ON THE BERKOVICH DOUBLE RESIDUE FIELDS AND BIRATIONAL MODELS

KEITA GOTO

Abstract. For each point of Berkovich analytic spaces, we can consider the residue field in the similar way as we do it for each point of algebraic varieties. This Berkovich residue field is a valuation field in the algebraic sense. Then we can take its residue field as a valuation field. This is called the (Berkovich) double residue field in [Jon16].

In this paper, we mainly consider valuations on varieties. As a result, we identify their double residue field as the union of the residue fields of their center in birational models. In addition, when these valuations are 'monomial valuations', we compute their double residue field concretely.

1. Introduction

In this paper, trivially valued fields are included in non-Archimedean fields. For a point $x$ of a Berkovich analytic space, we can define the Berkovich residue field $\mathcal{H}(x)$. Then it is the complete valuation field with respect to $x$. We can define the residue field $\tilde{\mathcal{H}}(x)$ of $\mathcal{H}(x)$ as a valuation field.

We consider the Berkovich analytification in all of this paper. Now, we assume that $X$ is a variety over $k$, where $k$ is a non-Archimedean field and a variety over $k$ means separated integral scheme of finite type over $k$.

In certain situations, $x \in X^{\text{an}}$ has the center $c_X(x)$ in $\mathcal{X}$, where $\mathcal{X}$ is a model of $X$ in the sense of the following.

**Definition 1.1** (= Definition 2.25). In the above setting, a model $\mathcal{X}$ of $X$ is a flat integral $k^o$-scheme of finite type with the datum of an isomorphism $\mathcal{X} \times_{\text{Spec}k^o} \text{Spec}k \cong X$, where $k^o$ is the valuation ring of $k$.

We note that when $k$ is a trivially valued field, a model of $X$ is uniquely determined as $X$ itself.

When $x \in X^{\text{an}}$ is a valuation, for birational proper morphism $f : \mathcal{Y} \to \mathcal{X}$, where $\mathcal{Y}$ is a model of $Y$, we can regard $x$ as an element of $Y^{\text{an}}$ (which is a valuation again), and it follows that $f(c_Y(x)) = c_X(x)$. This gives the canonical inclusion

$$\kappa(c_X(x)) \hookrightarrow \kappa(c_Y(x)) \hookrightarrow \tilde{\mathcal{H}}(x).$$

Further, we obtain the following result.

**Theorem 1.2** (= Theorem 3.5). Let $X$ be a variety over a non-Archimedean field $k$. We suppose that $x \in X^{\text{an}}$ is a valuation and there exists a model $\mathcal{X}$ of $X$ such that $c_{\mathcal{X}}(x)$ exists. Then, it follows that

$$\tilde{\mathcal{H}}(x) = \bigcup_{\mathcal{X}} \kappa(c_{\mathcal{X}}(x)),$$

where $\mathcal{X}$ ranges over

$$\begin{cases} 
\text{all blow-ups of } X & \text{ (if } k = k^o \text{).} \\
\text{all models of } X \text{ in which } c_{\mathcal{X}}(x) \text{ exists} & \text{ (if } k \neq k^o \text{).}
\end{cases}$$

This is our first main result. This means that we can regard $\tilde{\mathcal{H}}(x)$ as the union of the residue field of the center of $x$ in birational models. To construct suitable birational models are often very difficult central problems in birational algebraic geometry or arithmetic geometry: for instance, log resolution, semistable reduction, minimal model, canonical model, Iitaka fibration, Mori fibration among others. Morally speaking, one main feature of the double residue field is it is defined intrinsically in terms of purely...
non-archimedean world, without relying on good model construction, while it captures certain important information on birational models as we show here.

We call $x \in X^{an}$ monomial valuation if $x$ satisfies the conditions that we will see later ($\S4$). From now on, we focus on these monomial valuations. The following is our second main result.

**Theorem 1.3** (Theorem 4.6). Let $k$ be a trivially valued field. Let $X$ be a variety over $k$. Let $p \in X$ be a nonsingular point. Let $x \in X^{an}$ be a monomial valuation on $p \in X$.

Then, $\widehat{\mathcal{H}}(x)$ is finitely generated over $\kappa(c_X(x))$ as a field. Further we can give the concrete description and there exists some blow-up $\pi : X' \to X$ such that

$$\widehat{\mathcal{H}}(x) = \kappa(c_{X'}(x)).$$

In this theorem, $k$ is a trivially valued field. Hence, $X$ is the unique model of $X$ itself. This theorem is an example such that $\widehat{\mathcal{H}}(x)$ is represented by the center of $x$ in some model.

The following is our third main result.

**Theorem 1.4** (Theorem 5.7). We suppose that $k$ is a trivially valued field. Let $X$ be a variety over $k$. Let $p \in X$ be a nonsingular point. Let $G$ be a finite group acting on $X$ whose order is relatively prime to the characteristic of $k$. Let $x \in X^{an}$ be a $G$-invariant monomial valuation on $p \in X$. We take $U$ as Lemma 5.4. We suppose that $\phi : U \to U/G$ is the geometric quotient and $\phi^{an}(x) = y \in (U/G)^{an}$.

Then, it follows that

$$\widehat{\mathcal{H}}(x)^G = \widehat{\mathcal{H}}(y).$$

This is the result for quotient singularities.

On these results for monomial valuations, we assume that a base field is a trivially valued field. In contrast, on the last result, we assume that a base field is a complete discrete valuation field (which is called DVF for short).

The following is our last result.

**Theorem 1.5** (Theorem 6.11). Let $K$ be a complete DVF. We suppose that $R$ is the complete DVR of $K$ and $k$ is the residue field of $K$. We assume that the characteristic of $k$ is 0. Let $X$ be a smooth connected projective $K$-analytic space.

If $x$ is a quasi monomial valuation, then there exists a SNC model $X'$ of $X$ such that $\widehat{\mathcal{H}}(x) = \kappa(c_{X'}(x))$. 
In §2, we prepare many terminology and facts about Berkovich analytic spaces and centers of multiplicative (semi)norms. Those are well-known. From §3, we start to state our original results.

In §3, we state general properties of $\mathcal{H}(x)$. In particular, the relation between centers of a valuation $x$ and $\mathcal{H}(x)$ is important.

In §4, we study $\mathcal{H}(x)$ when $x$ is a monomial valuation. Because of the good properties of monomial valuations, we can compute $\mathcal{H}(x)$ concretely. By using the result which is obtained in §3, we can construct birational models which is suitable for discussing the valuation $x$.

In §5, we study $\mathcal{H}(x)$ such that the center of $x$ in $X$ is a quotient singularity. By considering group actions, we extend the previous result to quotient singularities.

In §6, we give a property of quasi monomial valuations over a complete DVF, as an application of our discussion in §4.

Acknowledgements
This paper is a revised version of my master thesis. I would like to thank Associate Professor Yuji Odaka at Kyoto University who is my research advisor for a lot of suggestive advice and productive discussions. And I would like to thank Professor Mattias Jonsson at the University of Michigan for helpful comments. This work is supported by JSPS KAKENHI Grant Number JP20J23401.

2. Preliminaries

2.1. Berkovich Spectrums.

Let $A$ be a commutative ring with identity 1.

Definition 2.1. A seminorm on $A$ is a function $|\cdot| : A \to \mathbb{R}_{\geq 0}$ possessing the following properties:

1. $|0| = 0$,
2. $|f - g| \leq |f| + |g|$, 
3. $|fg| \leq |f||g|$, 

for all $f, g \in A$. Furthermore a seminorm $|\cdot|$ on $A$ is called

- a norm if the equality $|f| = 0$ induces $f = 0$.
- non-Archimedean if $|f - g| \leq \max\{|f|, |g|\}$ for all $f, g \in A$.
- multiplicative if $|fg| = |f||g|$ for all $f, g \in A$.

For each seminorm $|\cdot|$, $|\cdot|$ is a norm on $A$ if and only if the induced topology is Hausdorff.

Definition 2.2. A Banach ring $\mathcal{A} = (\mathcal{A}, ||\cdot||)$ is a normed ring $\mathcal{A}$ that is complete with respect to its norm $||\cdot||$. 

Example 2.3. We can consider any ring $A$ as a Banach ring by the trivial norm $| \cdot |_0$ defined as below.

For each $f \in A$, 

$$|f|_0 := \begin{cases} 
1 & \text{(if } f \neq 0) \\
0 & \text{(if } f = 0) 
\end{cases}$$

The trivial norm is a non-Archimedean norm. Moreover it is clear that $(A, | \cdot |_0)$ is complete. Hence it is a Banach ring. Further, when $A$ is a domain, the norm is multiplicative.

Definition 2.4. A norm $| \cdot |$ is called a valuation if it is multiplicative.

As the above example, for any field $k$, the trivial norm $| \cdot |_0$ is a valuation. Then $(k, | \cdot |_0)$ is called a trivially valued field.

Example 2.5. A complete DVR is a Banach ring with respect to the norm induced by the discrete valuation. The norm is multiplicative and non-Archimedean.

Definition 2.6. Let $(\mathcal{A}, || \cdot ||)$ be a Banach ring. A seminorm $| \cdot |$ on $\mathcal{A}$ is bounded if there exists $C > 0$ such that $|f| \leq C||f||$ for all $f \in \mathcal{A}$.

Let $(\mathcal{A}, || \cdot ||)$ be a Banach ring and $I$ be an ideal of $\mathcal{A}$. We define the residue seminorm on $\mathcal{A}/I$ as follows.

$$|f| := \inf \{||g|| \mid g = f\}$$

It is a seminorm. However, in general, it is not a norm. $I$ is closed if the residue seminorm is norm. When $I$ is closed, $\mathcal{A}/I$ is a Banach ring by the residue seminorm.

Now we suppose that $(\mathcal{A}, || \cdot ||_{\mathcal{A}})$ and $(\mathcal{B}, || \cdot ||_{\mathcal{B}})$ are Banach rings.

Definition 2.7. Let $\varphi : \mathcal{A} \to \mathcal{B}$ be a ring homomorphism.

$\varphi : \mathcal{A} \to \mathcal{B}$ is bounded if there exists $C > 0$ such that $||\varphi(f)||_{\mathcal{B}} \leq C||f||_{\mathcal{A}}$ for each $f \in \mathcal{A}$.

$\varphi : \mathcal{A} \to \mathcal{B}$ is admissible if the residue seminorm of $\mathcal{A}/\ker \varphi$ coincides with the norm $|| \cdot ||_{\mathcal{B}}$ of $\mathcal{B}$ through $\mathcal{A}/\ker \varphi \cong \text{Im} \varphi \subset \mathcal{B}$.

A bounded homomorphism is the most fundamental morphism between two Banach rings. An admissible homomorphism is the bounded homomorphism which holds the fundamental theorem on homomorphisms as Banach rings.

From now on, for two Banach rings $\mathcal{A}$ and $\mathcal{B}$, $\varphi : \mathcal{A} \to \mathcal{B}$ means a bounded homomorphism.
Definition 2.8 (§1.2 of [Ber90]). Let $\mathcal{A}$ be a commutative Banach ring with identity. The spectrum $\mathcal{M}(\mathcal{A})$ is the set of all bounded multiplicative seminorms on $\mathcal{A}$ provided with the weakest topology with respect to which all real valued functions on $\mathcal{M}(\mathcal{A})$ of the form $|\cdot| \mapsto |f|$, $f \in \mathcal{A}$, are continuous.

When $\varphi : \mathcal{A} \to \mathcal{B}$ is given, it induces the continuous map $\varphi^\# : \mathcal{M}(\mathcal{B}) \to \mathcal{M}(\mathcal{A})$ defined by $|f|_{\varphi^\#(x)} := |\varphi(f)|_x$ for all $f \in \mathcal{A}$ for each $x \in \mathcal{M}(\mathcal{B})$.

Theorem 2.9 (Theorem 1.2.1 of [Ber90]). Let $\mathcal{A}$ be a commutative Banach ring with identity. The spectrum $\mathcal{M}(\mathcal{A})$ is a nonempty, compact Hausdorff space.

For $x \in \mathcal{M}(\mathcal{A})$, we denote by $p_x$ the kernel of $|\cdot|_x$. This is a prime ideal of $\mathcal{A}$ and $x$ defines a valuation $\varpi$ on $\mathcal{A}/p_x$. More concretely,

$$|f|_x := |\varpi(f)|_x$$

for each $f \in \mathcal{A}$. We also denote $\varpi$ by $x$. The completion of the fraction field of $\mathcal{A}/p_x$ with respect to this valuation $x$ is a complete valuation field $\mathcal{H}(x)$. In this paper, we refer to $\mathcal{H}(x)$ as the Berkovich residue field of $x$ although this is not a common way to call it. By the way, the definition of ‘complete valuation field’ is as specified below.

Definition 2.10.

- A Banach field is the Banach ring which is a field.
- A complete valuation field is the commutative Banach field whose norm is multiplicative.
- A non-Archimedean field is the complete valuation field whose norm is non-Archimedean.

By this definition, a trivially valued field is a non-Archimedean field.

For complete valuation field $k$, we can see $\mathcal{M}(k) = \{1pt\}$ [Ber90]. Moreover, it is clear that any complete valuation field is a valuation field in the algebraic sense.

For any complete valuation field $k = (k, |\cdot|)$, the value group of $k$ is defined by

$$|k^\times| := \{|f| \in \mathbb{R} \mid f \in k^\times (= k \setminus \{0\})\}.$$

Further, we set

$$\sqrt{|k^\times|} := \{a \in \mathbb{R}_{\geq 0} \mid a^n \in |k^\times| \text{ for some } n \in \mathbb{Z}_{>0}\}.$$

Then $|k^\times|$ is a $\mathbb{Z}$-module and $\sqrt{|k^\times|}$ is a $\mathbb{Q}$-vector space by taking the logarithm. It is clear that $\sqrt{|k^\times|} \cong |k^\times| \otimes_\mathbb{Z} \mathbb{Q}$.

We set $x \in \mathcal{M}(\mathcal{A})$. We call $\dim_{\mathbb{Q}} \sqrt{\mathcal{H}(x)^\times}$ the rational rank of $x$. 
From now on, we define the double residue field \( \tilde{\mathcal{H}}(x) \) in the sense of Jonsson.

For \( x \in \mathcal{M}(\mathcal{A}) \), we obtain the Berkovich residue field \( \mathcal{H}(x) \). Then \( \mathcal{H}(x) \) is a valuation field in the algebraic sense. Therefore,

\[
\mathcal{H}(x)^\circ := \{ f \in \mathcal{H}(x) \mid |f|_x \leq 1 \}
\]

is a valuation ring and

\[
\mathcal{H}(x)^\circ\circ := \{ f \in \mathcal{H}(x) \mid |f|_x < 1 \}
\]

is its maximal ideal. Hence,

\[
\tilde{\mathcal{H}}(x) := \mathcal{H}(x)^\circ / \mathcal{H}(x)^\circ\circ
\]

is a field. This \( \tilde{\mathcal{H}}(x) \) is the residue field of the valuation field \( \mathcal{H}(x) \).

We compute \( \tilde{\mathcal{H}}(x) \) concretely when \( x \) is a monomial valuation which we define later, among other cases.

On the other hand, \( \tilde{\mathcal{H}}(x) \) is computed concretely when \( x \) is a point of the Shilov boundary of a strictly \( k \)-affinoid space (cf. Proposition 2.4.4 of [Ber90]) or \( x \) is a point of the Berkovich affine line (cf. Proposition 2.3 of [BR10]).

For any non-Archimedean field \( k \), we also define \( k^\circ \), \( k^\circ\circ \) and \( \tilde{k} \) in the same manner.

### 2.2. Berkovich analytifications.

Now we review the construction of Berkovich analytification \( X^\text{an} \) for any scheme \( X \) of locally finite type over a non-Archimedean field \( k \) in the sense of Berkovich [Ber90].

At first, we define the Banach ring corresponding to a closed disc.

**Definition 2.11.** Let \( (k, | \cdot |) \) be a non-Archimedean field.

For \( r_1, \ldots, r_n > 0 \), we set:

\[
k\{r_1^{-1}T_1, \ldots, r_n^{-1}T_n\} := \{ f = \sum_{I \in \mathbb{Z}_{\geq 0}^n} a_I T^I \mid a_I \in k, |a_I r^I| \to 0 \text{ as } |I| \to 0 \},
\]

where \( I = (i_1, \ldots, i_n) \), \( |I| = i_1 + \cdots + i_n \), \( T^I = T_1^{i_1} \cdots T_n^{i_n} \) and \( r^I = r_1^{i_1} \cdots r_n^{i_n} \). This is a commutative Banach ring with respect to the valuation \( ||f|| = \max_I |a_I|r^I \). For brevity, this algebra will also be denoted by \( k\{r^{-1}T\} \).

\( E(0, r) := \mathcal{M}(k\{r^{-1}T\}) \) is an analogue of the complex closed disc at the origin with radii \( r = (r_1, \ldots, r_n) \).
Example 2.12. Let us assume that the valuation on \( k \) is trivial. If \( r_i \geq 1 \) for all \( 1 \leq i \leq n \), \( k\{r^{-1}T\} \) coincides with the polynomial ring \( k[T_1, \ldots, T_n] \). If \( r_i < 1 \) for all \( 1 \leq i \leq n \), \( k\{r^{-1}T\} \) coincides with the ring of formal power series \( k[[T_1, \ldots, T_n]] \).

By the definition of \( k\{r^{-1}T\} \), there is the natural admissible injection \( k \hookrightarrow k\{r^{-1}T\} \). More generally, we define this property as follows.

Definition 2.13. \( \mathcal{A} \) is a Banach \( k \)-algebra if there is the \( k \hookrightarrow \mathcal{A} \) is admissible injective.

From now on, we assume that \( \varphi : \mathcal{A} \rightarrow \mathcal{B} \) for two Banach \( k \)-algebras is compatible with the morphisms from \( k \). Now we define the important class of Banach \( k \)-algebra as follows.

Definition 2.14. Let \( \mathcal{A} \) be a Banach \( k \)-algebra. \( \mathcal{A} \) is \( k \)-affinoid if there exists an admissible surjection \( k\{r^{-1}T\} \twoheadrightarrow \mathcal{A} \).

Definition 2.15. \( X \) is \( k \)-affinoid space if \( X = \mathcal{M}(\mathcal{A}) \) for some \( k \)-affinoid algebra \( \mathcal{A} \).

Example 2.16. \( k\{r^{-1}T\} \) is a typical example of a \( k \)-affinoid algebra. Moreover \( E(0, r) = \mathcal{M}(k\{r^{-1}T\}) \) which we saw above is a typical example of a \( k \)-affinoid space.

We will make use of the following proposition later.

Proposition 2.17 (Proposition 2.1.3 of [Ber90]). Any \( k \)-affinoid algebra is noetherian and all of its ideals are closed.

Definition 2.18. Let \( (\mathcal{A}, \| \cdot \|) \) be a \( k \)-affinoid algebra.

For \( r_1, \ldots, r_n > 0 \), we set:
\[
\mathcal{A}\{r_1^{-1}T_1, \ldots, r_n^{-1}T_n\} := \{ f = \sum_{I \in \mathbb{Z}_+^n} a_I T^I \mid a_I \in \mathcal{A}, |a_I|r^I \rightarrow 0 \text{ as } |I| \rightarrow 0 \},
\]
where \( I = (i_1, \ldots, i_n), |I| = i_1 + \cdots + i_n, T^I = T_1^{i_1} \cdots T_n^{i_n} \) and \( r^I = r_1^{i_1} \cdots r_n^{i_n} \). This is a commutative Banach ring with respect to the valuation \( \| f \| = \max_I |a_I|r^I \). For brevity, this algebra will also be denoted by \( \mathcal{A}\{r^{-1}T\} \).

By the definition, there is the natural inclusion \( \mathcal{A} \rightarrow \mathcal{A}\{r^{-1}T\} \). Moreover we can easily see that \( \mathcal{A}\{r^{-1}T\} \) is \( k \)-affinoid algebra.

Definition 2.19. Let \( \mathcal{A} \) be a \( k \)-affinoid algebra. Let \( f = (f_1, \ldots, f_n) \) and \( g = (g_1, \ldots, g_m) \) be sets of elements of \( \mathcal{A} \), and let \( p = (p_1, \ldots, p_n) \) and \( q = (q_1, \ldots, q_m) \) be sets of positive numbers. Then we define \( \mathcal{A}\{p^{-1}f, qg^{-1}\} \) as follows.
\[
\mathcal{A}\{p^{-1}f, qg^{-1}\} := \mathcal{A}\{p^{-1}T, qS\}/(T_1 - f_1, \ldots, T_n - f_n, g_1 S_1 - 1, \ldots, g_m S_m - 1).
\]
In general, $k$-affinoid algebra is noetherian and all of its ideals are closed. In particular, the quotient of $k$-affinoid algebra is $k$-affinoid. Therefore, $\mathcal{A}\{p^{-1}f, qg^{-1}\}$ is $k$-affinoid.

The natural morphism $\mathcal{A} \to \mathcal{A}\{p^{-1}f, qg^{-1}\}$ induce the closed immersion $\mathcal{M}(\mathcal{A}\{p^{-1}f, qg^{-1}\}) \hookrightarrow \mathcal{M}(\mathcal{A})$. We set $X = \mathcal{M}(\mathcal{A})$. Then, $X\{p^{-1}f, qg^{-1}\} := \{x \in X \mid |f_i|_x \leq p_i, |g_j|_x \geq q_j, 1 \leq i \leq n, 1 \leq j \leq m\}$ which is a closed set of $X$ coinsides with $\mathcal{M}(\mathcal{A}\{p^{-1}f, qg^{-1}\})$ through this closed immersion. Such affinoid spaces of the form $X\{p^{-1}f, qg^{-1}\}$ are called Laurent domains in $X$. We will make use of the following proposition later.

**Proposition 2.20** (§2.2 of [Ber90]). Let $X$ be a $k$-affinoid space. The Laurent neighborhoods of a point $x \in X$ form a basis of closed neighborhoods of $x$.

$X = \mathcal{M}(\mathcal{A})$ has the structure sheaf $\mathcal{O}_X$ that we will not define in detail. In particular, it holds that $\mathcal{A} = \mathcal{O}_X(X)$. Then an open set $U \subset X$ is a locally ringed space. It is called $k$-quasiaffinoid space.

Roughly speaking, $k$-analytic spaces in the Berkovich sense are obtained by glueing together $k$-quasiaffinoid spaces. $k$-analytic spaces have the structure sheaf by glueing together the structure sheaf of $k$-quasiaffinoid spaces.

Now, let us start to construct the Berkovich analytification concretely.

When $X = \mathbb{A}^n_k$, the Berkovich analytification of $X$ is denoted by

$$X^\text{an} := \bigcup_{r \in \mathbb{R}^n_{>0}} E(0, r) = \bigcup_{r \in \mathbb{R}^n_{>0}} D(0, r),$$

where $D(0, r) = \{x \in E(0, r) \mid |T_i|_x < r_i, 1 \leq i \leq n\}$. $D(0, r)$ is a $k$-quasiaffinoid space as a open set in $E(0, r)$. The structure of $X^\text{an}$ as $k$-analytic spaces is defined as follows.

There are natural open immersions $D(0, r) \hookrightarrow X^\text{an}$ for each $r \in \mathbb{R}^n_{>0}$. Moreover these two open immersions $D(0, r_i) \hookrightarrow X^\text{an}$ ($i = 1, 2$), where $r_1 \geq r_2$ which means $r_1 - r_2 \in \mathbb{R}^n_{\geq 0}$, are compatible with the natural open immersion $D(0, r_2) \hookrightarrow D(0, r_1)$. That is, the following diagram is commutative.
Next, let $A$ be a finitely generated $k$-algebra. We set $A \cong k[T_1, \ldots, T_n]/I$. When $X = \text{Spec } A$, the Berkovich analytification of $X$ is denoted by $X^\text{an} := \bigcup_{r \in \mathbb{R}_{>0}} \mathcal{M}(k\{r^{-1}T\}/I \cdot k\{r^{-1}T\})$.

The structure of $X^\text{an}$ is defined in the similar way.

Finally, let $X$ be a scheme of locally finite type over $k$. Then the Berkovich analytification $X^\text{an}$ is obtained by glueing together the $k$-analytic spaces $U^\text{an}$ for each affine open set $U \subset X$.

**Proposition 2.21.** Let $k$ be a non-Archimedean field. Now we set $X$ as a scheme of locally finite type over $k$. Then, there is a $k$-affinoid neighborhood $V = \mathcal{M}(\mathscr{A}) \subset X^\text{an}$ of $x$ for each $x \in X^\text{an}$.

**Proof.** By the construction of $X^\text{an}$, it is clear.

Of course, we can take some $k$-quasiaffinoid neighborhood. However, it does not mean that we can take some $k$-affinoid neighborhood. Indeed, we sometimes cannot take any $k$-affinoid neighborhood at a point.

We can obtain the canonical continuous map $\pi_X : X^\text{an} \to X$ defined as follows. For each affine open set $U \subset X$, $\pi_X|_U^\text{an}$ is defined by sending multiplicative seminorms on $A$ to their kernel which are prime ideals of $A$, where $U = \text{Spec } A$.

The Berkovich analytification $X \mapsto X^\text{an}$ has many properties including GAGA type theorems. We list some properties below.

**Proposition 2.22** (§ 3 of [Ber90]). Let $k$ be a non-Archimedean field. For any morphism $\varphi : X \to Y$ between two varieties over $k$, there exists the morphism $\varphi^\text{an} : X^\text{an} \to Y^\text{an}$ as $k$-analytic spaces such that the following diagram is commutative.

\[
\begin{array}{ccc}
X^\text{an} & \longrightarrow & Y^\text{an} \\
\downarrow \pi_X & & \downarrow \pi_Y \\
X & \varphi \longrightarrow & Y
\end{array}
\]

**Proposition 2.23** (§ 3 of [Ber90]). Let $\varphi$ and $\varphi^\text{an}$ be morphisms as above. The following hold.

- If $\varphi$ is open immersion, then so is $\varphi^\text{an}$.
- If $\varphi$ is closed immersion, then so is $\varphi^\text{an}$.
- If $\varphi$ is surjective, then so is $\varphi^\text{an}$.

**Proposition 2.24** (§ 3 of [Ber90]). Let $X$ be a variety over $k$. The following hold.
\begin{itemize}
  \item $X^\text{an}$ is Hausdorff.
  \item $X^\text{an}$ is arcwise connected.
  \item $X$ is proper if and only if $X^\text{an}$ is compact.
\end{itemize}

2.3. Centers.

Let $X$ be a variety over a non-Archimedean field $k$. For $x \in X^\text{an}$, we will define the center of $x$. Before that, we define a model of $X$.

**Definition 2.25.** In the above setting, a model $X$ of $X$ is a flat integral $k$-scheme of finite type with the datum of an isomorphism $X \times_{\text{Spec} k^\circ} \text{Spec} k \cong X$.

**Remark 2.26.** When $X$ is a projective variety, we can construct a projective model of $X$ in the following way. We consider a closed immersion $X \hookrightarrow \mathbb{P}^n_k$. Since $\mathbb{P}^n_k$ is an open set in $\mathbb{P}^n_{k^\circ}$, we can take $X$ as the closure of $X$ in $\mathbb{P}^n_{k^\circ}$. On the other hand, if $k = k^\circ$, a model of $X$ is uniquely determined as $X$ itself.

Now we consider the canonical morphism $\pi_X : X^\text{an} \to X$. The canonical homomorphism $\kappa(\pi_X(x)) \hookrightarrow \mathcal{H}(x)$ induces a morphism $\text{Spec} \mathcal{H}(x) \to X$. Then, we obtain $\text{Spec} \mathcal{H}(x) \to X \to X$. This morphism gives the following diagram.

\[
\begin{array}{ccc}
\text{Spec} \mathcal{H}(x) & \longrightarrow & X \\
\downarrow & & \downarrow \\
\text{Spec} \mathcal{H}(x)^\circ & \longrightarrow & \text{Spec} k^\circ
\end{array}
\]

This dotted arrow does not always exist. When it exists, we define the center of $x$ (in $X$) as its image of the unique closed point of $\text{Spec} \mathcal{H}(x)^\circ$. It is denoted as $c_X(x)$. By the valuative criterion of separatedness [Har77], such $c_X(x)$ is uniquely determined if it exists.

Moreover, the above diagram is factored as below.

\[
\begin{array}{ccc}
\text{Spec} \mathcal{H}(x) & \longrightarrow & \text{Spec} \kappa(\pi_X(x)) \\
\downarrow & & \downarrow \\
\text{Spec} \mathcal{H}(x)^\circ & \longrightarrow & \text{Spec} k^\circ
\end{array}
\]

The above $R_x$ is defined by
\[
R_x := \{ f \in \kappa(\pi_X(x)) \mid |f|_x \leq 1 \}.
\]

**Remark 2.27.** When $X$ is a proper $k^\circ$-scheme, the center of $x$ always exists for any $x \in X^\text{an}$. It follows from the valuative criterion of properness.

Now we describe the center of $x$ in $X$ more concretely. We suppose that $c_X(x) \in \text{Spec} A \subset X$. 

Then it holds that \( A \rightarrow R_x \subset \mathcal{H}(x)^\circ \).

Since \( \kappa(\pi_X(x)) \) is a valuation field with respect to \( x \) in the algebraic sense, \( R_x \) is valuation ring and

\[
m_x := \{ f \in \kappa(\pi_X(x)) \mid |f|_x < 1 \}
\]

is its maximal ideal. Then the center of \( x \) is the point \( c_X(x) \in \text{Spec}A \) given by the inverse image of \( m_x \) through the natural map \( A \rightarrow R_x \).

In other words,

\[
c_X(x) := \{ f \in A \mid |f|_x < 1 \} \in \text{Spec}A.
\]

Now we get back to the topic. When \( x \in X^{\text{an}} \) is a valuation, the residue field \( \kappa(\pi_X(x)) \) coincides with the function field \( K(X) \). In other words, the valuation \( x \) is defined on the function field \( K(X) \).

Therefore, for any affine open set \( U = \text{Spec}A \subset X \), we see \( x \in U^{\text{an}} \). Indeed, since \( x \) is the valuation on \( A \subset K(X) \) whose restriction to \( k \subset A \subset K(X) \) is exactly the equipped valuation, we obtain \( x \in U^{\text{an}} \) by the definition of \( U^{\text{an}} \).

In particular, for any birational map \( f : Y \rightarrow X \) between two \( k \)-varieties, we can identify this valuation \( x \) with \( x \in U^{\text{an}} \). Indeed, since we may assume that \( f|_V : V \cong U \subset X \) for some open affine set \( V \subset Y \) and \( x \in U^{\text{an}} \), we identify \( x \) with \( x \in V^{\text{an}} \subset Y^{\text{an}} \) through this \( f \).

Further, when the center of \( x \in X^{\text{an}} \) in \( \mathcal{X} \) exists and \( f : \mathcal{Y} \rightarrow \mathcal{X} \) is a proper birational morphism between two models, where \( \mathcal{X} \) is a model of \( X \) and \( \mathcal{Y} \) is a model of \( Y \), we can apply the valuative criterion of properness to the following diagram.

\[
\begin{array}{ccc}
\text{Spec}K(X) & \rightarrow & \mathcal{Y} \\
\downarrow & & \downarrow f \\
\text{Spec}R_x & \varphi_{x,Y} \rightarrow & \mathcal{X}
\end{array}
\]

Then we obtain the unique morphism \( \varphi_{x,Y} : \text{Spec}R_x \rightarrow \mathcal{Y} \).

We can identify this \( \varphi_{x,Y} \) with the morphism which appears when we define \( c_{\mathcal{Y}}(x) \) as above for \( x \in Y^{\text{an}} \).

Since \( \varphi_{x,X} = f \circ \varphi_{x,Y} \), we obtain \( f(c_{\mathcal{Y}}(x)) = c_X(x) \) by chasing the unique closed point of \( \text{Spec}R_x \).

In particular, there exists the inclusion \( \kappa(c_X(x)) \hookrightarrow \kappa(c_{\mathcal{Y}}(x)) \). It means that the lifting of the center induces the extension of the residue field of the center.
3. Some basic properties of $\mathcal{H}(x)$

In this section, we see general properties of the Berkovich residue field $\mathcal{H}(x)$ and the double residue field $\tilde{\mathcal{H}}(x)$.

**Proposition 3.1.** Let $A$ be a $k$-affinoid algebra. Then $\mathcal{H}(x)$ for $x \in \mathcal{M}(A)$ does not depend on the choice of Laurent neighborhood of $x$.

**Proof.** Let $V = \mathcal{M}(B) \subset \mathcal{M}(A)$ be a Laurent neighborhood of $x$. That is, we may assume $B = A\left\{\frac{p^{-1}f}{qg^{-1}}\right\}$, where $y(=x) \in X\left\{\frac{p^{-1}f}{qg^{-1}}\right\}$. In particular, it holds that $|g^J|_y \neq 0$ for all $J \in \mathbb{Z}_{\geq 0}$.

Then, there are bounded homomorphism $\varphi : A \to B$ and $y \in \mathcal{M}(B)$ such that $\varphi^\#(y) = x$. It is enough to show that the completion of $A/p_x$ coincides with the completion of $B/p_y$, where $p_x$ is the kernel of $x : A \to \mathbb{R}$ and $p_y$ is the kernel of $y : B \to \mathbb{R}$. Since $\varphi^\#(y) = x$, $\varphi : A \to B$ induces $\varphi : A/p_x \to B/p_y$.

Hence, it holds that

$$\iota : \text{Frac}(A/p_x) \subset \text{Frac}(B/p_y).$$

By Proposition 2.17 the residue seminorm on a quotient ring of $k$-affinoid algebra is a norm. Therefore, the residue norm on a quotient ring of $k$-affinoid algebra can extend to the unique norm on the fraction field of this quotient ring.

Since $\varphi : A \to B$ is admissible, so is $\varphi : A/p_x \to B/p_y$ with respect to their residue norms. For $\overline{h} \in B/p_y$, we set $h \in B = A\left\{\frac{p^{-1}f}{qg^{-1}}\right\}$ as

$$h = \sum_{I,J} a_{IJ} f^I g^{-J}.$$  

Then we set $\overline{h}_n \in \text{Frac}(A/p_x)$ as

$$\overline{h}_n = \sum_{|I|+|J| \leq n} a_{IJ} f^I g^{-J}.$$  

Since $|g^J|_y \neq 0$, it implies $(g^J)_y \neq 0$. Hence, $\overline{h}_n$ is well-defined. Now let us assume $B := B/p_y$. Then it is clear that $y$ induces a bounded multiplicative norm on $B$ in a natural way. It is also denoted by $y$. Therefore,

$$|\overline{h} - \iota(\overline{h}_n)|_y = \left| \sum_{|I|+|J| > n} a_{IJ} f^I g^{-J} \right|^y$$  

$$\leq \left\| \sum_{|I|+|J| > n} a_{IJ} f^I g^{-J} \right\|_B \leq \left\| \sum_{|I|+|J| > n} a_{IJ} f^I g^{-J} \right\|_B \to 0$$  

as $n \to \infty$. This convergence follows from the definition of $A\left\{\frac{p^{-1}f}{qg^{-1}}\right\}$. Since $x$ is non-Archimedean, $\{\overline{h}_n\}_n$ is a Cauchy sequence. Indeed, it follows
from
\[|\bar{h}_n - \bar{h}_m|_x \leq \max\{|\iota(h_n) - \bar{h}|_y, |\bar{h} - \iota(h_m)|_y\}.\]

It implies that
\[\mathcal{B} \subset \text{Frac}(\mathcal{A}/p_x),\]
where the right-hand side is the completion of \(\text{Frac}(\mathcal{A}/p_x)\) with respect to the norm induced by \(x\). This follows from \(\iota^*(y) = x\).

Hence, it holds that
\[\text{Frac}(\mathcal{A}/p_x) = \text{Frac}(\mathcal{B}/p_y),\]
where the left-hand side is the completion of \(\text{Frac}(\mathcal{A}/p_x)\) with respect to the norm induced by \(x\) and the right-hand side is the completion of \(\text{Frac}(\mathcal{B}/p_y)\) with respect to the norm induced by \(y\). In the end, the assertion follows. □

By Proposition 2.20, this means \(\mathcal{H}(x)\) is a local object which depends only on a point \(x\) of (good) \(k\)-analytic space. In particular, this proposition and Proposition 2.21 imply that \(\mathcal{H}(x)\) is a local object of \(X^\text{an}\).

Next, we consider the case when \(X\) is the Berkovich analytification of some \(k\)-variety.

**Proposition 3.2.** Let \(A\) be finitely generated over non-Archimedean field \(k\). For \(x \in (\text{Spec}\,A)^\text{an}\), we suppose \(\ker x = p_x\). Then
\[\mathcal{H}(x) = \text{Frac}(A/p_x),\]
where the right-hand side is the completion of \(\text{Frac}(A/p_x)\) with respect to the norm induced by \(x\).

In other words, \(\mathcal{H}(x)\) is the completion of the residue field \(\kappa(p_x)\) at \(p_x \in \text{Spec} A\) with respect to \(x\).

**Proof.** We may assume \(A = k[T_1, \ldots, T_n]\). Now we can take some \(E(0, r) = \mathcal{M}(k\{r^{-1}T\})\) such that \(x \in E(0, r)\). By Proposition 3.1, it is enough to show the assertion for the case that \(\mathcal{H}(x)\) is defined by \(x \in E(0, r)\).

It is clear that \(A \hookrightarrow k\{r^{-1}T\} = \mathcal{A}\) induces \(\iota : A/p_x \hookrightarrow \mathcal{A}/(p_x\mathcal{A})\). For brevity \(\mathcal{A}/(p_x\mathcal{A})\) is denoted by \(\mathcal{A}/p_x\). Indeed, it coincides with the quotient ring \(\mathcal{A}/p_x\), which appears when the definition of \(\mathcal{H}(x)\).

For \(f \in \mathcal{A}/p_x\), we set \(f \in \mathcal{A} = k\{r^{-1}T\}\) as
\[f = \sum_{I} a_I T^I.\]

Then we set \(f_n \in A\) as
\[f_n = \sum_{|I| \leq n} a_I T^I.\]
Now $x$ induces a bounded multiplicative norm on $\mathcal{O}/\mathfrak{p}_x$ in a natural way. It is also denoted by $x$. Then,

$$
|f - f_n|_x = \sum_{|I|>n} a_IT^I|_x
$$

$$
\leq \sum_{|I|>n} a_IT^I|_{\mathcal{O}/\mathfrak{p}_x} \leq \sum_{|I|>n} a_IT^I|_{\mathcal{O}} \to 0
$$

as $n \to \infty$. This convergence follows from the definition of $k\{r^{-1}T\}$. In the similar way as the discussion of the above proposition, it implies that $\{f_n\}$ is the Cauchy sequence whose limit is $\bar{f}$.

Hence, the assertion follows.  

**Corollary 3.3.** Let $X$ be a variety over non-Archimedean field $k$. We set $\pi_X : X^{\text{an}} \to X$ as before. Then, for any $x \in X^{\text{an}},$

$$
\mathcal{H}(x) = \kappa(\pi_X(x)),
$$

where the right-hand side is the completion of the residue field $\kappa(\pi_X(x))$ at $\pi_X(x) \in X$ with respect to $x$.

**Proof.** It follows from the above proposition. 

Let $k$ be a non-Archimedean field. Let $\mathcal{X}$ be a model of $k$-variety $X$. We set $\pi_X : X^{\text{an}} \to X$ as before. We suppose $x \in X^{\text{an}}$. We recall the definitions of the center $c_X(x)$ and the double residue field $\mathcal{H}(x)$.

If $c_X(x)$ exists, there is the canonical inclusion

$$
\kappa(c_X(x)) \subset \mathcal{H}(x).
$$

Let us assume that $f : Y \to X$ is a proper birational morphism and $x \in X^{\text{an}}$ is a valuation. Then, it holds that

$$
\kappa(c_X(x)) \subset \kappa(c_Y(x)) \subset \mathcal{H}(x).
$$

In general, $\kappa(c_X(x)) \neq \mathcal{H}(x)$. However, by taking appropriate blow-up, we can obtain $Y$ which satisfies $\kappa(c_Y(x)) = \mathcal{H}(x)$ in some situations. This is the main theme of this paper.

In general, we obtain the following results.

**Lemma 3.4.** Let $X$ be a variety over non-Archimedean field $k$. We set $\pi_X : X^{\text{an}} \to X$ as before. Then, for any $x = | \cdot | \in X^{\text{an}}$, it holds that

$$
\mathcal{H}(x) = \kappa(\pi_X(x)),
$$

where the right-hand side is the residue field of the algebraic valuation field $\kappa(\pi_X(x))$ with respect to $x$. 

In particular, when \( x \) is a valuation, it holds that
\[ \widetilde{\mathcal{H}}(x) = \widetilde{K}(X), \]
where \( K(X) \) is the function field of \( X \).

Proof. By the above corollary, for any \( f \in \mathcal{H}(x) \setminus \mathcal{H}(x)^{\circ} \) and any \( \varepsilon > 0 \), there exists \( g \in \kappa(\pi_X(x)) \) such that \( |f - g| < \varepsilon \). Now we take \( \varepsilon < 1 \). Then, we find that \( |g| = |f| = 1 \) and \( \overline{f} = \overline{g} \in \kappa(\pi_X(x)) \). In conclusion, we obtain \( \widetilde{\mathcal{H}}(x) = \kappa(\pi_X(x)) \).

In particular, when \( x \) is a valuation, \( \kappa(\pi_X(x)) = K(X) \) implies the last assertion. \( \square \)

**Theorem 3.5.** Let \( X \) be a variety over a non-Archimedean field \( k \). We suppose that \( x \in X^{\text{an}} \) is a valuation and there exists a model \( \mathcal{X} \) of \( X \) such that \( c_X(x) \) exists. Then, it follows that
\[ \widetilde{\mathcal{H}}(x) = \bigcup_{\mathcal{X}} \kappa(c_X(x)), \]
where \( \mathcal{X} \) ranges over
\[ \begin{cases} \text{all blow-ups of } X & (\text{if } k = k^\circ), \\ \text{all models of } X \text{ in which } c_X(x) \text{ exists} & (\text{if } k \neq k^\circ). \end{cases} \]

Proof. The right hand side means the union of the image of canonical inclusions \( \kappa(c_X(x)) \hookrightarrow \mathcal{H}(x) \). We may assume that \( \mathcal{X} \) is a model of \( X \) which is given by the assumption and \( c_X(x) \in \text{Spec} \ A = U \subset \mathcal{X} \). It suffices to show that for this model \( \mathcal{X} \), the following holds.
\[ \widehat{\mathcal{H}}(x) = \bigcup_{\pi: \mathcal{X}' \to \mathcal{X}} \kappa(c_{\mathcal{X}'}(x)), \]
where \( \pi \) ranges over all blow-ups. By the above lemma, we obtain
\[ \widehat{\mathcal{H}}(x) = \widehat{K}(X), \]
where \( \widehat{K}(X) \) is defined by taking the residue field of the valuation field \( K(X) \) in the algebraic sense with respect to \( x \) in the same way as \( \widehat{\mathcal{H}}(x) \).

Now for each \( f = g/h \in \mathcal{H}(x) \setminus \kappa(c_X(x)) \), where \( g, h \in A \), we set \( I = (g, h) \subset A \) which is an ideal of \( A \). Then, there is an ideal sheaf \( \mathcal{I} \) on \( \mathcal{X} \) such that \( \overline{I} = \mathcal{I}|_U \) [Har77]. Now we consider the blow-up \( \pi \) of \( \mathcal{X} \) along \( \mathcal{I} \). That is,
\[ \pi : \mathcal{X}' = \mathcal{B}l_{\mathcal{I}} \mathcal{X} \to \mathcal{X}. \]
\( \mathcal{X} \) has an open affine scheme \( U' = \text{Spec} A'[g/h] \). Now, \(|g|_x = |h|_x \) follows from \( f = \overline{g/h} \in \widetilde{H}(x) \). We set \( A'[g/h] = A' \). Then it holds \( A' \subset R_x \). It implies \( c_{\mathcal{X}'}(x) \in \text{Spec} A' \). Then, it is clear that \( g/h \in A'/c_{\mathcal{X}'}(x) \subset \kappa(c_{\mathcal{X}'}(x)) \).

Thus the natural inclusion \( \kappa(c_{\mathcal{X}'}(x)) \rightarrow \widetilde{H}(x) \) sends \( g/h \) to \( f \). It implies the assertion when \( k \) is a trivially valued field.

When \( k \neq k^\circ \), there exists \( a \in k^\circ \) such that \(|a|_x \leq |g|_x = |h|_x \) for some \( l \in \mathbb{Z}_{\geq 0} \). By taking \( I = (g, h, a^l) \subset A \) instead of \( (g, h) \), the above \( \pi : \mathcal{X}' \rightarrow \mathcal{X} \) holds the condition that \( \mathcal{X}' \) is a model of \( X \). Indeed, \( V(\mathcal{F}) \cap X = \emptyset \) since \( a^l \in k^\circ \) is a unit in \( k \). Hence, \( \mathcal{X}' \times_{\text{Spec} k^\circ} \text{Spec} k \cong X \). Moreover, \( \mathcal{X}' \) has an open affine scheme \( U' = \text{Spec} A'[g/h, a^l/h] \). Since \(|a^l/h|_x \leq 1 \), it holds that \( A'[g/h, a^l/h] \subset R_x \). It means that \( c_{\mathcal{X}'}(x) \in \text{Spec} A'[g/h, a^l/h] \). Therefore, the last assertion holds.

**Remark 3.6.** In the above situation, if \( k \) is a trivially valued field, \( X \) is the unique model of \( X \). When we consider a blow-up \( \pi : X' \rightarrow X \), \( X' \) is no longer a model of \( X \). To include such \( X' \), we state that \( X \) ranges over not only all models in which \( c_{\mathcal{X}'}(x) \) exists but also blow-ups of such models.

For the sake of the formulation of \( \widetilde{H}(x) \) without fixing a model, the above statement is a little vague. However, we can state it more specifically once we fix a model. As you saw in the above discussion, the following was essential.

**Corollary 3.7.** In the same situation, we fix a model \( \mathcal{X} \) such that \( c_{\mathcal{X}'}(x) \) exists. Then, it holds that

\[
\widetilde{H}(x) = \bigcup_{\pi : \mathcal{X}' \rightarrow \mathcal{X}} \kappa(c_{\mathcal{X}'}(x)),
\]

where \( \pi \) ranges over all blow-ups. Moreover, if \( k \neq k^\circ \), we can impose the condition that \( \mathcal{X}' \) is a model of \( X \) on this \( \pi \).

**Proof.** It follows from the discussion in the above proof. \( \square \)

**Corollary 3.8.** In the same situation, we assume that \( \widetilde{H}(x) \) is finitely generated over the residue field \( \kappa(c_{\mathcal{X}'}(x)) \) as a field.

Then, there exists some blow-up \( \pi : \mathcal{X}' \rightarrow \mathcal{X} \) such that

\[
\widetilde{H}(x) = \kappa(c_{\mathcal{X}'}(x)).
\]

Moreover, if \( k \neq k^\circ \), we can impose the condition that \( \mathcal{X}' \) is a model of \( X \) on this \( \pi \).
Proof. By the assumption, we can see that
\[ \tilde{\mathcal{H}}(x) = \kappa(c_{\mathcal{X}}(x))(f_1, \ldots, f_n) \text{ for some } f_1, \ldots, f_n \in \tilde{\mathcal{H}}(x). \]
In the similar way as the above, we set \( f_i = g_i/h_i \), where \( g_i, h_i \in A \). First, we set \( I_1 = (g_1, h_1) \subset A \) which is an ideal of \( A \). Then there is an ideal sheaf \( \mathcal{I}_1 \) on \( \mathcal{X} \) such that \( \tilde{I}_1 = \mathcal{I}_1|_U \) in the same way as the above. Now we consider the blow-up \( \pi_1 \) of \( \mathcal{X} \) along \( \mathcal{I}_1 \). That is,
\[ \pi_1 : \mathcal{X}_1 = \mathcal{B}l_{\mathcal{I}_1} \mathcal{X} \to \mathcal{X}. \]
\( \mathcal{X}_1 \) has the open affine scheme \( U_1 = \text{Spec} A[g_1/h_1] \). We set \( A[g_1/h_1] = A_1 \). Then it holds \( c_{\mathcal{X}_1}(x) \in \text{Spec} A_1 \) in the same way. Then, it is clear that
\[ f_1 \in \kappa(c_{\mathcal{X}_1}(x)). \]
Further, it holds \( \kappa(c_{\mathcal{X}}(x)) \subset \kappa(c_{\mathcal{X}_1}(x)) \).
Next, we replace \( A \) by \( A_1 \) and \( I_1 \) by \( I_2 = (g_2, h_2) \subset A_1 \) which is an ideal of \( A_1 \). Then, in the same way as the above, we obtain the following.
\[ \pi_2 : \mathcal{X}_2 = \mathcal{B}l_{\mathcal{I}_2} \mathcal{X}_1 \to \mathcal{X}_1, \]
\[ f_2 \in \kappa(c_{\mathcal{X}_2}(x)), \]
\[ \kappa(c_{\mathcal{X}_1}(x)) \subset \kappa(c_{\mathcal{X}_2}(x)). \]
Inductively, we obtain the following for each \( i = 1, \ldots, n - 1 \).
\[ \pi_{i+1} : \mathcal{X}_{i+1} = \mathcal{B}l_{\mathcal{I}_{i+1}} \mathcal{X}_i \to \mathcal{X}_i, \]
\[ f_{i+1} \in \kappa(c_{\mathcal{X}_{i+1}}(x)), \]
\[ \kappa(c_{\mathcal{X}_i}(x)) \subset \kappa(c_{\mathcal{X}_{i+1}}(x)). \]
Hence \( \pi = \pi_n \circ \cdots \circ \pi_1 : \mathcal{X}_n \to \mathcal{X} \) is the blow-up which satisfies
\[ f_i \in \kappa(c_{\mathcal{X}_n}(x)) \]
for all \( i \). Since \( \kappa(c_{\mathcal{X}}(x)) \subset \kappa(c_{\mathcal{X}_n}(x)) \), it holds \( \kappa(c_{\mathcal{X}_n}(x)) = \tilde{\mathcal{H}}(x) \). The last assertion holds by replacing \( \mathcal{I}_i \) in the similar manner as the latter half of the proof of the Theorem 3.5. \( \square \)

In Theorem 3.5, the existence of a model is crucial. If \( X \) or \( k^\circ \) satisfy some conditions, such a model always exists. The followings are results concerning such conditions.

**Corollary 3.9.** Let \( X \) be a projective variety over a non-Archimedean field \( k \). For any valuation \( x \in X^{an} \), it holds that
\[ \tilde{\mathcal{H}}(x) = \bigcup_{\mathcal{X}} \kappa(c_{\mathcal{X}}(x)), \]
where $\mathcal{X}$ ranges over

\[
\begin{cases}
  \text{all blow-ups of } X & \text{(if } k = k^\circ), \\
  \text{all projective models of } X & \text{(if } k \neq k^\circ).
\end{cases}
\]

**Proof.** Since $X$ is projective, we can take some projective model $\mathcal{X}$ of $X$ as Remark 2.26. For any projective model $\mathcal{X}$, $c_{\mathcal{X}}(x)$ always exists by the valuative criterion of properness. Hence, the assertion holds if $k$ is a trivially valued field. If $k \neq k^\circ$, we obtain the following by applying Corollary 3.7 after fixing the above model $\mathcal{X}$.

\[
\tilde{\mathcal{H}}(x) = \bigcup_{\pi: \mathcal{X}' \to \mathcal{X}} \kappa(c_{\mathcal{X}'}(x)),
\]

where $\pi$ ranges over all blow-ups such that $\mathcal{X}'$ is also a model of $X$. Since blow-up $\pi$ of projective $k^\circ$-variety $\mathcal{X}$ is projective, $\mathcal{X}'$ is also projective. Hence, the last assertion holds. $\square$

**Corollary 3.10.** Let $X$ be a proper variety over a non-Archimedean field $k$. We assume that $k^\circ$ is a DVR (not a field). For any valuation $x \in X^\mathrm{an}$, it holds that

\[
\tilde{\mathcal{H}}(x) = \bigcup_{\mathcal{X}} \kappa(c_{\mathcal{X}}(x)),
\]

where $\mathcal{X}$ ranges over all proper models of $X$.

**Proof.** Since $k^\circ$ is a DVR, $k$ is finitely generated over $k^\circ$. Hence $X$ is integral scheme of finite type over Noetherian integral scheme $\text{Spec} k^\circ$. Therefore we can take some proper $k^\circ$-variety $\mathcal{X}$ such that $X \hookrightarrow \mathcal{X}$ is a open immersion as $k^\circ$-scheme by Nagata compactification [Nag62]. Then $\mathcal{X} \to \text{Spec} k^\circ$ is surjective by the valuative criterion of properness. Since $k^\circ$ is one dimensional, $\mathcal{X} \to \text{Spec} k^\circ$ is flat. Now $X \hookrightarrow \mathcal{X}_k := \mathcal{X} \times_{\text{Spec} k^\circ} \text{Spec} k$ is an open immersion. Since $\mathcal{X} \to \text{Spec} k^\circ$ is proper, $\mathcal{X}_k \to \text{Spec} k$ is also proper. These give the following diagram.

\[
X \xrightarrow{\text{open}} \mathcal{X}_k \xrightarrow{\text{proper}} \text{Spec} k
\]

It follows from the above diagram that $X \hookrightarrow \mathcal{X}_k$ is proper. In particular, $X$ is open and closed in $\mathcal{X}_k$. Since $\mathcal{X}_k$ is integral, it holds that $X = \mathcal{X}_k$. Hence $\mathcal{X}$ is a proper model of $X$.

For any proper model $\mathcal{X}$, $c_{\mathcal{X}}(x)$ always exists by the valuative criterion of properness. Since $k \neq k^\circ$, we obtain the following by applying Corollary
3.7 after fixing the above model $\mathcal{X}$.

$$\widehat{\mathcal{H}}(x) = \bigcup_{\pi: \mathcal{X} \to \mathcal{X}} \kappa(c_{\mathcal{X}'}(x)),$$

where $\pi$ ranges over all blow-ups such that $\mathcal{X}'$ is also a model of $\mathcal{X}$. Since blow-up $\pi$ is proper, $\mathcal{X}'$ is also proper. Hence, the assertion holds. $\square$

We assume that $k^o$ is a DVR. Let $X$ be a variety over $k$. Then we can take proper $k$-variety $Y$ such that $X \hookrightarrow Y$ is an open immersion as $k$-scheme by Nagata compactification. We fix such $Y$. Now we can regard $x \in X^\text{an}$ as an element of $Y^\text{an}$ through $X^\text{an} \hookrightarrow Y^\text{an}$. Then it follows from the above Corollary that for any valuation $x \in X^\text{an}$,

$$\widehat{\mathcal{H}}(x) = \bigcup_{\mathcal{Y}} \kappa(c_{\mathcal{Y}}(x)),$$

where $\mathcal{Y}$ ranges over all proper models of $X$. For any compactification $Y$ of $X$, the same result holds. Hence, we can rephrase it as follows.

For any valuation $x \in X^\text{an}$, it holds that

$$\widehat{\mathcal{H}}(x) = \bigcup_{\mathcal{Y}} \kappa(c_{\mathcal{Y}}(x)),$$

where $\mathcal{Y}$ ranges over all proper models of all compactifications $Y$ of $X$.

4. $\widehat{\mathcal{H}}(x)$ FOR MONOMIAL VALUATIONS

In this section, we consider monomial valuations.

We give two different definitions of monomial valuations. We consider the case when the base field $k$ is a trivially valued field.

The first one is the following.

Definition 4.1 (Monomial valuation on a polynomial ring). Let $k$ be a field. Let us assume that $A = k[X_1, \ldots, X_n]$. Then, a monomial valuation $| \cdot |$ on $A$ is defined as below.

There are positive real numbers $r_1, \ldots, r_n$ such that for any

$$f = \sum_{I \in \mathbb{Z}_{\geq 0}^n} a_I X^I \in k[X_1, \ldots, X_n],$$

$| \cdot |$ returns the following values.

$$|f| := \max_{a_I \neq 0} r^I,$$

where $I = (i_1, \ldots, i_n)$, $a_I \in k$, $X^I = X_1^{i_1} \cdots X_n^{i_n}$ and $r^I = r_1^{i_1} \cdots r_n^{i_n}$. 
This monomial valuation is an element of \((\text{Spec}\, A)^{\text{an}}\), where \(k\) is a trivially valued field.

Since this definition is too restrictive, we want to define monomial valuation more generally. Then we make use of Cohen’s structure theorem.

**Definition 4.2** (Monomial valuation on a nonsingular point of variety). Let \(k\) be a field with the trivial norm. Let \(X\) be a variety over \(k\). Let \(p \in X\) be a nonsingular point. (We do not assume that \(p \in X\) is a closed point.)

By using Cohen’s structure theorem, there exists the inclusion \(\kappa(p) \hookrightarrow \mathcal{O}_{X,p}\) (which is not unique) such that for \((f_1, \ldots, f_m)\) which is a system of algebraic coordinates at a point \(p \in X\), we obtain the following isomorphism as \(\kappa(p)\)-algebra to the ring of formal power series.

\[
\hat{\mathcal{O}}_{X,p} \cong \kappa(p)[[t_1, \ldots, t_m]],
\]

where this isomorphism sends \(f_i\) to \(t_i\) and depends on the choice of the embedding of the residue field \(\kappa(p) \hookrightarrow \mathcal{O}_{X,p}\).

In the above situation, a monomial valuation \(\cdot\) on a nonsingular point \(p \in X\) is defined as follows.

There are positive real numbers \(r_1, \ldots, r_n\) which are less than 1 such that for each

\[
f = \sum_{I \in \mathbb{Z}_{\geq 0}^n} a_I f^I \in \mathcal{O}_{X,p} \subset \kappa(p)[[f_1, \ldots, f_m]],
\]

\(\cdot\) returns the following values.

\[
|f| := \max_{a_I \neq 0} |r^I|,
\]

where \(I = (i_1, \ldots, i_m), a_I \in \kappa(p), f^I = f_1^{i_1} \cdots f_m^{i_m}\) and \(r^I = r_1^{i_1} \cdots r_m^{i_m}\).

At a glance, this definition depends on the choice of algebraic coordinates at \(p \in X\), their values and the embedding of the residue field. However it does not depend on the choice of the embedding of the residue field [IM10].

Then it is clear that \(c_X(x) = p\).

Now we state a key lemma for monomial valuations.

**Lemma 4.3.** Let \(x = \cdot\) be a monomial valuation on the polynomial ring \(k[X_1, \ldots, X_n]\). We suppose that \(\sqrt{|\mathcal{H}(x)^{\times}|} \cong \mathbb{Q}^r\).

Then, \(\mathcal{H}(x)\) is the rational function field of \(n-r\) variables over \(k\). Further we can give a concrete description of generators.

**Proof.** We define the homomorphism \(\varphi : \mathbb{Z}^n \to |\mathcal{H}(x)^{\times}|\) by

\[
I = (i_1, \ldots, i_n) \mapsto |X^I| = |X_1^{i_1} \cdots X_n^{i_n}|.
\]

First of all, we see that \(\varphi\) is surjective.
Since $\mathcal{H}(x)$ is the completion of $k(X_1, \ldots, X_n)$ with respect to $x$, for any $f \in \mathcal{H}(x)$ and any $\varepsilon > 0$, there exists $g \in k(X_1, \ldots, X_n)$ such that $|f - g| < \varepsilon$. Now we take $\varepsilon$ such that $\varepsilon < |f|$. Then $|f| = |g|$ holds since $x$ is non Archimedean. Hence it holds that $|k(X_1, \ldots, X_n)^\times| = |\mathcal{H}(x)^\times|$.

As $x$ is a monomial valuation, for $f = \sum a_I X^I \in k[X_1, \ldots, X_n]$, we have $|f| = \max \{|X^I| \in \mathbb{R} \mid a_I \neq 0\}$. So $|k(X_1, \ldots, X_n)^\times| = \text{Im} \varphi$. Therefore $\varphi$ is surjective. It follows that the sequence as below is exact.

$$0 \to \ker \varphi \to \mathbb{Z}^n \to |\mathcal{H}(x)^\times| \to 0$$

It implies that $\ker \varphi$ is a free $\mathbb{Z}$-module since it is the submodule of $\mathbb{Z}^n$ which is a free $\mathbb{Z}$-module. Furthermore, it holds that $\ker \varphi \cong \mathbb{Z}^{n-r}$ because of the above exact sequence and the isomorphism $\sqrt{|\mathcal{H}(x)^\times|} \cong \mathbb{Q}^r$.

Then we show that

$$\widehat{\mathcal{H}(x)} = \text{Frac}(k[\ker \varphi]),$$

where $k[\ker \varphi]$ is the group ring defined by $\ker \varphi \supseteq I \mapsto X^I$.

In particular, there is the natural inclusion $k[\ker \varphi] \subset k(X_1, \ldots, X_n)\mathcal{O}$, where the right-hand side is the valuation ring of the algebraic valuation field $k(X_1, \ldots, X_n)$ with respect to $x$. Then it implies $k[\ker \varphi] \to \widehat{\mathcal{H}(x)}$. Moreover it is clear that this morphism is injective. Hence we have the natural inclusion $\text{Frac}(k[\ker \varphi]) \subset \widehat{\mathcal{H}(x)}$.

Therefore we have to show $\widehat{\mathcal{H}(x)} \subset \text{Frac}(k[\ker \varphi])$. By Lemma \ref{lem:fract}, we obtain $\widehat{\mathcal{H}(x)} = k(X_1, \ldots, X_n)$.

Now we can write any element in $\widehat{\mathcal{H}(x)}$ as $\widehat{f}$, where $f \in k(X_1, \ldots, X_n)\mathcal{O}$. Let us choose $g, h \in k[X_1, \ldots, X_n]$ with $f = g/h$. Now we can write $g = \sum a_I X^I$. If $a_I X^I$ satisfies $|a_I X^I| < |g|$, then

$$\left( \frac{a_I X^I}{h} \right) = 0.$$

So we have

$$\widehat{f} = \sum_{|a_I X^I| = |g|} \left( \frac{a_I X^I}{h} \right).$$

Hence it is enough to show that $\widehat{X^I/h} \in \text{Frac}(k[\ker \varphi])$ holds for each $X^I/h$ such that $|X^I| = |h|$. Then we may assume $|X^I/h| = 1$. It means that $\widehat{X^I/h} \neq 0$. Since $\text{Frac}(k[\ker \varphi])$ is a field, it is enough to show that $h/X^I \in \text{Frac}(k[\ker \varphi])$. If we write $h = \sum b_J X^J$, then, in the same way,

$$\left( \frac{h}{X^I} \right) = \sum_{|b_J X^J| = |X^I|} \left( \frac{b_J X^J}{X^I} \right) = \sum_{|X^{j-I}| = 0} b_J X^{j-I}.$$
Since $X^{J-I} \in k[\ker \varphi]$, it follows that $\overline{h/X} \in \text{Frac}(k[\ker \varphi])$. Thus it holds that $\widehat{\mathcal{H}}(x) = \text{Frac}(k[\ker \varphi])$.

Furthermore, we can see the following isomorphism

$$k[\ker \varphi] \cong k[Y_1, \ldots, Y_{n-r}]_{Y_1 \ldots Y_{n-r}} = k[Y^\pm_1, \ldots, Y^\pm_{n-r}]$$

as we saw $\ker \varphi \cong \mathbb{Z}^{n-r}$ earlier.

Hence it follows that $\widehat{\mathcal{H}}(x)$ is a rational function field of $n - r$ variables over $k$.

This is the result for monomial valuations on the affine space. In Lemma 5.8 of [Ber99], this is mentioned abstractly for any non-Archimedean field $k$. However, $\widehat{\mathcal{H}}(x)$ is not computed explicitly. This theorem means that we compute it explicitly at least when $k$ is a trivially valued field.

In contrast with its looks, this gives many applications to us. The following is important.

**Corollary 4.4.** In the above situation, if there exists the center of $x$ in $X = \mathbb{A}^n_k$ (that is, the value of coordinate $r_i$ is not greater than 1 for all $i$), there exists a blow-up $\pi : X' \to X$ such that

$$\widehat{\mathcal{H}}(x) = \kappa(c_{X'}(x)).$$

**Proof.** It follows from Lemma 4.3 and Corollary 3.8.

**Corollary 4.5.** In the above conditions, the transcendental degree of $\widehat{\mathcal{H}}(x)$ over $k$ is $n - r$.

**Proof.** From the above discussion, we saw that $\widehat{\mathcal{H}}(x)$ is a rational function field of $n - r$ variables over $k$. Hence it is clear.

In general, for valuation $x$, the following holds.

$$\dim_k \sqrt{|\mathcal{H}(x)|} + \text{trdeg}_k \widehat{\mathcal{H}}(x) \leq \dim X$$

This is called the Abhyankar inequality (cf. [Ste17] and [Abh56]). We call $x$ an Abhyankar valuation when the equality is achieved.

This corollary implies that monomial valuations are Abhyankar valuations since $\dim_k \sqrt{|\mathcal{H}(x)|} = r$, $\text{trdeg}_k \widehat{\mathcal{H}}(x) = n - r$ and $\dim X = n$ hold.

Now, we can extend Corollary 4.4 to monomial valuations on a nonsingular point as follows.

**Theorem 4.6.** Let $k$ be a trivially valued field. Let $X$ be a variety over $k$. Let $p \in X$ be a nonsingular point. Let $x \in X^{\text{an}}$ be a monomial valuation on $p \in X$. 

\[\dim_k \sqrt{|\mathcal{H}(x)|} + \text{trdeg}_k \widehat{\mathcal{H}}(x) \leq \dim X\]

This is called the Abhyankar inequality (cf. [Ste17] and [Abh56]). We call $x$ an Abhyankar valuation when the equality is achieved.
Then, \( \hat{\mathcal{H}}(x) \) is finitely generated over \( \kappa(c_X(x)) \) as a field. Further we can give the concrete description and there exists some blow-up \( \pi: X' \to X \) such that
\[
\hat{\mathcal{H}}(x) = \kappa(c_X(x)).
\]

**Proof.** We suppose that \( \sqrt{\mathcal{H}(x)^{\times}} \cong \mathbb{Q}^r \) and \( \dim \mathfrak{O}_{X,p} = m \). Since \( x \in X^{an} \) is a monomial valuation on \( p \in X \), \( x \) is defined as follows.

We take the \((f_1, \ldots, f_m)\) which is a system of algebraic coordinates at a nonsingular point \( p \in X \) and fix the following isomorphism as \( \kappa(p) \)-algebra to the ring of formal power series.
\[
\hat{\mathfrak{O}}_{X,p} \cong \kappa(p)[[t_1, \ldots, t_m]],
\]
where this isomorphism sends \( f_i \) to \( t_i \). In addition, we also fix the positive real numbers \( r_1, \ldots, r_n \) which are less than 1. Then \( x \) gives the values
\[
|f| := \max_{a_i \neq 0} |r^I|,
\]
for each
\[
f = \sum_{I \in \mathbb{Z}^m_{\geq 0}} a_I f^I \in \mathfrak{O}_{X,p} \subset \kappa(p)[[f_1, \ldots, f_m]].
\]

Now we set \( A := \kappa(p)[f_1, \ldots, f_m] \subset \mathfrak{O}_{X,p} \). Since \( \mathfrak{O}_{X,p} \) is isomorphic to the polynomial ring over \( \kappa(p) \). That is, \( A \cong \kappa(p)[t_1, \ldots, t_m] \). Then, we can regard \( y \) as a monomial valuation on \( A \) in the first definition of monomial valuations. Hence we can apply Lemma 4.3 for \( A \). It implies that \( \hat{\mathcal{H}}(y) \) is the rational function field of \( m - r \) variables over \( \kappa(c_Y(y)) \). In particular, \( \hat{\mathcal{H}}(y) \) is finitely generated over \( \kappa(c_Y(y)) \) as a field. Since \( \kappa(c_Y(y)) \subset \kappa(c_X(x)) \), it follows that \( \hat{\mathcal{H}}(x) \) is finitely generated over \( \kappa(c_X(x)) \) as a field.

Finally, we can construct the blow-up \( \pi: X' \to X \) such that
\[
\hat{\mathcal{H}}(x) = \kappa(c_X(x))
\]
by Corollary 3.8. \( \square \)

5. **Quotient Singularities and \( \hat{\mathcal{H}}(x) \)**

In the previous section, we defined a monomial valuation on a nonsingular point. Then, we want to consider a monomial valuation on a singular point.

Let us consider quotient singularities.

**Definition 5.1.** Let \( X \) be a variety over a field \( k \). Let \( G \) be a finite group. \( G \) acts on \( X \) if there is a group homomorphism \( G \to \text{Aut}(X) \).
For brevity, we identify $\sigma \in G$ with its image by the above homomorphism.

**Definition 5.2.** Let $k$ be a non-Archimedean field. Let $X$ be a variety over $k$. Let $G$ be the finite group acting on $X$. We suppose that $x \in X^{\text{an}}$ is a valuation. Then $x$ is $G$-invariant if it satisfies the following.

$$|f|_x = |\sigma^\sharp(f)|_x \quad \forall f \in K(X), \forall \sigma \in G,$$

where the ring isomorphism $\sigma^\sharp : K(X) \to K(X)$ is induced by the morphism $\sigma : X \to X$. It means that $x = \sigma^{\text{an}}(x)$ holds for all $\sigma \in G$, where the morphism $\sigma^{\text{an}} : X^{\text{an}} \to X^{\text{an}}$ is induced by the morphism $\sigma : X \to X$ through Proposition 2.22.

From now on, we consider the specific case as below.

We suppose that $k$ is a trivially valued field. Let $X$ be a variety over $k$. Let $G$ be a finite group acting on $X$. Let $p \in X$ be a nonsingular point. Let $x \in X^{\text{an}}$ be a $G$-invariant monomial valuation on $p \in X$.

**Lemma 5.3.** In the above situation, $p \in X$ is a fixed point of $G$.

**Proof.** Each $\sigma \in G$ gives the $k$-isomorphism $\sigma : X \to X$. Now we consider the morphism $\iota : \text{Spec} K(X) \to X$ induced by $\iota^\sharp = \text{id} : \mathcal{O}_{X, \eta} = K(X) \to K(X)$, where $\eta$ is the generic point of $X$.

Then we obtain the following diagram.

$$\begin{array}{ccc}
\text{Spec} K(X) & \xrightarrow{\iota} & X \\
\downarrow & & \downarrow \\
\text{Spec} R_x & \xrightarrow{\sigma \cong} & X
\end{array}$$

Now $\sigma(p)$ is defined by the image of the closed point of $\text{Spec} R_x$ through the following diagram.

$$\begin{array}{ccc}
\text{Spec} K(X) & \xrightarrow{\iota} & X \\
\downarrow & & \downarrow \\
\text{Spec} R_x & \xrightarrow{\sigma} & X
\end{array}$$

On the other hand, the valuation $\sigma^{\text{an}}(x)$ is defined as follows.

$$|f|_{\sigma^{\text{an}}(x)} := |\sigma^\sharp(f)|_x \quad \text{for any } f \in K(X).$$
This implies that we identify $\sigma(p)$ as the image of the closed point of $\text{Spec} R_{\sigma_{\text{an}}(x)}$ through the following diagram.

$$
\text{Spec} K(X) \xrightarrow{i} X \\
\downarrow \downarrow \\
\text{Spec} R_{\sigma_{\text{an}}(x)} \xrightarrow{\iota} \text{Spec} k
$$

Since $x$ is $G$-invariant, then it holds that $R_x = R_{\sigma_{\text{an}}(x)}$ in $K(X)$. It means that the above diagram coincides with the following.

$$
\text{Spec} K(X) \xrightarrow{i} X \\
\downarrow \downarrow \\
\text{Spec} R_x \xrightarrow{\iota} \text{Spec} k
$$

In this way, we obtain the two morphisms $\text{Spec} R_x \to X$ which make the following diagram commutative.

$$
\text{Spec} K(X) \xrightarrow{i} X \\
\downarrow \downarrow \\
\text{Spec} R_x \xrightarrow{\iota} \text{Spec} k
$$

One is the morphism by which the closed point of $\text{Spec} R_x$ is sent to $p \in X$. The other is the morphism by which the closed point of $\text{Spec} R_x$ is sent to $\sigma(p) \in X$. Since $X$ is separated, these two morphisms are the same by the valuative criterion of separatedness.

In other words, it implies $p = \sigma(p)$.

Hence, the assertion follows. \qed

Moreover, the following holds.

**Lemma 5.4.** In the same situation as above, we can take some affine open set $U \subset X$ such that $U$ is stable under the group actions of $G$ and $U$ contains $p \in X$ as a fixed point of $G$.

**Proof.** Any $\sigma \in G$ corresponds with the $k$-isomorphism $\sigma : X \to X$. In particular, $\sigma$ is an affine morphism. Now we take some open affine neighborhood $V \subset X$ of $p \in X$. Then we set

$$
U := \bigcap_{\sigma \in G} \sigma^{-1}(V).
$$

Since $\sigma$ is an affine morphism, $\sigma^{-1}(V)$ is affine. Moreover $p \in \sigma^{-1}(V)$ holds since $p$ is a fixed point by the above lemma. Since $X$ is separated
and $G$ is finite, it implies that $U$ is an affine neighborhood of $p \in X$. By
the definition of $U$, it is clear that $U$ is stable under $G$. Hence the assertion
follows.

This lemma implies that $G$ acts on the affine variety $U$. Hence, we can
take the geometric quotient $\phi : U \to U/G$ for this affine neighborhood $U$
of $p \in X$. If $U = \text{Spec} A$, then the above morphism is given by the natural
inclusion $A^G \hookrightarrow A$, where $A^G$ is the invariant ring of $G$-actions on $A$.

Any quotient singularity is described as $\phi(p)$ by taking suitable $X, p \in X$
and $\phi : U \to U/G$ in the same way.

The following is well-known.

**Proposition 5.5** (cf. Proposition 6.2 of [Muk03]). We suppose that a lin-
early reductive algebraic group $G$ acts on an affine variety $X$, and that there
exists a stable point for the action. Then every invariant rational function

\[ K(X)^G \]

\[ K(X/G) \]

coincides with the field of fractions of $K(X/G)$.

In particular, we make use of the following.

**Corollary 5.6.** We suppose that a finite group $G$ acts on an affine variety
$X$. Then, it holds that

\[ K(X)^G = K(X/G) . \]

**Proof.** It is well-known that a finite group is linearly reductive. Hence, the
assertion follows from the above proposition. However, we can also prove
this directly as follows.

$K(X^G) \subset K(X)^G$ is trivial. We show that $K(X)^G \subset K(X^G)$. We
suppose that $X = \text{Spec} A$. For $f/g \in K(X)^G$ such that $f, g \in A$, we take

\[ h := \prod_{\sigma \in G} \sigma(g) . \]

Then it is clear that $h \in A^G$ and $f/g \cdot h \in A^G$. Hence, it holds that

\[ f/g = (f/g \cdot h)/h \in K(X^G) . \]

Finally, we obtain the following theorem.

**Theorem 5.7.** We suppose that $k$ is a trivially valued field. Let $X$ be a
variety over $k$. Let $p \in X$ be a nonsingular point. Let $G$ be a finite group
acting on $X$ whose order is relatively prime to the characteristic of $k$. Let
$x \in X^\text{an}$ be a $G$-invariant monomial valuation on $p \in X$. We take $U$ as
Lemma 5.4. We suppose that $\phi : U \to U/G$ is the geometric quotient and
$\phi^\text{an}(x) = y \in (U/G)^\text{an}$. 

Then, it follows that
\[ \widehat{\mathcal{H}}(x)^G = \widehat{\mathcal{H}}(y). \]

Proof. In short, this proof is obtained by refining the proof of Corollary 3.8.

By Lemma 5.4, for this open affine neighborhood \( \text{Spec} A \cong U \subset X \) of \( p \in X \), we see that \( U \) is stable under \( G \). Since \( x \) is a monomial valuation on \( p \in X \), it follows that
\[ \widehat{\mathcal{H}}(x) = \kappa(c_X(x))(s_1, \ldots, s_r) \text{ for some } s_1, \ldots, s_r \in \widehat{\mathcal{H}}(x). \]

In the similar way as Corollary 3.8, we set \( s_i = \frac{f_i}{g_i} \), where \( f_i, g_i \in A \). Now we may assume that \( |f_i| = |g_i| = r_i < 1 \). Indeed, if \( r_i = 1 \), then \( \frac{f_i}{g_i} \in \text{Frac}(A/c_X(x)) = \kappa(c_X(x)) \) holds. We may assume that the order of \( G \) is \( n \). By the construction of \( A \), \( G \) acts on \( A \). That is, each \( \sigma \in G \) gives isomorphism \( \sigma : A \to A \).

First, we set \( I_1 = (f_1, g_1) \subset A \) which is an ideal of \( A \). For this \( I_1 \), we define \( J_1 \) as follows.
\[ J_1 := GI_1 \cap B_1 \subset A, \]
where
\[ GI_1 := \sum_{\sigma \in G} \sigma(I_1), \quad B_1 := \{ f \in A \mid |f|_x \leq r_1^n \}. \]

It is clear that \( GI_1 \) is an ideal of \( A \). Since \( x \) is non-Archimedean and \( A \subset R_x \), we find \( B_1 \) is also an ideal of \( A \). Therefore \( J_1 \) is also an ideal of \( A \). Since \( x \) is \( G \)-invariant, \( G \) acts on \( J_1 \). We set \( J_1 = (a_{11}, \ldots, a_{1m_1}) \subset A \). Now we suppose
\[ h_1 := \prod_{\sigma \in G} \sigma(g_1) \in A. \]
Then it is clear that \( h_1/g_1 \in A \).

In the similar way as Corollary 3.8, there is an ideal sheaf \( \mathcal{J}_1 \) on \( X \) such that \( \overline{J}_1 = \mathcal{J}_1|_U \). Now we consider the blow-up \( \pi_1 \) of \( X \) along \( \mathcal{J}_1 \). That is,
\[ \pi_1 : X_1 = \mathcal{B}l_{\mathcal{J}_1}X \to X. \]

\( X_1 \) has the open affine scheme \( U_1 = \text{Spec} A_1 \), where
\[ A_1 := A \left[ \frac{a_{11}}{h_1}, \ldots, \frac{a_{1m_1}}{h_1} \right]. \]
Indeed, we can take this affine open set \( U_1 \) as follows.

We obtain the following diagram by the properties of blow-up.
\[
\begin{array}{ccc}
\mathcal{B}l_{\mathcal{J}_1}U & \xrightarrow{\text{open}} & X_1 \\
\pi_1 \downarrow & & \pi_1 \\
U & \xrightarrow{\text{open}} & X
\end{array}
\]
ON THE BERKOVICH DOUBLE RESIDUE FIELDS AND BIRATIONAL MODELS 29

Then

\[ U_1 := D_+(h_1) \subset X_1 \]

is the open affine set of \( \mathcal{B}l_{\mathcal{J}_1} X \) which is described as above.

Now we can easily see that \( A_1 \subset R_x, G \) acts on \( A_1 \) and

\[ \frac{f_1}{g_1} = \frac{f_1 \cdot (h_1/g_1)}{h_1} \in A_1. \]

Indeed, \( f_1 \cdot (h_1/g_1) \in J_1 \) implies the last condition.

In the same way, we set

\[ I_2 := (f_2, g_2)A_1, \]

\[ B_2 := \{ f \in A_1 \mid |f|_x \leq r_n^a \}, \]

\[ J_2 := GI_2 \cap B_2 = (a_{21}, \ldots, a_{2m_2}), \]

\[ h_2 := \prod_{\sigma \in G} \sigma(g_2) \in A \subset A_1. \]

Moreover, we set \( \mathcal{J}_2 \) an ideal sheaf on \( X_1 \) such that \( \tilde{\mathcal{J}}_2 = \mathcal{J}_2|_{U_1} \). We consider the following blow-up in the same way.

\[ \pi_2 : X_2 = \mathcal{B}l_{\mathcal{J}_2} X_1 \to X_1. \]

Then we can take the open affine set \( U_2 = \text{Spec} A_2 \) of \( X_2 \), where

\[ A_2 := A_1 \left[ \frac{a_{21}}{h_2}, \ldots, \frac{a_{2m_2}}{h_2} \right]. \]

It implies that \( A_2 \subset R_x, G \) acts on \( A_2 \) and

\[ \frac{f_2}{g_2} = \frac{f_2 \cdot (h_2/g_2)}{h_2} \in A_2. \]

Inductively, we can construct the blow-up \( \pi = \pi_r \circ \cdots \circ \pi_1 : X_r \to X_1 \) and take the open affine set \( U_r = \text{Spec} A_r \) of \( X_r \), where

\[ A_r := A_{r-1} \left[ \frac{a_{r1}}{h_r}, \ldots, \frac{a_{rm_r}}{h_r} \right]. \]

It satisfies that \( A_r \subset R_x, G \) acts on \( A_r \) and \( f_i/g_i \in A_r \) for all \( i \).

Now we can write \( c_{X_r}(x) \) as \( m_x \cap A_r \in U_r \). Hence,

\[ \text{Frac}(A_r/m_x \cap A_r) = \kappa(c_{X_r}(x)). \]

Since \( \kappa(c_{X}(x)) \subset \kappa(c_{X_r}(x)) \) and \( f_i/g_i \in \kappa(c_{X_r}(x)) \) for each \( i \), it holds that

\[ \kappa(c_{X_r}(x)) = \mathcal{H}(x). \]

By Corollary [5.6], it follows that

\[ \text{Frac}(A)^G = \text{Frac}(A^G). \]
Hence it follows that $A_r^G \to \text{Frac}(A)^G = \text{Frac}(A^G)$. Further, $A_r^G \subset R_y$ follows from $A_r^G \subset R_x$. Now, we define $c_r^G(y)$ as the center of $y$ in $U_r/G$.

Then we obtain the following diagram.

$$
\begin{array}{ccc}
A_r^G & \longrightarrow & \mathcal{H}(y)^o \\
\downarrow & & \downarrow \\
\text{Frac}(A_r^G/c_r^G(y)) & \longrightarrow & \mathcal{H}(y)
\end{array}
$$

It is clear that $\widehat{\mathcal{H}(y)} \subset \widehat{\mathcal{H}(x)}^G$.

Hence it is enough to show that $\widehat{\mathcal{H}(x)^G} \subset \widehat{\mathcal{H}(y)}$.

For brevity, we redefine $c_r(x)$ as the center of $x$ in $U_r$. That is, $c_r(x) = c_{X_r}(x)$. Then we consider the following diagram.

$$
\begin{array}{ccc}
A_r^G & \longrightarrow & A_r/c_r(x) \\
\downarrow & & \downarrow \\
(A_r/c_r(x))^G & \longrightarrow & \mathcal{H}(y)
\end{array}
$$

It implies

$$A_r^G/c_r^G(y) \cong (A_r/c_r(x))^G.$$

Indeed, it is injective since $c_r^G(y) = A_r^G \cap m_y = A_r^G \cap c_r(x)$. On the other hand, the surjectivity follows as below.

For each $\overline{f} \in (A_r/c_r(x))^G$, where $f \in A_r$, we can take

$$f' := \frac{1}{n} \sum_{\sigma \in G} \sigma(f) \in A_r^G,$$

where $1/n \in k$ since $n$ is relatively prime to the characteristic of $k$.

Then, it follows that $\overline{f'} = \overline{f}$. Hence, it is surjective.

Now, we suppose $B := A_r/c_r(x)$. Then Frac($B)^G = \text{Frac}(B^G)$ follows from Corollary 5.6.

By the above discussion, it follows that

$$\text{Frac}(B) = \widehat{\mathcal{H}(x)}$$

and $\text{Frac}(B^G) \subset \widehat{\mathcal{H}(y)}$.

Therefore, it follows that

$$\widehat{\mathcal{H}(x)}^G \subset \widehat{\mathcal{H}(y)}.$$ 

\[ \square \]

**Corollary 5.8.** In the above situation, we suppose that

$$\dim X - \dim_Q \sqrt{\mid \mathcal{H}(x)^{\times} \mid} = 1.$$
If \( p \in X \) is a closed point whose residue field is \( k \), then \( \hat{\mathcal{H}}(y) \) is the rational function field over \( k \) of dimension 1.

**Proof.** By Theorem 5.7, it holds that

\[
k \subset \hat{\mathcal{H}}(y) = \hat{\mathcal{H}}(x)^G \subset \hat{\mathcal{H}}(x).
\]

By the proof of Theorem 4.6, \( \hat{\mathcal{H}}(x) \) is the rational function field over \( k \) of dimension 1. Hence, by applying the Lüroth Theorem, \( \hat{\mathcal{H}}(y) \) is also the rational function field over \( k \) of dimension 1. \( \square \)

In the same way as above, by applying well-known results for the Lüroth problem, the following also holds.

**Corollary 5.9.** In the above situation, we suppose that

\[
\dim X - \dim \mathbb{Q} \sqrt{|\hat{\mathcal{H}}(x)\times|} = 2.
\]

If \( p \in X \) is a closed point, and \( k \) is an algebraically closed field of characteristic 0, then \( \hat{\mathcal{H}}(y) \) is the rational function field over \( k \) of dimension 2.

**Proof.** The proof is exactly the same as above. By Theorem 5.7, it holds that

\[
k \subset \hat{\mathcal{H}}(y) = \hat{\mathcal{H}}(x)^G \subset \hat{\mathcal{H}}(x).
\]

By the proof of Theorem 4.6, \( \hat{\mathcal{H}}(x) \) is the rational function field over \( k \) of dimension 2. Hence, by applying the result for the Lüroth Problem, \( \hat{\mathcal{H}}(y) \) is also the rational function field over \( k \) of dimension 2. \( \square \)

6. **Quasi monomial valuations and \( \hat{\mathcal{H}}(x) \)**

In §4, 5, we only considered the case when the base field is a trivially valued field. In this section, we consider the case when the base field \( K \) is a complete DVF. We suppose that \( R \) is the complete DVR of \( K \) and \( k \) is the residue field of \( K \). We assume that the characteristic of \( k \) is 0. Then, Cohen’s structure theorem implies the isomorphism \( R \cong k[[\varpi]] \). In particular, we obtain the injection \( k \hookrightarrow R \). Now we regard \( K \) as a non-Archimedean field by the valuation uniquely determined by \( |\varpi| = \exp(-1) \).

We write \( S := \text{Spec} R \). We prepare the following terminology as [BFJ14].

**Definition 6.1.** \( \mathcal{X} \) is an \( S \)-variety if it is a flat integral \( S \)-scheme of finite type. We denote by \( \mathcal{X}_0 \) its central fibre and by \( \mathcal{X}_K \) its general fibre.
**Definition 6.2.** Let $\mathcal{X}$ be an $S$-variety. An ideal sheaf $\mathcal{I}$ on $\mathcal{X}$ is vertical if it is co-supported on the central fibre.

A vertical blow-up $\mathcal{X}' \to \mathcal{X}$ is the normalized blow-up along a vertical ideal sheaf.

Given an $S$-variety $\mathcal{X}$, let $\{E_i\}_{i \in I}$ be the finite set of irreducible components of its central fibre $\mathcal{X}_0$. We endow each $E_i$ with the reduced scheme structure. For each subset $J \subset I$, we set

$$E_J := \bigcap_{j \in J} E_j.$$  

**Definition 6.3.** Let $\mathcal{X}$ be an $S$-variety. $\mathcal{X}$ is SNC if it satisfies the following.

1. the central fibre $\mathcal{X}_0$ has normal crossing support,
2. $E_J$ is irreducible (or empty) for each $J \subset I$.

Condition (1) is equivalent to the following two conditions. First, $\mathcal{X}$ is regular. Given a point $\xi \in \mathcal{X}_0$, let $I_\xi \subset I$ be the set of indices $i \in I$ for which $\xi \in E_i$, and we pick a local equation $z_i \in \mathcal{O}_{\mathcal{X}, \xi}$ of $E_i$ at $\xi$ for each $i \in I_\xi$. Then we also impose that $\{z_i \mid i \in I_\xi\}$ can be completed to a regular system of parameters of $\mathcal{O}_{\mathcal{X}, \xi}$.

Condition (2) depends on the literatures. It is not imposed in the usual definition of a simple normal crossing divisor, however, can always be achieved from (1) by further blow-up along components of the possibly non-connected $E_J$'s.

We denote by $\text{Div}_0(\mathcal{X})$ the group of vertical Cartier divisors on $\mathcal{X}$. When $\mathcal{X}$ is normal, we can see that $\text{Div}_0(\mathcal{X})$ is a free $\mathbb{Z}$-module of finite rank.

We often make use of the following.

**Theorem 6.4** (cf. Theorem 1.1 of [Tem08]). For any $S$-variety $\mathcal{X}$ with smooth generic fibre, there exists a vertical blow-up $\mathcal{X}' \to \mathcal{X}$ such that $\mathcal{X}'$ is SNC.

Let $\mathcal{X}$ be a smooth connected projective $K$-analytic space in the sense of Berkovich. In other words, for some smooth projective $K$-variety $Y$, we can identify $\mathcal{X}$ with $Y^{\text{an}}$.

**Definition 6.5.** $S$-variety $\mathcal{X}$ is a model of $X$ if it is a normal and projective $S$-variety together with the datum of an isomorphism $\mathcal{X}^{\text{an}}_K \cong X$.

We note that $\mathcal{X}$ is a model of $\mathcal{X}_K$ in the sense of Definition 2.25.

We denote by $\mathcal{M}_X$ the set of models of $X$. Then, $\mathcal{M}_X$ is non empty. Indeed, given an embedding $Y$ into a suitable projective space $\mathbb{P}^m_K$ we can take $\mathcal{X}'$ as the normalization of the closure of $Y$ in $\mathbb{P}^m_S$. A similar construction shows that $\mathcal{M}_X$ becomes a directed set by declaring $\mathcal{X}' \geq \mathcal{X}$ if there exists a vertical blow-up $\mathcal{X}' \to \mathcal{X}$.
For any model $\mathcal{X}$ of $X$ and any $x \in X$, we can define the center $c_\mathcal{X}(x)$ of $x$ in the similar way as before. That is, we consider the following diagram.

$$
\text{Spec } \kappa(\pi_\mathcal{X}(x)) \longrightarrow \mathcal{X} \\
\downarrow \quad \quad \quad \downarrow \\
\text{Spec } R_x \longrightarrow S
$$

Then $c_\mathcal{X}(x) \in \mathcal{X}$ is obtained by the image of the closed point of $\text{Spec } R_x$.

More precisely, we can easily see that $c_\mathcal{X}(x) \in \mathcal{X}_0$.

Let $\mathcal{X}$ be an SNC model of $X$. We can write the central fibre as

$$\mathcal{X}_0 = \sum_{i \in I} m_i E_i,$$

where $(E_i)_{i \in I}$ are irreducible components.

Then, it follows that

$$\text{Div}_0(\mathcal{X}) = \bigoplus_{i \in I} Z E_i.$$

We set

$$\text{Div}_0(\mathcal{X})^*_\mathbb{R} := \text{Hom}(\text{Div}_0(\mathcal{X}), \mathbb{Z}) \otimes_\mathbb{Z} \mathbb{R}.$$

We denote by $E_i^*$ the dual element of $E_i$ and we set

$$e_i := \frac{1}{m_i} E_i^*.$$

For each $J \subset I$ such that $E_J \neq \emptyset$, let $\hat{\sigma}_J \subset \text{Div}_0(\mathcal{X})^*_\mathbb{R}$ be the simplicial cone defined by

$$\hat{\sigma}_J := \sum_{j \in J} \mathbb{R}_{\geq 0} e_j.$$

We fix the basis of $\text{Div}_0(\mathcal{X})^*_\mathbb{R}$ as above. That is, $s = (s_j) \in \hat{\sigma}_J$ means $s = \sum s_j e_j$. These cones naturally defines a fan $\hat{\Delta}_X$ in $\text{Div}_0(\mathcal{X})^*_\mathbb{R}$.

We define the dual complex of $\mathcal{X}$ by

$$\Delta_X := \hat{\Delta}_X \cap \{ \langle X_0, \cdot \rangle = 1 \},$$

where $\langle \cdot, \cdot \rangle$ is the natural bilinear form on $\text{Div}_0(\mathcal{X})^*_\mathbb{R}$.

Each $J \subset I$ such that $E_J \neq \emptyset$ corresponds to a simplicial face

$$\sigma_J := \hat{\sigma}_J \cap \{ \langle X_0, \cdot \rangle = 1 \} = \text{Conv} \{ e_j \mid j \in J \}$$

of dimension $|J| - 1$ in $\Delta_X$, where Conv denotes convex hull. This endows $\Delta_X$ with the structure of a simplicial complex, such that $\sigma_J$ is a face of $\sigma_L$ if and only if $J \supset L$.

We denote by $\mathcal{M}'_X$ the set of SNC models of $X$. By Theorem 6.4, $\mathcal{M}_X \neq \emptyset$ implies $\mathcal{M}'_X \neq \emptyset$. We can see that $\mathcal{M}'_X \subset \mathcal{M}_X$ and $\mathcal{M}'_X$ is also a directed set.
When \( \mathcal{X}' \geq \mathcal{X} \), where \( \mathcal{X}', \mathcal{X} \in \mathcal{M}'_{\mathcal{X}} \), we obtain the natural map \( \Delta_{\mathcal{X}'} \to \Delta_{\mathcal{X}} \). Hence, the following is well-defined.

\[
\lim_{\mathcal{X} \in \mathcal{M}'_{\mathcal{X}}} \Delta_{\mathcal{X}}.
\]

The following, which is a highly suggestive result, is stated by [KS06]. Furthermore the proof is written by [BFJ14].

**Theorem 6.6 (Corollary 3.2 of [BFJ14]).** In the above situation, we obtain the following homeomorphism.

\[
X \cong \lim_{\mathcal{X} \in \mathcal{M}'_{\mathcal{X}}} \Delta_{\mathcal{X}}.
\]

Now for each \( J \subset I \) the intersection \( E_J := \bigcap_{j \in J} E_j \) is either empty or a smooth irreducible \( k \)-variety. Let \( \xi_j \) be a generic point of \( E_j \) if \( E_j \neq \emptyset \). For each \( j \in J \) we can choose a local equation \( z_j \in \mathcal{O}_{\mathcal{X}, \xi_j} \), so that \( (z_j)_{j \in J} \) is a regular system of parameters of \( \mathcal{O}_{\mathcal{X}, \xi_j} \) because of the SNC condition.

For this \( \mathcal{X} \) and any (nonsingular) point \( p \in \mathcal{X} \), we obtain the sequence \( k \hookrightarrow R \to \mathcal{O}_{\mathcal{X}, p} \). It implies \( k \hookrightarrow \mathcal{O}_{\mathcal{X}, p} \).

Hence, by Cohen’s structure theorem, after taking a field of representatives of \( \kappa(\xi_j) \), we obtain that

\[
\iota : \hat{\mathcal{O}}_{\mathcal{X}, \xi_j} \cong \kappa(\xi_j)[[t_j, j \in J]]
\]

defined by \( \iota(z_j) = t_j \).

**Definition 6.7.** \( x \) is a quasi monomial valuation if there exists a SNC model \( \mathcal{X} \) of \( X \) and \( s \in \sigma_J \subset \Delta_{\mathcal{X}} \) such that \( x \) is a valuation on \( \mathcal{O}_{\mathcal{X}, \xi_J} \) defined by the restriction of the valuation on \( \hat{\mathcal{O}}_{\mathcal{X}, \xi_J} \) defined by

\[
f = \sum_{\alpha \in \mathbb{Z}^{[J]}} c_{\alpha}z^\alpha \in \hat{\mathcal{O}}_{\mathcal{X}, \xi_J} \mapsto |f| = \max_{c_{\alpha} \neq 0} r^\alpha,
\]

where each \( c_{\alpha} \) is either zero or unit of \( \mathcal{O}_{\mathcal{X}, \xi_J} \), that is \( \iota(c_{\alpha}) \in \kappa(\xi_J) \), and \( |z_j| = r_j = \exp(-s_j) < 1 \).

**Remark 6.8.** By the condition of \( \Delta_{\mathcal{X}} \), \( x \) is an extension of the equipped valuation on \( K \). In other words, \( x \in \mathcal{X} \) follows. It is clear that \( c_X(x) = \xi_J \).

Our definition above is slightly a priori different from the original one in [BFJ14] though it is still equivalent.

From now on, we list a few properties of quasi monomial valuations.

**Proposition 6.9 (cf. Definition 3.7 and §3.3 of [BFJ14]).** In the same situation as above, we denote by \( \Delta_{\mathcal{X}}' \) the inverse image of \( \Delta_{\mathcal{X}} \) through the homeomorphism in Theorem 6.6. Then, it holds that
This is the original definition of quasi monomial valuations in [BFJ14]. The following is a topological property.

**Proposition 6.10** (Corollary 3.9 of [BFJ14]). In the above situation, we denote by \( X_{\text{qm}} \) the set of quasi monomial valuation of \( X \). Then, it follows that \( X_{\text{qm}} \) is dense in \( X \).

Lastly, we state a property of quasi monomial valuations as an application of the discussion in Theorem 4.6.

**Theorem 6.11.** Let \( X \) be a smooth connected projective \( K \)-analytic space. If \( x \) is a quasi monomial valuation, then there exists a SNC model \( \mathcal{X} \) of \( X \) such that \( \overline{\mathcal{H}}(x) = \kappa(c_{\mathcal{X}}(x)) \).

**Proof.** This proof is essentially given by Corollary 3.8. By the assumption, we can take a SNC model \( \mathcal{X} \) satisfying that \( x \) gives a monomial valuation on \( \mathcal{O}_{\mathcal{X},c_{\mathcal{X}}}(x) \) as above.

Now we construct desirable vertical blow-up \( \pi : \mathcal{X}' \to \mathcal{X} \) such that \( \overline{\mathcal{H}}(x) = \kappa(c_{\mathcal{X}'}(x)) \) by refining the construction of Theorem 4.6.

By Theorem 4.6, we see \( \overline{\mathcal{H}}(x) = \kappa(c_{\mathcal{X}}(x))(f_1, \ldots, f_n) \) for some \( f_1, \ldots, f_n \in \overline{\mathcal{H}}(x) \).

Now we may assume that \( f_i = g_i/h_i \), where \( g_i, h_i \in m_{c_{\mathcal{X}}(x)}(x) \subset \mathcal{O}_{\mathcal{X},c_{\mathcal{X}}}(x) \) in the same way as the discussion of Theorem 5.7. We denote by \( \varpi \in \mathcal{O}_{\mathcal{X},c_{\mathcal{X}}}(x) \) the local equation of the central fibre \( \mathcal{X}_0 \) at \( c_{\mathcal{X}}(x) \). Since \( |\varpi|_x < 1 \) and \( |g_i|_x = |h_i|_x < 1 \), we see \( |\varpi'|_x \leq |g_i|_x = |h_i|_x \) for some \( l \in \mathbb{N} \). This \( l \) is independent of the choice of \( i \).

Now we consider the blow-up along the closed subscheme \( V(\varpi', g_1, h_1) \) in some neighborhood of \( c_{\mathcal{X}}(x) \). Since \( V(\varpi', g_1, h_1) \) is also a closed subscheme of \( \mathcal{X}_0 \), the defining ideal sheaf of \( V(\varpi', g_1, h_1) \) extend to some defining ideal sheaf on \( \mathcal{X} \) which contains the defining ideal sheaf of \( \mathcal{X}_0 \) on \( \mathcal{X} \) in the same way as Theorem 3.5. Then the blow-up along this ideal sheaf can be regarded as a vertical blow-up after taking further blow-up by [Tem08]. We denote by \( \pi_1 : \mathcal{X}_1 \to \mathcal{X} \) this blow-up. Then, we see \( f_1 \in \kappa(c_{\mathcal{X}_1}(x)) \).

Indeed, we can take \( U^1 = \text{Spec} A^1 \) as the affine neighborhood of \( c_{\mathcal{X}_1}(x) \).
such that \( g_1/h_1 \in A^1 \) since we can take \( U^1 \) which satisfies below.

\[
\begin{align*}
U^1 = \text{Spec}A^1 & \xrightarrow{\pi_1} U = \text{Spec}A \\
& \cap \\
& \text{Spec}A[\varpi^l/h_1, g_1/h_1]
\end{align*}
\]

The above \( U \) is an affine neighborhood of \( c_{\mathcal{X}}(x) \). This diagram is obtained by considering the image of \( \text{Spec}R_x \). It induces \( f_1 \in \kappa(c_{\mathcal{X}}^1(x)) \).

In the similar way as above, we construct the vertical blow-up \( \pi_{i+1} : \mathcal{X}^{i+1} \to \mathcal{X}^i \) with respect to \( V(\varpi^l, g_{i+1}, h_{i+1}) \) inductively. Then, it follows that

\[
\kappa(c_{\mathcal{X}^n}(x)) = \mathcal{H}(x).
\]

In this way, we construct desirable vertical blow-up

\[
\pi(= \pi_n \circ \cdots \circ \pi_1) : \mathcal{X}'' \to \mathcal{X}.
\]

Then \( \mathcal{X}'' \) is a SNC-model of \( X \). Therefore, the assertion follows. \( \square \)
