BIG RAMSEY DEGREES OF 3-UNIFORM HYPERGRAPHS ARE FINITE

MARTIN BALKO, DAVID CHODOUNSKÝ, JAN HUBIČKA, MATĚJ KONEČNÝ, AND LLUIS VENA

ABSTRACT. We prove that the universal homogeneous 3-uniform hypergraph has finite big Ramsey degrees. This is the first case where big Ramsey degrees are known to be finite for structures in non-binary language.

Our proof is based on vector (or product) form of the Milliken’s tree theorem and demonstrates a general method to carry existing results on structures in binary relational languages to higher arities.

1. INTRODUCTION

Given 3-uniform hypergraphs $A$ and $B$, we denote by $(B)^{A}_{k,l}$ the set of all embeddings from $A$ to $B$. We write $C \rightarrow (B)^{A}_{k,l}$ to denote the following statement:

For every colouring $\chi$ of $(B)^{A}_{k}$ with $k$ colours, there exists an embedding $f : B \rightarrow C$ such that $\chi$ does not take more than $l$ values on $(f[B])^{A}_{k}$.

For a countably infinite structure $B$ and its finite induced sub-structure $A$, the big Ramsey degree of $A$ in $B$ is the least number $L \in \omega + 1$ such that $B \rightarrow (B)^{A}_{k,L}$ for every $k \in \omega$; see [KPT05]. A countably infinite structure $B$ has finite big Ramsey degrees if the big Ramsey degree of $A$ in $B$ is finite for every finite substructure $A$ of $B$.

A countable hypergraph $A$ is (ultra)homogeneous if every isomorphism between finite induced sub-hypergraphs extends to an automorphism of $A$. It is well known that there is (up to isomorphism) a unique countable homogeneous 3-uniform hypergraph $H$ with the property that every countable 3-uniform hypergraph can be embedded into $H$, see e.g. [Mac11].

Solving a question of Sauer\footnote{Personal communication, 2014.} we prove the following result, which was announced in [BCH+19].

**Theorem 1.1.** The universal homogeneous 3-uniform hypergraph $H$ has finite big Ramsey degrees.

Our result is a contribution to the ongoing project of characterising big Ramsey degrees of homogeneous structures [KPT05], [Tod10, Chapter 6]. This project was motivated by the work of Laver who, in late 1969, proved that the big Ramsey degrees of the order of the rationals, denoted by $(\mathbb{Q}, \leq)$, are finite (see [Dev79, Page 73], [EH74, Lav84]). Using Milliken’s tree theorem (Theorem 2.2) for a single binary tree his argument is particularly intuitive: The vertices of a binary tree can be seen as infinite $\{0, 1\}$-words and those as rationals in the range $(0, 1)$ written as

binary numbers (with additional digit 1 added to the end of each word to avoid ambiguities). Since this is a dense linear order it follows that \((\mathbb{Q}, \leq)\) can be embedded to it. A colouring finite subsets of \(\mathbb{Q}\) then corresponds to a colouring finite subtrees and thus leads to an application of the Milliken’s tree theorem. In 1979, Devlin [Dev79] refined the technique to fully characterise the big Ramsey degrees of \((\mathbb{Q}, \leq)\). See [Tod10, Section 6.3] for further details.

Similar ideas can be applied to graphs; here a graph is coded using a binary tree, where 1 is used to code an edge. In the passing number representation, a pair of words \(w, w'\) with \(|w| \leq |w'|\) is adjacent if \(w'[w] = 1\) [Tod10, Theorem 6.25]. Here, \(|w|\) denotes the length of the word \(w\) and \(w_i\) is the letter of \(w\) on index \(i\), where the indices start from 0. This representation was used by Sauer [Sau06] and Laflamme, Sauer, Vuksanovic [LSV06] who, in 2006, characterised big Ramsey degrees of the Rado graph. This was refined to unconstrained structures in binary languages [LSV06] and additional special classes [DLS16, NVT09, LNVTS10, Mas20].

Milliken’s tree theorem remained the key in all results in the area (here we consider Ramsey theorem as a special case of Milliken’s tree theorem for the unary tree).

A generalization of these results to structures of higher arities (such as hypergraphs) and to structures forbidding non-trivial substructures remained open for over a decade. Recent connections to topological dynamics [Zuc19] renewed the interest in the area and both these problems were solved recently. Using set-theoretic techniques, Dobrinen [Dob20a] proved that the universal homogeneous triangle free graph has finite big Ramsey degrees and subsequently generalized this result to graphs omitting a clique \(K_k\) for any \(k \geq 3\) [Dob19]. This was further generalised by Zucker [Zuc20] to free amalgamation classes in binary languages. Hubička applied parameter spaces and the Carlson–Simpson theorem to show the finiteness of big Ramsey degrees for partial orders and metric spaces [Hub20] giving also a straightforward proof of [Dob20a].

The main goal of this note is to demonstrate a proof technique, which allows to reprove some of the aforementioned results in the context of relational structures with higher arities. The proof, for the first time in this area, makes use of the vector (also called product) form of Milliken’s tree theorem. To our knowledge this may be also the first combinatorial application of Milliken’s tree theorem for trees of unbounded branching [Dod15].

Similar results on big Ramsey degrees of relational structures were recently independently obtained by Coulson, Dobrinen and Patel [CDP20]. Their proof technique is different. Instead of using the vector Milliken’s tree theorem, the proof from [CDP20] is based on the Dobrinen’s method of strong coding trees involving techniques from forcing and the Erdős–Rado theorem (see [Dob20b] for a recent survey).

2. Preliminaries

Our argument will make use of the vector (or product) Milliken’s tree theorem. All definitions and results in this section are taken from [DK16]. Given an integer \(\ell\), we use both the combinatorial notion \([\ell] = \{1, \ldots, \ell\}\) and the set-theoretical convention \(\ell = \{0, 1, \ldots, \ell - 1\}\).

A tree is a (possibly empty) partially ordered set \((T, \prec_T)\) such that, for every \(t \in T\), the set \(\{s \in T : s \prec_T t\}\) is finite and linearly ordered by \(\prec_T\). All nonempty trees we consider are rooted, that is, they have a unique minimal element called the root of the tree. An element \(t \in T\) of a tree \(T\) is called a node of \(T\) and its level, denoted by \(|t|_T\), is the size of the set \(\{s \in T : s \prec_T t\}\). Note that the root has level 0. For \(D \subseteq T\), we write \(L_T(D) = \{|t|_T : t \in D\}\) for the level set of \(D\) in \(T\). We use \(T(n)\) to denote the set of all nodes of \(T\) at level \(n\), and by \(T(<n)\) the set
\{ t \in T : |t|_T < n \}. The \textit{height} of \( T \) is the minimal natural number \( h \) such that \( T(h) = \emptyset \). If there is no such number \( h \), then we say that the height of \( T \) is \( \omega \). We denote the height of \( T \) by \( h(T) \).

Given a tree \( T \) and nodes \( s,t \in T \) we say that \( s \) is a \textit{successor} of \( t \) in \( T \) if \( t \leq_T s \). The node \( s \) is an \textit{immediate successor} of \( t \) in \( T \) if \( t <_T s \) and there is no \( s' \in T \) such that \( t <_T s' <_T s \). We denote the set of all successors of \( t \) in \( T \) by \( \text{Succ}_T(t) \) and the set of immediate successors of \( t \) in \( T \) by \( \text{ImmSucc}_T(t) \). We say that the tree \( T \) is \textit{finely branching} if \( \text{ImmSucc}_T(t) \) is finite for every \( t \in T \).

For \( s,t \in T \), the \textit{meet} \( s \land_T t \) of \( s \) and \( t \) is the largest \( s' \in T \) such that \( s' <_T s \) and \( s' <_T t \). A node \( t \in T \) is \textit{maximal} in \( T \) if it has no successors in \( T \). The tree \( T \) is \textit{balanced} if it either has infinite height and no maximal nodes, or all its maximal nodes are in \( T(h - 1) \), where \( h \) is the height of \( T \).

A \textit{subtree} of a tree \( T \) is a subset \( T' \) of \( T \) viewed as a tree equipped with the induced partial ordering such that \( s \land_T t = s \land_T t' \) for each \( s,t \in T' \). Note that our notion of a subtree differs from the standard terminology, since we require the additional condition about preserving meets.

**Definition 2.1.** A subtree \( S \) of a tree \( T \) is a \textit{strong} subtree of \( T \) if either \( S \) is empty, or \( S \) is nonempty and satisfies the following three conditions.

1. The tree \( S \) is balanced and has a root node.
2. Every level of \( S \) is a subset of some level of \( T \), that is, for every \( n < h(S) \) there exists \( m \in \omega \) such that \( S(n) \subseteq T(m) \).
3. For every non-maximal node \( s \in S \) and every \( t \in \text{ImmSucc}_T(s) \) the set \( \text{ImmSucc}_S(s) \cap \text{Succ}_T(t) \) is a singleton.

**Observation 2.1.** If \( E \) is a subtree of a balanced tree \( T \), then there exists a strong subtree \( S \supseteq E \) of \( T \) such that \( L_T(E) = L_T(S) \). \( \square \)

A \textit{vector} tree (sometimes also called a \textit{product} tree) is a finite sequence \( T = (T_1, \ldots, T_d) \) of trees having the same height \( h(T_i) \) for all \( i \in [d] \). This common height is the \textit{height} of \( T \) and is denoted by \( h(T) \). A vector tree \( T = (T_1, \ldots, T_d) \) is \textit{balanced} if the tree \( T_i \) is balanced for every \( i \in [d] \).

If \( T = (T_1, \ldots, T_d) \) is a vector tree, then a vector \textit{subset} of \( T \) is a sequence \( D = (D_1, \ldots, D_d) \) such that \( D_i \subseteq T_i \) for every \( i \in [d] \). We say that \( D \) is \textit{level compatible} if there exists \( L \subseteq \omega \) such that \( L_{T_i}(D_i) = L \) for every \( i \in [d] \). This (unique) set \( L \) is denoted by \( L_T(D) \) and is called the \textit{level set} of \( D \) in \( T \).

**Definition 2.2.** Let \( T = (T_1, \ldots, T_d) \) be a vector tree. A \textit{vector strong} subtree of \( T \) is a level compatible vector subset \( S = (S_1, \ldots, S_d) \) of \( T \) such that \( S_i \) is a strong subtree of \( T_i \) for every \( i \in [d] \).

For every \( k \in \omega + 1 \) with \( k \leq h(T) \), we use \( \text{Str}_k(T) \) to denote the set of all vector strong subtrees of \( T \) of height \( k \). We also use \( \text{Str}_{\leq k}(T) \) to denote the set of all strong subtrees of \( T \) of height at most \( k \).

**Theorem 2.2** (Milliken [Mil79]). For every rooted, balanced and finely branching vector tree \( T \) of infinite height, every nonnegative integer \( k \) and every finite colouring of \( \text{Str}_k(T) \) there is \( S \in \text{Str}_\omega(T) \) such that the set \( \text{Str}_k(S) \) is monochromatic.

3. Proof of Theorem 1.1

Given an integer \( n \geq 0 \), a \{0,1\}-vector \( \vec{v} \) of length \( n \) is a function \( \vec{v} : n \to 2 \). We write \( ||\vec{v}|| = n \) to denote the length of \( \vec{v} \) and, for \( i < ||\vec{v}|| \), we use \( v_i \) to denote the \( i \)-th coordinate \( \vec{v}(i) \) of \( \vec{v} \). In particular, we permit the empty vector and the first coordinate has index 0. We use the standard vocabulary for matrices. An \( n \times n \) \{0,1\}-matrix \( A \) is a function \( A : n \times n \to 2 \). We use \( |A| = n \) to denote the number
of rows (and columns) of $A$. For $k \leq |A|$, we write $A \upharpoonright k$ for the sub-matrix of $A$ with domain $k \times k$. The $i$th row of the matrix $A$ is the vector $\vec{v}_i : j \mapsto A_{i,j}$. The value $A(i,j)$, the entry in the $i$th row and the $j$th column of $A$ is denoted by $A_{i,j}$. Note that we start the indexing of entries of $A$ from 0. The matrix $A$ is strictly lower triangular if $A_{i,j} = 0$ for all $i$ and $j$ with $i < j$. For a matrix $A$ and a vector $\vec{v}$ with $|A| = |v| = n$, the extension $A^c \vec{v}$ of $A$ is the $(n + 1) \times (n + 1)$ matrix

$$
\begin{pmatrix}
A & \vdots \\
\vdots & \\
0 & \\
\vdots & \\
0 & 0
\end{pmatrix}.
$$

More precisely, the matrix $A^c \vec{v}$ is given by setting

1. $(A^c \vec{v})_{i,j} = A_{i,j}$ for all $i, j \in n$,
2. $(A^c \vec{v})_{n,i} = v_i$ for every $i \in n$, and
3. $(A^c \vec{v})_{j,n} = 0$ for every $j \in n + 1$.

Note that if $A$ is a strictly lower triangular matrix, then $A^c \vec{v}$ is strictly lower triangular as well.

Let $T = (T_1, T_2)$ be the vector tree, where:

1. The binary tree $(T_1, <_{T_1})$ consists of all finite $\{0, 1\}$-vectors ordered by the end-extension. More precisely, we have $\vec{u} \leq_{T_1} \vec{v}$ if $|u| \leq |v|$ and $u_i = v_i$ for every $i \in |u|$. The root of $T_1$ is the empty vector.
2. Nodes of the tree $T_2$ are all finite strictly lower triangular (square) $\{0, 1\}$-matrices ordered by extension. That is, we have $A \leq_{T_2} B$ if and only if $|A| \leq |B|$ and $A_{i,j} = B_{i,j}$ for every $i, j \in |A|$. The root of $T_2$ is the empty matrix.

**Definition 3.1.** Let $(S_1, S_2)$ be a strong vector subtree of $T$ of height $k \in \omega + 1$. In other words, $(S_1, S_2) \in \text{Str}_k(T)$. The valuation tree $\text{val}(S_1, S_2)$ corresponding to $(S_1, S_2)$ is a subset of $S_2$ defined by the following recursive rules:

1. The root of $\text{val}(S_1, S_2)$ is the root of $S_2$.
2. If $A \in \text{val}(S_1, S_2)$, $\vec{v} \in S_1(\{A\}_{S_2})$, and $\{C\} = \text{ImmSucc}_{S_2}(A) \cap \text{Succ}_{T_2}(A^c \vec{v})$, then $C \in \text{val}(S_1, S_2)$.
3. There are no other nodes in $\text{val}(S_1, S_2)$.

Note that $\text{val}(S_1, S_2)$ is a subtree of $S_2$ and hence also a subtree of $T_2$. Also, the height of $\text{val}(S_1, S_2)$ equals $k$ and the number of nodes of $\text{val}(S_1, S_2)$ depends only on $k$, see Lemma 3.1.

A tree $T \subseteq T_2$ is a valuation tree if $T = \text{val}(S_1, S_2)$ for some $(S_1, S_2) \in \text{Str}_k(T)$.

For two subtrees $T$ and $T'$ of $T_2$, a function $f : T \rightarrow T'$ is a structural isomorphism if it is an isomorphism of trees (preserving relative heights of nodes), and for every $A, B, C \in T$ with $|A| \leq |B| < |C|$ it also holds that $f(C)|_{f(B)\cup f(A)} = C|_{B\cup A}$.

**Lemma 3.1.** For every $k \in \omega + 1$ and every valuation subtree $T$ of $T_2$ of height $k$, there exists a unique structural isomorphism $f : T_2(\langle k \rangle) \rightarrow T$.

**Proof.** We use induction on $k$. There is nothing to prove for $k = 0$. If $k = 1$, then the function $f$ mapping the empty matrix to the root of $T$ is the unique structural isomorphism. Assume the induction hypothesis does hold for $k > 0$. Let $T = \text{val}(S_1, S_2)$ be of height $k + 1$. By the induction hypothesis for the valuation tree $T(\langle k \rangle)$ there exists a unique structural isomorphism $f : T_2(\langle k \rangle) \rightarrow T(\langle k \rangle)$. Denote by $e : k + 1 \rightarrow \omega$ the increasing enumeration of $L_{T_2}(T)$. Fix a node $\vec{u} \in T_1(k - 1)$, there is a unique $\vec{v} \in S_1(k - 1)$ such that $u_i = v_{e(i)}$ for every $i \in k$. For every $A \in T_2(k - 1)$, there is a unique $C \in \text{ImmSucc}_{S_2}(f(A)) \cap \text{Succ}_{T_2}(f(A)^c \vec{v})$. We
extend the map \( f \) by declaring \( f : A^c \mapsto C \), and we do this for each choice of \( \bar{u} \) and \( A \). It is easy to check that the extended map is a structural isomorphism of \( T_2(2k+1) \) and \( T \), and that the extension was in fact defined in the unique possible way.

If \( k = \omega \), then by the induction hypothesis there are structural isomorphisms 
\[ f_i : T_2(<i) \rightarrow T(<i) \] for each \( i \in \omega \). Since these isomorphism are unique, we get 
\[ f_i \subset f_j \] for \( i < j \), and 
\[ f = \bigcup \{ f_i : i \in \omega \} \] is the desired structural isomorphism (uniqueness is easy to check). \( \square \)

Let \( G \) be a 3-uniform hypergraph defined by the following two rules:

1. The vertex set of \( G \) consists of all nodes of \( T_2 \). In particular, the vertices of \( G \) are square \( \{0, 1\} \)-matrices.

2. There is a hyperedge \( \{ A, B, C \} \) in \( G \) if and only if \( A, B, C \in T_2 \) are matrices satisfying \(|A| < |B| < |C| \) and \( C_{[B],[A]} = 1 \).

Recall that \( H \) denotes the universal countable homogeneous 3-uniform hypergraph. Without loss of generality, we assume that the vertex set of \( H \) is \( \omega \). Let \( \varphi : H \rightarrow G \) be an embedding defined by setting \( \varphi(i) = A^i \), where \( A^i \) is a \((2i+1) \times (2i+1)\) matrix such that if \( j, k, i \) is a hyper-edge of \( H \) for \( j < k < i \), then 
\[ A_{2k+1,2j} = A_{2k+1,2j+1} = 1, \text{ and there are no other non-zero values in } A^i; \text{ see Example 1}. \]

**Example 1.** Assume that \( H \) starts with vertices \( \{0, 1, 2, 3\} \) with hyper-edges \( \{0, 1, 2\}, \{0, 1, 3\} \) and \( \{1, 2, 3\} \). Then the corresponding images in \( G \) are:

\[
\varphi(0) = (0), \varphi(1) = \begin{pmatrix} 0 & 0 & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix}, \varphi(2) = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \varphi(3) = \begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}.
\]

It is easy to check that \( \varphi \) is indeed a hypergraph embedding. We also have the following simple observation.

**Observation 3.2.** For any two matrices \( A, B \in \varphi[S] \),

1. all even rows are constant 0-vectors and so \([A \wedge T, B] \) is odd, and
2. if \( \bar{u} \neq \bar{u} \) are two rows of \( A \) and \( B \), respectively, then \([\bar{u} \wedge T, \bar{u}] \) is even. \( \square \)

Now, we prove the last auxiliary result that we use in the proof of Theorem 1.1. This is a standard step of constructing the envelope of a set as used by Laver and Milliken [Tod10, Section 6.2]. Here we additionally need to take care of the interactions between the two trees.

**Lemma 3.3.** For every \( k \in \omega \), there exists \( R(k) \in \omega \) such that, for every set \( S \subset \omega \) of size \( k \), there exists a valuation tree of height at most \( R(k) \) containing all vertices of \( \varphi[S] \).

**Proof.** Choose an arbitrary natural number \( k \) and a set \( S \) of \( k \)-many elements of \( \omega \). We will construct the required strong vector subtree \((S_1, S_2) \) of \( T \) such that \( \text{val}(S_1, S_2) \) contains all matrices from \( \varphi[S] \). To achieve this, we define envelopes \( E_1 \) and \( E_2 \) in the trees \( T_1 \) and \( T_2 \), respectively, by first collecting all necessary matrices in \( E_2 \), then inserting all necessary vectors into \( E_1 \), which in turn requires adding more matrices to \( E_2 \). The important upshot of our construction is that we can argue that this process promptly terminates and the resulting envelopes are bounded in size.
We proceed in four steps, first defining auxiliary sets $E_0^2 \subseteq T_1$ and $E_0^3 \subseteq T_2$ that will be further extended to $E_1$ and $E_2$, respectively.

(i) Let $E_0^2 = \{ A \land T_2 : A, B \in \varphi[S] \} \subseteq T_2$. This is necessary to obtain a subtree of $T_2$. Observe that $|E_0^2| \leq 2k - 1$.

(ii) Let $E_0^3 \subseteq T_1$ consist of all $|B|$th rows of $A$ for all $A, B \in E_0^2$, $|B| < |A|$ and a constant 0-vector of length $\max L_{T_2}(E_0^3)$. This is necessary to obtain a valuation tree that contains all of $E_0^3$. The additional zero vector is added to make level sets of $E_0^3$ and $E_0^2$ equal. Observe that $|E_0^3| \leq |E_0^2|^2 + 1$.

(iii) Let $E_1 = \{ u \land T_1 \in \varphi : u, v \in E_0^3 \}$. This is necessary to obtain a subtree of $T_1$.

Observe that $|E_1| \leq 2 |E_0^3| - 1$.

(iv) Let $E_2$ extend $E_0^3$ by all matrices $A \upharpoonright [\overline{v}]$ where $A \in E_0^3$ and $\overline{v} \in E_0^2$.

This is necessary to synchronize levels between both subtrees. Observe that $|E_2| \leq |E_0^3| (|E_0^3| + 1)$.

It follows from step (iii) that $E_1$ is meet closed in $T_1$ and thus a subtree of $T_1$. Similarly, step (i) implies that $E_0^2$ is a subtree of $T_2$ and thus also $E_2$ is a subtree of $T_2$, as we did not introduce any new meets in step (iv). It follows from the upper bounds on $|E_1|$ and $|E_2|$ that the height of $E_2$ is bounded from above by a function of $k$.

By step (iv), the level sets of $E_1$ and $E_2$ are the same, that is, $L = L_{T_2}(E_2) = L_{T_1}(E_1)$. Now, let $S_1$ be some strong subtree of $T_1$ containing $E_1$ such that $L_{T_1}(S_1) = L$ and let $S_2$ be some strong subtree of $T_2$ containing $E_2$ such that $L_{T_2}(S_2) = L$. Such trees $S_1$ and $S_2$ exist by Observation 2.1.

We claim that $\text{val}(S_1, S_2)$ contains $\varphi[S]$. Choose any matrix $A \in \varphi[S] \subseteq E_2 \subseteq S_2$. We prove by induction on the level $\ell \in L$, where $\ell \leq |A|$, that $A \upharpoonright \ell \in \text{val}(S_1, S_2)$. For the base of the induction, if $\ell$ is the minimal element of $L$, then $A \upharpoonright \ell$ is the root of $S_2$ and hence the root of $\text{val}(S_1, S_2)$.

To prove the induction step, we need to check that if $A \upharpoonright \ell \subseteq S_2$ for $\ell < |A|$, then the $\ell$th row $v$ of $A$ is a node of $S_1$. Observe that level sets of the constructed sets “$E^\ell$” are extended only at steps (i) and (iii) of the construction. Moreover, all new levels introduced during step (i) are odd by part (1) of Observation 3.2 while levels introduced at step (iii) are even by part (2) of Observation 3.2.

We distinguish two cases based on the parity of the level $\ell$. If $\ell$ is odd, then $\ell \in L_{T_2}(E_0^3)$, since all odd levels are introduced only in step (i). By step (ii), we then have $v \in E_0^3$. Since $E_0^3 \subseteq E_1 \subseteq S_1$, we have $v \in S_1$.

Otherwise $\ell$ is even. Then $v$ is a constant 0-vector by part (1) of Observation 3.2. We have $v \in S_1$, since one of the maximal nodes of $S_1$ is a constant 0-vector by step (ii).

Altogether, $\text{val}(S_1, S_2)$ contains all matrices from $\varphi[S]$, which finishes the proof.

We can now proceed with the proof of Theorem 1.1.

Proof of Theorem 1.1. Fix a finite 3-uniform hypergraph $A$. Recall that we want to prove that there exists a number $n = n(A)$ such that for every finite colouring $\chi^0 : (A^H) \to r$ there is an embedding $g : H \to H$ such that $\chi^0$ does not take more than $n$ values on $(g^H)\!$.

Consider the 3-uniform hypergraph $G$. Since $G$ is a countable 3-uniform hypergraph, it follows from the properties of $H$ that there is an embedding $\theta : G \to H$. Consider the colouring $\chi : (G^\Lambda) \to r$ obtained by setting $\chi(\overline{\Lambda}) = \chi^0(\theta(\overline{\Lambda}))$ for every $\overline{\Lambda} \in (G^\Lambda)\!$. 

□
Consider the vector tree \( T = (T_1, T_2) \) defined earlier. Let \( k = R(|A|) \) be given by Lemma 3.3. Let \( G_k \) be the induced sub-hypergraph of \( G \) on \( T_2(<k) \). We enumerate the copies of \( A \) in \( {2^k \choose A} \) as \( \{ A_i : i \in n \} \) for some \( n \in \omega \).

By Lemma 3.1, for every valuation tree \( T \) of height \( k \), there is a structural isomorphism \( f_T : G_k \to T \) that is also an isomorphism of the corresponding sub-hypergraphs of \( G \). Let \( S = (S_1, S_2) \) be a strong subtree of \( T \) of height \( k \) and consider the structural isomorphism \( f = f_{val(S_1, S_2)} : G_k \to val(S_1, S_2) \). Put

\[
\bar{\chi}(S) = \left\langle \chi \left( f \left( \tilde{A}_i \right) \right) : i \in n \right\rangle,
\]

which is a finite colouring of \( \text{Str}_k(T) \). By Theorem 2.2, there is an infinite strong subtree of \( T \) monochromatic with respect to \( \bar{\chi} \). Let \( U \) be its corresponding valuation subtree. The structural isomorphism \( \psi : T_2 \to U \) given by Lemma 3.1 is a hypergraph embedding \( \psi : G \to G \). Since, by Lemma 3.3, every \( \tilde{A} \in {2^k \choose A} \) is contained in at least one valuation subtree of height \( k \), we know that \( \chi \) takes at most \( n \) different values on \( \psi(G) \). Considering the embedding \( \varphi : H \to G \) defined earlier, the image \( \theta [\psi[\varphi[H]]] \) is the desired copy \( g[H] \) of \( H \), where copies of \( A \) have at most \( n \) different colours in \( \chi^0 \).

**4. Concluding remarks**

1. The construction naturally generalises to \( d \)-uniform hypergraphs for any \( d \geq 2 \). The construction is then based on a vector tree \( T_d = (T_1, \ldots, T_{d-1}) \) defined as follows. Nodes of a tree \( T_i \) with \( 1 \leq i \leq d-1 \) are \{0, 1\}-tensors of order \( i \) ordered analogously as in the tree \( T_2 \) used in Section 3. The definition of the valuation tree can be also naturally generalised: given a vector strong subtree \( S = (S_1, \ldots, S_{d-1}) \) one first obtains the valuation tree \( val(S_1, S_2) \). Based on \( val(S_1, S_2) \) and \( S_3 \) the valuation subtree \( val(S_1, S_2, S_3) \) can be constructed in analogy to Definition 3.1. The construction then proceeds similarly for higher orders. A detailed description of these constructions is going to appear in full generality in [BCH+20].

Also observe that the special case \( d = 2 \) of this generalised setting corresponds to the passing number representation.

2. More generally, structures in finite relational language with symbols of maximum arity \( d \) can be represented by vector trees \( T_d = (T_1, \ldots, T_{d-1}) \). In this case, the nodes of a tree \( T_i \) with \( 1 \leq i \leq d-1 \) are sequences of tensors of order \( i - d + a \) for every relational symbol of arity \( a > i - d \).

3. We aimed for simplicity in our proof of Theorem 1.1. The bounds obtained in the proof are not optimal. Structures defined in [BCH+19] can be used to produce more careful embedding of hypergraphs to \( H \). They describe the order in which the branchings of the trees \( T_1 \) and \( T_2 \) and of the actual vertices appear. This is also going to appear in [BCH+20].

4. The tree \( T_1 \) in our construction has a natural meaning: while the tree \( T_2 \) represents vertices and hyper-edges, the tree \( T_1 \) represents the union of all graphs that are created from a 3-uniform hypergraph by fixing a vertex \( v \) and considering the graph on the same vertex set where edges are induced by all hyper-edges containing \( v \).

5. **Acknowledgement**

We would like to thank to Stevo Todorcevic for his kind remarks and for helpful discussion regarding the history and context of this area.
