

Project selection with partially verifiable information *

Sumit Goel [†] Wade Hann-Caruthers [‡]

Abstract

We consider a problem where the principal chooses a project from a set of available projects for the agent to work on. Each project provides some profit to the principal and some payoff to the agent and these profits and payoffs are the agent's private information. The principal has a belief over these values and his problem is to find an incentive compatible mechanism without using transfers that maximizes expected profit. Importantly, we assume partial verifiability so that the agent cannot report a project to be more profitable to the principal than it actually is. In this setup, we find a neat characterization of the set of incentive compatible mechanisms. Using this characterization, we find the optimal mechanism for the principal when there are two projects. Within a subclass of incentive compatible mechanisms, we show that a single cutoff mechanism is optimal and conjecture that it is the optimal incentive compatible mechanism.

1 Introduction

There exist many situations in which a principal, who has to make a decision, relies on the information reported by an agent about the true state of the world. Since their preferences might be misaligned, the agent has to be incentivized to truthfully reveal his private information. These incentive constraints depend on the agent's set of feasible messages which has typically been assumed to be fixed and independent of the true state of the world. This is a valid assumption if the agent can always manipulate information without incurring any cost or penalties. However, the agent's ability to manipulate may be limited due to various physical and mental costs associated with lying or due to existence of some form of evidence which the agent is required to furnish. The existence of such environments where manipulation is costly motivates the literature on mechanism design with partially verifiable information.

The assumption of partial verifiability can take different forms depending upon the environment. In this paper, we focus on settings where the agent cannot oversell an alternative to the principal. In particular, we consider a problem where the principal has to choose a project from N different projects but does not know how profitable each is. The agent gets an independent payoff from working on the chosen project and is aware of both the principal's profit and his own payoff from each of the N projects. Thus, the principal needs to incentivize the agent to reveal this private information. The idea of no-overselling is formalized by assuming that the agent cannot report a project to be more profitable for the principal than it actually is. With this partial verifiability constraint of no-overselling, we consider the problem of characterizing the set of implementable mechanisms and finding one that maximizes the principal's expected profit.

Since partial verifiability reduces the set of incentive constraints that the

principal faces, the set of implementable mechanisms is potentially larger. Thus, there is reason to believe that with partial verifiability, the principal can obtain a higher expected profit than what is possible in the standard problem with no constraints on the message space. However, previous research suggests that this is not always the case. For instance, Celik [8] considers the problem of regulation of a monopolist in which the monopolist can understate its productivity by hiding equipment but cannot overstate it by disclosing equipment that does not exist. He identifies a sufficient condition under which the solutions to the two problems coincide. Another example is Moore [22], who shows that in an auction environment where the buyer cannot imitate higher valuation types, the solution to the principal’s expected revenue maximization problem remains the same. Thus, even though it seems intuitive that partial verifiability should allow the principal to obtain higher rent, the above results suggest it is not always true. Our objective is to study if the no-overselling constraint in our setup leads to a different solution and higher profits for the principal.

We restrict attention to truthfully implementable direct mechanisms without transfers in our analysis [15]. In these mechanisms, the principal commits to choosing a project based on the profits and payoffs reported by the agent. We obtain a neat characterization of incentive compatible (IC) mechanisms and call them “table mechanisms.” In a table mechanism, the principal commits to choosing the agent’s favorite project among those that satisfy a criterion. The set of projects satisfying the criterion (those that are “on the table”) is increasing in the reported profit values and always includes a default project. Next, we show that the optimal IC mechanism for two projects is a cutoff mechanism. In the class of cutoff mechanisms, we show that a single cutoff mechanism defined by a parameter c is optimal. In this mechanism, a project is on the table if and only if its reported profit meets the cutoff profit c . This cutoff mechanism is different from the optimal incentive

compatible mechanism in the standard problem and leads to higher profits for the principal. Indeed, without partial verifiability, the best the principal can do is select a project without soliciting any information from the agent. Thus, in contrast to the results mentioned above, there is a significant gain for the principal from the partial verifiability constraint of no-overselling in this setup.

1.1 Literature review

Mechanism design has often been used to deal with problems of asymmetric information [24], [25]. An important theme in the literature on mechanism design is characterizing the set of implementable mechanisms [14], [27], [9], [15]. In particular, Green and Laffont [15] introduce the idea of partially verifiable information in mechanism design and identify a necessary and sufficient condition, called the “Nested Range Condition”, under which the set of implementable mechanisms coincides with the set of truthfully implementable mechanisms (i.e. the revelation principle holds). Later research focuses on identifying implementability conditions in other environments with partially verifiable information; [18] looks at Nash implementation, [10] considers lying with finite costs, [4] and [30] allow for transfers, and [7] considers probabilistic verification. Some computer scientists have looked at the trade-off between monetary transfers and partial verifiability in terms of implementing social choice functions [12], [13]. Our setup belongs to the environment considered by Green and Laffont and satisfies their “Nested Range Condition”. Thus, without loss of generality, we restrict attention to truthfully implementable mechanisms in our analysis.

Some applied papers in this literature find optimal or efficient mechanisms in environments with a specific form of partial verifiability ([21], [20], [22], [8]). For instance, [23] argues using a model in which only some expenditure

can be hidden that spouses hiding income and assets from one another is efficient. [11] explains the complicated selling practices of real-world monopolists by considering an economy where some agents have limited ability to misrepresent their preferences. This paper considers the partial verifiability constraint of no-overselling and potentially explains the use of cutoff mechanisms in settings where evidence is significantly easier to verify than to obtain.

Our work is most closely related to [2], [26] and [1]. [2] and [26] consider a problem where the principal has to choose one of N agents who prefer being chosen and provide some private value to the principal from being chosen. In [2], the principal can verify his value from agent i at a cost c_i , while [26] assumes ex-post verifiability so that the principal can penalize the winner by destroying a certain fraction of the surplus. [1] considers a project delegation problem in which the principal can verify characteristics of the chosen project but is uncertain about the set of available projects. These papers find their respective optimal mechanisms for the principal and call them the favored agent mechanism [2], shortlisting procedure [26], and the threshold rule [1]. While these mechanisms have some flavor of the cutoff mechanisms we obtain in this paper, there are important differences in the setup we consider here. Primarily, in their setups, the principal is empowered by ex-post verifiability of the reported values and the ability to use a prohibitively high punishment to deter the agent from telling *any* lie, whereas in our setup, the agent is constrained in that he cannot oversell, but the principal does not have the power to directly deter the agent from underselling.

The paper proceeds as follows. In section 2, we present the model and definitions. Section 3 contains all the results. In section 4, we discuss some other variants of the model and also compare our results with those from some related papers. Section 5 concludes. The more technical proofs are in the appendix.

2 Model

There are two parties: a principal and an agent. The principal has to choose a single project from the set of available projects $[N] = \{1, 2, \dots, N\}$. Each project $i \in [N]$ leads to values (p_i, a_i) where p_i denotes the profit for the principal and a_i is the payoff to the agent. For all $i \in [N]$, we assume $p_i \sim F$ and $a_i \sim G$ where both F and G have support in $X = [0, 1]$ and that all p_i s and a_i s are independent. While the principal has the correct belief about the project values, the agent actually knows the profit vector $p = (p_1, p_2, \dots, p_N) \in X^N$ and the payoff vector $a = (a_1, a_2, \dots, a_N) \in X^N$ for the N projects.

Given this setup, the principal chooses a mechanism $d : X^N \times X^N \rightarrow [N]$ which maps a profile of reported profits $\pi = (\pi_1, \pi_2, \dots, \pi_N) \in X^N$ and payoffs $\alpha = (\alpha_1, \alpha_2, \dots, \alpha_N) \in X^N$ to a chosen project $i \in [N]$. The agent is constrained so that he cannot report a project to be more profitable for the principal than it actually is. This is the partial verifiability constraint of no overselling. Formally, the agent's message space under any mechanism d is

$$M(p, a) = \{(\pi, \alpha) \in (X^N)^2 : \pi_i \leq p_i \forall i \in [N]\}$$

If (p, a) is the project values and (π, α) is the report, the mechanism d leads to profit $p_{d(\pi, \alpha)}$ for the principal and payoff $a_{d(\pi, \alpha)}$ to the agent.

Definition 1. *A mechanism d is incentive compatible if for any (p, a) and $(\pi, \alpha) \in M(p, a)$*

$$a_{d(p, a)} \geq a_{d(\pi, \alpha)}.$$

In words, d is incentive compatible if for any possible realization of profits

p and payoffs a , it is weakly optimal for the agent to report the true values (among reports available to the agent).

Denote by \mathcal{IC} the set of incentive compatible mechanisms¹. Then the principal’s problem is:

$$\max_{d \in \mathcal{IC}} \mathbb{E}[p_{d(p,a)}].$$

2.1 Definitions

We define a few special classes of mechanisms. The first is table mechanisms.

Definition 2. *A mechanism d is a table mechanism if there exist functions $f_1, f_2, \dots, f_N : X^N \rightarrow \{0, 1\}$ such that*

- *there exists some i such that $f_i(p) = 1$ for all $p \in X^N$,*
- *for $i = 1, \dots, N$, $f_i(p)$ is weakly increasing in p_j for all $j = 1, \dots, N$,*

and such that

- *$d(p, a) \in \operatorname{argmax}_i \{a_i : f_i(p) = 1\}$ for all $(p, a) \in (X^N)^2$.*

Intuitively, one may think of a table mechanism d as follows. The principal commits to choosing the agent’s favorite project among those that satisfy a criterion (those that are “on the table”). There is some default project that is always on the table. Finally, the set of projects on the table is increasing in their profitability for the principal. That is, if the profits of all projects are weakly higher, the set of projects on the table is weakly greater.

For simplicity going forward, we will assume (without loss of generality) that $f_N(p) = 1$ for all $p \in X^N$. That is, in a table mechanism, project N is always on the table.

¹Note that it is without loss of generality to consider incentive compatible mechanisms. This is because our no-overselling constraint satisfies the Nested Range Condition ($\theta \in M(\theta'), \theta' \in M(\theta'') \implies \theta \in M(\theta'')$) which is both necessary and sufficient for the revelation principle to hold [15].

Definition 3. *A mechanism d is a cutoff mechanism if it is a table mechanism and for $i = 1, \dots, N - 1$, there exist cutoffs $c_i \in X$, such that $f_i(p) = 1$ if and only if $p_i \geq c_i$.*

In a cutoff mechanism, a project is on the table if the principal's profit from the project meets a threshold. That is, whether a project is on the table or not depends only on that particular project's profit value. The principal then chooses the agent's favorite project among those that meet the cutoff and the default.

Definition 4. *A mechanism d is a single cutoff mechanism if it is a table mechanism and there is a c such that for $i = 1, \dots, N - 1$, $f_i(p) = 1$ if and only if $p_i \geq c$.*

A single cutoff mechanism is a cutoff mechanism in which all cutoffs are the same.

3 Results

3.1 Preview

First, we characterize the set of incentive compatible mechanisms and show that it is exactly the set of table mechanisms. Next, we show that for two projects, a cutoff mechanism is optimal. Based on this result, we conjecture that a cutoff mechanism is optimal for N projects and consider the problem of finding the optimal cutoff mechanism and show that it is a single cutoff

mechanism whose cutoff is given by²

$$c(N) = 1 - \frac{1}{\sqrt{N}} + o\left(\frac{1}{\sqrt{N}}\right).$$

In particular, we show that the expected profit of the principal tends to 1 as N tends to ∞ .

3.2 Characterization of IC mechanisms

We begin by giving a characterization of the set of incentive compatible mechanisms \mathcal{IC} .

Theorem 1. *d is incentive compatible if and only if it is a table mechanism.*

It is fairly straightforward from the definitions to check that table mechanisms are incentive compatible. Indeed, under a table mechanism, the agent prefers reporting higher π 's to reporting lower ones and, given any report of π 's, prefers reporting her payoffs to misreporting her payoffs (since such a misrepresentation can only lead the principal to make a choice which gives the agent a lower payoff.) The other direction is more involved.

Proof of Theorem 1. Suppose d is a table mechanism. Consider any profile (p, a) . If the agent reports some (π, α) , we know that $\pi \leq p$ from the constraint $(\pi, \alpha) \in M(p, a)$. Since the f_i 's are increasing, this implies that

$$\{i \in [N] : f_i(\pi) = 1\} \subset \{i \in [N] : f_i(p) = 1\}$$

Since the agent gets his preferred project among those available and reporting truthfully maximizes his set of available projects, the agent cannot gain

²Recall that for functions $f(N), g(N)$, $f(N) \in o(g(N))$ if and only if

$$\lim_{N \rightarrow \infty} \frac{f(N)}{g(N)} = 0.$$

by misreporting. Therefore, d is incentive compatible.

Now, suppose that d is an incentive compatible mechanism. Define the functions (f_i) as follows: $f_i(p) = 1$ if and only if there exists some $(p', a') \in (X^N)^2$ with $p' \leq p$ such that $d(p', a') = i$. Now, we want to show that these functions satisfy the properties of the table mechanism. There is some $k \in [N]$ such that the decision at $a = p = (0, 0, 0, \dots)$ is k . Hence, by definition, $f_k(p) = 1$ for all p . Now, consider any j and $p' \geq p$ and suppose $f_j(p) = 1$. This implies that there exists some $(p'', a'') \in (X^N)^2$ with $p'' \leq p$ such that $d(p'', a'') = j$. Since $p'' \leq p \leq p'$, by definition $f_j(p') = 1$, which implies that f is increasing.

Now, consider any profile (p, a) . We want to show that $d(p, a) \in \operatorname{argmax}_i \{a_i : f_i(p) = 1\}$. Suppose towards a contradiction that $d(p, a)$ is not in this set. By definition, $d(p, a) \in \{i : f_i(p) = 1\}$. Thus, there exist $j, k \in \{i : f_i(p) = 1\}$ such that $a_j > a_k$ and $d(p, a) = k$. But then, there exist a' and $p' \leq p$ such that $d(p', a') = j$. Therefore, the agent has a profitable deviation (p', a') , which contradicts the fact that d is incentive compatible. Therefore, it must be that $d(p, a) \in \operatorname{argmax}_i \{a_i : f_i(p) = 1\}$. Thus, d is a table mechanism. \square

3.3 Optimal mechanisms

With this characterization of the incentive compatible mechanisms, we focus on finding the optimal table mechanism. Here and for the remainder of the paper, we will assume that $p_i, a_i \sim U([0, 1])$ for all i .

Theorem 2. *For $N = 2$, the optimal incentive compatible mechanism is a cutoff mechanism.*

Proof. Suppose d is incentive compatible. From Theorem 1, we know that d is a table mechanism. So $f_2(p) = 1$ for all $p \in X^2$. Define $c = \sup\{p_1 : f_1(p_1, p_1) = 0\}$. For any arbitrary $(p_1, p_2) \in X^2$, we show that the cutoff

mechanism d' with $c_1 = c$ is at least as good for the principal as the given mechanism d . Consider the following (exhaustive and mutually exclusive) cases:

- $p_1 \in [0, c), p_2 \in [0, c)$: Under both d and d' , $f_1(p) = 0$ and therefore, the second project is chosen for all such profiles. Thus, the two mechanisms are identical for such profiles.
- $p_1 \in [0, c), p_2 \in [c, 1]$: Under d' , $f_1(p) = 0$ and therefore, project 2 is chosen. Under d , the principal gets either p_2 or $\frac{p_1+p_2}{2}$ which are both at most p_2 . Thus, $p_{d'} \geq p_d$ for these profiles.
- $p_1 \in [c, 1], p_2 \in [0, c)$: Under d' , $f_1(p) = 1$ and since project 2 is always available, the principal gets p_1 with probability $\frac{1}{2}$ and p_2 with probability $\frac{1}{2}$. Under d , the principal gets either p_2 or $\frac{p_1+p_2}{2}$ which are both at most $\frac{p_1+p_2}{2}$. Thus, $p_{d'} \geq p_d$ for these profiles.
- $p_1 \in [c, 1], p_2 \in [c, 1]$: Under both d and d' , $f_1(p) = 1$ and therefore, the same project is chosen for all such profiles. Thus, the two mechanisms are identical in this set.

This shows that for any IC mechanism that is not a cutoff mechanism, there is a cutoff mechanism under which the principal's expected profit is strictly higher. Hence, any optimal IC mechanism must be a cutoff mechanism. And indeed, since the principal's expected profit from cutoff mechanisms is continuous in the cutoff and the set of possible cutoffs is compact, at least one cutoff mechanism is optimal.

□

Motivated by the result for two projects, we conjecture that a cutoff mechanism is optimal for an arbitrary number of projects and consider the problem of finding the optimal cutoff mechanism.

The following theorem gives the optimal table mechanism in the class of cutoff mechanisms.

Theorem 3. *For general N , the optimal cutoff mechanism has a single cutoff $c(N)$ that is defined by the equation*

$$N(1 - c)(1 - c + c^N) = 1 - c^N.$$

The principal's expected utility from the corresponding optimal cutoff mechanism is given by

$$\frac{1}{2} + \frac{c(N)}{2}(c(N) - c(N)^N)$$

While it is hard to obtain an exact closed form solution for the optimal single cutoff, we show that it has the following asymptotic property.

Lemma 4. *The optimal single cutoff $c(N) = 1 - \frac{1}{\sqrt{N}} + o\left(\frac{1}{\sqrt{N}}\right)$.*

Proof. Let

$$\phi_N(c) = N(1 - c)(1 - c + c^N) - (1 - c^N).$$

Then for any $\alpha > 0$,

$$\lim_{N \rightarrow \infty} \phi_N\left(1 - \frac{\alpha}{\sqrt{N}}\right) = \alpha^2 - 1,$$

and so for all sufficiently large N , the quantity

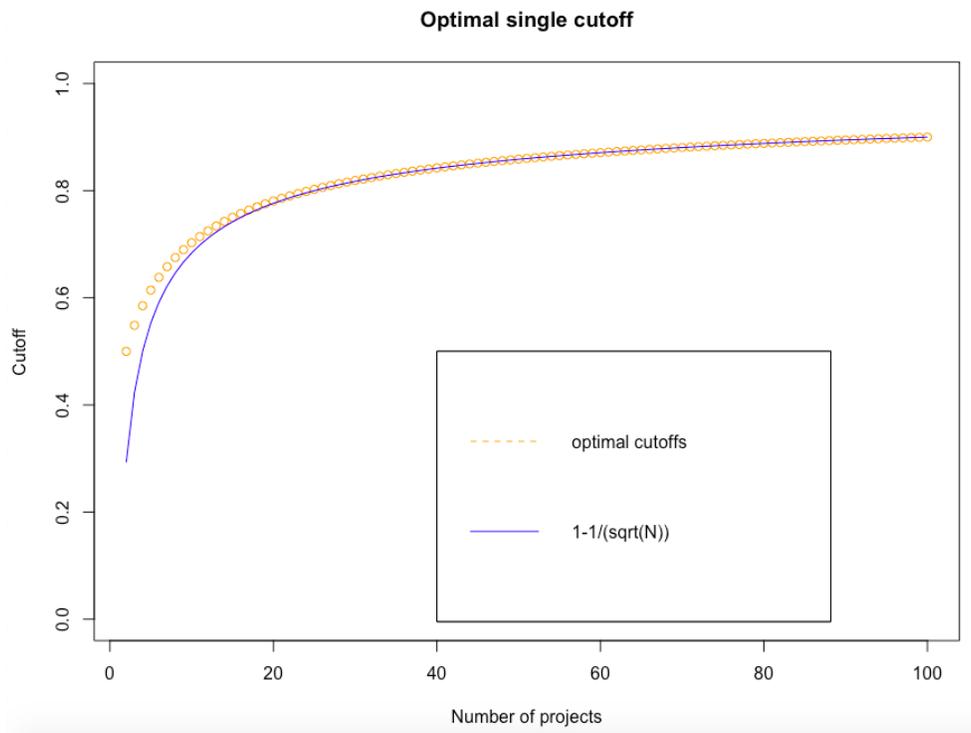

$$\phi_N\left(1 - \frac{\alpha}{\sqrt{N}}\right)$$

is positive if and only if $\alpha > 1$ and negative if and only if $\alpha < 1$. Hence, for any $\epsilon > 0$, it follows that the unique root $c(N)$ of the equation from Theorem 3 satisfies

$$(1 - \epsilon)\frac{1}{\sqrt{N}} \leq 1 - c(N) \leq (1 + \epsilon)\frac{1}{\sqrt{N}}.$$

□

It follows from Lemma 4 that as $N \rightarrow \infty$, the optimal single cutoff $c(N) \rightarrow 1$ and the expected utility of the principal $\rightarrow 1$. The following graph depicts the optimal cutoff for different number of projects.

Together, Theorems 2 and 3 give the solution to the principal's problem for the case of two projects.

Corollary 5. *For $N = 2$, the optimal incentive compatible mechanism is a cutoff mechanism with $c_1 = \frac{1}{2}$.*

4 Discussion and Future Work

In this section, we discuss how our results compare to some other results in the literature and also study some simple and important variants of our

model. We begin by discussing some useful interpretations of our model and result. We then turn to comparing our model with variants in which (i) the agent’s message space is state-independent, (ii) the principal can incentivize the agent with message-contingent transfers, and (iii) the agent must sequentially report the project values and there is no recall.

4.1 Some interpretations

The simplest implementation of the conjecturally optimal mechanism has a nice delegation interpretation. The principal selects a cutoff profit and a default project and delegates the project choice to the agent, in the sense that the agent can select either the default project or a project which meets the cutoff profit, and the principal signs off on the final decision. Under this delegation, the agent chooses his favorite project among those that meet the cutoff and the default project. Note in particular that this implementation only requires the agent to report information about the chosen project. This is outcome-equivalent to the cutoff mechanism.

We note that many instances of “cutoff mechanisms” with flavors similar to ours have appeared in the literature, but the optimality of such mechanisms has been driven by the assumption of ex-post verifiability ([2], [26] [1]). In particular, in most previous models the principal’s ability to punish in the case of a misreport is tantamount to the assumption that the agent cannot lie. Here, we offer an alternative way of rationalizing such cutoff mechanisms via the no-overselling (or more generally, interim partial verifiability) constraint, which alters the agents incentives but *not* by threatening the agent in the case of a misreport. To help elucidate this point, we make the following observation. If our model were altered so that the agent had an unconstrained message space, but the principal were required to take the default project in case the agent should oversell any of the projects, then all

of our results would carry over.

4.2 Without partial verifiability

To investigate the impact of the partial verifiability constraint on the principal's problem, we examine the principal's problem without the no-overselling constraint and compare the results to the ones obtained above. In this setting, the principal's problem is again to find an incentive compatible mechanism $d : X^{2N} \rightarrow [N]$ that maximizes his expected payoff. However, the incentive constraints on a mechanism are now stronger.

Definition 5. *A mechanism d is incentive compatible if for any (p, a) and $(\pi, \alpha) \in (X^N)^2$*

$$a_{d(p,a)} \geq a_{d(\pi,\alpha)}.$$

The following lemma characterizes the set of incentive compatible mechanisms in this setting.

Lemma 6. *Without the no-overselling constraint, the following are equivalent*

- *d is incentive compatible*
- *there exists $S \subset [N]$ with $S \neq \emptyset$ such that for all $(p, a) \in X^{2N}$*

$$d(p, a) = \operatorname{argmax}_i \{a_i : i \in S\}$$

- *d is a table mechanism such that for all $i \in N$*

$$f_i(p) = 0 \text{ for all } p \in X^N \text{ or } f_i(p) = 1 \text{ for all } p \in X^N$$

Observe that for any incentive compatible mechanism, the decision at any profile (p, a) is independent of p . That is, in an IC mechanism when the

agent can oversell, the choice of the project cannot depend on the profit it generates for the principal.

Lemma 7. *Without the no-overselling constraint, the principal's expected payoff from any incentive compatible mechanism is $\mathbb{E}[p_i]$.*

Proof. The result follows from the above discussion and also the assumption that the agent's and principal's values are iid. \square

In particular, when the principal's values are drawn uniformly from $[0, 1]$, his expected profit is $\frac{1}{2}$ for all N . That is, he can do no better by incentivizing the agent than by randomly choosing one of the projects. On the other hand, when the agent cannot oversell, the principal can get an expected profit that is greater than $\mathbb{E}(p_i)$ for any number of projects and increases to 1 as $N \rightarrow \infty$. Thus, the principal can obtain a significant gain from the no-overselling constraint.

4.3 With transfers

To compare the power that partial verifiability confers on the principal with the power that the ability to make transfers does, we examine the principal's problem when there is no partial verifiability but the principal can use transfers to incentivize the agent, and we compare the results to the ones obtained above. With transfers, a mechanism is defined by (d, t) where $d : (X^N)^2 \rightarrow [N]$ denotes the project choice as before, and $t : (X^N)^2 \rightarrow \mathbb{R}$ denotes the transfers from the principal to the agent. Note that we assume ex-post verifiability of the profit values $p_{d(p,a)}$ once the project has been chosen.

Consider the following mechanism:

$$d(p, a) = \operatorname{argmax}_{i \in [N]} (p_i + a_i)$$

and

$$t(\pi, \alpha) = p_{d(\pi, \alpha)} - \mathbb{E}[\max_{i \in [N]}(p_i + a_i)]$$

Under this mechanism, the principal essentially sells the firm to the agent. The principal charges the expected surplus under the efficient outcome $\mathbb{E}[\max_{i \in [N]}(p_i + a_i)]$ as a fixed cost which does not affect the agent's incentives. For any (p, a) , the agent's utility on reporting (π, α) will be $a_{d(\pi, \alpha)} + p_{d(\pi, \alpha)} - \mathbb{E}[\max_{i \in [N]}(p_i + a_i)]$ and this is maximized by reporting (p, a) . The agent's expected payoff is then 0. Thus, this mechanism is efficient and optimal for the principal in the presence of transfers. Thus, while the no-overselling constraint significantly empowers the principal, the gains from the ability to make transfers are even higher. Note that incentive compatibility of the above mechanism relies on ex-post verifiability. However, the mechanism with the same d as above and transfers given by

$$t(\pi, \alpha) = \pi_{d(\pi, \alpha)} - \mathbb{E}[\max_{i \in [N]}(p_i + a_i)]$$

is outcome equivalent to the above mechanism and implementable if we allow for transfers and assume no-overselling instead of ex-post verifiability.

4.4 Dynamics without recall

In order to understand environments in which information about the projects is obtained sequentially, we investigate a dynamic version of the principal's problem in which there is no recall. In this setting, the agent observes the profit p_i and payoff a_i for project i and must report these values to the principal. The principal must then decide whether to select project i or permanently abandon it. If the principal decides to abandon project i , the agent then observes p_{i+1} and a_{i+1} , and so on. In comparison to the static setup studied earlier, the dynamics without recall setup empowers the princi-

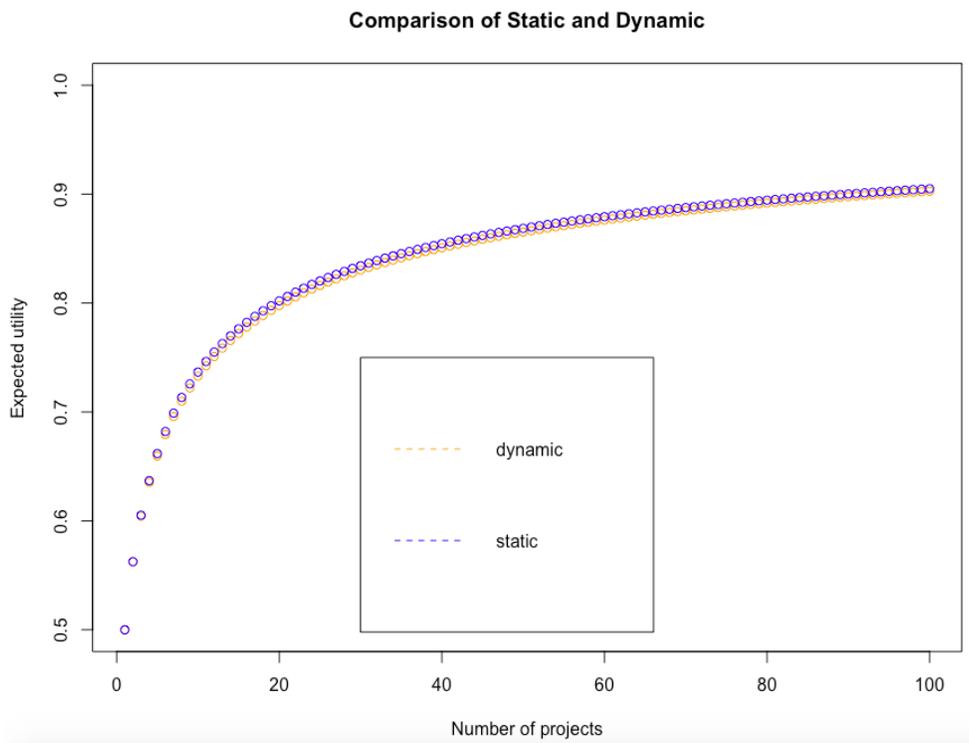

pal since the incentive constraints are weaker and also weakens him because there is no recall. The question is whether the net effect is positive or negative. In this section, we find the optimal mechanism under this setup and compare the expected profits with those from the optimal cutoff mechanism in the static setup.

Lemma 8. *In the dynamics without recall setup, the optimal incentive compatible mechanism is such that a project i is accepted if and only if $p_i \geq c_i$ and $a_i \geq c_i$ and for all $j < i$, either $p_j < c_j$ or $a_j < c_j$, where $\{c_i\}_{i=2}^N$ satisfies*

$$c_{i-1} = c_i + \frac{1}{2}(1 - c_i)^3$$

with $c_N = 0$.

The following plot demonstrates that the principal's profit from the optimal cutoff mechanism in the static setup is (just barely) higher than that from the optimal dynamic mechanism.

While we considered some simple extensions in this section, there are many interesting problems that remain unanswered. For instance, how much does the principal gain in a dynamic model where the agent has to sequentially report the project values and there is recall? Note that it is without loss of generality to assume that the agent reports all the project values. This follows from the observation that any mechanism where the principal chooses a project after learning only i project values is equivalent to a mechanism where the principal learns all project values from the agent but decides based on the first i project values. While the set of incentive compatible mechanisms in the dynamic setup is strictly bigger than the set of table mechanisms, it remains open whether there is a mechanism that generates higher expected profit. Also, many of these results likely extend (with minor modifications) to more general distributions—we leave this extension as future work.

5 Conclusion

In a principal agent problem of project selection with the partial verifiability constraint of no-overselling, we find a neat characterization of the set of incentive compatible mechanisms. We show that for two projects, a cutoff mechanism is optimal. Based on this result, we conjecture that a cutoff mechanism is optimal for any number of projects. We demonstrate that in the class of cutoff mechanisms, there is a unique optimal mechanism and that this mechanism is a single cutoff mechanism. We show that the cutoff corresponding to this mechanism increases with the number of projects, and that the principal's expected profit under the optimal mechanism converges to the upper bound of the support of the profit distribution (that is, the maximum possible profit) as the number of projects tends to ∞ .

On the contrary, we find that when the agent can oversell, the principal can do no better than choosing a project randomly. However, in cases where the principal can use transfers and there is ex-post verifiability, he can implement the efficient mechanism and extract the entire surplus by essentially selling the firm. Thus, we conclude that in settings where transfers are not feasible, there are significant gains to be had for the principal from the no-overselling constraint.

6 Appendix

Proof of Theorem 3. Note that since we are maximizing a continuous function over a compact space, a solution exists. We proceed in three steps. In step 1, we show that in any cutoff mechanism which has a cutoff that is 0 or 1 cannot be optimal. That is, the solution must be interior. In step 2, we show that a cutoff mechanism with different cutoffs cannot be optimal. Finally, we maximize the principal's utility with respect to the single cutoff c to get the optimal cutoff mechanism.

For any arbitrary cutoff mechanism with cutoffs $c = (c_1, c_2 \dots c_{N-1})$, we compute the expected utility of the principal. For the below expressions, consider $c_N = 0$.

$$EU_p(c) = \sum_{i=1}^N \frac{(1 + c_i)}{2} \mathbb{P}(d = i)$$

Note that $\mathbb{P}(d = i) = (1 - c_i) \mathbb{P}(d = N | c_i = 0)$. That is, conditional on $p_i \geq c_i$, the probability that the decision is i is the same as the probability that the decision is N when the cutoff $c_i = 0$ and the remaining cutoffs are the same. To find the probability that the last project N is chosen, we condition on its rank which is defined in terms of a_i s. That is, the rank of N is k if there are exactly $k - 1$ projects with higher a_i s.

$$\begin{aligned} \mathbb{P}(d = N) &= \sum_{k=1}^N \mathbb{P}(\text{rank of } N = k) \mathbb{P}(d = N | \text{rank of } N = k) \\ &= \frac{1}{N} \sum_{k=1}^N \mathbb{P}(d = N | \text{rank of } N = k) \end{aligned}$$

$$= \frac{1}{N} \sum_{k=1}^N \sum_{S \subset [N-1]: |S|=k-1} \frac{\prod_{i \in S} c_i}{\binom{N-1}{k-1}}$$

We first argue that cutoffs have to be interior in the optimal cutoff mechanism. Suppose d is a cutoff mechanism with cutoffs $c = (c_1, c_2, \dots, c_{N-1})$ and $c_i = 1$. In this case, let u^* denote the expected utility of the principal. Note that $u^* < 1$. Define a new cutoff mechanism in which all cutoffs remain the same except for i which now has the cutoff u^* . Now, with probability u^* , the principal gets u^* and with probability $1 - u^*$, the principal gets a convex combination of u^* and $\frac{1+u^*}{2} > u^*$. This means that his expected payoff under the new mechanism is $> u^*$. Therefore, an optimal mechanism cannot have the cutoff 1. Now, suppose there is an $i \in [N - 1]$ which has a cutoff of 0. Observe that the expected utility from any arbitrary project conditional on being chosen is $\frac{1+c}{2} \geq 0.5$. Now, consider increasing the cutoff to $c_i = \frac{1}{2}$ in the new mechanism while keeping every other cutoff the same. For every $p_i < \frac{1}{2}$, under the old mechanism, the principal's payoff was some convex combination of p_i and some $k \geq 1/2$. Under the new mechanism, it is just $k > p_i$. For $p_i \geq \frac{1}{2}$, the new mechanism is identical to the old one. Therefore, an optimal mechanism cannot have a cutoff of 0. Thus, we know that in the optimal cutoff mechanism, $c_i \notin \{0, 1\}$ for any $i \in [N - 1]$.

Now suppose that the mechanism d is such that there exist i, j with $c_i > c_j$. Define t so that $\bar{c} + t = c_i$ and $\bar{c} - t = c_j$. From the above calculations, we know that if we write $EU_p(c)$ in expanded form and plug in $c_i = \bar{c} + t$ and $c_j = \bar{c} - t$, we get a polynomial that is at most cubic in t . This is because we get a term that is at most quadratic in t for $\mathbb{P}(d = k)$ for any $k \in [n]$ and in the expected utility calculation, we multiply that with $\frac{1+c_k}{2}$. Note that by the symmetry of the projects, the principal should get the same expected utility if we changed t to $-t$. Therefore, the polynomial

should be of the form $at^2 + b$. Now, if a is > 0 or < 0 , the principal gains from increasing or decreasing t which is possible since we know that the solution is interior and $c_i > c_j$. Therefore, d cannot be optimal in either case. When $a = 0$, the principal is indifferent to increasing t till one of the cutoffs reaches an extreme of 1 or 0 which we know cannot be optimal. Therefore, a cutoff mechanism with different cutoffs cannot be optimal.

The above discussion implies that the solution to the optimization problem has to be a single cutoff mechanism. Let c be the single cutoff. Using the above calculations, we have that

$$\begin{aligned} \mathbb{P}(d = N) &= \frac{1}{N} \sum_{k=1}^N \sum_{S \subset [N-1]; |S|=k-1} \frac{\prod_{i \in S} c_i}{\binom{N-1}{k-1}} \\ &= \frac{1}{N} \sum_{k=1}^N c^{k-1} \\ &= \frac{1}{N} \frac{1 - c^N}{1 - c} \end{aligned}$$

Therefore,

$$\begin{aligned} EU_p(c) &= \frac{1}{2} \mathbb{P}(d = N) + \frac{1+c}{2} \mathbb{P}(d \neq N) \\ &= \frac{1}{2} + \frac{c}{2} \left(1 - \frac{1 - c^N}{N(1 - c)} \right) \end{aligned}$$

Differentiating with respect to c gives the desired optimal cutoff mechanism defined by single cutoff $c(N)$.

$$\begin{aligned}\frac{\partial EU_p(c)}{\partial c} &= \frac{1}{2} \left(1 - \frac{1 - c^N}{N(1 - c)} \right) - \frac{c}{2N} \left(\frac{(1 - c)(-Nc^{N-1}) + (1 - c^N)}{(1 - c)^2} \right) \\ &= \frac{1}{2} + \frac{c^N}{2(1 - c)} - \frac{1 - c^N}{2N(1 - c)^2}\end{aligned}$$

Setting it equal to zero gives us:

$$N(1 - c)(1 - c + c^N) = 1 - c^N$$

Plugging in the expected utility expression gives us the maximum utility of the principal in the class of cutoff mechanisms: $\frac{1}{2} + \frac{c(N)}{2}(c(N) - c(N)^N)$. \square

Proof of Lemma 6. First, we establish the equivalence of the first 2 statements.

Suppose d is such that there exists $S \subset [N]$ and $d(p, a) = \arg \max_i \{a_i : i \in S\}$. This mechanism is clearly incentive compatible because the agent is always getting his favorite project from his option set S which is the range of the mechanism.

Suppose d is an incentive compatible mechanism. Let $S = \{i \in N : \text{there exists } (p, a) \in X^{2N} \text{ with } d(p, a) = i\}$ be the range of the mechanism. Note that at any profile (p, a) , the agent can implement any project $i \in S$ by reporting the appropriate (π, α) . To incentivize truth-telling at (p, a) , it has to be the case that the agent's favorite project is chosen from S . Formally, for any (p, a)

$$d(p, a) = \arg \max_i \{a_i : i \in S\}$$

Thus, any incentive compatible mechanism has to be of the form described in the 2nd statement.

The equivalence of the 2nd and 3rd statement follows in a straightforward

manner by letting

$$S = \{i \in [N] : f_i(p) = 1 \text{ for all } p \in X^N\}$$

□

Proof of Lemma 8. We find the optimal mechanism in this setup by backward induction. When the agent investigates project $N-1$, both the principal and the agent know that project N will be chosen if project $N-1$ is rejected. Therefore, they want to accept project $N-1$ if and only if its returns are greater than the expected returns from project N . As a result, in the optimal incentive compatible mechanism, the principal accepts project $N-1$ if and only if $p_{N-1} \geq \frac{1}{2}$ and $a_{N-1} \geq \frac{1}{2}$. Similarly, they would want project $N-2$ to be accepted iff the returns from accepting are at least as much as the returns from rejecting which we can now compute. Repeating this, we obtain the optimal incentive compatible mechanism in this setup.

Note that the cutoff for a project $i-1$, c_{i-1} is equal to the expected profit upon rejecting project $i-1$. This gives the recursion:

$$c_{i-1} = \frac{1+c_i}{2}(1-c_i)^2 + (1-(1-c_i)^2)c_i$$

because with probability $(1-c_i)^2$, the principal gets an expected profit of $\frac{1+c_i}{2}$, and with the remaining probability, the principal rejects project i which gives an expected profit of c_i . Simplifying this gives the recursive relation as stated in the lemma.

Consequently, the expected profit for the principal from this mechanism is

$$\frac{1}{2}(1-c_1(N)^3 + 3c_1(N)^2 - c_1(N))$$

□
