( \Gamma \)**

The fictitious state \( \Gamma^{S^*ER} \) is defined as follows. We first define an extended system \( S^* \) by the system whose Hilbert space is given by \( \bigoplus_m \mathcal{H}_m^S \otimes \mathcal{H}_m^{S'}, \) where \( S' \) is the system with the same dimension as \( S. \) Similarly to \( S = S_{\text{rad}}S_{\text{in}}, \) \( S' \) can be decomposed into \( S'_{\text{rad}}S'_{\text{in}}. \) We also introduce a quantum system \( E \) that has the same dimension with \( S' \) and define \( \pi^{S'E} = \pi^{S'_{\text{rad}}} \otimes \Phi^{S'_{\text{in}}E}, \) where \( \pi^{S'_{\text{rad}}} \) is the completely mixed state in \( S'_{\text{rad}} \) and \( \Phi^{S'_{\text{in}}E} \) is the maximally entangled state between \( S'_{\text{in}} \) and \( E. \) The state \( \pi^{S'E} \) corresponds to that obtained from the channel-state duality \[33, 39\] of the non-unitary part of the BH dynamics \( \mathcal{L}^{S\rightarrow S_{\text{in}}}, \) i.e. the partial trace over \( S_{\text{rad}}. \) Denoting by \( \Psi^{SR} = \Phi^{AR} \otimes \xi_{B_{\text{in}}} \) the state in \( SR, \) the state \( \Gamma^{S^*ER} \) is defined by
\[ \Gamma^{S^*ER} = \sum_{m,m'=0}^{N+k} \frac{2^{N+k}}{d_m d_{m'}} \tau^{S'E}_{mm'} \otimes \Psi^{SR}_{mm'}, \]
\[ \text{where } d_m = \binom{N+k}{m}, \]
\[ \tau^{S'E}_{mm'} = \Pi_{m'}^{S'} \pi^{S'E} \Pi_{m}^{S'}, \text{ and } \Psi^{SR}_{mm'} = \Pi_{m'}^{S} \Psi^{SR} \Pi_{m}^{S'} \]
\[ \text{Using the partial decoupling theorem } [37] \text{ and its extension, we can show that the dynamics } \mathcal{L}_{\text{Kerr}} \text{ of the Kerr BH typically transforms } \Psi \text{ to } \mathcal{L}_{\text{Kerr}}(\Psi) \text{ such that} \]
\[ \left\| \mathcal{L}_{\text{Kerr}}^{S_{\text{in}}} (\Psi^{SR}) - \Gamma^{S_{\text{in}}R} \right\|_1 \leq 2^{-\frac{1}{2} H_{\text{min}}(S^*|ER)}, \]
where $\Gamma^S_{in} R$ is the state obtained simply by identifying $E$ of $\Gamma^{ER} := \text{Tr}_{S^r}[\Gamma^S ER]$ with $S_{in}$. By explicitly computing $\Gamma^S_{in} R$, Equation (3) is obtained.

**Upper bounds on the recovery errors**

Inequalities (4) and (5) can be obtained by extending the partial decoupling theorem [37], and combining it with the smoothing technique [44, 45], and the Uhlmann’s theorem [46, 47].

The most general way of smoothing is to extend the conditional min-entropy to the smooth conditional min-entropy, which however typically results in computationally intractable expressions. Hence, we exploit a limited smoothing, where we ignore “less probable” subspaces $\mathcal{H}_{S \text{rad}}^S$. To this end, let $\tilde{\Gamma}^S ER_n$ be the subnormalized state defined by $\Pi^S_{\text{rad}} \Gamma^S ER_n \Pi^S_{\text{rad}}$, which corresponds to the situation where the $Z$-axis AM in $S_{\text{rad}}$ is post-selected to be $n$. Using the probability $p_n = \text{Tr}[\tilde{\Gamma}^S ER_n]$ of the post-selection, we define the probable set $I_\epsilon$ by $\{n \in [0,\ell] : p_n \geq \epsilon\}$ for $\epsilon > 0$. We then call the subspaces $\mathcal{H}_{S \text{rad}}^S$ for $n \notin I_\epsilon$ rare events and ignore them. In this sense, the parameter $\epsilon$ should be regarded as a smoothing parameter.

To explicitly formulate this idea, let $\Pi^S_{\text{rad}}$ be the projection $\sum_{n \in I_\epsilon} \Pi^S_{\text{rad}}$. In the situation described above, the fictitious state $\Gamma$ is modified to $\tilde{\Gamma}(\epsilon)$, which is

$$\tilde{\Gamma}^S ER(\epsilon) = \Pi^S_{\text{rad}} \Gamma^S ER \Pi^S_{\text{rad}}.$$

We can then show that

$$\|L_{Kerr}^{S \rightarrow S_{in}}(\Psi^{SR}) - \Gamma^S_{in} R\|_1 \leq 2 \Theta_{\xi},$$

where $\Theta_{\xi} := \min_{\epsilon \geq 0} \{\Theta_{\xi}(\epsilon)\}$, $\Theta_{\xi}(\epsilon) = 2^{-\frac{1}{2}H_{\text{min}}(S^r|ER|_{\Gamma(\epsilon)})} + w(\epsilon)$, and $w(\epsilon) = 1 - \text{Tr}[\tilde{\Gamma}^S ER(\epsilon)]$. Combining Inequality (22) with the Uhlmann’s theorem [46, 47], we can show that the recovery error $\Delta_{inv}$ is bounded from above as follows:

$$\Delta_{inv} \leq 2 \Theta_{\xi}.$$

To investigate the recovery error $\Delta_{tot}$ for the whole information, we start with the triangle inequality to obtain

$$\|L_{Kerr}^{S \rightarrow S_{in}}(\Psi^{SR}) - \Gamma_{\text{in}} \otimes \pi^R\|_1 \leq 2 \Theta_{\xi} + \eta_\xi,$$

with $\eta_\xi = \|\Gamma^S_{in} R - \Gamma_{\text{in}} \otimes \pi^R\|_1$, which is explicitly given by

$$\eta_\xi = \frac{1}{2^k} \sum_{\nu=0}^{N+k-\ell} \sum_{\kappa=0}^{k} F_{k,\nu}(\xi) \binom{N+k-\ell}{\nu} \binom{k}{\kappa},$$

$$F_{k,\nu}(\xi) = \sum_{m=0}^{N+k} \chi_{m-k} \frac{k}{\kappa} \sum_{\kappa'=0}^{k} \chi_{m-k'},$$

with $\chi_{\mu} = \text{Tr}[\xi^B_{in} \Pi^B_{\mu}]$. Again, using the Uhlmann’s theorem [46, 47], we can show that Bob is able to decode with an error $\Delta_{tot}$ satisfying

$$\Delta_{tot} \leq 2 \Theta_{\xi} + \eta_\xi.$$
Methods for numerical calculations

For Figure 2, we have considered an initial state in the form of

$$|\xi\rangle_{B_{in}} = \sum_{\mu=0}^{N} \sqrt{\chi_{\mu}} |\varphi_{\mu}\rangle_{B_{in}},$$

(28)

with \(\sum_{\mu} \chi_{\mu} = 1\), where the coefficients \(\chi_{\mu}\) are set to be a normalized Gaussian distribution with mean \(L + N/2\) and standard deviation \(\delta L\), and \(|\varphi_{\mu}\rangle_{B_{in}}\) is an arbitrary pure state in \(\mathcal{H}^{B_{in}}_{\mu}\). Note that the mean is set to \(L + N/2\) because our notation here is based on the number of up-spins rather than the Z-axis AM. We can then show that a lower bound on \(H_{\min}(S^z|ER)_{\tilde{\Gamma}(\epsilon)}\) is given by \(k - \log \gamma_{\text{pure}}\) with

$$\gamma_{\text{pure}} = \sum_{n\in I_{x}} \left( \sum_{m=0}^{N} \sum_{\kappa=0}^{k} \sqrt{\frac{\chi_{m-\kappa}}{\binom{N+k}{m}}} \binom{N+k-\ell}{m-n} \binom{k}{\kappa} \right)^2.$$  

(29)

Note that, due to the partially scrambling dynamics \(\mathcal{L}_{\text{Kerr}}\), the results do not depend on the choice of \(|\varphi_{n}\rangle_{B_{in}}\).

For Figure 3, we chose an initial state in the form of

$$|\xi\rangle_{B_{in}B_{rad}} = \sum_{\mu=0}^{N} \sqrt{\chi_{\mu}} |\Phi_{\mu}\rangle_{B_{in}B_{rad}},$$

(30)

where \(|\Phi_{\mu}\rangle_{B_{in}B_{rad}}\) is a maximally entangled state between \(\mathcal{H}^{B_{in}}_{\mu}\) and \(\mathcal{H}^{B_{rad}}_{\mu}\). A lower bound on \(H_{\min}(S^z|ER)_{\tilde{\Gamma}(\epsilon)}\) is given by \(k - \log \gamma_{\text{mix}}\), where \(\gamma_{\text{mix}}\) is given by

$$\sum_{\mu=0}^{N} \chi_{\mu} \sum_{n\in I_{x}} \left( \sum_{m=0}^{N} \sum_{\kappa=0}^{k} \frac{1}{\binom{N+k}{m}} \binom{N+k-\ell}{m-n} \binom{k}{m-\mu} \right)^2.$$  

(31)

In the numerical calculations, we have first checked for randomly chosen \((L, \delta L)\) that the value of \(\Theta_{\xi}(\epsilon)\) smoothly changes when \(\epsilon\) is varied. We have also checked that \(\Theta_{\xi}(\epsilon)\) is likely to have one minimum. We have then computed \(\Theta_{\xi}(\epsilon)\) for a discrete parameter set \(E_0 = \{10^{-x}y : x = 1, \ldots, 9, y = 1, \ldots, 9\}\) and take the minimum value to find \(\Theta_{\xi}\). For \((L, \delta L) = (3N/8, 0.9\sqrt{N}), (0, 0.3N), (N/8, 0.3N), (N/4, 0.3N), \) and \((3N/8, 0.3N)\), the \(\min_{\epsilon\in E_0} \Theta_{\xi}(\epsilon)\) turns out not to monotonically decrease as \(\ell\) increases, which indicates that the minimization over the parameter set \(E_0\) is not sufficient. In these cases, we have computed \(\Theta_{\xi}(\epsilon)\) two more digits around the minimum over \(E_0\), which results in Figures 2 and 3.

Dimension condition for the information leakage

To derive Equation (7) from Inequality (6), we first explicitly write down the dimensions:

\[
\dim \mathcal{H}^{S_{rad}}_{n} = \binom{\ell}{n},
\]

(32)

\[
\dim \mathcal{H}^{S_{in}}_{L/h+(N+k)/2-n} = \binom{N+k-\ell}{L/h+(N+k)/2-n},
\]

(33)

and approximate them with the function \(s(\lambda)\) such that

\[
\log \dim \mathcal{H}^{S_{rad}}_{n} \approx \ell s\left(\frac{n}{\ell}\right),
\]

(34)

\[
\log \dim \mathcal{H}^{S_{in}}_{L/h+(N+k)/2-n} \approx (N+k-\ell) s\left(\frac{L/h+(N+k)/2-n}{N+k-\ell}\right).
\]

(35)
The number $n$ follows a hypergeometric distribution and its variance $\langle \delta n^2 \rangle$ is approximated by

$$\langle \delta n^2 \rangle \approx \left( 1 - \frac{\ell}{N + k} \right) \frac{\ell}{|s''(\lambda)|},$$

where $\lambda = L/(\hbar N)$, and we have assumed $k \ll N$ and $L/(N + k) \approx L/N$. Considering the worst case $n = (\lambda + 1/2)\ell + c\sqrt{\langle \delta n^2 \rangle}$ for $L \geq 0$ and solving Inequality (6) under the condition that $c\sqrt{\langle \delta n^2 \rangle} \ll \ell, N + k - \ell$, we obtain Equation (7).

**A Q function of quantum states**

We define an unnormalized Q function as follows: for a pure state $|\theta, \phi\rangle$,

$$Q_{\theta, \phi}(L_X, L_Z) = \langle \theta, \phi | \xi \rangle_{\text{fin}}^2,$$

where $|\theta, \phi\rangle := (\cos \frac{\theta}{2}|0\rangle + e^{i\phi} \sin \frac{\theta}{2}|1\rangle)^\otimes N$ and $(\theta, \phi)$ are given by $\sin \theta \cos \phi = 2L_X/N$ and $\cos \theta = 2L_Z/N$. Note that the function is regarded as the Husimi Q function for $N \to \infty$ when $\langle L_Y \rangle \approx N/2$.

In the right-hand side of Figure 12, we have plotted the Q function of a state $\xi$ given by Equation (28) with $|\varphi_n\rangle_{\text{fin}}$ being the state of equal superposition of all product basis states in $H_{\text{fin}}^n$.

**Information remnant and symmetry-breaking**

To relate the information remnant to the symmetry-breaking of the Kerr BH, we consider the situation where the $Z$-axis AM of the reference $R$ and the remaining BH $S_{\text{fin}}$ are separately measured. Denoting by $P(\nu|\kappa)$ be the probability distribution of the outcome $\nu$ in $S_{\text{fin}}$ given that the outcome in $R$ is $\kappa$, the $\eta_{\kappa}$ should satisfy

$$\eta_{\kappa} \geq \sum_{\kappa} q(\kappa) \sum_{\nu} |P(\nu|\kappa) - P(\nu)|,$$

where $q(\kappa)$ is the probability to obtain the outcome $\kappa$ in $R$, and $P(\nu) = \sum_{\kappa} q(\kappa)P(\nu|\kappa)$ is the probability to obtain $\nu$ in $S_{\text{fin}}$.

To evaluate each probability, we first assume that we may approximate the summation over $\nu$ by the integral over probability density functions $p(\nu|\kappa)$ and $p(\nu)$. We then assume that the $\kappa$-dependence of $p(\nu|\kappa)$ is approximated by a shift without changing its common shape $\bar{\nu}(\nu)$, namely, $p(\nu|\kappa) \approx \bar{\nu}(\nu - \alpha \delta \kappa)$ with $\bar{\nu}(\nu) := p(\nu|\kappa = \langle \kappa \rangle)$, where $\delta \kappa = \kappa - \langle \kappa \rangle$. Here, $\alpha = 1 - \ell/(N + k)$ is the ratio of the number of qubits in $S_{\text{fin}}$ to that in $S$, which appears since $\ell$ qubits are evaporated from the initial $N + k$ qubits. Assuming that $|\delta \kappa|$ is sufficiently small such that $\bar{\nu}(\nu - \alpha \delta \kappa) = \bar{\nu}(\nu) - \alpha \delta \kappa \bar{\nu}(\nu) + O(\delta \kappa^2)$, we have $p(\nu) = \bar{\nu}(\nu) + O(\delta \kappa^2)$ and

$$\eta_{\kappa} \geq \langle |\delta \kappa| \rangle \alpha \int d\nu \left| \frac{\partial \bar{\nu}(\nu)}{\partial \nu} \right| + O(\delta \kappa^2),$$

$$\geq 2\langle |\delta \kappa| \rangle \alpha \max_{\nu} p(\nu) + O(\delta \kappa^2).$$

Using the variance $\langle \delta \nu^2 \rangle := \langle \nu^2 \rangle - \langle \nu \rangle^2$ of the $Z$-axis AM in $S_{\text{fin}}$, we have a bound $\max_{\nu} p(\nu) \geq (2\sqrt{3}/\sqrt{\langle \delta \nu^2 \rangle})^{-1}$. Combining these altogether, we arrive at

$$\eta_{\kappa} \geq \frac{1}{\sqrt{3}} \langle |\delta \kappa| \rangle \left( 1 - \frac{\ell}{N + k} \right) \frac{1}{\sqrt{\langle \delta \nu^2 \rangle}} + O(\kappa^2).$$
On the other hand, we quantify the degree $\zeta(S_{\text{in}})$ of symmetry-breaking of a general state $\Psi$ of the Kerr BH $S_{\text{in}}$ as follows: let $|\Psi\rangle^{S_{\text{in}}S'_{\text{in}}}$, where $S'_{\text{in}} = R B_{\text{rad}} S_{\text{rad}}$, be a purification of $\Psi$. We then define

$$B_\theta(\Psi) := 1 - |\langle \Psi| e^{i\theta L_Z} \otimes I |\Psi\rangle|^2,$$

where the identity acts on $S'_{\text{in}}$. Note that the second term is the fidelity between the original state $|\Psi\rangle$ and the state $(e^{i\theta L_Z} \otimes I)|\Psi\rangle$ after the $\theta$-rotation of $S_{\text{in}}$ around the $Z$-axis. While $B_\theta(\Psi) = 0$ for any $\theta$ when $\Psi$ is $Z$-axial symmetric, $B_\theta(\Psi)$ increases as $O(\theta^2)$ even for infinitesimal $\theta$ when $\Psi$ breaks the symmetry. Hence, we define the degree $\zeta(S_{\text{in}})$ of symmetry-breaking by

$$\zeta(S_{\text{in}}) := \frac{\partial^2}{\partial \theta^2} B_\theta(\Psi) \bigg|_{\theta=0},$$

which can be shown to be equal to the twice of the variance of the $Z$-axis AM of $\Psi$, i.e. $2\langle \delta \nu^2 \rangle$. Substituting this into Equation (41), we arrive at Inequality (11).

Part II
Long version of the paper

I. INTRODUCTION

A black hole (BH) is one of the most peculiar objects in the universe. While macroscopic properties of BHs can be fairly understood by general relativity, finding microscopic descriptions of BHs has been a central problem in fundamental physics as it will unlock the unified theory of quantum gravity. A significant step was made by the discovery of Hawking radiation [1,2]: due to a quantum effect, a quantum BH emits thermal radiation and eventually evaporates, unveiling the close similarity between BHs and thermodynamics. This discovery however accelerates the question about the micro-macro relations of quantum BHs since it is not clear whether the information in a quantum BH, i.e. the microscopic description, is carried away by the radiation.

Despite the fact that information is unlikely to be carried away in classical cases due to the no-hair theorem [3-5], recent developments of the holographic principle indicate that information in a BH should be preserved in the whole process and will leak out as they evaporate, showing a gap between our macroscopic and microscopic understandings of BHs. This question is known as the information paradox. Fully clarifying microscopic details of the information leakage, and relating them to macroscopic properties, are crucial towards further development of fundamental physics.

A novel approach was proposed from the theory of quantum information [6]. The theory offers the way of dealing with quantum information in a BH in an operational manner. Based on a quantum mechanical model of BHs, it was shown that complex internal dynamics of quantum BHs, called scrambling [7,8], leads to extremely quick leakage of information, providing a hint to the detailed process of information leakage from a microscopic perspective. The result has spiked a number of novel research topics aiming to understand quantum information of BHs [7-27], which has largely contributed to the progress not only of fundamental physics but also of a wide range of theoretical physics, even indicating a possible duality between quantum BHs and quantum chaos.

The micro-macro correspondence in the information leakage is however yet to be clarified. The analysis based on scrambling predicts instant leakage of full information, in which there are few quantitative parameters to be connected with macroscopic properties of the BH. Thus, to obtain a deeper insight, it is of great importance to push forward quantum information theoretic approach, so that the information leakage can be understood also in terms of macroscopic BH physics.

In this paper, we study how information is carried away by the Hawking radiation when a quantum BH has symmetry. We especially consider an uncharged rotating BH, also known as a Kerr BH, by assuming the exact axial symmetry around the Z-axis. In this case, the conserved quantity is the Z-axis angular momentum, which we denote by the Z-axis AM for short.

We first provide rigorous upper bounds on the amount of radiation needed to recover any information in the Kerr BH. The bounds are given in terms of the conditional min-entropy and are obtained by generalizing decoupling approach [28-31] to the one applicable to the case where the system has symmetry. We call such a technique partial decoupling approach [32]. We then numerically provide how the information leaks out from the Kerr BH, which shows two significant deviations from the non-rotating case. One is a delay of the timing at which the information recovery from the radiation becomes possible, and the other is an information remnant that remains unaltered until the last moment. They should be understood as the consequences of the symmetry of the Kerr BH.

We further discuss the origins of the delay and the information remnant in terms of macro-
scopic properties of the Kerr BH. First, we show that the delay of information leakage consists of two types of delays: one originated for a purely information-theoretic reason, and the other closely related to the thermodynamic properties of the Kerr BH. Hence, the delay of information leakage reveals a highly non-trivial interplay between information theory and BH thermodynamics. Second, the information remnant is related to the symmetry-breaking of the initial state of the Kerr BH, indicating that the symmetry-breaking may be understood as a resource of the information leakage from the Kerr BH. Both reveal non-trivial relations between quantum information, symmetry of the BH, and macroscopic BH physics, providing a deep insight into the micro-macro correspondence in the information leakage problem of quantum BHs.

The paper is organized as follows. We start with preliminaries in Section II, where we also introduce our notation. In Section III, we provide a brief review of the HP model of a quantum BH. In Section IV, we propose a modified HP model that incorporates the symmetry of the Kerr BH. Based on an extension of the recently proposed one-shot partial decoupling theorem [32], we provide formal solutions to the information leakage from the Kerr BH. Section V is devoted to the numerical analysis of the problem based on the formal solutions. We then analyze in Section VI the information leakage problem from the Kerr BH from different perspectives, allowing us to understand the key physics behind the problem. After we provide a summary and discussions in Section VII, we explain in Sections IX, X, XI, and XII our methods and provide proofs of the statements.

II. PRELIMINARIES

We here introduce our notation and explain basic properties of the key quantities we use in the paper. We basically use the notation commonly used, so the readers familiar with those can skip this section. Important notations are summarized in Table I.

A. General notation

We use the following standard asymptotic notation. Let \( f(n) \) and \( g(n) \) be functions on \( \mathbb{R}^+ \). We say \( f(n) = O(g(n)) \) if there exist \( c, n_0 > 0 \) such that \( f(n) \leq cg(n) \) for all \( n \geq n_0 \). When there exist \( c, n_0 > 0 \) such that \( f(n) \geq cg(n) \) for all \( n \geq n_0 \), we say \( f(n) = \Omega(g(n)) \). If \( f(n) = O(g(n)) \) and \( f(n) = \Omega(g(n)) \), we denote it by \( f(n) = \Theta(g(n)) \). If \( \lim_{n \to \infty} f(n)/g(n) = 0 \), we write it by \( f(n) = o(g(n)) \). For two natural numbers \( i \) and \( j \) \((i \leq j)\), we often denote the sequence of integers between them, \( \{i, i+1, \ldots, j-1, j\} \), by \([i, j]\). The logarithm is always taken in base two.

When we consider a system \( S \) composed of qubits, the number of qubits is denoted by \(|S|\). For Hilbert spaces, operators, and superoperators, we explicitly write the relevant systems in the superscript. For instance, \( \mathcal{H}^S \) is a Hilbert space associated with a system \( S \), \( X^{SR} \) is an operator acting on the system \( SR \), \( E^{S \to B} \) is a superoperator from the system \( S \) to \( B \). For superoperators from e.g. \( S \) to itself, we denote it by \( E^S \). A reduced operator on \( S \) of \( \rho^{SR} \) is denoted by \( \rho^S \), that is, \( \rho^S = \text{Tr}_R[\rho^{SR}] \). Furthermore, as the identity operator \( I \) acts trivially, we often denote \((M^S \otimes I^R)\rho^{SR}(M^S \dagger \otimes I^R)\) simply by \( M^S \rho^{SR} M^S \). The identity superoperator is denoted by e.g. \( \text{id}_S \).

We denote a set of linear operators from \( \mathcal{H}^A \) to \( \mathcal{H}^B \) by \( \mathcal{L}(\mathcal{H}^A, \mathcal{H}^B) \), and \( \mathcal{L}(\mathcal{H}^A, \mathcal{H}^A) \) by \( \mathcal{L}(\mathcal{H}^A) \). Special operators on \( \mathcal{H} \), such as Hermitian operators, positive semi-definite operators, quantum
states, and sub-normalized states, are denoted by

\[
\text{Her}(\mathcal{H}) = \{ X \in \mathcal{L}(\mathcal{H}) : X = X^\dagger \},
\]

\[
\mathcal{P}(\mathcal{H}) = \{ X \in \text{Her}(\mathcal{H}) : X \geq 0 \},
\]

\[
\mathcal{S}(\mathcal{H}) = \{ \rho \in \mathcal{P}(\mathcal{H}) : \text{Tr}[\rho] = 1 \},
\]

\[
\mathcal{S}_{\leq}(\mathcal{H}) = \{ \rho \in \mathcal{P}(\mathcal{H}) : \text{Tr}[\rho] \leq 1 \},
\]

respectively.

For several important quantum states, we fix the notation. The maximally entangled state between \( S \) and \( S' \), where \( \mathcal{H}^S \cong \mathcal{H}^{S'} \), is always denoted by \( \Phi^{SS'} \). The completely mixed state on \( \mathcal{H}^S \) is denoted by \( \pi^S = I^S/d_S \) (\( d_S = \dim \mathcal{H}^S \)). For a quantum state \( \rho^S \in \mathcal{S}(\mathcal{H}^S) \), its purification by \( R \) (\( \mathcal{H}^R \cong \mathcal{H}^S \)) is often denoted by \( |\rho^{SR}\rangle \). Namely, it satisfies

\[
\text{Tr}_R[|\rho^{SR}\rangle\langle\rho^{SR}|] = \rho^S,
\]

where \( \text{Tr}_R \) is the partial trace over \( R \).

### B. Superoperators, channel-state duality, and norms

Conjugations by a unitary, an isometry, and a partial isometry are the fundamental superoperators in quantum mechanics. An isometry \( V^{\mathcal{H} \rightarrow \mathcal{K}} \) from a Hilbert space \( \mathcal{H} \) to another one \( \mathcal{K} \) (\( \dim \mathcal{H} \leq \dim \mathcal{K} \)) is defined by

\[
(V^{\mathcal{H} \rightarrow \mathcal{K}})^\dagger V^{\mathcal{H} \rightarrow \mathcal{K}} = I^\mathcal{H}.
\]

Note that \( V^{\mathcal{H} \rightarrow \mathcal{K}}(V^{\mathcal{H} \rightarrow \mathcal{K}})^\dagger \neq I^\mathcal{K} \) unless \( \dim \mathcal{H} = \dim \mathcal{K} \). When \( \dim \mathcal{H} = \dim \mathcal{K} \), an isometry is called a unitary. A partial isometry is a linear operator from \( \mathcal{H} \) to \( \mathcal{K} \), where no assumption is put on their dimensions, such that it is an isometry on its support. Important examples of a partial isometry are projections, isometries, and unitaries.

Another important class of superoperators is a quantum channel \( \mathcal{T}^{\mathcal{S} \rightarrow \mathcal{B}} \), which is a completely-positive (CP) and trace-preserving (TP) map. A map is called CP if \( \rho^{SS'} \geq 0 \) and is TP if \( \text{Tr}[\mathcal{T}^{\mathcal{S} \rightarrow \mathcal{B}}(\rho^S)] = \text{Tr}[\rho^S] \). We also say a superoperator \( \mathcal{T}^{\mathcal{S} \rightarrow \mathcal{B}} \) is sub-unital and unital if \( \mathcal{T}^{\mathcal{S} \rightarrow \mathcal{B}}(I^S) \leq I^B \) and \( \mathcal{T}^{\mathcal{S} \rightarrow \mathcal{B}}(I^S) = I^B \), respectively.

In quantum information theory, a complementary channel is also important (see e.g. [33]). Let \( \mathcal{T}^{\mathcal{A} \rightarrow \mathcal{B}} \) be a quantum channel, and \( V^{\mathcal{T} \rightarrow \mathcal{BE}} \) be its Steinspring dilation [34], i.e., \( V^{\mathcal{T} \rightarrow \mathcal{BE}} \) is an isometry such that

\[
\text{Tr}_E[V^{\mathcal{T} \rightarrow \mathcal{BE}} \rho^A (V^{\mathcal{T} \rightarrow \mathcal{BE}})^\dagger] = \mathcal{T}^{\mathcal{A} \rightarrow \mathcal{B}}(\rho^A),
\]

for any \( \rho^A \in \mathcal{L}(\mathcal{H}^A) \). The complementary channel \( \bar{\mathcal{T}}^{\mathcal{A} \rightarrow \mathcal{E}} \) of \( \mathcal{T}^{\mathcal{A} \rightarrow \mathcal{B}} \) is then defined by

\[
\bar{\mathcal{T}}^{\mathcal{A} \rightarrow \mathcal{E}}(\rho^A) := \text{Tr}_B[V^{\mathcal{T} \rightarrow \mathcal{BE}} \rho^A (V^{\mathcal{T} \rightarrow \mathcal{BE}})^\dagger],
\]

for any \( \rho^A \in \mathcal{L}(\mathcal{H}^A) \). The complementary channels is especially useful to quantify how much information of \( \rho^A \) is lost when it goes through the quantum channel \( \mathcal{T}^{\mathcal{A} \rightarrow \mathcal{B}} \).

Any superoperator \( \mathcal{T}^{\mathcal{S} \rightarrow \mathcal{B}} \) from \( \mathcal{S} \) to \( \mathcal{B} \) has a convenient representation in terms of an operator on \( \mathcal{H}^{SB} \), which is often referred to as the Choi-Jamiołkowski representation [35][36], or sometimes the channel-state duality, and defined by

\[
\mathcal{J}(\mathcal{T}^{\mathcal{S} \rightarrow \mathcal{B}}) := (\text{id}_\mathcal{S} \otimes \mathcal{T}^{\mathcal{S}' \rightarrow \mathcal{B}})(\Phi^{SS'}). \]

Norms, distance-like measures, and entropies

| \( \| X \|_1 \) | The trace norm of an linear operator \( X \): \( \| X \|_1 = \text{Tr}[\sqrt{XX^\dagger}] \) |
| \( \| X \|_2 \) | The Hilbert-Schmidt norm of an linear operator \( X \): \( \| X \|_2 = \sqrt{\text{Tr}[XX^\dagger]} \) |
| \( \| X \|_\infty \) | The operator norm given by the largest singular value of \( X \). |
| \( F(\phi, \sigma) \) | Fidelity between two states \( \Phi \in \mathcal{S}(\mathcal{H}) \) and \( \sigma \in \mathcal{S}(\mathcal{H}) \): \( F(\phi, \sigma) = \| \sqrt{\phi} \sqrt{\sigma} \|_1^2 \) |
| \( H(A)_{\phi} \) | The von Neumann entropy of \( \phi \): \( H(A)_{\phi} = -\text{Tr}[\phi \log \phi] \) |
| \( H(A|B)_{\phi} \) | The conditional entropy of \( \phi^{AB} \): \( H(A|B)_{\phi} = H(A)_{\phi} - H(B)_{\phi} \) |
| \( H_{\min}(A|B)_{\phi} \) | The conditional min-entropy of \( \phi^{AB} \): \( H_{\min}(A|B)_{\phi} = \sup_{\sigma \in \mathcal{S}(\mathcal{H}|B)} \sup_{\lambda \in \mathbb{R}} \{ -\lambda I^A \otimes \sigma^B - \phi^{AB} \geq 0 \} \) |

Properties of superoperators can be rephrased in terms of the Choi-Jamiołkowski representation. For instance, \( T^{S \rightarrow B} \) is CP, TP, and unital if and only if \( \mathcal{J}(T^{S \rightarrow B}) \geq 0 \), \( \text{Tr}_B[\mathcal{J}(T^{S \rightarrow B})] = \pi^S \), and \( \text{Tr}_S[\mathcal{J}(T^{S \rightarrow B})] = \pi^B \), respectively.

We use the Schatten \( p \)-norm \( \| \cdot \|_p \) (\( p \in [1, \infty] \)) for linear operators, which is defined by

\[
\| X \|_p := \left( \text{Tr}[(XX^\dagger)^{p/2}] \right)^{1/p}.
\] (53)

For \( p = 1, 2, \) and \( \infty \), the norm is often called the trace, Hilbert-Schmidt, and operator norm, respectively. Note that the operator norm is nothing but the maximum singular value. We also use the fidelity between quantum states \( \rho \) and \( \sigma \), defined by

\[
F(\rho, \sigma) := \| \sqrt{\rho} \sqrt{\sigma} \|_1^2.
\] (54)

For pure states \( |\phi\rangle \) and \( |\psi\rangle \), we denote the fidelity between them by \( F(|\phi\rangle, |\psi\rangle) \), which is simply equal to \( |\langle \phi| \psi \rangle|^2 \).
C. Random unitary and entropies

Throughout the paper, the unitary group of degree $d < \infty$ is denoted by $U(d)$. Since the unitary group of a finite degree is a compact group, there exists the unique left- and right-unitarily invariant probability measure, known as the Haar measure. We denote by $H$ the Haar measure. More specifically, the Haar measure satisfies the following property.

$$H(VW) = H(WV) = H(W).$$  \hfill (55)

When a unitary $U$ is chosen uniformly at random from $U(d)$ with respect to a given probability measure $\mu$, it is denoted by $U \sim \mu$. In particular, if a unitary is chosen with respect to the Haar measure, it is called a Haar random unitary and is denoted by $U \sim H$.

For a positive semi-definite operator $\rho_{AB}$, the conditional min-entropy is defined by

$$H_{\min}(A|B) = \sup_{\sigma_B \in S(H^B)} \sup\{\lambda \in \mathbb{R} | 2^{-\lambda} \sigma^A \otimes \sigma^B - \rho_{AB} \geq 0\}.$$  \hfill (56)

This is a generalization of the usual conditional entropy $H(A|B) = H(AB) - H(B)$, where $H(A) = -\text{Tr}[\rho_A \log \rho_A]$ is the von Neumann entropy. It is in general hard to compute the conditional min-entropy, but for a pure state, the following proposition is known.

**Proposition 1** (Ref. [37]). For a pure state $\psi_{AB}$, the conditional min-entropy is given by

$$H_{\min}(A|B) = -2 \log \left[ \text{Tr}[\sqrt{\psi^A}] \right] = -2 \log \left[ \text{Tr}[\sqrt{\psi^B}] \right].$$  \hfill (57)

Dimensional upper and lower bounds of the conditional min-entropy are also known:

$$-\min\{\log(\dim H^A), \log(\dim H^B)\} \leq H_{\min}(A|B) \leq H(A|B) \leq \log(\dim H^A).$$  \hfill (58)

Note that, unlike the classical counterpart, the conditional min-entropy can be negative. As a comprehensive introduction to entropies, see Ref. [38].

The following general upper and lower bounds on the conditional min-entropy hold when the state has a specific form.

**Proposition 2.** Let $\{H_j^A\}$ be mutually orthogonal subspaces of $H^A$, and $\pi_j^A$ be the completely mixed state on $H^A_j$. For a state $\Lambda_{ABC} = \sum_{j=0}^{J} p_j \pi_j^A \otimes \rho_j^{BC}$, where $\rho_j^{BC} \in S(H^{BC})$ and $\{p_j\}$ is a probability distribution,

$$-\log \left[ \sum_{j=0}^{J} \frac{p_j}{d_j} 2^{-H_{\min}(B|C)_{\rho_j}} \right] \leq H_{\min}(AB|C)_{\Lambda} \leq \min_{j \in [0,J]} \left\{ H_{\min}(B|C)_{\rho_j} - \log \left[ \frac{p_j}{d_j} \right] \right\},$$  \hfill (59)

where $d_j = \dim H_j^A$.

The proof of Proposition 2 is given in Appendix A.

III. QUANTUM INFORMATION THEORETIC APPROACH TO THE INFORMATION PARADOX

In recent years, the BH information paradox has been investigated from the viewpoint of quantum information. One of the pioneering works was by Hayden and Presill. They investigated how quickly the information leaks out from the BH [6] based on a quantum information theoretic toy model of a BH, which we refer to as a HP model. Since our study is also based on the HP model, we first overview it in Subsections III A and III B. Our motivation is then explaining in Subsection III C.
A. Hayden-Preskill’s model of quantum BH

We consider an $N$-qubit quantum BH $B_{\text{in}}$ in a quantum state $\xi_{B_{\text{in}}}$. The state $\xi_{B_{\text{in}}}$ is purified to be $|\xi\rangle_{B_{\text{in}}}B_{\text{rad}}$ by the “past radiation” $B_{\text{rad}}$, which is the system of the Hawking radiation emitted from the BH beforehand. In this paper, we especially consider two types of BHs, “pure” and “mixed” ones. A pure BH is the BH where $B_{\text{in}}$ is in a pure state $|\xi\rangle_{B_{\text{in}}}$. This could be the case when the BH has not emitted any Hawking radiation, or the past radiation emitted earlier has been measured by someone. The mixed BH is, on the other hand, the BH where $B_{\text{in}}$ is entangled with the past radiation $B_{\text{rad}}$. So, $\xi_{B_{\text{in}}}$ is a mixed state. In the original HP model [6], the pure and mixed BHs are called young and old BHs, respectively.

At time $T_1$, Alice throws a $k$-qubit quantum information source $A$ into an either pure or mixed BH $B_{\text{in}}$, enlarging the BH to $S = AB_{\text{in}}$ of $N + k$ qubits. To keep track of the quantum information of $A$, we introduce a reference system $R$, and set $AR$ in the maximally entangled state $|\Phi\rangle^{AR}$. The BH $S$ then undergoes time evolution given by the repetitions of internal unitary dynamics $U_i$, acting on $N + k - i + 1$ qubits, and the Hawking radiation of a single qubit, where $i = 1, 2, \ldots$. The radiation is described by the process that a randomly chosen qubit goes out from the BH. In Fig. 6, the unitary dynamics is depicted by a green box, and the radiation by a purple line.

Suppose that $\ell$ qubits, denoted by $S_{\text{rad}}$, have been evaporated from the BH $S$ by time $T_2$. We denote the whole dynamics of the BH by $\mathcal{L}_{S \rightarrow S_{\text{in}}}$, where $S_{\text{in}}$ is the remaining BH at time $T_2$ after $S_{\text{rad}}$ is evaporated from $S$. The $S_{\text{in}}$ is composed of $N + k - \ell$ qubits. In our analysis, we also use its complementary dynamics. Recalling that the dynamics $\mathcal{L}_{S \rightarrow S_{\text{in}}}$ of the BH consists of unitary dynamics and the partial trace, the complementary dynamics is given by the dynamics $\mathcal{L}_{S \rightarrow S_{\text{rad}}}$ from $S$ to the radiation $S_{\text{rad}}$.

To check whether or not the information of $A$ has been already leaked out from the BH, we introduce another person Bob. Bob is waiting outside of the BH and collects all the radiation $S_{\text{rad}}$. He then tries to recover the quantum information source $A$ as much as possible. In addition, he may make use of the past radiation $B_{\text{rad}}$ when the initial BH $B_{\text{in}}$ is mixed. Since the mixed BH is entangled with the past radiation, this may help Bob recover the information. We say that
TABLE II: Notation in the investigation of the BH information problem

</tr>
</tbody>
</table>

Bob succeeds in recovering the information source $A$ when he is able to establish the maximally entangled state between the reference $R$. If this is achieved, he can indeed access the information of $A$ in the sense that, if the initial state of $A$ had been $|\psi\rangle$, Bob would also be able to recover $|\psi\rangle$.

The whole process is described in Fig. 6. For clarity, we also provide a list of important quantities in Table II.

B. Review of the result by Hayden and Preskill: decoupling approach

The infidelity of entanglement as a measure of the recovery error, we define

$$\Delta_{\text{tot}}(\xi, L, D) := 1 - F(\Phi^{AR}, \hat{\Phi}^{AR})$$

which satisfies $0 \leq \Delta_{\text{tot}} \leq 1$. This error in general depends on the state $\xi_{B_{\text{in}}}$ of the initial BH $B_{\text{in}}$, the dynamics $L^{S\rightarrow S_{\text{in}}}$ of the BH, and the decoding operation $D^{S_{\text{rad}}B_{\text{rad}}\rightarrow A}$ by Bob.

The main concern in the HP model is the number $\ell$ of evaporated qubits for Bob to be able to recover the information source $A$, which is formally stated as follows:

**Question** (Information leakage problem). Let $S$ be $AB_{\text{in}} = S_{\text{rad}}S_{\text{in}}$. For a given state $\xi$ of the initial BH $B_{\text{in}}$ and the dynamics $L$ of the BH, how large should $\ell$ be so that

$$\Delta_{\text{tot}}(\xi, L) := \inf_D \Delta_{\text{tot}}(\xi, L, D) \ll 1?$$

Here, the infimum is taken over all quantum channels $D^{S_{\text{rad}}B_{\text{rad}}\rightarrow A}$.

As often the case in quantum information theory, we assume that Bob knows $\xi_{B_{\text{in}}}$ and $L^{S\rightarrow S_{\text{in}}}$, so that $D^{S_{\text{rad}}B_{\text{rad}}\rightarrow A}$ may depend on them. Although one may think that this is a strong assumption, we emphasize that this is compatible with the original spirit of the information paradox, which asks whether or not the information is lost during the evaporation. If the information is in principle recoverable from the radiation, it implies that the information is already outside of the BH, so that it is not lost.

The whole process is described in Fig. 6. For clarity, we also provide a list of important quantities in Table II.

B. Review of the result by Hayden and Preskill: decoupling approach

The information leakage problem is understood very well based on the decoupling approach [28, 29, 31]: for the information retrieval from the radiation to be possible, it is necessary and sufficient that the remaining BH $S_{\text{in}}$ is decoupled from the reference $R$ in the sense that

$$L^{S\rightarrow S_{\text{in}}}(\Phi^{AR} \otimes \xi_{B_{\text{in}}}) \approx \pi^{R} \otimes \sigma^{S_{\text{in}}},$$

(63)
where $\pi^R$ is the completely mixed state on $\mathcal{H}^R$, and $\sigma_{\text{in}}^{S_{\text{in}}} \in \mathcal{S}(\mathcal{H}_{\text{in}}^{S_{\text{in}}})$ is any state.

The key idea by Hayden and Preskill in Ref. [6] is to assume that each unitary $U_i$ during the dynamics $\mathcal{L}$ of the BH is well-approximated by a unitary drawn uniformly at random with respect to the Haar measure $H_i$ on the corresponding unitary group $U(2^{N+k-i+1})$, i.e. $U_i \sim H_i$. In other words, they assumed that the dynamics of the BH is Haar scrambling. The validity of this assumption and the time necessary for this assumption to be satisfied, known as the scrambling time, have been intensely discussed in recent years.

The most important property of Haar scrambling is that it results in decoupling with high probability [39], which further implies that, for almost any choice of unitaries $U_i \sim H_i$, the dynamics $\mathcal{L}$ of the BH leads to the recovery error bounded from above as [6, 31]

$$\log \left[ \Delta_{\text{tot}}(\xi, \mathcal{L}) \right] \leq k - \ell + \frac{N - H_{\text{min}}(B_{\text{in}})}{2}, \quad (64)$$

where $H_{\text{min}}(B_{\text{in}})\xi$ is the min-entropy of the state $\xi B_{\text{in}}$ of the initial BH. Thus, if $\ell \gg k + (N - H_{\text{min}}(B_{\text{in}}))/2$, $\Delta_{\text{tot}}(\xi, \mathcal{L}) \ll 1$. Since $H_{\text{min}}(B_{\text{in}})\xi$ quantifies the entanglement between the initial BH $B_{\text{in}}$ and the past radiation $B_{\text{rad}}$, this clearly implies that entanglement between them dominates how quickly the information leaks out from the BH.

In particular, for the pure BH, $H_{\text{min}}(B_{\text{in}})\xi = 0$ since $B_{\text{in}}$ is in a pure state $\xi_{\text{pure}}$. Hence, we obtain

$$\Delta_{\text{tot}}(\pi_{\text{in}}, \mathcal{L}) \leq 2^{k-\ell-N}. \quad (65)$$

This implies that, after a little more than half of the BH $S$ is evaporated, Bob becomes able to recover the information with high accuracy. On the other hand, when the initial BH $B_{\text{in}}$ is sufficiently mixed, such as that $\xi B_{\text{in}} B_{\text{rad}}$ is a maximally entangled state, $H_{\text{min}}(B_{\text{in}})\xi = N$. Thus, it follows that

$$\Delta_{\text{tot}}(\pi_{\text{in}}, \mathcal{L}) \leq 2^{k-\ell}. \quad (66)$$

This implies that Bob can recover the information from the radiation of a little more than $k$ qubits. In this case, the error is independent of the size $N$ of the initial BH. Hence, even if the BH is macroscopically large, Bob does not have to wait for long.

The approach by Hayden and Preskill has opened a number of research topics [7–27], such as scrambling, out-of-time-ordered-correlators (OTOCs), the relation between quantum chaos and quantum BHs, and novel approaches to the holographic principle.

C. Motivation -Symmetry and Information Leakage-

Despite the fact that the Hayden-Preskill’s result offers a deep insight into the BH information science, BHs in reality have symmetry, such as rotational, charge, and so on. Such global symmetries are often argued to be violated at the level of quantum gravity [40, 41]. However, to be consistent with classical BHs in a classical limit, quantum BHs should have approximate symmetries, making the dynamics hard to be fully scrambling due to the conservation law. Thus, it is natural to ask a question of how exact or approximate symmetry affects the information leakage problem.

To answer this question, we modify the HP model of quantum BHs such that it can be applied to the ones with exact symmetry. Since no full decoupling occurs when a BH has a symmetry, which is due to the absence of full scrambling, we cannot directly apply the conventional decoupling method. The main goal of this paper is first to extend the decoupling approach to the one
compatible with the symmetry, and then to reveal from the perspective of the macroscopic BH physics how information leaks out from a BH with exact symmetry.

The method we develop in this study is general and can be applied to any symmetry. In this paper, however, we deal only with a quantum Kerr BH, which is a BH with axial symmetry.

IV. DYNAMICS OF A KERR BH AND THE ERRORS OF THE INFORMATION RECOVERY

Let us now study the information leakage from a Kerr BH. Without loss of generality, we assume that the symmetric axis is the $Z$-axis, so that the conserved quantity is the $Z$-component of angular momentum, which we denote by the $Z$-axis AM for short.

In Subsection IV A, we first explain that we can divide the quantum information into two types in terms of symmetry. We also explain the dynamics restricted by the symmetry and argue its consequence in Subsection IV B. The main analysis is given in Subsection IV C, where we provide an upper bound on the recovery error when the BH has the $Z$-axis symmetry.

A. Symmetry and Information

Since the axial symmetry is abelian, the Hilbert space of the system with the symmetry can be decomposed into a simple form. For instance, the Hilbert spaces $H^A$, $H^{B_{in}}$, and $H^S$ are decomposed by the $Z$-axis AM into

$$H^A = \bigoplus_{\kappa=0}^{k} H^A_{\kappa}, \quad H^{B_{in}} = \bigoplus_{\mu=0}^{N} H^{B_{in}}_{\mu} \quad \text{and} \quad H^S = \bigoplus_{m=0}^{N+k} H^S_m,$$

(67)

respectively. Note that these notations are based on the number of up-spins, but it can be readily transformed to the $Z$-axis AM of the state with $\kappa$ up-spins in the system $W$ of $M$ qubits is simply given by $h(m - M/2)$ with $h$ being the Plank constant. We thus use both notations interchangeably. We denote the projection onto each subspace by e.g. $\Pi^R_{\kappa}$, $\Pi^B_{\mu}$, and $\Pi^S_m$. We assume that the reference $R$ has the same structure as the quantum information source $A$, i.e. $H^R$ is also decomposed as $H^A$ in terms of the number of up-spins.

According to the decomposition of $H^A$ by symmetry, we can define the symmetry-invariant information. To see this, we first define $\Phi^{AR}_{\text{diag}} = \sum_{\kappa=0}^{k} p_{\kappa} \Phi^{AR}_{\kappa}$, where $p_{\kappa} := \text{Tr}[\Phi^{AR} \Pi^R_{\kappa}]$ and $\Phi^{AR}_{\kappa} := \Pi^R_{\kappa} \Phi^{AR} \Pi^R_{\kappa}/p_{\kappa}$, and divide $\Phi^{AR}$ into

$$\Phi^{AR} = \Phi^{AR}_{\text{diag}} + \delta \Phi^{AR},$$

(68)

where $\delta \Phi^{AR} = \Phi^{AR} - \Phi^{AR}_{\text{diag}}$. By definition, $\Phi^{AR}_{\text{diag}}$ is invariant under the rotation of the system $A$ around $Z$-axis, which follows from the fact that $H^R$ has the same structure as $H^A$. Hence, we refer to the information in $\Phi^{AR}_{\text{diag}}$ as symmetry-invariant information. The symmetry-invariant information can be further decomposed into classical and quantum ones. The symmetry-invariant classical information is the information about the $Z$-axis AM $\kappa$, defined by $\{p_{\kappa}, \kappa\}$, while the symmetry-invariant quantum information is the information about e.g. which $\kappa$ spins out of $k$ spins are up.

Accordingly, we can define two types of errors in recovering information. One is $\Delta_{\text{inv}}$ for the recovery of symmetry-invariant information and the other is $\Delta_{\text{tot}}$ for the total information, which
are respectively defined by
\[
\Delta_{\text{inv}}(\xi, \mathcal{L}_{\text{Kerr}}) = \inf_D \left[ 1 - F(\Phi_{\text{diag}}^{AR} D_{\text{rad}}^{S_{\text{rad}}B_{\text{rad}}\rightarrow A} \circ \mathcal{L}_{\text{Kerr}}^{S_{\text{rad}}B_{\text{rad}}} (\Phi_{\text{diag}}^{AR} \otimes \xi_{B_{\text{rad}}B_{\text{rad}}})) \right], \tag{69}
\]
\[
\Delta_{\text{tot}}(\xi, \mathcal{L}_{\text{Kerr}}) = \inf_D \left[ 1 - F(\Phi_{\text{diag}}^{AR} D_{\text{rad}}^{S_{\text{rad}}B_{\text{rad}}\rightarrow A} \circ \mathcal{L}_{\text{Kerr}}^{S_{\text{rad}}B_{\text{rad}}} (\Phi_{\text{diag}}^{AR} \otimes \xi_{B_{\text{rad}}B_{\text{rad}}})) \right]. \tag{70}
\]

Here, \( \mathcal{L}_{\text{Kerr}} \) is the dynamics of the Kerr BH, which we next provide explicitly.

**B. Dynamics of the Kerr BH – symmetry-preserving scrambling –**

Similarly to the Hilbert space, each unitary \( U_i \) in \( \mathcal{L}_{\text{Kerr}} \) should be in the form of
\[
U_i = \bigoplus_{m=0}^{N+k-i+1} U_i^{(m)}, \tag{71}
\]
due to the axial symmetry of the Kerr BH, where \( U_i^{(m)} \) acts on the subspace spanned by the states with \( m \) up-spins. In the same spirit as the original HP model [3], we assume that \( U_i^{(m)} \) scrambles all information in the subspace. More precisely, we assume that \( U_i^{(m)} \sim H_i^{(m)} \), where \( H_i^{(m)} \) is the Haar measure on the unitary group on which \( U_i^{(m)} \) is defined. In this notation, we assume that
\[
U_i \sim H_i^{\text{Kerr}} := H_i^{(0)} \times H_i^{(1)} \times \cdots \times H_i^{(N+k-i+1)}. \tag{72}
\]

Note that \( U_i \sim H_i^{\text{Kerr}} \) does not change the number of up-spins in the system, or equivalently the Z-axis AM. Hence, it never scrambles all the Hilbert space. When each \( U_i \) in \( \mathcal{L}_{\text{Kerr}} \) is chosen in this way, we refer to the dynamics \( \mathcal{L}_{\text{Kerr}} \) of the Kerr BH as symmetry-preserving Haar scrambling.

The fact that the dynamics of the Kerr BH is symmetry-preserving scrambling indicates that full decoupling hardly occurs in the Kerr BH. Since full decoupling is the necessary and sufficient condition for Bob to be able to recover the information, this further implies that the information is carried away from the Kerr BH in a different manner. However, the dynamics \( \mathcal{L}_{\text{Kerr}} \) can still scramble each subspace with a fixed Z-axis AM since \( U_i^{(m)} \sim H_i^{(m)} \). Due to this partial scrambling, the decoupling is also expected to become partial in the sense that the correlation between \( S_{\text{in}} \) and \( R \) is only through the classical value \( m \) of the number of up-spins in \( S \) that remains unchanged under the dynamics.

This expectation gives us a great insight into the information leakage problem from a quantum BH with symmetry. To see this, we recall the *monogamous* nature of correlations in quantum systems [42]: when a tri-partite system is in a pure state, the amount of classical correlation between two subsystems and that of quantum correlation between another two subsystems are in total equal to the entropy in the common subsystem. We can apply this relation to the information leakage problem, since \( BS_{\text{in}}R \), where \( B = S_{\text{rad}}B_{\text{rad}} \) is the subsystem with Bob, is in a pure state.

First, after the Kerr BH is partially scrambled, it is expected that there is no correlation between \( S_{\text{in}} \) and \( R \) in each subspace with a fixed AM. This implies that \( B \) and \( R \) should have full quantum correlation in each subspace. As such a correlation defines the symmetry-invariant quantum information, we naturally expect that Bob should be able to recover the symmetry-invariant quantum information from the radiation. Furthermore, since \( S_{\text{in}} \) and \( R \) have no quantum correlation between different subspaces, Bob can also recover its counterpart with respect to the monogamy, i.e. the symmetry-invariant classical information. Finally, the fact that \( S_{\text{in}} \) and \( R \) may share a part of the symmetry-invariant classical information indicates that Bob should not be able to fully recover the information about the quantum coherence between different subspaces. Thus, we
overall expect that Bob can recover all the symmetry-invariant information, both classical and quantum ones, but not the whole information.

With this expectation in mind, we quantitatively investigate how quickly the leakage of each information occurs in the following Sections.

## C. Partial decoupling of the Kerr BH and recovery errors

The above intuitions can be made rigorous by using the recently proposed partial decoupling theorem\cite{32} and its extension. To this end, let $E$ be a system isomorphic to the remaining BH $S_{\text{in}}$, i.e. $\mathcal{H}^E \cong \mathcal{H}^{S_{\text{in}}}$, and $S' = S'_{\text{rad}}S'_{\text{in}}$ be isomorphic to the Kerr BH $S$. We then introduce states $\Psi^{SR}$ and $\tau^{SE}$ by

\[
\Psi^{SR} := \Phi^{AR} \otimes \xi^{B_{\text{in}}}, \quad \text{and} \quad \tau^{SE} := J (\text{Tr}_{S_{\text{rad}}}) = \pi^{S'_{\text{rad}}} \otimes \Phi^{S_{\text{in}} E},
\]

respectively. Using these states, we also define $\Psi_{mm'}^{SR} = \Pi^m \Psi^{SR} \Pi_{m'}^{*}$ and $\tau_{mm'}^{SE} = \Pi_m^{*} \tau^{SE} \Pi_{m'}$, which are in general sub-normalized. We also let $d_m$ be $\dim \mathcal{H}_m^{S_{\text{in}}} = (N + k)$. We then introduce an extended system $S^*$, whose Hilbert space is $\mathcal{H}^{S^*} := \bigoplus_m (\mathcal{H}_m^{S_{\text{in}}} \otimes \mathcal{H}_m^{S^*})$ and define a fictitious quantum state $\Gamma^{S^*ER}$ on $\mathcal{H}^{S^*ER}$ by

\[
\Gamma^{S^*ER} = \sum_{m, m'} \frac{2^{N + k}}{\sqrt{d_m d_m'}} \tau_{mm'}^{SE} \otimes \Psi_{mm'}^{SR}.
\]

Based on these notations, the following lemma provides upper bounds on the recovery errors.

**Lemma 3** (Upper bounds on recovery errors). The error $\Delta_{\text{inv}}(\xi, L_{\text{Kerr}})$ in recovering the symmetry-invariant information and the error $\Delta_{\text{tot}}(\xi, L_{\text{Kerr}})$ in recovering the whole information satisfy

\[
\begin{align*}
\Delta_{\text{inv}}(\xi, L_{\text{Kerr}}) &\leq \left| \left| L_{\text{Kerr}}^{S_{\text{in}} \rightarrow S_{\text{in}}} (\Psi^{SR}) - \Gamma^{S_{\text{in}} R} \right| \right|_1, \\
\Delta_{\text{tot}}(\xi, L_{\text{Kerr}}) &\leq \left| \left| L_{\text{Kerr}}^{S_{\text{in}} \rightarrow S_{\text{in}}} (\Psi^{SR}) - \Gamma^{S_{\text{in}} \otimes R} \right| \right|_1,
\end{align*}
\]

where $\Gamma^{S_{\text{in}} R}$ is isomorphic to $\Gamma^{ER} := \text{Tr}_{S^*}[\Gamma^{S^*ER}]$ by identifying $E$ with $S_{\text{in}}$.

This sort of lemma is often used in the decoupling approach\cite{28,31}. For completeness, we provide the proof in Subsection XA.

Due to Lemma A, it suffices to evaluate the R.H.S. of the inequalities. For a technical reason, we modify the state $\Gamma$ to a subnormalized one $\tilde{\Gamma}^{S^*ER} := \Pi_n^{S_{\text{rad}}} \Gamma^{S^*ER} \Pi_n^{S_{\text{rad}}}$, which corresponds to the situation where the number of up-spins in $S_{\text{rad}}$ is post-selected to be $n$. Using $p_n = \text{Tr}[\tilde{\Gamma}_n^{S^*ER}]$, we define a set $I_\epsilon$ by for $\epsilon \geq 0$

\[
I_\epsilon := \{ n \in [0, \ell] : p_n \geq \epsilon \}.
\]

Using a projection $\Pi_n^{S_{\text{rad}}} (\epsilon) = \sum_{n \in I_\epsilon} \Pi_n^{S_{\text{rad}}}$, we define

\[
\tilde{\Gamma}^{S^*ER}(\epsilon) := \Pi_n^{S_{\text{rad}}}(\epsilon) \Gamma^{S^*ER} \Pi_n^{S_{\text{rad}}}(\epsilon).
\]

The reason for introducing $I_\epsilon$ is to obtain good bounds on the recovery errors by using the so-called “smoothing” technique and will be explained later.

The key technical tool to investigate the R.H.S. of the inequalities in Lemma 3 is an extension of the partial decoupling theorem\cite{32}. The original theorem was shown in full generality, even dealing with a non-abelian symmetry and with a proper smoothing, but we here use the simplest one. By extending the partial decoupling theorem using the concentration of measure phenomena (see Section X for the formal statement and the proof), we arrive at the following proposition.
Proposition 4 (Informal). The dynamics $\mathcal{L}_{Kerr}^{S\rightarrow S_{in}}$ for almost any choice of unitaries $U_i \sim H_{Kerr}^*$ satisfies
\[
\|\mathcal{L}_{Kerr}^{S\rightarrow S_{in}}(\Psi_{SR}) - \Gamma_{S_{in}R}\|_1 \leq 2\Theta_\xi(N, k, \ell), \tag{79}
\]
\[
\|\mathcal{L}_{Kerr}^{S\rightarrow S_{in}}(\Psi_{SR}) - \Gamma_{S_{in} \otimes \pi R}\|_1 \leq 2\Theta_\xi(N, k, \ell) + \eta_\xi(N, k, \ell). \tag{80}
\]
Here, $\Theta_\xi(N, k, \ell)$ and $\eta_\xi(N, k, \ell)$ are, respectively, given by
\[
\Theta_\xi(N, k, \ell) = \min_{\epsilon \geq 0} \left\{ 2^{-\frac{1}{2}}H_{\min}(\xi_{ER}) + w(\epsilon) \right\}, \tag{81}
\]
\[
\eta_\xi(N, k, \ell) = \frac{1}{2k} \sum_{n=0}^{N+k} \sum_{\kappa=0}^{k} \left| \sum_{m=0}^{N+k} \binom{\ell}{m-n} \binom{k}{\kappa'} \right|^2 \left( \frac{N-k}{n} \right) \left( \frac{k}{\kappa} \right). \tag{82}
\]
where $w(\epsilon) := 1 - Tr[\tilde{\Gamma}(\epsilon)] = \sum_{i \notin I} p_n$ and $\chi_n = Tr[\xi B_n \Pi_{B_n}^{\perp}]$. Moreover, $p_n$ is explicitly given by
\[
p_n = \frac{1}{2k} \sum_{m=0}^{N+k} \sum_{\kappa=0}^{k} \chi_{m-n} \binom{\ell}{m-n} \binom{k}{\kappa} \left( \frac{n}{N+k} \right). \tag{83}
\]

Corollary 5. The errors $\Delta_{inv}(\xi, L_{Kerr})$ and $\Delta_{tot}(\xi, L_{Kerr})$ in recovering the symmetry-invariant and the whole information of the quantum information source $A$, respectively, from the radiation $S_{rad}$ satisfy the following:
\[
\Delta_{inv}(\xi, L_{Kerr}) \leq 2\Theta_\xi(N, k, \ell), \tag{84}
\]
\[
\Delta_{tot}(\xi, L_{Kerr}) \leq 2\Theta_\xi(N, k, \ell) + \eta_\xi(N, k, \ell). \tag{85}
\]

To better understand the meaning of the quantity $\Theta_\xi(N, k, \ell)$, it is helpful to start with the case of $\epsilon = 0$. In this case, we have $\Theta_\xi(N, k, \ell) = 2^{-\frac{1}{2}}H_{\min}(\xi_{ER})$. In this case, it is straightforward to improve the bounds by factor 2, which results in
\[
\Delta_{inv}(\xi, L_{Kerr}) \leq 2^{-\frac{1}{2}}H_{\min}(\xi_{ER}) \tag{86}
\]
\[
\Delta_{tot}(\xi, L_{Kerr}) \leq 2^{-\frac{1}{2}}H_{\min}(\xi_{ER}) + \eta_\xi(N, k, \ell). \tag{87}
\]
Hence, the conditional min-entropy $H_{\min}(\xi_{ER})$ of the state $\Gamma_{S_{in} \otimes \pi R}$ provides an upper bound of the recovery error. This bound however turns out not to be tight. This is typical when we use the min-entropy since its value is in general very sensitive to the events that rarely happen. By ignoring the rare events, the value of the min-entropy can be often improved drastically. To this end, a subset $I_\epsilon$ was introduced in Proposition [4]. It is, however, also true that ignoring the rare events results in an additional error, which is quantified by $w(\epsilon)$ in Proposition [4]. Thus, the $\Theta_\xi(N, k, \ell)$ in Proposition [4] quantifies the trade-off relation between the improvement of the conditional min-entropy and the error induced by ignoring rare events.

Proposition [4] shows that, when $\Theta_\xi(N, k, \ell) \ll 1$, which turns out to be fulfilled when $\ell$ is sufficiently large, the state in $S_{in}$ and $R$ is approximately given by
\[
\mathcal{L}_{Kerr}^{S\rightarrow S_{in}}(\Psi_{SR}) \approx \Gamma_{S_{in}R} = \sum_{m=0}^{N+k} \frac{2^{N+k-m} S_{min} \otimes \Psi_{Rm}}{d_m}. \tag{88}
\]
This implies that, after sufficiently many qubits are evaporated, the correlation between the remaining BH $S_{in}$ and the reference $R$ is only through the classical value $m$ of the Z-axis AM in the initial Kerr BH $B_{in}$, confirming our intuition in Subsection [IVB].
Corollary 5 also shows that there should be a gap between the errors in recovering the symmetry-invariant information and that for the whole information. The difference between them corresponds to \( \eta_k(N, k, \ell) \). Recalling the definition of the symmetry-invariant information, the difference should be related to the information that is \textit{variant} under the action of the symmetry, such as the \( X \) and \( -Y \) components of the AM.

V. NUMERICAL ANALYSIS OF THE INFORMATION LEAKAGE FROM THE KERR BH

Based on Proposition 4, we numerically evaluate the recovery errors. The pure Kerr BH is considered in Subsection VA and the mixed Kerr BH in Subsection VB.

A. Recovery errors for the pure Kerr BH

Let us consider the case where the initial Kerr BH \( B_{\text{in}} \) is in a pure state with the \( Z \)-axis AM \( L \) on average and its fluctuation \( \delta L \). We especially consider the pure state in the form of

\[
|\xi(L, \delta L)\rangle_{B_{\text{in}}} = \sum_{\mu = 0}^{N} \sqrt{\chi_{\mu}(L, \delta L)} |\varphi_{\mu}\rangle_{B_{\text{in}}},
\]

where \( \mu \) stands for the number of up-spins in \( B_{\text{in}} \), \( \chi_{\mu}(L, \delta L) \) is a normalized Gaussian distribution over \( \mu \in [0, N] \) with mean \( L - N/2 \) and standard deviation \( \delta L \), which is properly normalized so that \( \sum_{\mu = 0}^{N} \chi_{\mu}(L, \delta L) = 1 \), and \(|\varphi_{\mu}\rangle_{B_{\text{in}}} \) is an arbitrary pure state in \( H_{\text{in}} \). Note that, due to the symmetry-preserving scrambling, the recovery errors do not depend on the choice of \(|\varphi_{\mu}\rangle_{B_{\text{in}}} \).

In this case, the state \( \Gamma_{S^{*}ER} \) defined by Equation (74) is given by the following simple form:

\[
\Gamma_{S^{*}ER}(L, \delta L) = \sum_{n = 0}^{\ell} p_n \pi_{n}^{\text{rad}} \otimes \tilde{\Phi}_{n}^{S_{\text{in}}^{*}ESR}(L, \delta L),
\]

where \( \{p_n\} \) is the probability distribution given in Proposition 4 and the normalized pure state \(|\tilde{\Phi}_{n}(L, \delta L)\rangle_{S_{\text{in}}^{*}ESR} \) is given by

\[
|\tilde{\Phi}_{n}(L, \delta L)\rangle_{S_{\text{in}}^{*}ESR} \propto \sum_{m = 0}^{N + k} \sqrt{N + k \choose m} (\Pi_{m = n}^{S_{\text{in}}^{*}} |\Phi\rangle_{S^{*}ESR} \otimes (\Pi_{m}^{S} |\Phi\rangle_{AR} \otimes |\xi(L, \delta L)\rangle_{B_{\text{in}}})).
\]

Due to this simple form of \( \Gamma_{S^{*}ER}(L, \delta L) \), we can show that the conditional min-entropy \( H_{\min}(S^{*}|ER)_{\Gamma} \) satisfies

\[
H_{\min}(S^{*}|ER)_{\Gamma} \geq k - \log \left[ \sum_{n \in I_{\ell}} \left( \sum_{m = 0}^{N + k} \sum_{\kappa = 0}^{k} \sqrt{\chi_{m - \kappa}(L, \delta L) \choose m - n} \left( \frac{N + k - \ell}{\kappa} \right) \left( \frac{k}{\kappa} \right)^{2} \right) \right].
\]

See Subsection XI A for the further details.

By substituting this into Proposition 4, we can numerically compute the recovery errors \( \Delta_{\text{inv}}(\xi(L, \delta L), L_{\text{Kerr}}) \) for the symmetry-invariant information and \( \Delta_{\text{tot}}(\xi(L, \delta L), L_{\text{Kerr}}) \) for the whole information. Note that the bounds do not depend on the sign of \( L \). Namely, \( \xi(L, \delta L) \) with \( \pm L \) result in the same bound. This is naturally expected since the rotation direction of the Kerr BH should not affect any features of the information leakage.
FIG. 7: Recovery errors for the pure Kerr BH. The errors $\Delta_{\text{tot}}(\xi, L_{\text{Kerr}})$ (filled markers) and $\Delta_{\text{inv}}(\xi, L_{\text{Kerr}})$ (dashed lines) are plotted for $N = 500$ and $k = 5$. The state $\xi(L, \delta L)_{\text{B_{in}}}$ is a pure state in $\text{B_{in}}$, implying that there is no entanglement between the initial Kerr BH $\text{B_{in}}$ and the past radiation $\text{B_{rad}}$. In each figure, we have also plotted $\Delta_{\text{inv}}$ for the trivial case $L = \delta L = 0$ by a yellow dash-dotted line for the sake of comparison, with which we define the delay of information leakage: $\delta \ell_{\Delta}(L, \delta L) := \ell(L, \delta L) - (0, 0)$.

The numerically evaluated bounds on $\Delta_{\text{inv}}(\xi(L, \delta L), L_{\text{Kerr}})$ and $\Delta_{\text{inv}}(\xi(L, \delta L), L_{\text{Kerr}})$ are given in Figure 7 as functions of the number $\ell$ of evaporated qubits for $|L| = 0, N/4, N/2, N$, and $\delta L = 0.1\sqrt{N}$ (red), $0.5\sqrt{N}$ (blue), $0.9\sqrt{N}$ (green), and $0.3N$ (brown). The filled markers correspond to the upper bounds on $\Delta_{\text{tot}}(\xi, L_{\text{Kerr}})$, and the dashed lines to the bounds on $\Delta_{\text{inv}}(\xi, L_{\text{Kerr}})$. For comparison, we have also plotted the recovery error of the trivial case ($L = \delta L = 0$) by a yellow dash-dotted line.

From Figure 7 we observe the following:

1. The recovery error $\Delta_{\text{inv}}$ for the symmetry-invariant information starts decaying exponentially quickly after a certain number of qubits are evaporated. The number, as well as the decaying speed, strongly depends on both the AM $|L|$ and its fluctuation $\delta L$ of the initial Kerr BH $\text{B_{in}}$. Compared to the trivial case (yellow dash-dotted line), we observe that, to achieve the same error $\Delta$, there is a delay $\delta \ell_{\Delta}(L, \delta L)$ of information leakage when the Kerr BH has non-zero AM. In general, the delay becomes larger when $L$ or $\delta L$ is larger. In particular, when the fluctuation $\delta L$ is macroscopically large (brown plots) such as $\delta L = \Theta(N)$, then the delay appears to be especially large, indicating that the symmetry-invariant information cannot be recovered from the radiation until very late time.

2. The recovery error $\Delta_{\text{tot}}$ for the whole information behaves differently depending on whether the fluctuation $\delta L$ of the $Z$-axis AM in $\text{B_{in}}$ is $O(\sqrt{N})$ or $\Theta(N)$.

When $\delta L = O(\sqrt{N})$, $\Delta_{\text{tot}}$ first behaves similarly to $\Delta_{\text{inv}}$, that is, $\Delta_{\text{tot}}$ starts decreasing exponentially quickly after a certain number of qubits is evaporated, which occurs nearly at the same timing as $\Delta_{\text{inv}}$. However, soon after that, the decreasing of the error becomes slow, and $\Delta_{\text{tot}}$ remains at a non-negligible value until the last moment. This indicates that a part of the information remains unevaporated from the Kerr BH until late time. We call such residual information information remnant. By carefully looking at the plots for different $L$ but same $\delta L$, we also observe that the amount of information remnant is independent of $L$ but dependent on $\delta L$.

On the other hand, when $\delta L = \Theta(N)$, $\Delta_{\text{tot}} \approx \Delta_{\text{inv}}$, and no information is recovered from the radiation until the last moment.
Before we proceed, we emphasize that, in any case, Bob needs to wait until at least a half of the Kerr BH evaporates before he becomes able to retrieve any information from the radiation. This is a consequence of the no-cloning theorem [43]. If Bob were able to recover the information from $S_{rad}$ of $\ell \leq (N+k)/2$ qubits, it also implies that the information could be recovered from $S_{in}$ since it consists of at least $(N+k)/2$ qubits. That is, the information of $A$ could be recovered both inside and outside of the BH at the same time, which contradicts to the no-cloning theorem.

**B. Recovery errors for the mixed Kerr BH**

We next consider the mixed Kerr BH, which is initially entangled with the past radiation $B_{rad}$. For simplicity, we only consider the following entangled states:

$$|\xi(L, \delta L)\rangle_{B_{rad}} = \sum_{\mu=0}^{N} \sqrt{\chi_{\mu}(L, \delta L)} |\Phi_{\mu}\rangle_{B_{rad}},$$

where $\{\chi_{\mu}\}$ is a normalized Gaussian distribution over $\mu \in [0, N]$ with mean $L-N/2$ and standard deviation $\delta L$, and $|\Phi_{\mu}\rangle_{B_{rad}}$ is the maximally entangled state in $H_{B_{rad}}$.

In this case, the state $\Gamma^{S*ER}$ becomes

$$\Gamma^{S*ER} = \sum_{n=0}^{\ell} \sum_{\mu=0}^{N} p_{n,\mu} \pi^{S}_{\text{rad}} \otimes \pi_{\mu}^{B_{rad}} \otimes \Psi^{S*}_{n,\mu,ER},$$

where $p_{n,\mu}$ and the normalized pure state $\Psi^{S*}_{n,\mu,ER}$ are given by

$$p_{n,\mu} = \frac{\chi_{\mu}(L, \delta L)(\ell)}{2^k} \sum_{m=0}^{N+k} \frac{(N+k-\ell)(k)}{(m-k)} \sum_{m=0}^{N+k} \frac{1}{\sqrt{(N+k-m)}} \left( \prod_{n-m}^{S_{in}} |\Phi\rangle \right) \otimes \left( \prod_{m-\mu}^{A} |\Phi\rangle \right),$$

respectively. Note that $\sum_{\mu} p_{n,\mu} = p_n$, where $p_n$ is given in Proposition 4. Similarly to the case of the pure Kerr BH, we can show that

$$H_{\text{min}}(S^{*}|ER)_{\Gamma(\ell)} \geq k - \log[\gamma(N, k, \ell)]$$

where

$$\gamma(N, k, \ell) := \sum_{\mu=0}^{N} \frac{\chi_{\mu}(L, \delta L)}{(N)} \sum_{n \in L} \left( \sum_{m=0}^{N+k} \frac{1}{\sqrt{(N+k-m)}} \right) \frac{(N+k-\ell)}{(m-k)} \left( \frac{k}{m-\mu} \right)^2.$$

See Subsection XI.B for the details. Together with Proposition 3, we can obtain upper bounds on the recovery errors $\Delta_{\text{inv}}(\xi(L, \delta L), L_{Kerr})$ and $\Delta_{\text{tot}}(\xi(L, \delta L), L_{Kerr})$. We again note that $\pm L$ provides the same bounds.

The errors are numerically plotted in Figure 8 as a function of $\ell$. Similarly to the previous section, the plots are for $L = 0, N/8, N/4, 3N/8$, and $\delta L = 0.1\sqrt{N}$ (red), $0.5\sqrt{N}$ (blue), $0.9\sqrt{N}$ (green), and $0.3N$ (brown). The filled markers correspond to the upper bounds on $\Delta_{\text{tot}}$ and the dashed lines to the bounds on $\Delta_{\text{inv}}$. We have also plotted the recovery error for the trivial case of $L = \delta L = 0$ by a yellow dash-dotted line.

We observe the following.
The errors $\Delta_{\text{tot}}(\xi, L_{\text{Kerr}})$ (filled markers) and $\Delta_{\text{inv}}(\xi, L_{\text{Kerr}})$ (dashed lines) are plotted for the state $\xi(L, \delta L)$ with various $L$ and $\delta L$, where $N = 500$ and $k = 5$. The state $|\xi(L, \delta L)\rangle_{\text{in}} |\text{rad}\rangle$ is entangled between the initial Kerr BH $B_{\text{in}}$ and the past radiation $B_{\text{rad}}$. In each figure, we have also plotted $\Delta_{\text{inv}}$ for $L = \delta L = 0$ by a yellow dash-dotted line as a reference.

1. The $\Delta_{\text{inv}}$ decays in a similar manner to the pure Kerr BH. That is, it starts decreasing after a certain number of qubits are evaporated. Moreover, in comparison with the trivial Kerr BH (yellow dash-dotted line), there exists a delay $\delta \ell$ of the leakage when the Kerr BH has non-zero $Z$-axis AM or fluctuation. When $L$ and $\delta L$ are small, the delay is not so large. However, when the initial BH $B_{\text{in}}$ has a macroscopically large fluctuation such as $\delta L = \Theta(N)$, the delay becomes substantially large. Thus, in the case of the mixed Kerr BH, the information recovery from the radiation becomes possible at various timings, ranging from $O(k)$ to $O(N)$. The timing seems to be highly dependent on the $Z$-axis AM $L$ and its fluctuation $\delta L$ of the initial Kerr BH.

2. About $\Delta_{\text{tot}}$, we observe that the whole information still remains unleaked until the last moment of the complete evaporation of the Kerr BH. This implies that, even for the mixed Kerr BH, the information remnant exists. It turns out that the amount of information remnant depends only on $\delta L$ and is exactly the same as that for the pure Kerr BH for the same $\delta L$, which will be elaborated later.

VI. PHYSICS BEHIND THE INFORMATION LEAKAGE

The analysis in Section IV is all about upper bounds on the recovery errors, and their tightness is unclear. Hence, the information could leak out more quickly than shown in Section IV. We here show that this is unlikely the case by providing heuristic lower bounds on the errors. At the same time, the analysis in this section reveals the physics behind the information leakage from the Kerr BH.

We first elaborate on the delay of information leakage in Subsection VI A and then the information remnant in Subsection VI B.

A. Delay of the information leakage due to symmetry

From the numerical analysis, we have observed that, when the initial Kerr BH $B_{\text{in}}$ has non-zero $Z$-axis AM or fluctuation, the information retrievable from the radiation becomes possible later...
than the trivial Kerr BH with zero AM. To formulate this more precisely, we introduce the number \( \ell_\Delta(L,\delta L) \) of evaporated qubits needed to achieve \( \Delta_{\text{inv}} \leq \Delta \). Here, we use \( \Delta_{\text{inv}} \), rather than \( \Delta_{\text{tot}} \) in order to get rid of the effect of information remnant. We then define the delay \( \delta \ell_\Delta(L,\delta L) \) by

\[
\delta \ell_\Delta(L,\delta L) := \ell_\Delta(L,\delta L) - \ell_\Delta(0,0).
\]

(99)

In Subsection VI A 1, we analyze the delay from the viewpoint of typical entanglement generated by the scrambling dynamics of the BH and, in Subsection VI A 2, we show how the delay can be understood in terms of the macroscopic properties of the initial Kerr BH. In Subsection VI A 3, we numerically compare the result with those obtained by the partial decoupling argument.

1. Cramping of entanglement and dimension condition

To intuitively understand the information leakage from a quantum BH, we first consider the BH without symmetry. The dynamics \( L \) of such a BH is fully scrambling and is known to generate extremely high entanglement between subsystems, which is known as typical entanglement [44]. Hence, when the BH \( S \) has no symmetry, the radiation \( S_{\text{rad}} \) and the remaining BH \( S_{\text{in}} \) are highly entangled. This plays a crucial role in the information leakage from the BH as follows.

The typical entanglement makes the marginal state in a smaller subsystem, \( S_{\text{rad}} \) or \( S_{\text{in}} \), completely mixed. Hence, if one has access only to the smaller subsystem, the marginal state after the scrambling dynamics \( L \) looks identical irrespective of the initial state, implying that it contains no information about \( S \). The complete erasure of the information, however, does not occur in the larger subsystem since the Schmidt decomposition of a bi-partite quantum state [45] guarantees that any bipartite pure state should have an equal size of spreads in the two subsystems. Thus, the spread in the larger system should be “cramped” at the size of the dimension of the smaller subsystem. This cramping makes it possible to retrieve the information about \( S \) from the larger subsystem.

The information leakage from the pure BH without symmetry can be readily understood from the cramping: when more than a half of the qubits are evaporated from a pure BH, \( S_{\text{rad}} \) becomes the larger one and the cramping sets in. The mixed BH then sees the onset much earlier since it is already on the verge of cramping initially due to the entanglement between the initial BH \( B_{\text{in}} \) and the past radiation \( B_{\text{rad}} \). This can be captured more quantitatively by introducing a degree of cramping \( C \) in the radiation \( S_{\text{rad}} \), defined by

\[
C := H(B_{\text{in}})\xi + \log \left( \frac{\dim \mathcal{H}_{S_{\text{rad}}}}{\dim \mathcal{H}_{S_{\text{in}}}} \right).
\]

(100)

When \( C > k \), the \( k \)-qubit information of \( A \) is likely to have no significant overlap and should be recoverable from the radiation \( S_{\text{rad}} \). As \( \dim \mathcal{H}_{S_{\text{rad}}} = 2^\ell \) and \( \dim \mathcal{H}_{S_{\text{in}}} = 2^{N+k-\ell} \) for the BH without symmetry, we can easily solve \( C > k \), resulting in \( \ell > k + N/2 \) for the pure BH, and \( \ell > k + (1 - H(B_{\text{in}})\xi)N/2 \) for the mixed BH. Both agree well with the result obtained from the decoupling argument (see Inequalities (65) and (66)).

Let us now apply the cramping argument to the information leakage from the Kerr BH. For simplicity, we consider the case where the initial Kerr BH \( B_{\text{in}} \) has a fixed Z-axis AM \( L \), which is equivalent to that the number of up-spins in \( B_{\text{in}} \) is \( L/h + N/2 \), where \( h \) is the Plank constant. This implies that the number of up-spins in \( S = AB_{\text{in}} \) is \( L/h + (N + k)/2 \) since the quantum information source \( A \) has \( k/2 \) up-spins on average. When the Kerr BH \( S \) is split into the radiation
$S_{\text{rad}}$ and the remaining BH $S_{\text{ini}}$, the subspace $\mathcal{H}_{L/h+(N+k)/2}^S$ is divided into

$$\mathcal{H}_{L/h+(N+k)/2}^S = \bigoplus_{n=0}^\ell \mathcal{H}_{n}^{S_{\text{rad}}} \otimes \mathcal{H}_{L/h+(N+k)/2-n}^{S_{\text{ini}}}$$

(101)

where $n$ represents the number of up-spins in $S_{\text{rad}}$. Since the dynamics $L_{\text{Kerr}}$ is symmetry-preserving scrambling, the dynamics generates high entanglement only between the subspaces $\mathcal{H}_{n}^{S_{\text{rad}}}$ and $\mathcal{H}_{L/h+(N+k)/2-n}^{S_{\text{ini}}}$ but not between $\mathcal{H}_{n}^{S_{\text{rad}}}$ and $\mathcal{H}_{L/h+(N+k)/2-n'}^{S_{\text{ini}}}$ for $n \neq n'$. Thus, the cramping argument should be applied to each pair $(\mathcal{H}_{n}^{S_{\text{rad}}}, \mathcal{H}_{L/h+(N+k)/2-n'}^{S_{\text{ini}}})$ of subspaces individually, which leads to a modified cramping condition

$$C(n) := H(B_{\text{ini}}) + \log \left[ \frac{\dim \mathcal{H}_{n}^{S_{\text{rad}}}}{\dim \mathcal{H}_{L/h+(N+k)/2-n}} \right] > k,$$

(102)

for each $n \in [0, \ell]$. We then require Inequality (102) to hold for most $n$ but not all since, if it is required so, the condition is hardly fulfilled due to extreme cases, such as $n = 0$, that can be practically ignored since it rarely happens. We hence take only non-extreme $n$ into account. If the condition is not satisfied for certain $n$, the information in the corresponding subspace is counted as recovery error. This is similar to the smoothing in the partial decoupling.

Before we proceed, we emphasize that the cramping condition (102) is extremely useful since it can be applied to the BHs with any symmetry and is calculable only from the initial entanglement, $H(B_{\text{ini}})$, and the dimension of each invariant subspace of a given symmetry. Thus, we think that the dimensional constraint (102) provides a general and concise method to check how quickly the information starts leaking from a BH with any symmetry.

2. Physics behind the threshold

The dimension condition (102) has a great advantage that we can better understand $\ell_\Delta(L, \delta L)$. For simplicity, we consider the case where $1 \ll k \ll N$, and $L = h\lambda N$ and $\delta L = 0$, where $h$ is the Planck constant. Without loss of generality, we assume that $\lambda \in [0, 1/2]$ since the rotation direction of the Kerr BH does not affect the information leakage.

As an estimate of $\ell_\Delta(L, \delta L)$, we introduce the number $\hat{\ell}_c(L)$ of qubits to be evaporated such that the modified cramping condition $C(n) > k$ holds for all $n$ with $|\delta n| \geq c((\delta n^2))^{1/2}$, where $\delta n := n - \langle n \rangle$ and $\langle \cdot \rangle$ is the average over the distribution of the number of up-spins in $S_{\text{ini}}$ induced by the evaporation process. The $c$ is a parameter related to the recovery error since taking a larger $c$ means that we require Inequality (102) for a wider range of $n$, resulting in less error. Since we have assumed $1 \ll k \ll N$, dimensions in Inequality (102) are well approximated using $s(\lambda) := -(1/2-\lambda) \log[1/2-\lambda] - (1/2+\lambda) \log[1/2+\lambda]$. We also denote the initial degree of cramping before radiation is emitted (i.e., $\ell = 0$) by $C_{\text{ini}} \approx H(B_{\text{ini}}) - (N + k)s(\lambda) < 0$. We can then show that

$$\hat{\ell}_c(L) \approx \ell_0(L) + c\ell_\|L),$$

(103)

where

$$\ell_0(L) = -\frac{C_{\text{ini}}}{2s(\lambda)} + \frac{k}{2s(\lambda)},$$

(104)

$$\ell_\|L) = \frac{|s(\lambda)|}{s(\lambda)} \sqrt{\frac{\ell_0(L)}{|s'(\lambda)|} \left(1 - \frac{\ell_0(L)}{N + k}\right)},$$

(105)
FIG. 9: Delay of information leakage from partial decoupling and cramping argument: the delay \( \delta \mathcal{L}(\lambda) := \ell(\hbar \lambda N, 0) - \ell(0, 0) \), computed by the partial decoupling approach (Proposition 4), and the delay \( \delta \hat{\mathcal{L}}(L) := \hat{\ell}(\hbar \lambda N) - \hat{\ell}(0) \), obtained from the cramping condition (Equation (103)), are plotted as functions of the ratio \( \lambda = L/(\hbar N) \) of the Z-axis AM in the initial Kerr BH \( B_{in} \). The upper and lower figures show the delays for the pure and mixed Kerr BHs, respectively. The size \( N \) of the initial Kerr BH \( B_{in} \) is set to 300, and the size \( k \) of the quantum information source \( A \) is fixed to 3. In both figures, \( \delta \mathcal{L}(\lambda) \) is computed for \( \Delta = 0.005 \) (red plots), 0.05 (blue plots), and 0.5 (green plots), while \( \delta \hat{\mathcal{L}}(L) \) is computed for \( c = 3.4 \) (red dashed line), 2.6 (blue dashed line), and 1.6 (green dashed line) for the pure BH, and 10.8 (red dashed line), 8.7 (blue dashed line), and 6.2 (green dashed line) for the mixed BH. In both pure and mixed Kerr BHs, they nearly coincide, indicating that the cramping argument provides good estimations.

and \( s'(w) \) and \( s''(w) \) are the first and second derivatives of \( s(w) \), respectively. See Subsection XII A for the derivation.

In Figure 9, we numerically compare \( \delta \ell(\lambda) := \ell(\hbar \lambda N, 0) - \ell(0, 0) \) with \( \delta \hat{\ell}(L) := \hat{\ell}(\hbar \lambda N) - \hat{\ell}(0) \) for various \( \Delta \). We observe that, by appropriately choosing \( c \), they coincide very well, suggesting that the cramping condition provides a good estimation of the number of evaporated qubits needed for the information recovery.

In Equation (7), we have decomposed \( \hat{\ell}(L) \) into two terms. The first term, \( \ell_0(L) \), represents a delay originated from an information theoretic reason: noting that evaporation of a qubit with entropy \( \approx s(\lambda) \) increases the degree of cramping by \( 2s(\lambda) \), \( \ell_0(L) \) qubits should be necessarily evaporated for the radiation to typically have a sufficiently large space to store information of \( k \) qubits. Hence, we refer to \( \ell_0(L) \) as an information-theoretic delay. Note that the information-theoretical delay also depends on the entanglement between the initial Kerr BH \( B_{in} \) and the past Harking radiation \( B_{out} \), quantified by the entanglement entropy \( H(B_{in}) \).

It is the second term \( \ell_f(L) \) that is a non-trivial consequence of the symmetry. It stems from the fluctuation of the Z-axis AM in the radiation, making the cramping condition harder to be fulfilled. We hence call \( \ell_f(L) \) a fluctuational delay. Note also that, when the Z-axis AM \( L \) of the initial Kerr BH is small, the delay of information leakage is simply proportional to \( \ell_f(L) \) because the delay is given by \( \delta \ell_f(\lambda) = \ell_f(\lambda N) - \ell_f(0) \), and \( \ell_0(\lambda N) \approx \ell_0(0) \) and \( \ell_f(0) = 0 \) for small \( L \).

We can further rewrite the fluctuational delay \( \ell_f(L) \), which is the essential effect of the symmetry in the delay of information leakage, in terms of thermodynamic quantities of the Kerr BH.

We especially consider the Kerr BH with temperature \( T \) sufficiently higher than the energy scale of the Hamiltonian, so that the thermodynamic entropy \( S(\lambda, L, T) \) of the Kerr BH is independent of \( T \), and the free energy \( F(T, \lambda, L) \) is approximately given by \( -TS(\lambda, L) \). We require these conditions because the Hamiltonian of the Kerr BH should necessarily have much randomness for the dynamics to be symmetry-preserving scrambling, but we would like to focus on the thermodynamics that does not strongly rely on such randomness. Note however that, as we will soon see, the final result does not depend on the temperature.

We particularly consider two thermodynamic quantities. One is the intensive state function
\( \omega(T, \lambda) \) conjugate to the extensive state function \( L \) of the Z-axis AM of \( B_{in} \). The other is the coefficient \( \alpha(T, \lambda) \) of thermal “expansion” of the Z-axis AM, which measures how sensitive the Z-axis AM \( L \) is to the change of temperature. They are, respectively, defined by

\[
\omega := -\left( \frac{\partial F}{\partial L} \right)_{T,N}, \quad \text{and} \quad \alpha := -\left( \frac{1}{L} \frac{\partial L}{\partial T} \right)_{\omega,N}.
\]

(106)

Recalling that the product of two quantities that are conjugate has units of energy, the state function \( \omega(T, \lambda) \) corresponds to the angular velocity of the BH.

In our particular model, the thermodynamic entropy \( S(\lambda, L) \) is given by \( k_B s(\lambda) N \), where \( k_B \) is the Boltzmann constant. Based on this fact, we can rewrite \( \omega(T, \lambda) \) and \( \alpha(T, \lambda) \) in terms of \( s(\lambda) \) such as

\[
\omega(T, \lambda) = -\frac{k_B T s'(\lambda)}{\hbar}, \quad \text{and} \quad \alpha(T, \lambda) := -\frac{s'(\lambda)}{s''(\lambda) \lambda T}.
\]

(107)

This allows us to rewrite Equation (9) as follows:

\[
L_{\text{fl}} \approx \frac{L}{S(\lambda, L)} \sqrt{k_B |\omega(T, \lambda)\alpha(T, \lambda)| \left( 1 - \frac{L_0}{L} \right) L_0},
\]

(108)

where \( L_{\text{fl}} := \hbar \lambda \ell_{\text{fl}}(L) \) and \( L_0 := \hbar \lambda \ell_0(L) \) are approximately the Z-axis AM corresponding to the fluctuational delay \( \ell_{\text{fl}}(L) \) and the information-theoretic delay \( \ell_0(L) \), respectively. Note that \( \omega(T, \lambda)\alpha(T, \lambda) \) is independent of the temperature \( T \), and so is \( L_{\text{fl}} \).

Equation (108) shows that, after radiating \( L_0 \) of the Z-axis AM to fulfill the information-theoretic requirement, the Kerr BH must further radiate an extra amount \( L_{\text{fl}} \) of the Z-axis AM to release the information. This amount \( L_{\text{fl}} \) is solely determined by the intensive thermodynamic quantities of the initial Kerr BH, that is, the Z-axis AM per entropy, \( L/S(\lambda, L) \), the angular velocity \( \omega(T, \lambda) \), and the coefficient \( \alpha(T, \lambda) \) of thermal expansion of the Z-axis AM. Thus, the delay of information leakage, consisting of the information-theoretic and fluctuational ones, reveals an intriguing interplay between information theory and thermodynamic properties of the Kerr BH in the information leakage problem. That is, if one is interested in how much delay would occur, what he has to do is first to check the information-theoretically trivial delay and then to investigate thermodynamic properties of the BH. From these factors, the delay can be fully characterized. This also implies that the delay, which is by definition microscopic phenomena, can be estimated only from the macroscopic properties of the Kerr BH. In this sense, Equation (108) provides a novel micro-macro correspondence of a quantum Kerr BH.

To conclude this section, we also emphasize that, although our conclusion was obtained based on the HP model of a quantum BH, Equation (108) is in terms of macroscopic quantities and is totally independent of the details of the model. Thus, we conjecture that, for any abelian symmetry that leads to an extensive conserved quantity, the same relation universally holds even in a different model of the BH.

3. Comparison with the analysis based on the partial decoupling

So far, we have considered only the case of \( \delta L = 0 \). To check if our results, e.g. Equation (103), can be applied even for non-zero fluctuations \( \delta L \), we here numerically provide the delay \( \delta \ell_{\Delta}(L, \delta L) \) based on the upper bound on the recovery errors \( \Delta_{\text{inv}} \) given in Proposition 4.
FIG. 10: Figures of the delay $\delta\ell_{\Delta}(L,\delta L)$ in the case of a pure Kerr BH for different $Z$-axis AM $L$ and different standard deviations $\delta L$. They are numerically computed based on Proposition 4. The size $k$ of the quantum information source $A$ is set to 1. For simplicity, we set $\Delta = 0$. In each plot, the solid line shows the fitting by the function $ax + b\sqrt{x} + c$, where $(a, b, c)$ is decided by the least squared fitting.

FIG. 11: Figures for the delay $\delta\ell_{\Delta}(L,\delta L)$ for the mixed Kerr BH with different $Z$-axis AM $L$ and different standard deviations $\delta L$ of the initial Kerr BH $B_{in}$. They are plotted as a function of the number $N$ of qubits in the mixed Kerr BH. The size $k$ of the quantum information source $A$ is set to 1. The $\Delta$ is set to 0.1 for simplicity.

Figure [10] is for the pure Kerr BH, and Figure [11] for the mixed Kerr BH. There, $\delta\ell_{\Delta}(L,\delta L)$ is plotted as a function of the size $N$ of the initial Kerr BH $B_{in}$ for various $L$ and $\delta L$.

First, by looking at the case of $\delta L = 0$ (black circles in the figures (II), (III), and (IV)), we observe that $\delta\ell_{\Delta}(L,0) = \Theta(\sqrt{N})$ for the pure Kerr BH (see Figure [10]). For the mixed BH, Figure [11] shows that $\delta\ell_{\Delta}(L,0)$ is independent of $N$. Both are consistent with the result based on the cramping argument.

When the $Z$-axis AM of the initial Kerr BH is fluctuating, i.e. $\delta L > 0$, we observe that, for the pure Kerr BH, the delay $\delta\ell_{\Delta}(L,\delta L)$ remains $\Theta(\sqrt{N})$ when the fluctuation is small such as
δL = O(\sqrt{N}) \quad \text{1, but the scaling seems to be gradually changed to } Θ(N) \text{ as the fluctuation grows to a macroscopic value such as } δL = Θ(N). \text{ On the other hand, for the mixed Kerr BH, the delay } \delta \ell_Δ(L, δL) \text{ remains constant in terms of } N \text{ when } δL = Θ(\sqrt{N}). \text{ For macroscopically large fluctuations (} \delta L = Θ(N)\text{), the delay depends on } L; \text{ although } \delta \ell_Δ(L, δL) \text{ seems to be constant when } L \approx 0, \text{ it gradually becomes } O(N) \text{ as } L \text{ increases.}

For clarity, the dependence of the delay } \delta \ell_Δ(L, δL) \text{ on the fluctuation } δL \text{ of the } Z\text{-axis AM in the initial Kerr BH is summarized in Table III.}

### B. Information Remnant and Symmetry-breaking

We finally investigate the information remnant, which is another crucial phenomena caused by the symmetry of the Kerr BH. The information remnant is characterized by } η_k(N, k, ℓ), \text{ whose exact expression is given in Equation (82) in Proposition 4. However, it is hard to obtain any insight from it. Thus, we investigate } η_k(N, k, ℓ) \text{ from a different viewpoint and show that it is related to the symmetry-breaking of the BH.}

We first show a numerical evidence that the symmetry-breaking of } ξ \text{ is related to } η_k(N, k, ℓ) \text{ by visualizing the symmetry-breaking using an unnormalized Q function. For a pure state } |ξ⟩_{B\text{in}}, \text{ the Q function is defined by}

\[ Q_ξ \left( \frac{L_X}{\sqrt{N/2}}, \frac{L_Z}{\sqrt{N/2}} \right) = |⟨\theta, φ|ξ⟩_{B\text{in}}|^2, \quad (109) \]

where \( |\theta, φ⟩ := (\cos \frac{θ}{2}|0⟩ + e^{iφ} \sin \frac{θ}{2}|1⟩)^\otimes N \) and \( (θ, φ) \) are given by \( \sin θ \cos φ = 2L_X/N \) and \( \cos θ = 2L_Z/N \). Note that the function is regarded as the Husimi Q function for \( N → ∞ \) when ⟨L_Y⟩ ≈ N/2 since, in that case, it follows that \( ⟨[L_X, L_Z]/\sqrt{N}⟩ \) ≈ 1/2. See Figure 12 (i) for the visualization of the Q function.

In Figure 12 (ii), we provide both } η_k(N, k, ℓ) \text{, as a function of } ℓ, \text{ and the visualization of the symmetry-breaking of the initial state } ξ(L, δL) \text{ of the pure Kerr BH, which is given by Equation (89). It is clear that the less information remnant is, the more strongly the symmetry is broken in } ξ(L, δL). \text{ This also explains why } η_k(N, k, ℓ) \text{ does not depend on the average } Z\text{-axis AM } L \text{ of } ξ(L, δL) \text{ since varying } L \text{ does not change the degree of symmetry-breaking of the state.}

The relation between } η_k(N, k, ℓ) \text{ and symmetry-breaking can be analytically elaborated. We first recall the monogamous nature of the correlations in quantum system explained in Subsection IV B. It states that, for the whole information to be recoverable from the radiation } S_{rad}, \text{ the

---

1 In Figure 10, it is not clear whether the scaling of } δ \ell_Δ \text{ for } δL = 0.5\sqrt{N}, 0.9\sqrt{N} \text{ is } O(\sqrt{N}) \text{ or } Θ(N). \text{ However, this is likely due to the fact that } N \text{ is taken up to 1000. We think that the scaling is } δ \ell_Δ = Θ(\sqrt{N}) \text{ for any } δL = O(\sqrt{N}) \text{ when } N \text{ is sufficiently large.}
FIG. 12: Figure (i) explains the $Z$-axial symmetry of a state and the Husimi Q function. The Husimi Q function is defined on a sphere. For simplicity, we expand the sphere surface to a 2-dimensional plain as in the right side of the figure. Figure (ii) shows the semi-log plot of $\eta_\xi(N,k,\ell)$, which characterizes the information remnant, for various states $\xi$ of the initial BH with different fluctuations of $Z$-axis AM, $\delta L = 0$ (black), $0.1\sqrt{N}$ (red), $0.5\sqrt{N}$ (blue), $0.9\sqrt{N}$ (green), and $3.0N$ (brown). The size $N$ of the initial BH is fixed to 1000, and $k$ is set to 1. The average $Z$-axis AM $L$ can be arbitrary since $\eta_\xi(N,k,\ell)$ does not depend on $L$. Comparing this with the Husimi Q functions for each $\xi$, which visualizes the symmetry-breaking of $\xi$, we clearly observe that $\eta_\xi(N,k,\ell)$ is small when the degree of symmetry-breaking is large. We can also observe that $\eta_\xi(N,k,\ell)$ behaves differently depending on whether $\ell \ll (\delta L)^2$ or $\ell \gg (\delta L)^2$ as explained in the main text. The former case is most prominently observed for $\delta L = 0.3N$ (brown line), where the $\eta$ is nearly constant. The latter case is observed for $\delta L = 0$ (black line), where $\eta_\xi(N,k,\ell)$ decreases as $\approx \ell^{-0.5}$ for small $\ell$.

Symmetry-invariant classical information should be necessarily erased from the remaining BH $S_{\text{in}}$. The amount of symmetry-invariant classical information remained in $S_{\text{in}}$ can be quantitatively evaluated by measuring the $Z$-axis AM in $R$ and $S_{\text{in}}$ separately. Since $R$ is the reference system that keeps track of the information of $A$, if the outcome in $R$ is hard to be deduced from the outcome in $S_{\text{in}}$, we can conclude that the symmetry-invariant classical information has been wiped out from $S_{\text{in}}$.

Let $P(\nu|\kappa)$ be the probability distribution of the outcome $\nu$ in $S_{\text{in}}$ given that the outcome in $R$ is $\kappa$. Then, it follows that

$$\eta_\xi \geq \sum_\kappa q(\kappa) \sum_\nu |P(\nu|\kappa) - P(\nu)|,$$

(110)

where $q(\kappa)$ is the probability to obtain the outcome $\kappa$ in $R$, and $P(\nu) := \sum_\kappa q(\kappa)P(\nu|\kappa)$ is the probability to obtain $\nu$ in $S_{\text{in}}$. We also introduce the degree of symmetry-breaking $\zeta(S_{\text{in}})$ of the remaining Kerr BH $S_{\text{in}}$ as follows: First, let $|\Psi\rangle_{S_{\text{in}}S'_{\text{in}}}$ be a purification of the state $\Psi_{S_{\text{in}}}$. We then define $B_\theta(\Psi) := 1 - \langle \langle \psi | e^{i\theta L_z} \otimes I | \psi \rangle \rangle_\Psi^2$, where $L_z$ is the $Z$-axis AM operator in $S_{\text{in}}$ and the second identity acts on $S'_{\text{in}}$. Note that the second term is the fidelity between the original state $|\psi\rangle$ and the state $(e^{i\theta L_z} \otimes I) |\psi\rangle$ after the $\theta$-rotation of $S_{\text{in}}$ around the $Z$-axis. While $B_\theta(\psi) = 0$ for any $\theta$ when $\psi$ is $Z$-axial symmetric, $B_\theta(\psi)$ increases even for infinitesimal $\theta$ if $\rho$ breaks the symmetry. Hence, we define the degree $\zeta(S_{\text{in}})$ of symmetry-breaking by

$$\zeta(S_{\text{in}}) := \frac{\partial^2}{\partial^2 \theta} B_\theta(\Psi) \bigg|_{\theta=0}.$$

(111)

The degree of symmetry-breaking defined in this way turns out to be equal to twice the variance of the $Z$-axis AM in $\Psi_{S_{\text{in}}}$. 
By explicitly writing down the probabilities in Inequality (110), we can relate \( \eta_\xi \) and the degree \( \zeta(S_{in}) \) of symmetry-breaking as follows:

\[
\eta_\xi \gtrsim \langle |\delta \kappa| \rangle \left( 1 - \frac{\ell}{N + k} \right) \sqrt{\frac{2}{3 \zeta(S_{in})}},
\]

where \( \delta \kappa := \kappa - \langle \kappa \rangle \) and \( \langle \cdot \rangle \) is the expectation over the probability distribution \( q(\kappa) \). Hence, when information remnant is little, \( \zeta(S_{in}) \) should be necessarily large, and the Z-axis symmetry in \( S_{in} \) should be necessarily broken strongly. See Subsection XII B for more details.

When \( \sqrt{\ell} \ll \delta L \), where \( \delta L \) is the fluctuation of the Z-axis AM of the initial Kerr BH \( B_{in} \), the degree \( \zeta(S_{in}) \) of symmetry-breaking in \( S_{in} \) should be inherited from that of the initial Kerr BH \( B_{in} \). This is because the degree of symmetry-breaking is given by the variance of the conserved quantity as we have mentioned. After \( \ell \) qubits are evaporated, the fluctuation, i.e. the standard deviation, of the Z-axis AM in the remaining Kerr BH \( S_{in} \) is approximately given by \( \delta L + \sqrt{\ell} \). Hence, if \( \sqrt{\ell} \ll \delta L \), the initial fluctuation \( \delta L \) is dominant. Recalling that \( \zeta(B_{in}) = 2(\delta L)^2 \), we conclude that \( \eta_\xi \gtrsim \zeta(B_{in})^{-1/2} \) when \( \ell \ll (\delta L)^2 \). On the other hand, when \( \ell \gg (\delta L)^2 \), the fluctuation is dominated by the one due to the evaporation and \( \zeta(S_{in}) \approx \ell \). Thus, we obtain

\[
\eta_\xi(N, k, \ell) \gtrsim \begin{cases} 
\zeta(B_{in})^{-1/2} & \text{when } \ell \ll (\delta L)^2, \\
\ell^{-1/2} & \text{when } \ell \gg (\delta L)^2,
\end{cases}
\]

where we have omitted the coefficients in the right-hand side.

Recalling that the recovery error \( \Delta_{tot} \) is roughly given by \( \Delta_{inv} + \eta_\xi \), we can now see how the information remnant behaves. For the pure Kerr BH, \( \Delta_{inv} \leq 1 \) only when \( \ell \geq N/2 \) due to the non-cloning theorem. Hence, if \( \delta L \ll \sqrt{N} \), the first case of Inequality (113) is never observed, so that \( \eta_\xi = O(\ell^{-1/2}) \), which can be rephrased as \( O(N^{-1/2}) \) as \( \ell \) needs to be at least \( N/2 \). On the other hand, when the initial fluctuation in the BH is large such as \( \delta L = O(N) \), the first case of Inequality (113) always holds. As \( \zeta(B_{in}) = O(N^2) \) in this case, \( \eta_\xi = O(N^{-1}) \). From these considerations, we see that, in any cases, the information remnant is little when the size \( N \) of the initial Kerr BH is sufficiently large.

For the mixed Kerr BH, there are cases where \( \Delta_{inv} \leq 1 \) for \( \ell = O(k) \). In this case, \( \eta_\xi \gtrsim \zeta(B_{in})^{-1/2} \). Since this is independent of \( \ell \), the total error \( \Delta_{tot} \) remains at a constant value even when the evaporation proceeds. Thus, a certain amount of information remains in the Kerr BH for a long time. This is especially remarkable when the symmetry-breaking of the initial Kerr BH is constant in terms of \( N \). In that case, the information remnant becomes non-negligible even in the thermodynamic limit \((N \to \infty)\).

\textbf{VII. SUMMARY AND DISCUSSIONS}

In this paper, we have investigated the information leakage from a quantum Kerr BH with Z-axis symmetry. We have first provided general formulas for upper bounds on the errors to recover the information in the Kerr BH from the Hawking radiation. The key technique is the extension of the partial decoupling theorem. The bounds have been numerically evaluated, from which we have clarified how information is carried away by the Hawking radiation from the Kerr BH (see Table IV). We have further investigated the delay of information leakage and the information remnant from the physics point of view, and have revealed that the delay is related to the force needed to drive the Z-axis AM of the Kerr BH and that the information remnant is to the symmetry-breaking of the initial Kerr BH.

TABLE IV: A summary of how information leaks out from the Kerr BH. We have shown that 1. the more the initial Kerr BH is entangled with the past radiation, the more quickly it starts releasing information, 2. the larger Z-axis AM of the initial Kerr BH is, the later the BH starts releasing the information, and 3. the more strongly the symmetry is broken in the initial Kerr BH, the less the information remnant exists. While the first feature is common with the BH without symmetry, the second and the third features are induced by the symmetry of the Kerr BH. Although they are rigorously shown only for the Kerr BHs, we conjecture that similar features are observed for the BHs with extensive conserved quantities.

We conjecture that the results obtained in this paper, the delay of information leakage and the information remnant can be generalized to quantum BHs with any symmetry. In particular, we strongly think that any BHs with abelian symmetry can be addressed using the same technique. We will leave the analysis of the information leakage from the BH with non-abelian symmetry an interesting future problem, where the information cannot be simply divided into the symmetry-invariant and the variant ones, and more careful analysis will be needed. Note however that the partial decoupling theorem in Ref. [32] can be applied even for such BHs.

Another important open problem is how long it takes to approximately achieve symmetry-preserving Haar scrambling. All of our analyses rely on the assumption that the internal unitary dynamics of the Kerr BH is symmetry-preserving scrambling, but this assumption will not be exactly satisfied by the time-evolution of the BH since it is known that implementing the Haar random unitary generally takes exponentially long time. Hence, it is of crucial importance to consider approximations. Approximations of random unitary are studied in terms of unitary t-designs, which mimic the tth order statistical moments of a Haar random unitary on average, and a couple of results are known about the time needed to achieve t-designs [46–49]. It will be of great interest to investigate how symmetries affect such results [50, 51]. More explicitly, how can we construct symmetry-preserving unitary t-designs by e.g. quantum circuits?

Our analysis may also provide an operational approach to study weak violations of symmetries in the regime of quantum gravity. In this paper, we have assumed that the dynamics exactly preserves the symmetry. When symmetries are weakly violated, the time evolution eventually approaches a fully random unitary, rather than a symmetry-preserving random one, and hence, the violation of symmetries leads to deviations from our results in the long time limit. From the deviations, it may be possible to estimate how strongly symmetries are violated in quantum gravity. It would be thus fruitful to study the trade-off relation between the violation of symmetries and the amount of radiation needed to recover the information. This will lead to a novel insight into the symmetry in quantum gravity from the operational perspective.

This problem may possibly be captured in a broader framework of the resource theory. In this paper, we have revealed that symmetry-breaking of the initial state of the Kerr BH reduces the information remnant. This can be rephrased as that symmetry-breaking is a resource of information transmission when the dynamics is limited by symmetry. Similarly, it will be possible to quantify the violations of symmetry in the dynamics as a resource. Thus, using the framework of the resource theory, we may be able to understand the symmetry-breaking of states as well as that of dynamics in a unified manner, which will be an interesting open question.
VIII. ORGANIZATION OF THE REST OF THE PAPER

The remaining of the paper is organized as follows. In Section IX, we provide our technical contribution, namely, the concentration phenomena of partial decoupling. In Section X, we derive formal upper bounds on the recovery errors using the partial decoupling approach. The technique we have used in the numerical evaluation of the bounds is provided in Section XI where the main contribution is to derive lower bounds on the conditional min-entropy for special cases. The detailed analyses on the delay of information leakage and the information remnant are given in Section XII.

IX. PARTIAL DECOUPLING AND ITS CONCENTRATION

We here provide the concentration phenomena of partial decoupling. We begin with a review of the partial decoupling theorem and its extension in Subsection IX A. The proof is given in Subsection IX B. In this Section, the systems’ labeling, such as $S$, $A$, $E$, and so on, does not necessarily correspond to those of the BH information leakage problem.

A. Review of the partial decoupling theorem

The partial decoupling theorem is proposed by two of the authors in Ref. [32]. We here explain it in its simplest form, which suffices in the analysis of the information leakage problem. The readers interested in the full version should refer to Ref. [32].

**Theorem 6** (Non-smoothed partial decoupling theorem [32]). Consider a Hilbert space $\mathcal{H}^S$ (dim $\mathcal{H}^S = D_S$) decomposed into $\bigoplus_{j \in J} \mathcal{H}^S_j$ (dim $\mathcal{H}^S_j = d_j$) and a unitary $U^S$ in the form of $\bigoplus_{j \in J} U^S_j$, where $U^S_j \in \mathcal{U}(d_j)$ acts on $\mathcal{H}^S_j$. Let $\mathcal{H}_x$ be a product probability measure induced by the Haar measures $\mathcal{H}^S_j$ on the unitary group $\mathcal{U}(d_j)$ on $\mathcal{H}^S_j$, i.e. $\mathcal{H}_x = \mathcal{H}_1 \times \cdots \times \mathcal{H}_J$. For any $\Psi^{SR} \in S_\leq(\mathcal{H}^{SR})$, and any trace-non-increasing CP map $C^{S \rightarrow E}$, let $\Gamma^{S\rightarrow E} \in S_\leq(\mathcal{H}^{S\rightarrow E})$ be

$$\Gamma^{S\rightarrow E} = \sum_{j,j' \in J} \frac{D_S}{\sqrt{d_j d_{j'}}} \zeta^{S'E}_{jj'} \otimes \Psi^{SR}_{jj'}, \quad (114)$$

where $\mathcal{H}^{S'} := \bigoplus_{j \in J}(\mathcal{H}^S_j \otimes \mathcal{H}^S_j)$, $\zeta^{S'E}_{jj'} = \Pi^S_j \zeta^{S'E} \Pi^S_{j'}$ with $\zeta^{S'E} = \mathcal{J}(C^{S \rightarrow E})$ being the Choi-Jamiołkowski representation of $C^{S \rightarrow E}$, and $\Psi^{SR}_{jj'} = \Pi^S_j \Psi^{SR} \Pi^S_{j'}$. Then, it holds that

$$\mathbb{E}_{U^S \sim \mathcal{H}_x} \left\| C^{S \rightarrow E} \left( U^S \Psi^{SR} U^S \right) - \Gamma^{E} \right\|_1 \leq 2^{-\frac{1}{2} H_{\text{min}}(S'|E)_\Gamma}, \quad (115)$$

where $H_{\text{min}}(S'|E)_\Gamma$ is the conditional min-entropy of $\Gamma^{S\rightarrow E}$.

We also have the relation that

$$\Gamma^{E} := \text{Tr}_{S^c} [\Gamma^{S\rightarrow E}] = \mathbb{E}_{U^S \sim \mathcal{H}_x} \left[ C^{S \rightarrow E} \left( U^S \Psi^{SR} U^S \right) \right]. \quad (116)$$

Theorem 6 is useful when we are interested in encoding quantum information with a restriction of symmetry, which is the case in the information leakage problem of a Kerr BH. Although Theorem 6 may be sufficient from an information theoretic viewpoint, where the main concern is to find at least one good encoder, it is of crucial importance in physics to strengthen the statement such that it holds for almost any unitary chosen uniformly at random from $\mathcal{H}_x$. We thus show a probabilistic statement based on the concentration of the Haar measure [52, 53].
**Theorem 7** (Concentration phenomena for the partial decoupling). In the same setting as Theorem 6, it holds for any \( \varepsilon > 0 \) that

\[
\text{Prob}_{U^S \sim \mathcal{H}_x} \left[ \left\| C^{S \rightarrow E} \left( U^S \Psi^{SR} U^S \dagger \right) - \Gamma^{ER} \right\|_1 \leq 2^{-\frac{1}{2} H_{\min}(S^*|ER)} \varepsilon \right] \geq 1 - \exp \left[ -\frac{\varepsilon^2 d_{\min}}{48\|\Psi^S\|_\infty} \right],
\]

where \( d_{\min} = \min\{d_1, \ldots, d_J\} \).

Noting that \( \|\Psi^S\|_\infty \leq 1 \) since \( \Psi^{SR} \in S_{\geq}(\mathcal{H}^{SR}) \), Theorem 7 implies that the probability is exponentially close to 1 in terms of \( d_{\min} \).

There may however exist the cases where \( d_{\min} \) is small, such as \( d_{\min} = 1 \). If this is the case, Theorem 7 fails to provide a strong concentration. Below, we provide a little more generalization of the statement by setting a “threshold” dimension (see Appendix B for the proof):

**Corollary 8.** Consider the same setting as in Theorem 7. Let \( d_{th} \) be an arbitrary threshold dimension, and \( \Pi^S \geq \) be the projection onto the subspaces \( \mathcal{H}^S_{\geq} \) with dimension greater than or equal to \( d_{th} \), i.e. \( \Pi^S_{\geq} = \sum_{j \in J_{\geq}} \Pi^S_j \), where \( J_{\geq} = \{ j \in J : d_j \geq d_{th} \} \). If \( \text{Tr}[\Psi^{SR} \Pi^S_{\geq}] \geq 1 - \delta \), then it holds for any \( \varepsilon > 0 \) that

\[
\text{Prob}_{U^S \sim \mathcal{H}_x} \left[ \left\| C^{S \rightarrow E} \left( U^S \Psi^{SR} U^S \dagger \right) - \Gamma^{ER} \right\|_1 \leq 2^{-\frac{1}{2} H_{\min}(S^*|ER)} \varepsilon \right] \geq 1 - \exp \left[ -\frac{\varepsilon^2 d_{th}}{48C} \right],
\]

where \( C = \min\{1, \frac{\|\Psi^S\|_\infty}{1-\delta}\} \), and \( f(\delta) = 2\sqrt{\delta} + \delta + \frac{\delta}{1-\delta} \).

**B. Proof of Theorem 7**

To prove Theorem 7, we use the concentration of measure phenomena for product measures. We first define the \( L_2 \)-sum of the Hilbert-Schmidt norms on the product of unitary groups.

**Definition 9** (\( L_2 \)-sum of the Hilbert-Schmidt norms). Let \( \mathcal{U}_x \) be a product of unitary groups \( \mathcal{U}(d_1) \times \cdots \times \mathcal{U}(d_J) \). For \( U = (U_1, \cdots, U_J) \in \mathcal{U}_x \) and \( V = (V_1, \cdots, V_J) \in \mathcal{U}_x \), the \( L_2 \)-sum \( D(U, V) \) of the Hilbert-Schmidt norms on \( \mathcal{U}_x \) is defined by \( D(U, V) = \sqrt{\sum_{j \in J} \|U_j - V_j\|_2^2} \).

We also use Lipschitz functions, which is a generalization of uniformly continuous functions.

**Definition 10** (Lipschitz functions (see e.g. [52])). A real-valued function \( F \) on a metric space \((X, d)\) is said to be Lipschitz if

\[
\| F \|_{\text{Lip}} := \sup_{x \neq y \in X} \frac{|F(x) - F(y)|}{d(x, y)} < \infty.
\]

The \( \| F \|_{\text{Lip}} \) is called an Lipschitz constant of \( F \). The function \( F \) with a Lipschitz constant \( L \) is called \( L \)-Lipschitz.

It is well-known that a Haar random unitary has concentration properties when the degree of the group is large, which finds a number of applications in quantum information science. In most cases, the Haar measure on the whole unitary group is concerned. However, the concentration also happens for the product measure \( \mathcal{H}_x = H_1 \times \cdots \times H_J \) on \( \mathcal{U}(d_1) \times \cdots \times \mathcal{U}(d_J) \), where each unitary group \( \mathcal{U}(d_j) \) is equipped with the Haar measure \( H_j \).
Theorem 11 (Concentration of measure on the product space \([\mathbb{53}])\). Let \(U_\times\) be the product of unitary groups \(U(d_1) \times \cdots \times U(d_J)\) equipped with the \(L_2\)-sum of Hilbert-Schmidt norms, and \(H_\times = H_1 \times \cdots \times H_J\) be the product probability measure of the Haar measure \(H_j\) on each unitary group \(U(d_j)\). Suppose that a function \(F : U_\times \to \mathbb{R}\) is \(L\)-Lipschitz. Then, for every \(\varepsilon > 0\),

\[
\text{Prob}_{(U_1, \ldots, U_J) \sim H_\times}\left[F(U_1, \ldots, U_J) \geq \mathbb{E}(U_1, \ldots, U_J) \sim H_\times[F] + \varepsilon\right] \leq \exp\left[-\frac{\varepsilon^2 d_{\text{min}}}{12L^2}\right],
\]

(120)

where \(d_{\text{min}} = \min\{d_1, \ldots, d_J\}\).

Based on Theorem 11, we now prove Theorem \([\mathbb{57}]\) by identifying the unitary \(U^S = \bigoplus_{j \in J} U_j^S\) as a point \((U_1^S, \ldots, U^S_J)\) on \(U_\times = U(d_1) \times \cdots \times U(d_J)\).

**Proof** (Theorem \([\mathbb{57}]\)). For a given \(U^S = \bigoplus_{j \in J} U_j^S\), let \((U_1^S, \ldots, U^S_J)\) be the corresponding point on \(U_\times\) equipped with the \(L_2\)-sum of Hilbert-Schmidt norms \(D\). By a slight abuse of notation, we also denote the point by \(U^S\).

Let \(F : U_\times \to \mathbb{R}\) be a function given by

\[
F(U_1^S, \ldots, U^S_J) := \left\|C^{S \rightarrow E}(U^S \Psi^{SR} U^S\dagger) - \text{Tr}_{S^*} \left[\Gamma^{S^*ER}\right]\right\|_1.
\]

(121)

In the following, we compute the Lipschitz constant of \(F\). Using the triangle inequality, we obtain

\[
|F(U_1^S, \ldots, U^S_J) - F(V_1^S, \ldots, V^S_J)| \leq \left|C^{S \rightarrow E}(U^S \Psi^{SR} U^S\dagger) - C^{S \rightarrow E}(V^S \Psi^{SR} V^S\dagger)\right|_1
\]

(122)

\[
\leq \left|U^S \Psi^{SR} U^S\dagger - V^S \Psi^{SR} V^S\dagger\right|_1
\]

(123)

\[
\leq 2\|\left(U^S - V^S\right) \Psi^{SR}\|_2
\]

(124)

\[
\leq 2\|\Psi^S\|_{\infty}^2 \|U^S - V^S\|_2
\]

(125)

where the second inequality follows from the monotonocity of the trace distance under any trace-non-increasing map, the third one from that \(\Psi^{SR}\) is a pure state and the exact diagonalization with the use of the inequality \(\sqrt{1-x^2} \leq \sqrt{2(1-x)}\) for any \(x \in [0, 1]\), and the last one from the fact that

\[
\|M^X|\phi\rangle\langle \phi|\rangle^Y\|_2^2 = \text{Tr}[M^X \phi^X M^X]\]

(126)

\[
= \|\phi^X M^X\dagger M^X\|_1
\]

(127)

\[
\leq \|\phi^X\|_1 \|M^X\dagger M^X\|_1
\]

(128)

\[
= \|\phi^X\|_1 \|M^X\|_2^2
\]

(129)

due to the Hölder’s inequality. Explicitly writing \(U^S\) and \(V^S\) as \(\bigoplus_{j \in J} U_j^S\) and \(\bigoplus_{j \in J} V_j^S\), respectively, \(\|U^S - V^S\|_2\) is given by \(\sum_{j \in J}\|U_j^S - V_j^S\|_2^2\), i.e., \(\|U^S - V^S\|_2 = D(U^S, V^S)\). Hence, for any \(U^S \in U_\times\) and \(V^S \in U_\times\), we obtain

\[
\frac{|F(U_1^S, \ldots, U^S_J) - F(V_1^S, \ldots, V^S_J)|}{D(U^S, V^S)} \leq 2\|\Psi^S\|_\infty,
\]

(130)

which implies that the Lipschitz constant of \(F\) is bounded from above by \(2\|\Psi^S\|_\infty\).

We then apply Theorem 11 and obtain

\[
\text{Prob}_{U^S \sim H_\times}\left[F(U_1^S, \ldots, U^S_J) \geq 2 - \frac{\varepsilon^2 d_{\text{min}}}{48\|\Psi^S\|_\infty}\right] \leq \text{Prob}_{U^S \sim H_\times}\left[F(U_1^S, \ldots, U^S_J) \geq \mathbb{E}[F] + \varepsilon\right]
\]

(131)

\[
\leq \exp\left[-\frac{\varepsilon^2 d_{\text{min}}}{48\|\Psi^S\|_\infty}\right],
\]

(132)

where \(d_{\text{min}} = \min\{d_1, \ldots, d_J\}\), and Theorem \([\mathbb{56}]\) stating that \(\mathbb{E}[F] \leq 2 - \frac{\varepsilon^2 d_{\text{min}}}{48\|\Psi^S\|_\infty}\), is used in the first line. This concludes the proof. \(\blacksquare\)
X. FORMAL ANALYSIS OF THE INFORMATION LEAKAGE FROM THE KERR BH

In this section, we prove the statements in Section IV C, i.e. Lemma 3 and Proposition 4. We first show Lemma 3 in Subsection X A, using the standard technique based on the Uhlmann’s theorem. We then prove Proposition 4 in Subsection X B.

A. Proof of Lemma 3

Lemma 3 states the following.

\textbf{Lemma 3 (Restatement)} The error $\Delta_{\text{inv}}(\xi, \mathcal{L}_{\text{Kerr}})$ in recovering the symmetry-invariant information and the error $\Delta_{\text{tot}}(\xi, \mathcal{L}_{\text{Kerr}})$ in recovering the whole information satisfy

\begin{align}
\Delta_{\text{inv}}(\xi, \mathcal{L}_{\text{Kerr}}) & \leq \| L_{\text{Kerr}}^{S \rightarrow S_{\text{in}}}(\Psi^{SR}) - \Gamma_{\text{in}}^{R} \|_{1}, \\
\Delta_{\text{tot}}(\xi, \mathcal{L}_{\text{Kerr}}) & \leq \| L_{\text{Kerr}}^{S \rightarrow S_{\text{in}}}(\Psi^{SR}) - \Gamma_{\text{in}}^{R} \otimes \pi^{R} \|_{1}.
\end{align}

Here, $\Gamma_{\text{in}}^{R}$ is isomorphic to $\Gamma_{\text{ER}}$ by identifying $E$ and $S_{\text{in}}$, and is explicitly given by

\begin{equation}
\Gamma_{\text{in}}^{R} := \sum_{m=0}^{N+k} \frac{2^{N+k}}{d_{m}} \tau_{m}^{S_{\text{in}}} \otimes \Psi_{m}^{R}.
\end{equation}

The Lemma follows from the Uhlmann’s theorem.

\textbf{Theorem 12 (Uhlmann’s theorem \cite{54}).} Let $|\rho\rangle^{AB}$ and $|\sigma\rangle^{AC}$ be a purification of $\rho^{A} \in S(\mathcal{H}^{A})$ and $\sigma^{A} \in S(\mathcal{H}^{A})$, respectively. Then,

\begin{equation}
F(\rho^{A}, \sigma^{A}) = \max_{V_{C \rightarrow B}} |\langle \rho|^{AB} V_{C \rightarrow B} |\sigma\rangle^{AC}|^{2},
\end{equation}

where the maximization is taken over all partial isometries from $\mathcal{H}^{C}$ to $\mathcal{H}^{B}$.

It is convenient to rewrite the Uhlmann’s theorem in an approximate form as follows, which we call the Uhlmann’s trick:

\textbf{Corollary 13 (Uhlmann’s trick (see e.g. Ref. \cite{39}).} For any pure states $|\rho\rangle^{AB}$ and $|\sigma\rangle^{AC}$, there exists a partial isometry $V_{B \rightarrow C}$ such that

\begin{equation}
1 - F(V_{B \rightarrow C} \rho^{AB} (V_{B \rightarrow C})^{\dagger}, \sigma^{AC}) \leq \| \rho^{A} - \sigma^{A} \|_{1}.
\end{equation}

Note that Corollary 13 implies that if $\rho^{AB}$ and $\sigma^{AC}$ are extensions of $\rho^{A}$ and $\sigma^{A}$, respectively, in the sense that $\text{Tr}_{B}[\rho^{B}] = \rho^{A}$ and $\text{Tr}_{C}[\sigma^{AC}] = \sigma^{A}$, there exists a CPTP map $D^{B \rightarrow C}$ such that

\begin{equation}
1 - F(D^{B \rightarrow C} (\rho^{AB}), \sigma^{AC}) \leq \| \rho^{A} - \sigma^{A} \|_{1},
\end{equation}

which follows from the monotonicity of the fidelity under partial trace. We now prove Lemma 3.

\textbf{Proof (Lemma 3).} We first show Inequality (133). It is convenient to denote $S_{\text{in}}$ by $E$, so we will show that

\begin{equation}
\Delta_{\text{inv}}(\xi, \mathcal{L}_{\text{Kerr}}) \leq \| L_{\text{Kerr}}^{S \rightarrow E}(\Psi^{SR}) - \Gamma_{\text{ER}} \|_{1}.
\end{equation}
An extension of $\Gamma^{SR}_{in}$ is by definition given by $\Gamma^{ER}_{SR}$. We also recall that the dynamics $\mathcal{L}_{\text{Kerr}}$ consists of the unitary dynamics and the partial trace. Hence, an extension of $\mathcal{L}^{SR}_{\text{Kerr}}(\Psi^{SR})$ is given by
\[
\Psi^{ES}_{U, RB_{\text{rad}}} = U^S(\Phi)^{AR} \otimes |\xi^{B_{\text{in}}}_{B_{\text{rad}}})
\]
where $\Psi^{SR}_{U}$ is a unitary part of the dynamics $\mathcal{L}_{\text{Kerr}}$ and we have used that $S = ES_{\text{rad}}$. Hence, there exists a CPTP map $\mathcal{D}^{SR}_{B_{\text{rad}} \rightarrow S^*}$ such that
\[
1 - F(\Gamma^{ER}_{SR}, \mathcal{D}^{SR}_{B_{\text{rad}} \rightarrow S^*}(\Psi^{ES}_{U, RB_{\text{rad}}})) \leq \|\mathcal{L}^{SR}_{\text{Kerr}}(\Psi^{SR}) - \Gamma^{ER}_{SR}\|_1.
\]
Noting that $S^*$ is isomorphic to $SS' = AB_{B_{\text{in}}}$, we take the partial trace over $S'EB_{\text{in}}$. Using the monotonicity of the fidelity under partial trace, we have
\[
1 - F(\Gamma^{AR}_{SR}, \mathcal{D}^{SR}_{B_{\text{rad}} \rightarrow A} \circ \mathcal{L}^{SR}_{\text{Kerr}}(\Phi^{AR} \otimes \xi^{B_{\text{in}}}_{B_{\text{rad}}})) \leq \|\mathcal{L}^{SR}_{\text{Kerr}}(\Psi^{SR}) - \Gamma^{ER}_{SR}\|_1
\]
where $\Gamma^{AR}_{SR} := \text{Tr}_{S'B_{\text{in}}}^{-1}[\Gamma^{SR}_{S'B_{\text{in}}}]$, and we have used $\text{Tr}_{E}[\Psi^{U}] = \mathcal{L}^{SR}_{\text{Kerr}}(\Phi^{AR} \otimes \xi^{B_{\text{in}}}_{B_{\text{rad}}})$. Noting that $\frac{2^{N+k}}{\sqrt{d_{m}d_{m}^{'}}} \text{Tr}[\tau_{mm^{'}}^{S'}] = \delta_{mm^{'}}$, the state $\Gamma^{AR}$ is given by
\[
\Gamma^{AR}_{SR} = \sum_{m=0}^{N+k} \text{Tr}_{B_{\text{in}}} \Psi^{SR}_{mm} = \sum_{m=0}^{N+k} \text{Tr}_{B_{\text{in}}} \Pi^{S}_{m} (\Phi^{AR} \otimes \xi^{B_{\text{in}}}_{B_{\text{rad}}}) \Pi^{SR}_{m}. \tag{143}
\]
We further apply the pinching map $\mathcal{C}^{R}$ onto $R$, mapping $\Phi^{AR}$ to $\sum_{\kappa=0}^{k} \Pi^{R}_{\kappa} \Phi^{AR}_{\kappa} \Pi^{R}_{\kappa}^{} = \Phi^{AR}_{\text{diag}}$, which leads to
\[
1 - F(\mathcal{C}^{R}(\Gamma^{AR}_{SR}), \mathcal{D}^{S'B_{\text{rad}} \rightarrow A} \circ \mathcal{L}^{SR}_{\text{Kerr}}(\Phi^{AR}_{\text{diag}} \otimes \xi^{B_{\text{in}}}_{B_{\text{rad}}})) \leq \|\mathcal{L}^{SR}_{\text{Kerr}}(\Psi^{SR}) - \Gamma^{ER}_{SR}\|_1. \tag{144}
\]
We finally compute $\mathcal{C}^{R}(\Gamma^{AR})$ using the fact that $\Pi^{S}_{m} = \sum_{\kappa=0}^{k} \Pi^{A}_{\kappa} \otimes \Pi^{B_{\text{in}}}_{m - \kappa}$, where $\Pi^{B_{\text{in}}}_{m - \kappa}$ is defined by the zero operator when $m < \kappa$ or $N < m - \kappa$. It follows that
\[
\mathcal{C}^{R}(\Gamma^{AR}) = \sum_{\kappa=0}^{N+k} \sum_{m=0}^{N+k} \text{Tr} \Pi^{B_{\text{in}}}_{m - \kappa} \xi^{B_{\text{in}}}_{B_{\text{rad}}} \Pi^{A}_{\kappa} \Phi^{AR}_{\kappa} \Pi^{A}_{\kappa}, \tag{145}
\]
where we used $\sum_{m=0}^{N+k} \Pi^{B_{\text{in}}}_{m - \kappa} = I^{B_{\text{in}}}$. We thus arrive at our conclusion:
\[
1 - F(\Phi^{AR}_{\text{diag}}, \mathcal{D}^{S'B_{\text{rad}} \rightarrow A} \circ \mathcal{L}^{SR}_{\text{Kerr}}(\Phi^{AR}_{\text{diag}} \otimes \xi^{B_{\text{in}}}_{B_{\text{rad}}})) \leq \|\mathcal{L}^{SR}_{\text{Kerr}}(\Psi^{SR}) - \Gamma^{SR}_{in}\|_1, \tag{146}
\]
which implies that $\Delta_{\text{inv}}(\xi, \mathcal{L}_{\text{Kerr}}) \leq \|\mathcal{L}^{SR}_{\text{Kerr}}(\Psi^{SR}) - \Gamma^{SR}_{in}\|_1$.

Inequality (134) can be similarly shown based on Corollary 13.

\[\square\]

**B. Errors of the information leakage from the Kerr BH**

We next prove Proposition 4. Let us recall some notation:
\[
\Gamma^{SR}_{in} = \sum_{m=0}^{N+k} \frac{2^{N+k}}{d_{m}} \tau_{mm}^{S'R} \otimes \Psi^{SR}_{mm}, \tag{149}
\]
\[
\Gamma^{SR}_{in} = \sum_{m=0}^{N+k} \frac{2^{N+k}}{d_{m}} \tau_{mm}^{S'R} \otimes \Psi^{SR}_{mm} \cong \text{Tr}_{S'}[\Gamma^{SR}_{in}], \tag{150}
\]
where $\tau_{mn}^{S^E} = \Pi_{mn}^{S^E} \tau_{mn}^{E} \Pi_{mn}^{S^E}$, $\Psi_{mn}^{SR} = \Pi_{mn}^{S} \Psi_{mn}^{SR} \Pi_{mn}^{S}$, and $d_m = \binom{N+k}{m}$. We use a subnormalized state $\hat{\Gamma}_n^{S^*ER}$ and its normalization factor $p_n$, which are defined by

$$\hat{\Gamma}_n^{S^*ER} := \Pi_{n}^{S^*rad} \Gamma^{S^*ER} \Pi_{n}^{S^*rad},$$

$$p_n := \text{Tr} [\hat{\Gamma}_n^{S^*ER}].$$

Using $p_n$, we define a probable set $I_\epsilon = \{n \in [0, \ell] : p_n \geq \epsilon\}$, and a subnormalized state $\hat{\Gamma}(\epsilon)$ as

$$\hat{\Gamma}^{S^*ER}(\epsilon) := \Pi_{\epsilon}^{S^*rad} \Gamma^{S^*ER} \Pi_{\epsilon}^{S^*rad},$$

where $\Pi_{\epsilon}^{S^*rad} := \sum_{n \in I_\epsilon} \Pi_{n}^{S^*rad}$. We finally define

$$d_{\min}(\epsilon) = \min \left\{ \binom{N+k}{m+n} : m \in [0, N+k-\ell], n \in I_\epsilon \right\}.$$

A formal statement of Proposition 4 is then given as follows.

**Proposition 4** [Formal statement] The dynamics $L_{Kerr}^{S \rightarrow S_{in}}$ for almost any choice of unitaries $U_i \sim \mathcal{H}_i^{Kerr}$ satisfies that, for any $\epsilon > 0$,

$$\| L_{Kerr}^{S \rightarrow S_{in}} (\Psi^{SR}) - \Gamma^{S_{in}R} \|_1 \leq 2 \Theta_\epsilon(N, k, \ell),$$

$$\| L_{Kerr}^{S \rightarrow S_{in}} (\Psi^{SR}) - \Gamma^{S_{in} \otimes \eta^R} \|_1 \leq 2 \eta_\epsilon(N, k, \ell),$$

with probability at least $1 - \exp[-\epsilon^2 d_{\min}(\epsilon)/48]$. Here, $\Theta_\epsilon(N, k, \ell)$ and $\eta_\epsilon(N, k, \ell)$ are, respectively, given by

$$\Theta_\epsilon(N, k, \ell) = \min_{\epsilon \geq 0} \left\{ 2^{\frac{1}{2} H_{\min}(\epsilon) \Gamma(\epsilon)} + w(\epsilon) \right\} + \epsilon,$$

$$\eta_\epsilon(N, k, \ell) = \frac{1}{2^k} \sum_{n=0}^{N+k-\ell} \sum_{m=0}^{N+k} \sum_{\kappa=0}^{\ell} \binom{m-n}{N+k} \binom{k}{m} \binom{k}{\kappa} \chi_{m-n} \chi_{m-\kappa} \binom{N+k-\ell}{\kappa},$$

where $w(\epsilon) := 1 - \text{Tr}[\hat{\Gamma}(\epsilon)] = \sum_{n \notin I_\epsilon} p_n$, and $\chi_\mu = \text{Tr}[\hat{S}_{\mu} \hat{\Pi}_{\mu}]$. Moreover, $p_n$ is explicitly given by

$$p_n = \frac{1}{2^k} \sum_{m=0}^{N+k} \sum_{\kappa=0}^{\ell} \chi_{m-\kappa} \binom{\ell}{\kappa} \binom{N+k-\ell}{\kappa} \binom{k}{\kappa} \binom{N+k}{m}.$$
where \( \text{Tr}_i \) is the partial trace over a randomly chosen \( i \)th qubit, representing the Hawking radiation of one qubit. This can be rewritten as follows:

\[
L^{S \rightarrow S_{\text{in}}}_{\text{Kerr}}(\zeta^S) = \text{Tr}_{i_1 \ldots i_\ell}[(I_{i_1} \otimes U_{i_2}) \ldots (I_{i_1} \otimes U_2)U_1^T \zeta^S U_1^T \ldots (I_{i_1} \otimes U_2) \ldots (I_{i_1} \otimes U_2)], \tag{161}
\]

where \( I_{i_j} \) is the identity operator action on the \( i \)th, \( \ldots j \)th qubits, and \( \text{Tr}_{i_1 \ldots i_\ell} = \text{Tr}_{S_{\text{rad}}} \) is the partial trace over \( i_1 \)th, \( \ldots i_\ell \)th qubits.

Since each \( U_i \) is assumed to be symmetry-preserving scrambling, it is in the form of \( \bigoplus_n U_i^{(n)} \) and \( U_i^{(n)} \) is unitarily invariant in the sense that, for any unitary \( V \) acting on the same space of \( U_i^{(n)} \), the distribution of \( VU_i^{(n)} \) is the same as that of \( U_i^{(n)} \). Using this property, the statistics of the dynamics \( L^{S \rightarrow S_{\text{in}}}_{\text{Kerr}}(\zeta^S) \) is the same as that of the Tr\(_{i_1 \ldots i_\ell} [U^S \zeta^S U^S]\), where \( U^S = U_1 \) in the previous notation. In particular, we have

\[
\mathbb{E}_{U_i \sim H_{\text{Kerr}}} \left\| L^{S \rightarrow S_{\text{in}}}_{\text{Kerr}}(\Psi^{SR}) - \Gamma^{S_{\text{in}}R} \right\|_1 = \mathbb{E}_{U_i \sim H_{\text{Kerr}}} \left\| \text{Tr}_{S_{\text{rad}}} (U^S \Psi^{SR} U^S) - \Gamma^{S_{\text{in}}R} \right\|_1. \tag{162}
\]

Note also that the unitarily invariance of \( U^S \) also implies that any choice of the \( \ell \) qubits that are going to be traced out leads to the same result. Hereafter, we use this simplification.

2. Proof of Proposition 4

**Proof (Proposition 4).** In order to show Inequality (155), let \( \tilde{\Gamma}^{S_{\text{in}}R}(\epsilon) \) be isomorphic to Tr\(_{S^* \rightarrow [\Gamma^S_{\text{in}}]_{ER}} \) by identifying \( E \) with \( S_{\text{in}} \). Using the simplification of the dynamics and the triangle inequality, we obtain

\[
\left\| L^{S \rightarrow S_{\text{in}}}_{\text{Kerr}}(\Psi^{SR}) - \Gamma^{S_{\text{in}}R} \right\|_1 \leq \left\| \text{Tr}_{S_{\text{rad}}} [\Psi^{SR}_U] - \text{Tr}_{S_{\text{rad}}} [\Pi^{S_{\text{rad}}} \Psi^{SR}_U \Pi^{S_{\text{rad}}}] \right\|_1 + \left\| \text{Tr}_{S_{\text{rad}}} [\Pi^{S_{\text{rad}}} \Psi^{SR}_U \Pi^{S_{\text{rad}}} - \tilde{\Gamma}^{S_{\text{in}}R}(\epsilon)] \right\|_1 + \left\| \tilde{\Gamma}^{S_{\text{in}}R}(\epsilon) - \Gamma^{S_{\text{in}}R} \right\|_1, \tag{163}
\]

where \( \Psi^{SR}_U = U^S \Psi^{SR}(U^S)^\dagger \).

Using Theorem 7, the second term is bounded from above as

\[
\left\| \text{Tr}_{S_{\text{rad}}} [\Pi^{S_{\text{rad}}} \Psi^{SR}_U \Pi^{S_{\text{rad}}} - \tilde{\Gamma}^{S_{\text{in}}R}(\epsilon)] \right\|_1 \leq 2^{-\frac{1}{2}H_{\text{min}}(S^* | ER)_{C(\epsilon)} + \epsilon}, \tag{164}
\]
with probability at least $1 - \exp(-\varepsilon^2 d_{\min}(\epsilon)/48)$ for any $\varepsilon > 0$. Note that the minimum dimension is given by $d_{\min}(\epsilon)$ due to the application of $\Pi^{S_{\text{rad}}}$. When the second term of Inequality (163) is small, the first term of Inequality (163) should be also small. To observe this, we use the fact that $\Psi^{S_{\text{rad}}} \geq \Pi^{S_{\text{rad}}} \Psi^{S_{\text{rad}}} \Pi^{S_{\text{rad}}}$, which leads to

$$
\left\| \text{Tr}_{S_{\text{rad}}} \left[ \Psi^{S_{\text{rad}}} \right] - \text{Tr}_{S_{\text{rad}}} \left[ \Pi^{S_{\text{rad}}} \Psi^{S_{\text{rad}}} \Pi^{S_{\text{rad}}} \right] \right\|_1 = \left| \text{Tr}[\Psi^{S_{\text{rad}}}] - \text{Tr}[\Pi^{S_{\text{rad}}} \Psi^{S_{\text{rad}}} \Pi^{S_{\text{rad}}}] \right| = 1 - \text{Tr}[\Pi^{S_{\text{rad}}} \Psi^{S_{\text{rad}}} \Pi^{S_{\text{rad}}}].
$$

Using the monotonicity of the trace distance, we also obtain from Inequality (164) that

$$
\left| \text{Tr}[\Pi^{S_{\text{rad}}} \Psi^{S_{\text{rad}}} \Pi^{S_{\text{rad}}}] - \text{Tr}[\Gamma^{S_{\text{in}}}] \right| \leq 2 - \frac{1}{2} H_{\min}(S^{*\text{rad}}) \Gamma(\epsilon) + \varepsilon.
$$

Since $\Gamma^{S_{\text{in}}}(\epsilon) = \text{Tr}_S \left[ \Gamma^{S^{*\text{rad}}} \right]$, we have $\text{Tr}[\Gamma^{S_{\text{in}}}] = \text{Tr}[\Gamma] = 1 - w(\epsilon)$ and so,

$$
\text{Tr}[\Pi^{S_{\text{rad}}} \Psi^{S_{\text{rad}}} \Pi^{S_{\text{rad}}}] \geq 1 - w(\epsilon) - 2 - \frac{1}{2} H_{\min}(S^{*\text{rad}}) \Gamma(\epsilon) - \varepsilon.
$$

Thus,

$$
\left\| \text{Tr}_{S_{\text{rad}}} \left[ \Psi^{S_{\text{rad}}} \right] - \text{Tr}_{S_{\text{rad}}} \left[ \Pi^{S_{\text{rad}}} \Psi^{S_{\text{rad}}} \Pi^{S_{\text{rad}}} \right] \right\|_1 \leq 2 - \frac{1}{2} H_{\min}(S^{*\text{rad}}) \Gamma(\epsilon) + w(\epsilon) + \varepsilon,
$$

when Inequality (164) holds. Note that this evaluation is not tight since, when $\epsilon = 0$, the L.H.S. is trivially zero, but the R.H.S. is in general non-zero.

For the third term, note that $S_{\Gamma^{S^{*\text{rad}}}} \geq \Gamma^{S_{\text{in}}}$, implying that $S_{\Gamma^{S^{*\text{rad}}}} \geq \Gamma^{S_{\text{in}}}(\epsilon)$. Thus, we have

$$
\left\| \Gamma^{S_{\text{in}}}(\epsilon) - \Gamma^{S_{\text{in}}}(\epsilon) \right\| = \text{Tr}[\Gamma^{S_{\text{in}}}(\epsilon) - \Gamma^{S_{\text{in}}}(\epsilon)] = 1 - \text{Tr}[\Gamma(\epsilon)] = w(\epsilon).
$$

Altogether, we obtain that, for any $\varepsilon > 0$,

$$
\left\| \mathcal{L}_{\text{Kerr}}^{S_{\text{rad}}} (\Psi^{S_{\text{rad}}}) - \Gamma^{S_{\text{in}}} \right\|_1 \leq 2 (2 - \frac{1}{2} H_{\min}(S^{*\text{rad}}) \Gamma(\epsilon) + w(\epsilon) + \varepsilon)
$$

with probability at least $1 - \exp[-\varepsilon^2 d_{\min}(\epsilon)/48]$. Since the left-hand side is independent of $\epsilon$, we take the minimum of the right-hand side over $\epsilon > 0$ and arrive at the desired statement that

$$
\left\| \mathcal{L}_{\text{Kerr}}^{S_{\text{rad}}} (\Psi^{S_{\text{rad}}}) - \Gamma^{S_{\text{in}}} \right\|_1 \leq 2 \Theta_{\xi}(N, k, \ell),
$$

where

$$
\Theta_{\xi}(N, k, \ell) = \min_{\varepsilon > 0} \left\{ 2 - \frac{1}{2} H_{\min}(S^{*\text{rad}}) \Gamma(\epsilon) + w(\epsilon) + \varepsilon \right\}.
$$

with probability at least $1 - \exp[-\varepsilon^2 d_{\min}(\epsilon)/48]$.

We next derive Inequality (156). Using the simplification of the dynamics and the triangle inequality, we obtain

$$
\left\| \mathcal{L}_{\text{Kerr}}^{S_{\text{rad}}} (\Psi^{S_{\text{rad}}}) - \Gamma^{S_{\text{in}}} \otimes \pi^{R} \right\|_1 \leq \left\| \text{Tr}_{S_{\text{rad}}} [\Psi^{S_{\text{rad}}} \Gamma^{S_{\text{in}}} \otimes \pi^{R}] \right\|_1 + \left\| \Gamma^{S_{\text{in}}} \otimes \pi^{R} \right\|_1
$$

with probability at least $1 - \exp[-\varepsilon^2 d_{\min}(\epsilon)/48]$ for any $\varepsilon > 0$, where we have used Inequality (155).

The $\Gamma^{S_{\text{in}}}$ and $\Gamma^{S_{\text{in}}}$ are explicitly computed to be

$$
\Gamma^{S_{\text{in}}} = \frac{1}{2k} \sum_{m=0}^{N+k} \sum_{n=0}^{k} \sum_{\kappa=0}^{\ell} \frac{\ell}{m} \left( \frac{k}{\kappa} \right) \left( \frac{N+k-\ell}{m-n} \right) \chi_{m-n}^{m-n} \pi^{S_{\text{in}}} \otimes \pi^{R},
$$

$$
\Gamma^{S_{\text{in}}} = \frac{1}{2k} \sum_{m=0}^{N+k} \sum_{n=0}^{k} \sum_{\kappa=0}^{\ell} \frac{\ell}{m} \left( \frac{k}{\kappa} \right) \left( \frac{N+k-\ell}{m-n} \right) \chi_{m-n}^{m-n} \pi^{S_{\text{in}}} \otimes \pi^{R},
$$

(177) (178)
where we have used \( \Pi_m^S = \sum_{n=0}^{\ell} \Pi_{m-n}^S \otimes \Pi_{m-n}^{rad} \) and \( \Pi_m^S = \sum_{\kappa=0}^{k} \Pi_{m-k}^\Lambda \otimes \Pi_{m-k}^{\Gamma}. \) Since both are already diagonal, we can explicitly compute their distance such as

\[
\|\Gamma^{S_R^R - S_{in}}_n \otimes \pi^R\|_1 = 2 \frac{d N + k}{d m} \sum_{m=0}^{N+k} \left( \begin{array}{c} (N+k) \\ m \end{array} \right) \left( \begin{array}{c} \chi_{m-k} - 1 \\ 2 \end{array} \right) \left( \begin{array}{c} \chi_{m-k'} \\ k \end{array} \right) \left( \begin{array}{c} (N + k - \ell) \\ m - n \end{array} \right) \left( \begin{array}{c} k \end{array} \right).
\]

This is exactly \( \eta(N, k, \ell) \) defined by Equation (158). Hence, we obtain that, for any \( \varepsilon > 0, \)

\[
\| \Gamma^{S_R^R \rightarrow S_{in}}(\Psi^R) - \Gamma^{S_{in}}_n \otimes \pi^R\|_1 \leq 2\Theta(\varepsilon)(N, k, \ell) + \eta(N, k, \ell),
\]

with probability at least \( 1 - \exp(-\varepsilon^2 d_{min}(\varepsilon)/48) \).

We finally compute \( p_n := \text{Tr}[\Gamma_n]: \)

\[
p_n = \sum_{m=0}^{N+k} \frac{2 N + k}{d_m d_{m'}} \text{Tr}[\Pi_m^{S_{rad} \rightarrow S_{rad}'} E] \text{Tr}[\Psi_{mm'}^{S}] = \sum_{m=0}^{N+k} \frac{2 N + k}{d_m} \text{Tr}[\Pi_m^{S_{rad} \rightarrow S_{rad}'} \Pi_m^{S_{rad}}] \text{Tr}[\Pi_m^{S} \Psi^{S}].
\]

Recalling that \( \Psi^S = \pi^A \otimes \xi^{B_{in}} \), we obtain

\[
\text{Tr}[\Pi_m^{S} \Psi^{S}] = \sum_{\kappa=0}^{\ell} \text{Tr}[\Pi_{m-k}^\Lambda \otimes \Pi_{m-k}^{\Gamma}](\pi^A \otimes \xi^{B_{in}})] = \frac{1}{2} \sum_{\kappa=0}^{\ell} \chi_{m-k} \left( \begin{array}{c} k \end{array} \right).
\]

Since \( \tau^{S'} = \pi^{S'} \), it follows that

\[
\text{Tr}[\Pi_m^{S_{rad} \rightarrow S_{rad}'} \Pi_m^{S'} \Pi_m^{S'}] = \frac{1}{2 N + k} \text{Tr}[\Pi_m^{S_{rad} \rightarrow S_{rad}'} \Pi_m^{S'}] = \frac{1}{2 N + k} \left( \begin{array}{c} (N + k - \ell) \\ m - n \end{array} \right) \left( \begin{array}{c} k \end{array} \right).
\]

As \( d_m = \left( \begin{array}{c} N+k \\ m \end{array} \right) \), we obtain \( p_n = \frac{1}{2} \sum_{m=0}^{N+k} \sum_{\kappa=0}^{\ell} \chi_{m-k} \left( \begin{array}{c} (N + k - \ell) \\ m - n \end{array} \right) \left( \begin{array}{c} k \end{array} \right). \)

\[\Box\]

XI. QUANTITATIVE ANALYSIS OF THE INFORMATION LEAKAGE FROM THE KERR BH

We here break down the formal upper bounds on the recovery errors to the numerically evaluable ones. We do so by providing a lower bound on the conditional min-entropy \( H_{min}(S^* | ER)_{\tilde{f}_c}) \). We also derive an upper bound and show that, for \( I = [0, \ell] \), the lower and upper bounds nearly coincide, implying that the lower bound is likely to be tight. We then use the lower bound of the conditional min-entropy to numerically compute an upper bound of

\[
\Theta(\varepsilon)(N, k, \ell) = \min_{\varepsilon \geq 0} \left\{ 2^{-\frac{1}{2} H_{min}(S^* | ER)_{\tilde{f}_c}} + w(\varepsilon) \right\}.
\]

The pure and mixed Kerr BHs are dealt with in Subsections [XI A] and [XI B] respectively.
A. $H_{\text{min}}(S^*|ER)_\Gamma$ for the pure Kerr BH

Let us derive upper and lower bounds on $H_{\text{min}}(S^*|ER)_\Gamma(\epsilon)$ when the initial BH $B_{\text{in}}$ is in a pure state $\xi$. We first consider the case of $\epsilon = 0$, that is, $\Gamma(\epsilon) = \Gamma$. Noting that the Choi-Jamiolkowski representation of the partial trace $\text{Tr}_{\text{rad}}$ is $\tau^{SE} = \pi^{S_{\text{rad}}}_n \otimes \Phi^{S_{\text{in}}}_n$, $\Gamma$ is explicitly given by

\[
\Gamma^{S*ER} = \sum_{m,m' = 0}^{N+k} \frac{2^{N+k}}{\sqrt{d_m d_{m'}}} \left( \Pi_{m'}^{S_{\text{rad}}} \otimes \Phi^{S_{\text{in}}}_n \right) \otimes \left( \Pi_{m}^{S_{\text{rad}}} \otimes \xi^{B_{\text{in}}} \right),
\]

which can be further simplified to

\[
\Gamma^{S*ER} = \sum_{n = 0}^{\ell} \sum_{n = 0}^{\ell} p_n^{S_{\text{rad}}} \otimes \Phi^{S_{\text{in}}}_n E_{SR}.
\]

Here, the probability distribution $\{p_n\}$ is given in Proposition 4 and the normalized pure state $|\Phi^{S_{\text{in}}}_n E_{SR}\rangle$ is defined by

\[
|\Phi^{S_{\text{in}}}_n E_{SR}\rangle = \sqrt{\frac{2^{N+2k-\ell}}{M_n} \sum_{m = 0}^{N+k} \frac{1}{\binom{N+k}{m}} \left( \Pi_{m}^{S_{\text{rad}}} |\Phi^{S_{\text{in}}}_n \rangle \right) \otimes \left( \Pi_{m}^{S_{\text{rad}}} |\Phi^{S_{\text{in}}}_n \rangle \right)},
\]

where $M_n = \sum_{m = 0}^{N+k} \frac{k}{\binom{N+k}{m}} \chi_{m-k}/\binom{N+k}{m}$, and $\chi_n = \text{Tr}[\xi^{B_{\text{in}}} B_{\text{in}}]$. By applying Proposition 2 we obtain

\[
-\log \left[ \sum_{n = 0}^{\ell} \frac{M_n}{2^k} 2^{-H_{\text{min}}(S_{\text{in}}^* S|ER)_{\Phi_n}} \right] \leq H_{\text{min}}(S^*|ER)_\Gamma_{\text{pure}} \leq \min_{n \in [0,\ell]} \left\{ H_{\text{min}}(S_{\text{in}}^* S|ER)_{\Phi_n} - \log \left[ \frac{M_n}{2^k} \right] \right\}.
\]

Furthermore, since $\Phi^{S_{\text{in}}}_n E_{SR}$ is a pure state, using Proposition 4 its conditional min-entropy can be computed in terms of a marginal state:

\[
H_{\text{min}}(S_{\text{in}}^* S|ER)_{\Phi_n} = -2 \log \left[ \text{Tr}[\sqrt{\Phi^{ER}_n}] \right],
\]

where $\Phi^{ER}_n$ is explicitly given by

\[
\Phi^{ER}_n = \frac{1}{M_n} \sum_{m = 0}^{N+k} \sum_{\kappa = 0}^{k} \frac{\chi_{m-k}}{\binom{N+k}{m}} \Pi_{m-n}^{E} \otimes \Pi_{\kappa}^{R}.
\]

This is already a diagonal form, so $\text{Tr}[\sqrt{\Phi^{ER}_n}]$, and hence $H_{\text{min}}(S_{\text{in}}^* S|ER)_{\Phi_n}$, can be exactly obtained. We thus have

\[
k - \log \gamma(N, k, \ell) \leq H_{\text{min}}(S^*|ER)_\Gamma \leq k - \max_{n \in [0,\ell]} \{ \log \gamma_n(N, k, \ell) \},
\]

where

\[
\gamma_n(N, k, \ell) := \left( \sum_{m = 0}^{N+k} \sum_{\kappa = 0}^{k} \frac{\chi_{m-k}}{\binom{N+k}{m}} \binom{N+k-\ell}{m-n} \binom{k}{\kappa} \right)^2,
\]

\[
\gamma(N, k, \ell) := \sum_{n = 0}^{\ell} \gamma_n(N, k, \ell).
\]
53

FIG. 14: Numerical evaluations of the lower bound (Inequalities (194)) on the conditional min-entropy $H_{\text{min}}(S^*|ER)$ for the state $|\xi(L, \delta L)\rangle_{B_{\text{in}}}$ given by Equation (197). The state has the $Z$-axis AM $L$ and the standard deviation $\delta L$. The size $N$ of the initial BH $B_{\text{in}}$ is set to 300, and the size $k$ of the quantum information source $A$ to 5. Figure (i) is for $L = 0$, and (ii) for $|L| = N/4$. In each figure, the standard deviation $\delta L$ is chosen to be 0 (black), $0.1\sqrt{N}$ (red), $0.5\sqrt{N}$ (blue), $0.9\sqrt{N}$ (green), and $0.3N$ (brown). For comparison, we have also plotted the state-independent lower bound by solid yellow lines, and the $y$-axis is taken up to the state-independent upper bound, which are both given by Inequalities (58). The inset shows the difference between the upper bound and lower bounds in Inequalities (194), showing that they nearly coincide.

To check how tight the upper and lower bounds in Inequalities (194) are, we especially choose the state of the initial Kerr BH $B_{\text{in}}$ as $|\xi(L, \delta L)\rangle_{B_{\text{in}}}$ with the $Z$-axis AM $L$ and its standard deviation $\delta L$:

$$|\xi(L, \delta L)\rangle_{B_{\text{in}}} = \sum_{\mu=0}^{N} \sqrt{\chi_{\mu}(L, \delta L)} |\varphi_{\mu}\rangle_{B_{\text{in}}},$$

(197)

where $\{\chi_{\mu}\}$ is the Gaussian distribution over $\mu$ with mean $L + N/2$ and standard deviation $\delta L$, which is properly normalized so that $\sum_{\mu=0}^{N} \chi_{\mu} = 1$, and $|\varphi_{\mu}\rangle_{B_{\text{in}}}$ is an arbitrary state in $\mathcal{H}_{B_{\text{in}}}$. In Figure 14, the lower bound is plotted for $L = 0$ (Figure 14 (i)) and $|L| = N/4$ (Figure 14 (ii)), where $N = 300$ and $k = 5$. In each case, $\delta L$ is chosen to be $0, 0.1\sqrt{N}, 0.5\sqrt{N}, 0.9\sqrt{N}$, and $0.3N$. To check the tightness of the bounds, the insets show the difference between the lower and upper bounds in Inequalities (194). From these figures, it is observed that the lower and upper almost coincide in both cases.

We next consider $\tilde{\Gamma}^{S^*ER}(\epsilon) = \Pi_{\text{rad}}^{S^*}(\epsilon)\tilde{\Gamma}^{S^*ER}\Pi_{\text{rad}}^{S^*}(\epsilon)$ for $\epsilon > 0$. It is explicitly given by

$$\tilde{\Gamma}^{S^*ER}(\epsilon) = \sum_{n \in I_{\epsilon}} p_n \tilde{\Phi}_{n,ESR}^{S^*},$$

(198)

We can similarly derive a lower bound on its conditional min-entropy $H_{\text{min}}(S^*|ER)_{\tilde{\Gamma}(\epsilon)} \geq k - \log[\gamma_{\text{pure}}(N, k, \ell|\xi)]$, where

$$\gamma_{\text{pure}}(N, k, \ell|\xi) := \sum_{n \in I_{\epsilon}} \left( \sum_{m=0}^{N+k} \sum_{\kappa=0}^{k} \sqrt{\chi_{m-\kappa}(L, \delta L)} \left( \frac{N+k-\ell}{m-n} \right)^{k} \right)^{2}.$$  

(199)
By using this lower bound on the conditional min-entropy, an upper bound of $\Theta_\xi(N, k, \ell)$ is obtained as follows:

$$\Theta_\xi(N, k, \ell) = \min_{\epsilon \geq 0} \left\{ 2^{-\frac{1}{2} H_{\text{min}}(S^* | ER)_{\ell}(\epsilon)} + w(\epsilon) \right\}$$  \hspace{1cm} (200)$$

$$\leq \min_{\epsilon \geq 0} \left\{ 2^{-k/2} \sqrt{\gamma_{\text{pure}}(N, k, \ell | \xi) + w(\epsilon)} \right\}.$$  \hspace{1cm} (201)$$

Noting that $w(\epsilon)$ is given by $\sum_{n \notin I} p_n$, we can numerically evaluate this bound.

### B. $H_{\text{min}}(S^* | ER)_\Gamma$ for the mixed Kerr BH

We next consider the case when $\xi^{B_{\text{in}} B_{\text{rad}}}$ is entangled between $B_{\text{in}}$ and $B_{\text{rad}}$. Since it is hard to deal with general states, we focus on the state in the form of

$$|\xi\rangle^{B_{\text{in}} B_{\text{rad}}} = \sum_{\mu=0}^{N} \sqrt{X_\mu} |\Phi_\mu\rangle^{B_{\text{in}} B_{\text{rad}}},$$  \hspace{1cm} (202)$$

where $\{\chi_\mu\}$ is the aforementioned probability distribution, and $|\Phi_\mu\rangle^{B_{\text{in}} B_{\text{rad}}}$ is the maximally entangled state in $H_{\mu}^{B_{\text{in}}} \otimes H_{\mu}^{B_{\text{rad}}}$. For those $\xi$, the state $\Gamma^{S^* ER}$ can be explicitly written down as

$$\Gamma^{S^* ER} = \sum_{n=0}^{\ell} \sum_{\mu=0}^{N} p_{n, \mu} S^{\prime}_{\text{in}} \otimes \pi_n \otimes \Psi_{n, \mu}^{S^{\prime}_{\text{in}} ER},$$  \hspace{1cm} (203)$$

where $p_{n, \mu}$ and the normalized pure state $\Psi_{n, \mu}^{S^{\prime}_{\text{in}} ER}$ are given by, respectively,

$$p_{n, \mu} = \frac{\chi_\mu(\ell)}{2} \sum_{m=0}^{N+k} \frac{\binom{N+k}{m} \binom{k}{m-\mu}}{\binom{N+k}{m}},$$  \hspace{1cm} (204)$$

$$|\Psi_{n, \mu}^{S^{\prime}_{\text{in}} ER}\rangle = \sqrt{\frac{2^{N+2k-\ell}}{L_{n, \mu}}} \frac{1}{\sqrt{\binom{N+k}{m}}} (\Pi_{m-n}^{S^{\prime}_{\text{in}}} |\Phi\rangle^{S^{\prime}_{\text{in}} E}) \otimes (\Pi_{m-\mu}^{A} |\Phi\rangle^{A_{\text{rad}}}),$$  \hspace{1cm} (205)$$

and $L_{n, \mu} = \sum_{m=0}^{N+k} \binom{N+k}{m-n} \binom{k}{m-\mu} / \binom{N+k}{m}$. Note that $\sum_{\mu} p_{n, \mu} = p_n$ with $p_n$ being the one given in Proposition 4.

Similarly to the previous section, using Propositions 1 and 2, lower and upper bounds on $H_{\text{min}}(S^* | ER)_\Gamma$ are obtained as

$$k - \log \left[ \gamma' (N, k, \ell) \right] \leq H_{\text{min}}(S^* | ER)_\Gamma \leq k - \max_{n \in [0, \ell], \mu \in [0, N]} \left\{ \log \left[ \gamma'_{n, \mu} (N, k, \ell) \right] + \log \left[ \frac{\chi_\mu}{\binom{N}{\mu}} \right] \right\},$$  \hspace{1cm} (206)$$

where

$$\gamma'_{n, \mu} (N, k, \ell) := \left( \sum_{m=0}^{N+k} \frac{1}{\binom{N+k}{m}} \binom{N+k-\ell}{m-n} \binom{k}{m-\mu} \right)^2,$$  \hspace{1cm} (207)$$

$$\gamma' (N, k, \ell) := \sum_{n=0}^{\ell} \sum_{\mu=0}^{N} \frac{\chi_\mu}{\binom{N}{\mu}} \gamma'_{n, \mu}.$$  \hspace{1cm} (208)$$
FIG. 15: Numerical evaluations of the lower bound in Inequalities (206), on the conditional min-entropy $H_{\min}(S^*|{ER})$ for entangled state $|\xi(L,\delta L)\rangle^{B_{in}B_{rad}}$ with a specific form given by Equation (202). The average Z-axis AM is $L$ and its standard deviation is $\delta L$. The size $N$ of the initial BH $B_{in}$ is set to 300, and the size $k$ of the quantum information source $A$ to 5. Figure (i) is for $L = 0$, and (ii) for $|L| = N/4$. In each figure, the standard deviation $\delta L$ is chosen to be 0 (black), $0.1\sqrt{N}$ (red), $0.5\sqrt{N}$ (blue), $0.9\sqrt{N}$ (green), and $0.3N$ (brown). The inset shows the difference between the upper bound and the lower bound in Inequalities (206), showing that they nearly coincide.

In Figure 15, we plot these bounds when $\{\chi_n\}$ is the normalized Gaussian distribution over $n$ with mean $L + N/2$ and standard deviation $\delta L$, which is the same choice as that in Subsection XI A. We particularly plotted the lower bound for $L = 0$ (Figure 15 (i)) and $|L| = N/4$ (Figure 15 (ii)), where $N = 300$ and $k = 5$. In each case, $\delta L$ is chosen to be $0, 0.1\sqrt{N}, 0.5\sqrt{N}, 0.9\sqrt{N}$, and $0.3N$. The difference between the lower and the upper bounds is given in the inset of each figure. We again observe that the bounds nearly coincide, implying that the bounds are almost tight.

For $\epsilon > 0$, $\tilde{\Gamma}^{S^*ER}(\epsilon)$ is given by

$$\tilde{\Gamma}^{S^*ER}(\epsilon) = \sum_{n \in I} \sum_{\nu = 0}^{N} p_{n,\nu}^{\rho_{n}^{S^*}} \otimes \pi_{\nu}^{B_{in}} \otimes \tilde{\Psi}_{n,\nu}^{S_{in}^{\rho}}{ER},$$

for which a lower bound of the conditional min-entropy is similarly given by $H_{\min}(S^*|{ER})_{\tilde{\Gamma}(\epsilon)} \geq k - \log[\gamma_{\text{mixed}}(N, k; \ell|\xi)],$ where

$$\gamma_{\text{mixed}}(N, k; \ell|\xi) = \sum_{n \in I} \sum_{\nu = 0}^{N} \chi_{\nu}(L, \delta L) \left( \sum_{m=0}^{N+k} \frac{1}{\binom{N+k}{m}} \binom{N+k-\ell}{m-n} \right) \left( \frac{k}{m-\nu} \right)^2.$$  

Using this lower bound, we obtain

$$\Theta_\xi(N, k, \ell) \leq \min_{\epsilon \geq 0} \left\{ 2^{-k/2} \sqrt{\gamma_{\text{mixed}}(N, k; \ell|\xi) + w(\epsilon)} \right\},$$

by which we can numerically evaluate $\Theta_\xi(N, k, \ell).$
C. Methods for numerics

To obtain Figures 7 and 8, we have numerically evaluated the R.H.S. of Inequality (201) and Inequality (211), respectively.

Let us denote by $\Theta_\xi(\epsilon)$ the quantity to be minimized over $\epsilon$, i.e. $\Theta_\xi = \min_{\epsilon > 0} \Theta_\xi(\epsilon)$. In the numerical calculations, we have first checked for randomly chosen $(L, \delta L)$ that the value of $\Theta_\xi(\epsilon)$ smoothly changes when $\epsilon$ is varied. We have also checked that $\Theta_\xi(\epsilon)$ is likely to have one minimum. We then computed $\Theta_\xi(\epsilon)$ for a discrete parameter set $E_0 = \{10^{-x}y : x = 1, \ldots, 9, y = 1, \ldots, 9\}$ and take the minimum value to find $\Theta_\xi$. For $(L, \delta L) = (3N/8, 0.9\sqrt{N})$, $(0, 0.3N)$, $(N/8, 0.3N)$, $(N/4, 0.3N)$, and $(3N/8, 0.3N)$, the $\min_{\epsilon \in E_0} \Theta_\xi(\epsilon)$ turns out not to monotonically decrease as $\ell$ increases, which indicates that the minimization over the parameter set $E_0$ is not sufficient. In these cases, we have computed $\Theta_\xi(\epsilon)$ two more digits around the minimum over $E_0$.

XII. HEURISTIC ANALYSIS OF THE INFORMATION LEAKAGE FROM THE KERR BH

In this Section, we provide derivations of the delay $\delta \ell_{\lambda}(L, \delta L)$ of information leakage in Subsection XII A, and the information remnant in Subsection XII B.

A. Delay of information leakage

Here, we show Equation (103) from the modified cramping condition that $C(n) > k$, where $n \in [0, \ell]$ represents the number of up-spins in $S_{rad}$, and the degree of cramping is defined as

$$C(n) := H(B_{in})_\xi + \log \left[ \frac{\dim H_{n}^{S_{rad}}} {\dim H_{L/h+(N+k)/2-n}^{S_{in}}} \right].$$

(212)

Note that $L/h + (N + k)/2$ is the number of up-spins in $S = AB_{in}$. We require that this modified cramping condition holds for non-extreme values of $n$. In the following, we consider the case where the initial Kerr BH $B_{in}$ has a fixed Z-axis AM $L = h\lambda N$ with $\lambda \in [0, 1/2]$. Note that it suffices to consider $\lambda \in [0, 1/2]$ since the rotation direction does not change the features of information leakage. Indeed, our final result will be expressed for $\lambda \in [-1/2, 1/2]$.

We then define $\ell_{\xi}(L)$ by the minimum $\ell$ for which the modified cramping condition hold for all $n$ with $|\delta n| \leq c\sqrt{\langle \delta n^2 \rangle}$, where $\delta n := n - \langle n \rangle$, $\langle \cdot \rangle$ is the average over the distribution over the number of up-spins in $S_{rad}$, which is induced by the evaporation process, and $c$ is a parameter of $O(1)$. Our goal is to show Equation (103), which is

$$\ell_{\xi}(L) \approx \ell_0(L) + c\ell_{fl}(L),$$

(213)

where

$$\ell_0(L) = -\frac{C_{ini}}{2s(\lambda)} + \frac{k}{2s(\lambda)},$$

(214)

$$\ell_{fl}(L) = \frac{|s(\lambda)|}{s(\lambda)} \sqrt{\frac{\ell_0(L)}{s''(\lambda)} \left( 1 - \frac{\ell_0(L)}{N + k} \right)}.$$  

(215)

Here, $\lambda := |L|/N$ is the Z-axis AM ratio in $B_{in}$, $C_{ini} \approx H(B_{in})_\xi - (N + k)s(\lambda) < 0$ is the initial degree of cramping, i.e. the degree of cramping when no radiation is emitted ($\ell = 0$), $s(\lambda) :=
where the second line follows from the assumption that $|1/W_n|$. We now expand $s$ and these are well-approximated by a function $(\cdot)$, the weight of the state on $S$ such as $2C$. Thus, in terms of the initial degree of cramping, $C_{\text{ini}} \approx H(B_{\text{ini}}) - (N + k)s(\lambda)$, and we obtain

$$
W^{S_{\text{rad}}}(n) = \left(\frac{\ell}{n}\right) \left(\frac{N + k - \ell}{L/h + (N + k)/2 - n}\right).
$$

This can be approximated by $s(\lambda)$ as well. Rewriting $n$ as $n = (\lambda + 1/2)\ell + x$, we obtain

$$
\log[W^{S_{\text{rad}}}(n)] \approx \ell s(\lambda + \frac{x}{\ell}) + (N + k - \ell)s(\lambda - \frac{x}{N + k - \ell}) - (N + k)s(\lambda),
$$

and

$$
\approx \frac{1}{2} \left(\frac{N + k}{\ell(N + k - \ell)} s''(\lambda)\right) x^2 + O(x^3).
$$

Combining this with the fact that $W^{S_{\text{rad}}}(n)$ can be also approximated by a Gaussian distribution when $1 \ll k \ll N$, the variance $\langle\delta n^2\rangle$ is approximately given by

$$
\langle\delta n^2\rangle \approx \left(1 - \frac{\ell}{N + k}\right) \frac{\ell}{s''(\lambda)}.
$$

Thus, in terms of the initial degree of cramping, $C_{\text{ini}} \approx H(B_{\text{ini}}) - (N + k)s(\lambda)$, we obtain

$$
C_{\text{ini}} + 2\tilde{c}(L)s(\lambda) + 2cs'(\lambda) \sqrt{\left(1 - \frac{\tilde{c}(L)}{N + k}\right) \frac{\tilde{c}(L)}{s''(\lambda)}} = k.
$$

In the following, we denote $\tilde{c}(L)$ by $\tilde{c}$ for short. This can be simplified by introducing $\ell_0$ as $(k - C_{\text{ini}})/(2s(\lambda))$ such that

$$
\tilde{c} = \ell_0 - \frac{s'(\lambda)}{s(\lambda)} \sqrt{-\left(1 - \frac{\tilde{c}(L)}{N + k}\right) \frac{\tilde{c}(L)}{s''(\lambda)}}.
$$
Since we have assumed \(1 \ll k \ll N\), it is straightforward to obtain
\[
\ell_c \approx \ell_0 - \frac{s'(\lambda)}{s(\lambda)} \sqrt{\left(1 - \frac{\ell_0}{N + k}\right) \frac{\ell_0}{s''(\lambda)}}.
\] (227)

Finally, since both \(s'(\lambda)\) and \(s''(\lambda)\) are non-positive, we obtain
\[
\ell_c \approx \ell_0 + \frac{|s'(\lambda)|}{s(\lambda)} \sqrt{\left(1 - \frac{\ell_0}{N + k}\right) \frac{\ell_0}{|s''(\lambda)|}}
\] (228)
\[
= \ell_0(L) + \ell_{\text{fl}}(L),
\] (229)
which is valid for \(\lambda \in [-1/2, 1/2]\).

### B. Information remnant \(\eta_{\xi}\)

We here show Inequality (112). To this end, we consider the situation where the Z-axis AM of the reference \(R\) and the remaining BH \(S_{\text{in}}\) are separately measured. Denoting by \(P(\nu|\kappa)\) be the probability distribution of the outcome \(\nu\) in \(S_{\text{in}}\) given that the outcome in \(R\) is \(\kappa\), the \(\eta_{\xi}\) should satisfy
\[
\eta_{\xi} \geq \sum_{\kappa} q(\kappa) \sum_{\nu} \left| P(\nu|\kappa) - P(\nu) \right|,
\] (230)
where \(q(\kappa)\) is the probability to obtain the outcome \(\kappa\) in \(R\), and \(P(\nu) = \sum_{\kappa} q(\kappa) P(\nu|\kappa)\) is the probability to obtain \(\nu\) in \(S_{\text{in}}\). Each probability is given in terms of the state \(\Psi_{S_{\text{in}}, R}\). Denoting by \(\Pi_{\nu}^{S_{\text{in}}}\) and \(\Pi_{\kappa}^{R}\) the projection onto the subspace of \(\mathcal{H}_{S_{\text{in}}}\) with the AM \(\nu\) and that onto the subspace of \(\mathcal{H}_R\) with the AM \(\kappa\), respectively, the probabilities are given by
\[
q(\kappa) = \text{Tr}[\Pi_{\kappa}^R \Psi_{\kappa}],
\] (231)
\[
P(\nu|\kappa) = \text{Tr}[\Pi_{\nu}^{S_{\text{in}}} \Psi_{\kappa}], \quad \text{where } \Psi_{\kappa}^{S_{\text{in}}} = \text{Tr}_R[\Pi_{\kappa}^R \Psi_{S_{\text{in}}, R}] / q(\kappa),
\] (232)
\[
P(\nu) = \text{Tr}[\Pi_{\nu}^{S_{\text{in}}} \Psi_R] = \sum_{\kappa} q(\kappa) P(\nu|\kappa).
\] (233)

The goal here is to relate \(\eta_{\xi}\) with the degree \(\zeta(S_{\text{in}})\) of symmetry-breaking in \(S_{\text{in}}\), which is defined by
\[
\zeta(S_{\text{in}}) := \left. \frac{\partial^2}{\partial \theta^2} B_{\theta}(\Psi) \right|_{\theta=0},
\] (234)
where \(B_{\theta}(\Psi) := 1 - |\langle \Psi | e^{i\theta L_Z} \otimes I | \Psi \rangle|^2\), \(|\Psi \rangle^{S_{\text{in}}}_{\nu, \kappa}\) is a purification of \(\Psi_{S_{\text{in}}}\) by \(\nu, \kappa\), and \(L_Z\) is the Z-axis AM operator in \(S_{\text{in}}\) and the second identity acts on \(S_{\text{in}}'\).

We now assume that we may approximate the value of \(\nu\) by continuous values, allowing us to replace the above probabilities with probability density functions \(p(\nu|\kappa), p(\nu), \) and \(\bar{p}(\nu - \alpha \delta \kappa)\). We also assume that the \(\kappa\)-dependence of \(p(\nu|\kappa)\) is approximated by a shift without changing its common shape. Namely, we assume that
\[
\text{Tr}[\Pi_{\nu}^{S_{\text{in}}} \Psi_{\kappa}^{S_{\text{in}}}] \approx \text{Tr}[\Pi_{\nu - \alpha \delta \kappa}^{S_{\text{in}}} \Psi_{\kappa}^{S_{\text{in}}}]
\] (235)
with \(\alpha = 1 - \ell/(N + k)\), where \(\delta \kappa = \kappa - \langle \kappa \rangle\) and \(\langle \cdot \rangle\) is the expectation over the probability distribution \(q(\kappa)\). Note that the rescaling by \(\alpha\) is needed since \(S\) is composed of \(N + k\) qubits.
while $S_{\text{in}}$ is of $N + k - \ell$ qubits. Denoting $\text{Tr}[\Pi_{\mu}^{S_{\text{in}}} \Psi_{\nu}^{S_{\text{in}}}]$ by $\bar{p}(\mu) = p(\mu | \kappa = \langle \kappa \rangle)$, it follows that $p(\nu | \kappa) \approx \bar{p}(\nu - \alpha \delta \kappa)$.

We then assume that $|\delta \kappa|$ is sufficiently small so that $\bar{p}(\nu - \alpha \delta \kappa) = \bar{p}(\nu) - \alpha \delta \kappa \bar{p}'(\nu) + O(\delta \kappa^2)$, which further implies that $p(\nu) = \bar{p}(\nu) + O(\delta \kappa^2)$. Using these and replacing the summation over $\nu$ in Inequality (230) by the integral, we obtain

$$\eta_{\xi} \geq \alpha \sum_{\kappa} q(\kappa) |\delta \kappa| \int d\nu \left| \frac{\partial \bar{p}(\nu)}{\partial \nu} \right| + O(\delta \kappa^2),$$

where $\langle |\delta \kappa| \rangle := \sum_{\kappa} q(\kappa) |\delta \kappa|$ is the mean absolute deviation of the $Z$-axis AM in $R$. The integral in Equation (237) can be bounded from below by $2 \max_{\nu} p(\nu)$. Thus, we have

$$\eta_{\xi} \geq 2 \langle |\delta \kappa| \rangle \alpha \max_{\nu} p(\nu) + O(\delta \kappa^2).$$

The $\max_{\nu} p(\nu)$ can be further bounded from below in terms of the variance $\langle \delta \nu^2 \rangle$ of the $Z$-axis AM in $S_{\text{in}}$, i.e. $\langle \delta \nu^2 \rangle := \langle \nu^2 \rangle - \langle \nu \rangle^2 = \text{Tr}[L_Z^2 \Psi] - (\text{Tr}[L_Z \Psi])^2$. This follows from the fact that the probability distribution that has the least standard deviation under the condition that the maximum probability is given is the rectangle function $r(x) = r_{\max}$ for $x \in [-1/2r_{\max}, 1/2r_{\max}]$ and 0 otherwise. In that case, the variance $V$ is

$$V = \int_{-1/2r_{\max}}^{1/2r_{\max}} x^2 r_{\max} dx = \frac{1}{12} r_{\max}^{-2}.$$  \hspace{1cm} (239)

This implies that, for any probability density function $p(x)$, $\max_{\nu} p(x) \geq (2\sqrt{3}/\sqrt{V})^{-1}$. Thus, we arrive at

$$\eta_{\xi} \geq \frac{1}{\sqrt{3}} \langle |\delta \kappa| \rangle \left( 1 - \frac{\ell}{N + k} \right) \frac{1}{\sqrt{\langle \delta \nu^2 \rangle}} + O(\delta \kappa^2).$$

We now relate the variance $\langle \delta \nu^2 \rangle$ of the $Z$-axis AM in $S_{\text{in}}$ to the degree of symmetry-breaking $\zeta(S_{\text{in}})$. It is straightforward to explicitly write down $B_{\theta}(\Psi)$ since $|\langle \Psi | e^{i\theta L_Z} \otimes I | \Psi \rangle|^2$ is given by

$$|\langle \Psi | e^{i\theta L_Z} \otimes I | \Psi \rangle|^2 = |\text{Tr}[e^{i\theta L_Z} \Psi]|^2$$

$$= |1 + i\theta \text{Tr}[L_Z \Psi] - \frac{\theta^2}{2} \text{Tr}[L_Z^2 \Psi]|^2 + O(\theta^3)$$

$$= 1 + \theta^2 \left( (\text{Tr}[L_Z \Psi])^2 - \text{Tr}[L_Z^2 \Psi] \right) + O(\theta^3)$$

$$= 1 - \theta^2 \langle \delta \nu^2 \rangle + O(\theta^3).$$

Thus, we have $\zeta(S_{\text{in}}) = 2 \langle \delta \nu^2 \rangle$ and so, it follows that

$$\eta_{\xi} \geq \frac{1}{\sqrt{3}} \langle |\delta \kappa| \rangle \left( 1 - \frac{\ell}{N + k} \right) \frac{1}{\sqrt{\zeta(S_{\text{in}})}} + O(\delta \kappa^2).$$

---

[34] A. Jamiołkowski. Linear transformations which preserve trace and positive semidefiniteness of oper-
Appendix A: Proof of Proposition 2

We here prove Proposition 2. The statement to be shown is the following: let \( \{\mathcal{H}_j^A\} \) be mutually orthogonal subspaces of \( \mathcal{H}^A \), and \( \pi_j^A \) be the completely mixed state on \( \mathcal{H}_j^A \). For a state \( \Lambda^{ABC} = \sum_{j=0}^J p_j \pi_j^A \otimes \rho_j^{BC} \), where \( \rho_j^{BC} \in \mathcal{S}(\mathcal{H}^{BC}) \) and \( \{p_j\} \) is a probability distribution,

\[
-\log \left[ \sum_{j=0}^J \frac{p_j}{d_j} 2^{-H_{\min}(B|C)_{\rho_j}} \right] \leq H_{\min}(AB|C)_\Lambda \leq \min_{j \in [0,J]} \left\{ H_{\min}(B|C)_{\rho_j} - \log \frac{p_j}{d_j} \right\},
\]

where \( d_j = \text{dim} \mathcal{H}_j^A \).

Proof. By definition of the conditional min-entropy, \( \forall j \in [0,J], \exists \sigma_j^C \in \mathcal{S}(\mathcal{H}^C) \) such that
\[ 2^{-H_{\min}(B|C)_{\rho_j}} I^B \otimes \sigma_j^C \geq \rho_j^{BC}, \text{ from which it follows that} \]
\[ I^{AB} \otimes (2^{-H_{\min}(B|C)_{\rho_j}} \sigma_j^C) \geq \Pi_j^A \otimes \rho_j^{BC}. \tag{A2} \]
Since this holds for all \( j \in [1, J] \), we obtain
\[ \text{Tr}[\tilde{\sigma}^C] I^{AB} \otimes \tilde{\sigma}^C \geq \Lambda^{ABC}, \tag{A3} \]
where \( \tilde{\sigma}^C := \sum_j p_j / d_j 2^{-H_{\min}(B|C)_{\rho_j}} \sigma_j^C \) is an un-normalized state. This implies that
\[ -\log \left[ \sum_j p_j 2^{-H_{\min}(B|C)_{\rho_j}} \right] \leq H_{\min}(AB|C)_{\Lambda}. \tag{A4} \]

To obtain an upper bound, we start with the fact that there exists \( \sigma^C \) such that
\[ 2^{-H_{\min}(AB|C)_{\Lambda}} I^{AB} \otimes \sigma^C \geq \Lambda^{ABC} = \sum_j p_j \tau_j^A \otimes \rho_j^{BC}. \]
By applying the projection \( \Pi_j^A \) onto the both side, it implies that
\[ \forall j, 2^{-H_{\min}(AB|C)_{\Lambda}} I^B \otimes \sigma^C \geq \rho_j^{BC} \tag{A5} \]
\[ \iff \forall j, H_{\min}(B|C)_{\rho_j} \geq H_{\min}(AB|C)_{\Lambda} - \log \left[ \frac{p_j}{d_j} \right]. \tag{A6} \]

The desired upper bound is immediately obtained from this.

\[ \square \]

**Appendix B: Proof of Corollary 8**

To show Corollary 8, we use the gentle measurement lemma:

**Lemma 14** (Gentle measurement lemma [55]). Let \( \Phi \) be in \( \mathcal{S}(\mathcal{H}) \) and \( \Lambda \) be an Hermitian operator such that \( 0 \leq \Lambda \leq I \). If they satisfy \( \text{Tr}[\Lambda \Phi] \geq 1 - \epsilon \), where \( 0 \leq \epsilon \leq 1 \), then \( |\Phi - \Phi'|_1 \leq 2\sqrt{\epsilon} \), where
\[ \Phi' = \frac{\sqrt{\Lambda} \Phi \sqrt{\Lambda}}{\text{Tr}[\Lambda \Phi]}. \tag{B1} \]

We also use a simple fact about the conditional min-entropy.

**Lemma 15** (Conditional min-entropy after projective measurement). Let \( \Pi^A \) be a projection operator, \( \Phi^{AB} \) be a quantum state. A post-measured state \( \tilde{\Phi}^{AB} := \Pi^A \Phi^{AB} \Pi^A / \text{Tr}[\Pi^A \Phi^{AB}] \) satisfies \( H_{\min}(A|B)_\Phi \geq H_{\min}(A|B)_{\tilde{\Phi}} + \log[\text{Tr}[\Pi^A \Phi^{AB}]]. \)

**Proof** (Lemma 15). Let \( \sigma^B \in \mathcal{S}(\mathcal{H}^B) \) be the state such that \( 2^{-H_{\min}(A|B)_{\Phi}} I^A \otimes \sigma^B \geq \Phi^{AB} \). Then, we have
\[ 2^{-(H_{\min}(A|B)_{\Phi} + \log[\text{Tr}[\Pi^A \Phi^{AB}])]} I^A \otimes \sigma^B \geq \tilde{\Phi}^{AB}, \tag{B2} \]
which implies the desired result. \[ \square \]

Using these lemmas, Corollary 8 can be shown as follows.
Proof (Corollary \[8\]). We first define the state $\tilde{\Psi}^{SR}$ by
\begin{equation}
\tilde{\Psi}^{SR} := \frac{\Pi^S_{\geq} \Psi^{SR} \Pi^S_{\geq}}{\text{Tr}[\Pi^S_{\geq} \Psi^{SR} \Pi^S_{\geq}]},
\end{equation}
(B3)
W also use the fact that $\Gamma^{ER} := \text{Tr}_{S^*}[\Gamma^{S^*ER}] = E_{US^*H_x}[C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T)]$. Using the triangle inequality, we obtain
\begin{equation}
\|C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T) - E_{US^*H_x}[C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T)]\|_1 \\
\leq \|C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T) - US^T\tilde{\Psi}^{SR}US^T\|_1 + \|C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T) - E_{US^*H_x}[C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T)]\|_1
\end{equation}
(B4)
In the following, we evaluate each term in the right-hand side of Inequality (B4) separately.

For the first term, noting that $C^{S^*E}$ is a trace-non-increasing map, and the trace norm is unitarily invariant, we have
\begin{equation}
\|C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T) - US^T\tilde{\Psi}^{SR}US^T\|_1 \leq \|\Psi^{SR} - \tilde{\Psi}^{SR}\|_1 \leq 2\sqrt{\epsilon},
\end{equation}
(B5)
where the last inequality follows from the gentle measurement lemma and the assumption that $\text{Tr}[\Psi^{SR} \Pi^S_{\geq}] \geq 1 - \epsilon$.

To evaluate the second term, we use Theorem \[7\]. Recalling that $\tilde{\Psi}^S$ does not have support on the subspace $H_j^S$ with dimension being smaller than $d_{th}$, it follows that, for any $\delta > 0$,
\begin{equation}
\|C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T) - E_{US^*H_x}[C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T)]\|_1 \leq 2^{-\frac{1}{2}H_{\min}(S^*|ER)} + \delta
\end{equation}
(B6)
with probability at least $1 - \exp[-\frac{\delta^2 d_{th}}{48\|\Psi\|_\infty}]$. Here, $\tilde{\Gamma}^{S^*ER} = \sum_{j,j' \in J} \frac{D_j}{\sqrt{d_j d_{j'}}} \tilde{\Psi}^{SE}_{jj'} \otimes \tilde{\Psi}^{SR}_{jj'}$. Since $\Pi^S_\geq$ is commutable with $\Pi^S_j$ for any $j$,
\begin{equation}
\tilde{\Gamma}^{S^*ER} = \frac{(I^S \otimes \Pi^S_{\geq}) \Gamma^{S^*ER} (I^S \otimes \Pi^S_{\geq})}{\text{Tr}[(I^S \otimes \Pi^S_{\geq}) \Gamma^{S^*ER}]}.
\end{equation}
(B7)
Using Lemma \[5\] we have
\begin{equation}
H_{\min}(S^*|ER)_\Gamma \geq H_{\min}(S^*|ER)_\Gamma + \log \left[\text{Tr}[\Pi^S_{\geq} \Gamma^{S^*ER}]\right]
\end{equation}
(B8)
\begin{equation}
= H_{\min}(S^*|ER)_\Gamma + \log \left[\text{Tr}[\Pi^S \Psi^{SR}]\right]
\end{equation}
(B9)
\begin{equation}
\geq H_{\min}(S^*|ER)_\Gamma + \log[1 - \epsilon],
\end{equation}
(B10)
where the second line is obtained since $\frac{D_j}{\sqrt{d_j d_{j'}}} \text{Tr}[\zeta^{SE}_{jj'}] = \delta_{jj'}$. Furthermore, it holds that
\begin{equation}
\|\Psi^S\|_\infty \leq \min\{1, \frac{\|\Pi^S\|_\infty \|\Psi^S\|_\infty}{\text{Tr}[\Pi^S \Psi^S]}\} \leq \min\{1, \frac{\|\Psi^S\|_\infty}{1 - \epsilon}\} =: C,
\end{equation}
(B11)
where we have used the sub-multiplicativity of the operator norm, and the assumption that $\text{Tr}[\Psi^{SR} \Pi^S_{\geq}] \geq 1 - \epsilon$. Combining all of these together, the second term is bounded as
\begin{equation}
\|C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T) - E_{US^*H_x}[C^{S^*E}(US^T\tilde{\Psi}^{SR}US^T)]\|_1 \leq \frac{2^{-\frac{1}{2}H_{\min}(S^*|ER)} + \delta}{\sqrt{1 - \epsilon}}
\end{equation}
(B12)
for any $\delta > 0$ with probability at least $1 - \exp[-\frac{\delta^2 d_{th}}{48C}]$. 

To evaluate the third term of Inequality (B4), we use the explicit form of the averaged operator

$$\mathbb{E}_{U^S \sim \mathcal{H}_x} \left[ C^{S \to E} \left( U^S \Psi^{SR} U^S \dagger \right) \right] = \sum_{j \notin J_2} \frac{D_S}{d_j} \zeta_{jj}^E \otimes \Psi_{jj}^R. \quad (B13)$$

Further, using the relation $\Pi_{\geq}^S = \sum_{j \in J_2} \Pi_j^S$, we obtain

$$\left\| \mathbb{E}_{U^S \sim \mathcal{H}_x} \left[ C^{S \to E} \left( U^S \tilde{\Psi}_{SR} U^S \dagger \right) \right] - \mathbb{E}_{U^S \sim \mathcal{H}_x} \left[ C^{S \to E} \left( U^S \Psi_{SR} U^S \dagger \right) \right] \right\|_1 \quad (B14)$$

$$= \left\| \sum_{j \in J_2} \frac{D_S}{d_j} \zeta_{jj}^E \otimes (\tilde{\Psi}_{jj}^R - \Psi_{jj}^R) \right\|_1 \quad (B15)$$

$$\leq \sum_{j \notin J_2} \left\| \frac{D_S}{d_j} \zeta_{jj}^E \otimes \Psi_{jj}^R \right\|_1 + \sum_{j \in J_2} \left\| \frac{D_S}{d_j} \zeta_{jj}^E \otimes (\tilde{\Psi}_{jj}^R - \Psi_{jj}^R) \right\|_1. \quad (B16)$$

Recalling that $\text{Tr}[\frac{D_S}{d_j} \zeta_{jj}^E] \leq 1$ and that $\tilde{\Psi}_{jj}^R = \Psi_{jj}^R / \text{Tr}[\Pi_{\geq}^S \Psi_{SR}]$ for $j \in J_2$, the first term of Inequality (B16) is bounded from above by

$$\sum_{j \notin J_2} \text{Tr}[\Psi_{jj}^R] = \text{Tr}[\Psi_{SR} (I^S - \Pi_{\geq}^S)] \leq \epsilon. \quad (B17)$$

An upper bound of the second term of Inequality (B16) is given by

$$\left| \frac{1}{\text{Tr}[\Pi_{\geq}^S \Psi_{SR}]} - 1 \right| \sum_{j \in J_2} \text{Tr}[\Psi_{jj}^{SR}] \leq \frac{\epsilon}{1 - \epsilon} \sum_{j \in J} \text{Tr}[\Psi_{jj}^{SR}] = \frac{\epsilon}{1 - \epsilon}. \quad (B18)$$

Combining the upper bounds of all three terms in Inequality (B4), we obtain the desired result:

$$\left\| C^{S \to E} \left( U^S \Psi^{SR} U^S \dagger \right) - \mathbb{E}_{U^S \sim \mathcal{H}_x} \left[ C^{S \to E} \left( U^S \Psi^{SR} U^S \dagger \right) \right] \right\|_1 \leq \frac{2 - \frac{1}{2} H_{\text{min}} (S^* | E R)_R}{\sqrt{1 - \epsilon}} + \delta + f(\epsilon), \quad (B19)$$

with probability at least $1 - \exp[-\frac{\epsilon^2 d_{45}}{48C}]$, where $f(\epsilon) = 2 \sqrt{\epsilon} + \epsilon + \frac{\epsilon}{1 - \epsilon}$. ■
