ON SYNCHRONIZATION IN COUPLED DYNAMICAL SYSTEMS ON HYPERGRAPHS

ANIRBAN BANERJEE & SAMIRON PARUI

Department of Mathematics and Statistics, Indian Institute of Science Education and Research Kolkata, Mohanpur-741246, India,

Abstract. Here we study both global and local synchronization in coupled dynamical systems on hypergraph. Diffusion Matrices, representing the diffusive influence of internal connectivities of the hypergraph on the dynamics occurring in the vertices, are constructed. Models are proposed for discrete-time and continuous-time dynamical systems on (weighted and un-weighted) hypergraphs. The interplay between the diffusion matrices and the dynamical systems on the vertices are analyzed to study synchronization of the dynamics under the influence of hyper-edge couplings. Sufficient conditions for synchronization in dynamical systems on hypergraphs are derived. Some of the derived sufficient conditions incorporate structural properties of the underlying hypergraphs. Numerical examples are given to illustrate the theoretical results. The results in this article can initiate and stimulate the generalization of the underlying structure considered in the study of dynamical networks from graphs to hypergraphs.

1. Introduction

During the last decade, growing interest in studying dynamical networks has been witnessed because of its wide range of applications in some crucial areas of multidisciplinary research involving Chemistry, Computer science, Physics, Mathematics, Biology, Social science, and Information science [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11]. The study of the dynamical network deals with the evolution of the individual dynamical systems taking place on the vertices of the underlying graph and the consequences of the interactions among the dynamical systems in the different vertices of the graph. This study involves many fundamental concepts from non-linear dynamics and spectral graph theory.

Synchronization, one of the widely studied phenomena in dynamical systems and networks, was discovered in the year 1665 by Huyghens [12, 13]. According to etymology, the word "Synchronization" has a Greek root "synkhronizein", that means "to occur at the same time", however, in science "synchronization" indicates the coherence of the rhythm of more than one processes. Of late, the field received more observance because of its numerous applications ranging from information spreading to neural networks and rigorous study has been done on different aspects of synchronization in both continuous-time and discrete-time dynamical networks [14, 15, 16, 17, 18, 19, 20, 21]. There are many real-world situations, which can not be properly represented by graphs and need more sophisticated tools to be explained appropriately. As an example, to model collaborations among three scientists with a graph, where scientists are considered as vertices and two of them are connected by an edge if they are involved in a project, if we consider a complete graph on three vertices it fails to distinguish between the case where we have one single project, pursued by all the three scientists together or whether

Date: August 31, 2020.
there are three different projects pursued by two scientists each. A similar problem arises to represent group formation among the people in social networking platforms like Facebook, WhatsApp, etc. To get rid of this problem, one may use hypergraphs in place of a graphs. A hypergraph is a generalization of a graph where the edges are nonempty subsets of the vertex set. A hypergraph is called \((m)-\) uniform hypergraph, if each of its edges contains the same \((m)\), number of vertices, otherwise it is known as general hypergraph (or simply hypergraph).

Though a large number of studies have been done on synchronizations of the trajectories of a dynamical network, only a few significant contributions have been made so far on the same for dynamical systems on hypergraphs. As some real-world phenomenon can be represented more appropriately in terms of hypergraphs comparing to graphs, it would be interesting to study synchronization on dynamical systems on hypergraphs. In [22], authors have studied synchronization on hyper-network, which is a combination of two or more graphs or simply, multi-layer networks. For more details and references on multi-layer and multiplex networks, readers can see [23, 24]. In literature, sometimes, multi-layer networks and multiplex networks are called hyper-network [22]. The underlying structure of multi-layer networks and multiplex networks are graphs or combinations of graphs, and hence should not be confused with hypergraphs. Throughout this article, we consider hypergraphs, a generalization of graphs, where each hyperedge can be any subset of the vertex set containing at least two elements. In 2014, the first attempt was made to analyze synchronization in dynamical systems on hypergraphs in which the authors have used continuous-time dynamical systems and analyzed local synchronization with 3-uniform hypergraphs [25]. Very recently a study has been made on local stability analysis of un-weighted continuous-time dynamical systems on hypergraphs in [26]. The diffusion matrix used here is different from ours.

Here, we study local and global synchronization in both, discrete-time and continuous-time dynamical systems on general hypergraphs as well as uniform hypergraphs. The required tools and techniques are developed to generalize the underlying structure of dynamical networks from graphs to hypergraphs. The Laplacian matrices associated with graphs are regarded as convenient tools for describing the diffusive action on the graphs. Later after the advent of the concepts of hypergraphs, the past decades have witnessed many attempts to develop Laplacians for hypergraphs. In this article, some linear operators (and corresponding matrices) are developed to represent the diffusive influence of hyperedges of the hypergraphs. In Section 2 we start with some preliminaries. The main results of this article are given in Section 3. Discrete dynamical systems on hypergraphs is discussed in Section 3.1. In this section, the models for discrete dynamical systems on hypergraphs are proposed and some results involving sufficient conditions on local and global synchronization are derived. A model on weighted discrete dynamical systems on hypergraphs involving variable coupling strength is proposed in Section 3.2 and some results related to global analysis and stability analysis have been stated. Few relations between the structural property of a hypergraph and synchronizability have been discussed in Section 3.3. The continuous-time dynamical systems on hypergraphs is discussed in Section 3.4. We also compute some numerical examples which are shown in Section 4. All the numerical examples are calculated by using MATLAB Online R2020a.

2. Preliminaries

In this section, we introduce and recall some essential and basic definitions and concepts. We start with the notations, that we are going to use throughout this article.

2.1. Notations.

- \(\mathbb{N}_k := \{x \in \mathbb{N} : x \leq k, k \in \mathbb{N}\}\).
- We denote a hypergraph by \(G = (V, E)\) where \(V\) and \(E\) are the sets of vertices and (hyper)edges respectively of \(G\). Since a graph is a special case of a hypergraph we also use the same notation for graphs. Whether \(G\) is a graph or hypergraph that will
be cleared from the context. If two distinct vertices, $v_i$ and $v_j$ are connected by an
(hyper)edge then we write, $v_i \sim v_j$.

- $m_{\text{max}} = \max \{|e_i| : e_i \in E\}$ is the maximum cardinality of the edges, $\text{rank}(G)$, of the
hypergraph $G = (V, E)$.

- We use the cursive script to denote tensors and the general script for matrices. For example, $A_G$ and $L_G$ denoted as the adjacency and Laplacian tensors of the hypergraph $G$, respectively, whereas, $A_G$ and $L_G$ are the adjacency and Laplacian matrices of the
$G$, respectively.

- Here we have considered that the state space of the dynamical systems on each vertex
is $\mathbb{R}^k$. The state of dynamical systems on hypergraphs at time $n$ is a quantity that
represents the situation of the dynamical systems on all the vertices of the systems on
hypergraphs at time $n$. Hence the state of the dynamical systems on the hypergraph,
$u$ is a function $u : T^D \times V \rightarrow \mathbb{R}^k$, where $T^D$ is the domain of time. For any time
$n \in T^D$, the state of the dynamical systems on a hypergraph at time $n$ is a function
$u(n) : V \rightarrow \mathbb{R}^k$. Thus the state space of the coupled dynamical systems on hypergraphs
is $\mathbb{R}^{kV}$, the set of all function from $V$ to $\mathbb{R}^k$. As we consider the cardinality of the vertex
set $V$ is equal to $N$, the state space of the coupled dynamical systems on hypergraphs
becomes $\mathbb{R}^{kV} = \mathbb{R}^{Nk}$. The state of the coupled dynamical systems on hypergraphs, with
$N$ vertices, at time $n$ is denoted by $u(n)$, a vector in $\mathbb{R}^{Nk}$. In this article, most of the
time the state vector $u(n)$ is represented by an $N \times k$ matrix, whose $N$ rows represent
the $k$ dimensional state of the $N$ vertices. However, $u(n)$ can be represented as a $kN$
dimensional vector, we also use the same. Later we will discuss this vector notation.
Unless otherwise stated, $u(n)$ is in matrix notation.

- The time is denoted by $n$ and $t$ when we consider the discrete and the continuous cases,
respectively.

- $\{u(n)\}_{n \in \mathbb{N}}$ or $\{u(n)\}$ ($\{u(t)\}$ in continuous case) represents the trajectory of a dynamical
systems on hypergraphs.

- Synchronized trajectories are of our special interest, hence different notation has been
used for this type of trajectories. A synchronized trajectory is denoted by $\{v(n)\}$ (or
by $\{v(t)\}$ in continuous case).

- For any symmetric matrices $A, B$, throughout this paper the following notations are used.
$A > 0$ means $A$ is positive definite, $A \geq 0$ means $A$ is positive semidefinite,
$A < 0$ means $A$ is negative definite, $A \leq 0$ means $A$ is negative semidefinite. $A > B$
means $A - B$ is positive definite and $A \geq B$ means $A - B$ is positive semidefinite.

- We denote $I_k$ to an identity matrix of order $k$ where $k \in \mathbb{N}$. Note that, some incidence
matrices are also denoted by $I_G$, $I_e$ where $G$ and $e$ are a hypergraph and a hyperedge,
respectively. Since, $G, e \notin \mathbb{N}$, the confusion can be avoided.

2.2. Basic definitions. Before going to define a hypergraph, let us recall the definition of a
graph. The order pair, $G = (V, E)$ is called a graph where $V$ is a set, whose elements are called
vertices and $E$ is a collection of two-element subsets of $V$, which are called edges. The underlying
topology of a dynamical network is a graph. One of the main objectives of this paper to provide
a general framework in which hypergraph can be used as the underlying topology of dynamical
networks. Replacing graphs by hypergraphs provides the scope of representing multi-nary
interactions rather than only binary interactions through the 2-graphs. This generalization
of dynamical networks is called coupled dynamical systems on hypergraphs. A hypergraph,
$G = (V, E)$, is a generalized notion of a graph, where a (hyper)edge $e \in E$ can be any nonempty
subset of the vertex set, $V$. In this article, our study is based on finite connected hypergraphs,
that is, the vertex sets of the respective hypergraphs are finite. A hypergraph $G(V, E)$ is
connected if for any two vertices $v_1, v_l \in V$, there exists a sequence of vertices $v_1 v_2 \cdots v_l$
such that, $v_i \sim v_{i+1}$, $i = 1, \ldots, l - 1$. Throughout the paper, it is considered that the cardinality of
vertex set, $|V| = N$ and that of the edge set, $|E| = M$. 
As we can represent a graph by different connectivity matrices, such as adjacency matrix, Laplacian matrix, signless Laplacian matrix, normalized Laplacian matrix, etc., analogously a hypergraph can be represented by adjacency tensor, Laplacian tensor, signless Laplacian tensor, normalized Laplacian tensor, etc. Now we recall some definitions of the tensors as described in [27].

**Definition 2.1.** Let \( G = (V, E) \) be the hypergraph with the vertex set \( V = \{v_1, v_2, \ldots, v_N\} \) and \( E = \{e_1, e_2, \ldots, e_M\} \). Let \( m_{\text{max}} \) be the rank\((G)\), of \( G \). The adjacency hyper-matrix of \( G \) is defined as the \( m_{\text{max}} \) order \( n \) dimensional tensor \( A_G = \{(a_{i_1i_2\cdots i_{m_{\text{max}}}})\}_{i_j \in \mathbb{N}_N} \). For all edges \( e = \{v_{i_1}, v_{i_2}, \ldots, v_{i_s}\} \in E \) of cardinality \( s \leq m_{\text{max}} \), defined by \( a_{p_1p_2\cdots p_{m_{\text{max}}}} = \frac{\alpha}{n} \), where \( \alpha = \sum_{k_1,k_2,\ldots,k_s \geq 1, \sum_j k_j = m_{\text{max}}} \), where \( p_1, p_2, \ldots, p_{m_{\text{max}}} \) are chosen from \( \{1, 2, \ldots, l_s\} \) in all possible ways with at least once for each element of the set. The other positions of the hyper-matrix are zero.

The degree, \( d(v) \), of a vertex \( v \in V \), is defined by the cardinality of the set \( \{e \in E : v \in e\} \). The hypermatrix \( D_G = \{(d_{i_1i_2\cdots i_{m_{\text{max}}}})\}_{i_j \in \mathbb{N}_N} \) of \( G \) is the \( m_{\text{max}} \) order \( n \) dimensional diagonal hypermatrix with the entries \( d_{i_i,i} = d(v_i) \) and others are zero.

**Definition 2.2.** Laplacian hyper-matrix, \( L_G = \{(l_{i_1i_2\cdots i_{m_{\text{max}}}})\}_{i_j \in \mathbb{N}_N} \) of the hyper graph \( G \) is the \( m_{\text{max}} \) order \( n \) dimensional diagonal hyper-matrix which is defined as, \( L_G = D_G - A_G \)

Adjacency, Laplacian, and normalized Laplacian matrices, respectively, for hypergraphs, are introduced in [28]. The operators due to these matrices are linear. Hence, despite the possibility of losing some information, using these matrices can make our analysis easier because the classical methods of studying synchronization in dynamical networks, which involves linearity of the matrices can be used with some required modification. Now, let us recall some definitions of the matrices from [28], which are used to characterize a hypergraph.

**Definition 2.3** (Adjacency matrix of hypergraphs). The adjacency matrix \( A_G = \left[ (A_G)_{ij} \right] \) of a hypergraph \( G = (V, E) \) is defined as \( (A_G)_{ij} = \sum_{e \in E, i,j \in e} \frac{1}{|e|-1} \) if \( i \sim j \), and elsewhere it is equal to 0.

**Definition 2.4** (Laplacian matrix for hypergraph). The Laplacian matrix \( L_G \) of a hypergraph \( G(V, E) \) on \( n \) vertices is defined as, \( L_G = D_G - A_G \), where \( D_G \) is the diagonal matrix where the entries are the degrees \( d(i) \) of the \( i \)-th vertex of \( G \). Thus,

\[
(L_G)_{ij} = \begin{cases} 
\frac{d(i)}{\sum_{e \in E, i,j \in e} \frac{1}{|e|-1}} & \text{if } i = j, \\
\frac{1}{|e|-1} & \text{if } i \sim j, \\
0 & \text{elsewhere.}
\end{cases}
\]

**Definition 2.5.** (Normalized Laplacian Matrix) The normalized Laplacian matrix \( \Delta_G \) is defined as,

\[
(\Delta_G)_{ij} = \begin{cases} 
\frac{1}{d(i)} \sum_{e \in E, i,j \in e} \frac{1}{|e|-1} & \text{if } i = j, \\
\frac{1}{|e|-1} & \text{if } i \sim j, \\
0 & \text{elsewhere.}
\end{cases}
\]

Note that \( \Delta_G = D_G^{-1} L_G \).

A dynamical system is a function that describes the evolution of some characteristics (it may be position, quantity, energy, velocity, etc.) of an object with respect to time. In a nutshell,

**Definition 2.6.** A dynamical system is a function describing the time dependence of the evolution of a variable. If the time is a set of all reals then it is a continuous-time dynamical system (or continuous dynamical system), and if the time is the set of all positive integers, it is called discrete-time dynamical system (or discrete dynamical system).
The examples of dynamical systems include the motion of a particle, swinging of a pendulum, population of a country in each decade, number of citations of a paper in each year, the bank balance of any bank account at the end of each financial year. In the first two examples, the time is continuous and takes values from non-negative real numbers, and in the other examples, it is a non-negative integer. Therefore the first two are examples of continuous-time dynamical systems, and the other examples are discrete-time dynamical systems.

A dynamical network is a graph representing the network with evolving dynamical systems on each of its vertices. The edges of the graph are acting as interconnection or coupling among the dynamical systems in the vertices. If we replace the graph by a hypergraph in the notion of a dynamical network, then we call it coupled dynamical systems on hypergraph (CDSH).

A CDSH is continuous-time (discrete-time) CDSH if the corresponding dynamical systems in the vertices are continuous (discrete) dynamical systems. Because of the diffusive nature of the couplings, in some cases, the component dynamical systems in all the vertices of the hypergraph may behave similarly after some time (steps). This phenomenon is called synchronization.

**Definition 2.7.** [Synchronization] A trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) of a CDSH \( G \), is said to be synchronized (or synchronous or in sync) if \( \lim_{n \to \infty} |u(n)(i) - u(n)(j)| = 0 \), for all \( i, j \in V(G) \), where \( u(n) = (u_ip(n))_{i \in \mathbb{N}, p \in \mathbb{N}_k} (\in \mathbb{R}^{Nk}) \) is the state of the CDSH at time \( n \). \( (u_ip(n)) \) denotes the \( p \)-th component of the state of the dynamical system on the \( i \)-th vertex at time \( n \) and the \( k \)-component row vector \( u(n)(i) (\in \mathbb{R}^k) \) denotes the state of the dynamics on \( i \)-th vertex at time \( n \). The trajectories of a CDSH which are not synchronized are called asynchronous.

The manifold, \( H = \{(x_ip)_{i \in \mathbb{N}, p \in \mathbb{N}_k} \in \mathbb{R}^{Nk} : x_{1p} = \ldots = x_{Np}, \forall p \} \) is called the manifold of synchronization of the CDSH. A CDSH synchronizes if its trajectories either fall into the manifold of synchronization after some time or asymptotically converge to the same as time flows. A synchronization is called global synchronization if the limit given in Definition 2.7 is 0 for any trajectory, that is independent of any initial conditions, of the CDSH. If a synchronization depends on initial conditions and a trajectory of the CDSH synchronizes, only if it starts from sufficiently close to the manifold of the synchronization, then it is called local synchronization.

Now we construct models for CDSH using tensors and matrices associated with hypergraphs and study their synchronizability.

### 3. Coupled dynamical systems on hypergraphs (CDSH)

In this section, first, we develop the models for coupled discrete dynamical systems on hypergraph, which not only represent the evolution of the dynamical systems in all the vertices by incorporating the interactions among them using the hyper-edge couplings of the systems on hypergraphs but are also the generalization of the models of dynamical networks. After developing the models, we analyze local and global synchronizability, respectively, of the trajectories of CDSH represented by the models.

#### 3.1. Coupled discrete dynamical systems on hypergraphs

Here we restrict ourselves only in the discrete-time CDSH, and we denote the discrete-time by \( n \). In the beginning, we consider only uniform hypergraphs. Later we extend it to provide a model for non-uniform (general) hypergraphs.

**3.1.1. Model for \( m \)-uniform hypergraphs.** Our coupled discrete dynamical systems on hypergraph model for \( m \)-uniform hypergraphs is represented as follows.

\[
(1) \quad u(n + 1)(i) = \tilde{g}(u(n))(i) + \epsilon \sum_{i_2, \ldots, i_m} a_{i_2, \ldots, i_m} \left( \frac{\sum_{j=2}^{m} \tilde{f}(u(n(i_j)))}{m-1} - \tilde{f}(u(n))(i) \right),
\]

where \( \tilde{g} : \mathbb{R}^k \to \mathbb{R}^k \) and \( \tilde{f} : \mathbb{R}^k \to \mathbb{R}^k \) are differentiable functions governing the dynamics in each vertex \( i \), \( u(n)(i) (\in \mathbb{R}^k) \) is a \( k \)-component row vector representing the state of the dynamics in \( i \)-th vertex of the systems on hypergraphs at the \( n \)-th time step. The \( p \)-th component of \( u(n)(i) \)
is denoted by \((u(n))_{i\rho}(\in \mathbb{R})\). \( \mathcal{A}_G = \{\{a_{i_1i_2...i_m}\}_{i_i\in \mathbb{N}_N}\}_{\alpha\in \mathbb{N}_m} \) and \(\epsilon\) are the adjacency tensor and the coupling strength, respectively, of the CDSH.

We use the concept of diffusion in this model. Diffusion is the movement of a substance from an area of high concentration to the same of low concentration to make the density uniform, and on the other hand, the hyper-edge couplings of the CDSH are diffusive in nature. Hence, the interactions through a hyper-edge always try to make the states of all the vertices incident to that hyper-edges equal.

If we put \(m = 2\) in Equation (1) then it becomes the dynamical network model which has been considered in [29, 30, 31, 32] and moreover, the interaction term that is the second term involving the summation in Equation (1) becomes 0 when the synchronization is reached. Hence the model represented in Equation (1) is a generalization of the dynamical-network models.

For an \(m\)-uniform hypergraph we can write the summation on the right side of Equation (1) as

\[
\sum_{i_2...i_m} a_{i_2...i_m} \left( \frac{\sum_{j=2}^{m} f(u(n(i_j)))}{m-1} - \bar{f}(u(n))(i) \right)
= \frac{m}{m-1} \sum_{i_2...i_m} a_{i_2...i_m} \left( \frac{\sum_{j=2}^{m} f(u(n(i_j))) + \bar{f}(u(n))(i)}{m} - \bar{f}(u(n))(i) \right).
\]

Hence the contribution of each hyper-edge \(e_r = \{i, j_2, j_3, \ldots, j_m\}\) containing the vertex \(i\) to the summation in Equation (2) is

\[
\frac{m}{m-1} \sum_{\{j_2...j_m\} \in \text{perm}\{j_2...j_m\}} a_{i_2...i_m} \left( \frac{\sum_{j=2}^{m} f(u(n(j_k))) + \bar{f}(u(n))(i)}{m} - \bar{f}(u(n))(i) \right),
\]

where \(\text{perm}\{j_2...j_m\}\) is the set of all possible permutation of \(\{j_2...j_m\}\).

\[
= \frac{m}{m-1} \left( \sum_{k=2}^{m} f(u(n(j_k))) + \bar{f}(u(n))(i) - \bar{f}(u(n))(i) \right) = \frac{m}{m-1} \left( \text{avg}_{j}(u(n))(e_r) - \bar{f}(u(n))(i) \right),
\]

where \(\text{avg}_{j}(u(n))(e_r) = \sum_{k=2}^{m} f(u(n(j_k))) + \bar{f}(u(n))(i)\), the average of the states of all the vertices associated with the edge \(e_r\) at the \(n\)-th time step.

Now, using Equation (2) and Equation (3), the Equation (1) becomes

\[
u(n+1)(i) = \bar{g}(u(n))(i) + \epsilon \sum_{i_2...i_m} a_{i_2...i_m} \left( \frac{\sum_{j=2}^{m} f(u(n(i_j)))}{m-1} - \bar{f}(u(n))(i) \right)
\]

\[
= \bar{g}(u(n))(i) + \epsilon \frac{m}{m-1} \sum_{e_r \in E(i)} \left( \text{avg}_{j}(u(n))(e_r) - \bar{f}(u(n))(i) \right)
\]

\[
= \bar{g}(u(n))(i) + \epsilon \frac{m}{m-1} \left[ \text{avg}_{e_r \in E(i)} \text{avg}_{j}(u(n))(e_r) - d(i) \bar{f}(u(n))(i) \right]
\]

So, \(u(n+1) = \{u(n+1)(i)\}_{i=1}^{N} = \{\bar{g}(u(n))(i) + \epsilon \frac{m}{m-1} \left[ \text{avg}_{e_r \in E(i)} \text{avg}_{j}(u(n))(e_r) - d(i) \bar{f}(u(n))(i) \right]\}_{i=1}^{N} \). Here \(E(i) = \{e_r \in E(G) : i \in e_r\}\) is the set of all the hyper-edges containing \(i\). Hence \(|E(i)| = d(i)\) is the degree of the \(i\)-th vertex.

Now we define the \(N \times M\) incidence matrix \(I_G = \{I_{ir}\}_{i \in \mathbb{N}_N, e_r \in \mathbb{N}_M}\) as

\[
I_{ir} = \begin{cases} 
1 & \text{if } v_i \in e_r \\
0 & \text{otherwise}
\end{cases}
\]
It can be easily verified that

\[
\frac{1}{m} I_G I_G^T f(u(n)) = \left\{ \sum_{e_r \in E(i)} av_j f(u(n))(e_r) \right\}_{i=1}^N \in \mathbb{R}^{Nk}
\]

Now, using Equation (4) and Equation (6) we get

\[
u(n+1) = \{u(n+1)(i)\}_{i=1}^N = \{\tilde{g}(u(n))(i) + \epsilon \frac{m}{m-1} \left[ \sum_{e_r \in E(i)} (av_j f(u(n))(e_r)) - d(i) \tilde{f}(u(n))(i) \right] \}_{i=1}^N
\]

\[
g(u(n)) + \epsilon \frac{m}{m-1} (I_G I_G^T - D_G) f(u(n)) = g(u(n)) + \epsilon \frac{m}{m-1} B f(u(n)),
\]

where \( B_m := (I_G I_G^T - D_G). \)

From now onwards, we consider Equation (8) as the model for CDSH of an \( m \)-uniform systems on hypergraphs, where \( u(n) = \{(u(n))_{ip}\}_{i \in \mathbb{N}_N, p \in \mathbb{N}_k} (\in \mathbb{R}^{Nk}) \) represents the state of the CDSH at time \( n \). Here \( (u(n))_{ip} \) is the \( p \)-th component of the \( i \)-th vertex at time \( n \). The state of the \( i \)-th vertex of the CDSH at time \( n \) is a \( k \)-component vector represented by the \( i \)-th row of \( u(n) \). The functions \( g : \mathbb{R}^{Nk} \to \mathbb{R}^{Nk} \) and \( f : \mathbb{R}^{Nk} \to \mathbb{R}^{Nk} \) which govern the dynamical systems in all the vertices of the systems on hypergraphs are of special forms, given by \( g(\{x_{ip}\}_{i \in \mathbb{N}_N, p \in \mathbb{N}_k}) = (\tilde{g}(x_{i1}, x_{i2}, x_{i3}, \ldots, x_{ik}))_{i \in \mathbb{N}_N} \) and \( f(\{x_{ip}\}_{i \in \mathbb{N}_N, p \in \mathbb{N}_k}) = (\tilde{f}(x_{i1}, x_{i2}, x_{i3}, \ldots, x_{ik}))_{i \in \mathbb{N}_N} \), respectively. The functions \( g \) and \( f \) take the above forms since all the vertices are similar, more precisely the dynamics of all the vertices are governed by the same functions \( \tilde{g} \) and \( \tilde{f} \). In matrix notation we write ,

\[
f(u(n)) = \begin{pmatrix}
\tilde{f}(u(n)(1)) \\
\vdots \\
\tilde{f}(u(n)(N))
\end{pmatrix} = \begin{pmatrix}
\tilde{f}_1(u(n)(1)) & \cdots & \tilde{f}_k(u(n)(1)) \\
\vdots & \ddots & \vdots \\
\tilde{f}_1(u(n)(N)) & \cdots & \tilde{f}_k(u(n)(N))
\end{pmatrix}
\]

that is, \( f(u(n)) = \{(\tilde{f}_p(u(n))(i))_{i \in \mathbb{N}_N, p \in \mathbb{N}_k}\} \).

Similarly we write \( g(u(n)) = \{(\tilde{g}_p(u(n))(i))_{i \in \mathbb{N}_N, p \in \mathbb{N}_k}\} \).

**Remark 3.1.** Note that \( u(n) \) is a vector in \( \mathbb{R}^{Nk} \) and also represented as an \( N \times k \) matrix in above. We usually consider \( u(n) \) as a matrix, but in some places, we take \( u(n) \) as an \( Nk \)-dimensional vector whose \((p-1)N+i\)-th component, which is the state of the \( p \)-th components of the dynamical system in \( i \)-th vertex, is the \((i,p)\)-th element in its matrix notation. Since most of the places we use the matrix notation unless otherwise stated, \( u(n) \) is in matrix notation.

**Lemma 3.1.** The matrix \( B_m \) is negative semi-definite.

**Proof.** Since \( I_G I_G^T \) and \( D_G \) are symmetric matrices, the matrix \( B_m = (\frac{m}{m} I_G I_G^T - D_G) \) is also symmetric. From Equation (2), Equation (3) and Equation (6), for any \( x \in \mathbb{R}^N \) we have,

\[
\frac{m}{m-1} B_m x = \sum_{i_2 \cdots i_m} a_{i_2 \cdots i_m} \left( \sum_{j=2}^{m} x(i) - x(i) \right) \implies B_m x = \frac{1}{m} \sum_{i_2 \cdots i_m} a_{i_2 \cdots i_m} \sum_{j=2}^{m} (x(i_j) - x(i)) \implies x^T B_m x = \sum_{i_2 \cdots i_m} \frac{1}{i} \sum_{i_2 \cdots i_m} a_{i_2 \cdots i_m} \sum_{j=2}^{m} ((x(i_j) - x(i))x(i)).
\]

Thus we can conclude

\[
x^T B_m x = \sum_{i_2 \cdots i_m} \frac{1}{i} \sum_{i_2 \cdots i_m} a_{i_2 \cdots i_m} \sum_{j=2}^{m} (x(i_j) - x(i))^2.
\]

Since \( A = \{a_{i_1 i_2 \cdots i_m}\}_{i \in \mathbb{N}_N} \) is a symmetric tensor, from Equation (11) we have

\[
x^T B_m x = -\frac{1}{m} \sum_{i} \frac{1}{i} \sum_{i_2 \cdots i_m} a_{i_2 \cdots i_m} \sum_{j=2}^{m} (x(i_j) - x(i))^2.
\]

Hence, \( B_m \) is negative semi-definite.

**Example 3.1.** See Example 4.1. All the eigenvalues of \( B_m \) are either negative or 0.
Lemma 3.2. For any column vector $x \in \mathbb{R}^N$, $x \in H$, the manifold of synchronization if and only if $x^T B_m x = 0$.

Proof. If $x \in \mathbb{R}^N$, $x \in H$, then by Equation (12) $x^T B_m x = 0$.

Conversely, if $x^T B_m x = 0$ then as the systems on hypergraphs is connected, using Equation (12) we can conclude that $x \in H$. □

3.1.2. Model for general hypergraphs. Now we consider the dynamical general systems on hypergraphs, i.e., the dynamical systems on hypergraphs whose underlying hypergraph is a general hypergraph. First let us define an $N \times M$ matrix $I_{mg} = \{I_{mg}^{(i)}\}_{i \in \mathbb{N}^m \in \mathbb{N}^M}$ as

$$I_{mg} = \begin{cases} 1 & \text{if } v_i \in e_r, |e_r| = m \\ 0 & \text{otherwise} \end{cases}$$

The model for coupled dynamical systems on general hypergraphs is as follows.

$$u(n+1)(i) = \bar{g}(u(n))(i) + \epsilon \sum_{m=2}^{m_{\text{max}}} \frac{m}{m-1} \sum_{e_r \in E(i); |e_r| = m} \left( \text{avg}(f(u(n)))(e_r) - \bar{f}(u(n))(i) \right)$$

Note that in a hypergraphs there may not exists any edge of cardinality $m(\in \mathbb{N}_{m_{\text{max}}} - \{1\})$. For that $m$, the sum,

$$\sum_{e_r \in E(i); |e_r| = m} \left( \text{avg}(f(u(n)))(e_r) - \bar{f}(u(n))(i) \right)$$

over a void set is assumed to be zero.

$$u(n+1) = \{u(n+1)(i)\}_{i=1}^N$$

(Here $d^{(m)}(i)$ = The total number of m-edges containing the $i$-th vertex $v_i$.)

$$= g(u(n)) + \epsilon \sum_{m=2}^{m_{\text{max}}} \frac{m}{m-1} \left( \frac{1}{m} I_{mg} M_{mg} - D_{mg} \right) f(u(n))$$

(The diagonal matrix $D_{mg}$ is defined by $D_{mg} := \text{diag}(d^{(m)}(i))$)

$$= g(u(n)) + \epsilon \sum_{m=2}^{m_{\text{max}}} \frac{m}{m-1} B_m f(u(n)) = g(u(n)) + \epsilon C f(u(n)),$$

where

$$C = \sum_{m=2}^{m_{\text{max}}} \frac{m}{m-1} B_m.$$

Remark 3.2. By the assumption made in Equation (15), if the systems on hypergraphs is l-uniform then, $C = \frac{1}{l-1} B_l$ and hence Equation (16) becomes Equation (8). Hence Equation (16) is the general model of the model considered in Equation (8).

Example 3.2. The hypergraph in Example 4.1 is a uniform hypergraph. Thus here $C = B$.

Before proceeding further with the model represented in Equation (16) we show some interesting properties of the matrix $C$.

Lemma 3.3. $C$ is negative semi-definite

Proof. As $\frac{m}{m-1} \geq 0$ for all $m = 2, \ldots, m_{\text{max}}$ and by Lemma 3.1 each $B_m$ is negative semi-definite, $C = \sum_{m=2}^{m_{\text{max}}} \frac{m}{m-1} B_m$ is also negative semi-definite. □

Example 3.3. All the eigenvalues of $C$ in Example 4.2 are approximately $-5.3, -4.7, -4.2, -3.4, -2.4, -8 \times 10^{-16} \approx 0$, and which are non-positive. The same can also be observed in the systems on hypergraphs given in Example 4.6, example 4.4, Example 4.3, Example 4.5 and Example 4.1.
Lemma 3.4. For any column vector \( x \in \mathbb{R}^N \), \( x \in H \), the manifold of synchronization, if and only if \( x^T C x = 0 \).

Proof. The proof follows from Lemma 3.2. \( \square \)

We can generalize the model described in Equation (16) a little more by introducing an inner coupling matrix \( \Gamma \), which is a \( k \times k \) matrix defined by \( \Gamma = (\Gamma_{ij})_{i,j \in \mathbb{N}_k} \) where \( \Gamma_{ij} = 1 \) if the \( j \)-th component of the state on a vertex is effected by the \( i \)-th components of the state on the other vertices, otherwise \( \Gamma_{ij} = 0 \). With \( \Gamma \), the model becomes

\[
\tag{18} u(n + 1) = g(u(n)) + \epsilon Cf(u(n))\Gamma = g(u(n)) + \epsilon CT_1(f(u(n))),
\]

where \( T_1 : \mathbb{R}^{N \times k} \to \mathbb{R}^{N \times k} \) is a linear operator defined by \( T_1(x) = x\Gamma \), where \( x \in \mathbb{R}^{N \times k} \), the set of all real \( N \times K \) matrices.

Remark 3.3. Note that \( T_1(Cu(n)) = Cu(n)\Gamma = CT_1(u(n)) \) and hence the operator norm of \( T_1 \) is \( \|T_1\| = \|\Gamma^T\| \). Hence, \( \|Cu(n)\Gamma\| \leq \|C\|\|u(n)\|\|\Gamma^T\| \).

Now we establish a relation between the matrix \( C \) and Laplacian matrix \( L_G \), defined in Definition 2.4.

Theorem 3.1. For any hypergraph \( G \), \( C = -L_G \).

Proof. We know that \( C = \sum_{m=2}^{m_{\text{max}}} \frac{1}{m-1}(I_{mg}I_{mg}^T - D_{mg}) = \sum_{m=2}^{m_{\text{max}}} D_{mg} \). Hence \( C \) can be expressed as the following.

\[
\tag{19} C = \left( \sum_{m=2}^{m_{\text{max}}} \frac{1}{m-1}(I_{mg}I_{mg}^T - D_{mg}) \right) - D_G.
\]

For any \( k \leq m_{\text{max}} \), each row of the matrix \( I_{kg} \) corresponds to a vertex of the hypergraph and each column of \( I_{kg} \) corresponds to a hyper-edge of cardinality \( k \). Thus

\[
\tag{20} (I_{kg}I_{kg}^T)_{ij} = \sum_{e_r \in E;|E|=k} (I_{kg})_{ir}(I_{kg})_{rj}^T
\]

Hence, the contribution of a hyper-edge \( e_r \) of cardinality \( k \) to \( (I_{kg}I_{kg}^T)_{ij} \) is 1 if \( v_i, v_j \in e_r \) and 0, otherwise. Thus the same to \((I_{kg}I_{kg}^T)_{ii}\) is 1 if \( v_i \in e_r \) and 0 otherwise. So we can write

\[
\tag{21} (I_{kg}I_{kg}^T)_{ij} = \begin{cases} 
\sum_{e_r \in E;|E|=k} d(k)(i) & \text{if } i \neq j \text{ and } i, j \in e_r \text{ for some } e_r \in E \text{ and } |e_r| = k, \\
0 & \text{if } i = j \text{ and } i \in e_r \text{ for some } e_r \in E \text{ and } |e_r| = k, \text{ otherwise.}
\end{cases}
\]

By Equation (21) we get the \( (i,j) \)-th position of the \( N \times N \) matrix \( \left( \sum_{m=2}^{m_{\text{max}}} \frac{1}{m-1}(I_{mg}I_{mg}^T - D_{mg}) \right) \) is

\[
\left( \sum_{m=2}^{m_{\text{max}}} \frac{1}{m-1}(I_{mg}I_{mg}^T - D_{mg}) \right)_{ij} = \begin{cases} 
\sum_{e_r \in E;|E|=k} \frac{1}{m-1} & \text{if } i, j (\neq i) \in e, \\
0 & \text{elsewhere.}
\end{cases}
\]

Thus by Definition 2.3,

\[
\left( \sum_{m=2}^{m_{\text{max}}} \frac{1}{m-1}(I_{mg}I_{mg}^T - D_{mg}) \right) = A_G.
\]

Hence from Equation (19) we have

\[
\tag{24} C = A_G - D_G = -L_G.
\]

\( \square \)
Theorem 3.2. If \( f \) and \( g \) are Lipschitz functions with Lipschitz constant \( k_f \) and \( k_g \), respectively, and \( |k_g + \epsilon|C||k_f||\Gamma^T|| < 1 \), where \( ||C|| \) is the operator norm of the matrix \( C \), then any trajectory of the CDSH represented by the model in Equation (18) achieves synchronization asymptotically. Moreover if \( f = g \) and \( \Gamma = I \), the identity matrix, then the condition for the synchronization is \( ||[I + \epsilon C]|| < \frac{1}{k_f} \).

Proof. By Equation (27) and Equation (28), \( \|e(n+1)\| \leq \|(u(n)) - g(v(n))\| + \epsilon||C||f(u(n) - f(v(n)))\|\|\Gamma^T\| \leq (k_g + \epsilon||C||k_f||\Gamma^T||)\|e(n)\| \). Clearly, if \( (k_g + \epsilon||C||k_f||\Gamma^T||) < 1 \), then \( e(n) \to 0 \) as \( n \to \infty \). This completes the proof of the first part of the theorem. When, if \( f = g \) and \( \Gamma = I_k \), the Equation (28) becomes \( e(n+1) = f(u(n)) - f(v(n)) + \epsilon(C(f(u(n) - f(v(n)))) = (I + \epsilon C)(f(u(n) - f(v(n)))). \) Hence the iteration-rule of the norm of error is \( \|e(n+1)\| \leq \|(I + \epsilon C)||k_f||\|e(n)\| \). Thus for \( f = g \), if \( ||[I + \epsilon C]|| < \frac{1}{k_f} \), then \( e(n) \to 0 \) as \( n \to \infty \). This completes the proof.

The operator norm of a symmetric matrix is the maximum of the absolute values of all the eigenvalues of the matrix. Thus we have the following corollary.

Corollary 3.1. If the functions \( f \) and \( g \) are Lipschitz functions with Lipschitz constant \( k_f \) and \( k_g \), respectively, and \( (k_g + \epsilon\lambda_{max}k_f||\Gamma^T||) < 1 \), where \( \lambda_{max} \) is the maximum of the absolute values of the eigenvalues of the matrix \( C \), then any trajectory of the CDSH represented by the model in Equation (18) achieves synchronization asymptotically. Moreover if \( f = g \) and \( \Gamma = I \), where \( I \) is the identity matrix, then the condition for the synchronization is \( \mu_{max} < \frac{1}{k_f} \), where \( \mu_{max} \) is the maximum of the absolute values of the eigenvalues of \( (I + \epsilon C) \).

Remark 3.5. Note that in the proof of Theorem 3.2 the condition given in Equation (10) have never been used on the functions \( f \) and \( g \). Hence this condition is not needed for the theorem to hold. However, if the functions \( f \) and \( g \) are such that the condition in Equation (10) holds with \( f,\tilde{g} \) and are Lipschitz functions with Lipschitz constants \( k_{\tilde{f}} \) and \( \tilde{k}_g \), respectively, then \( f, g \) are also Lipschitz functions with Lipschitz constants \( k_f, k_g \), respectively, such that \( k_f = k_{\tilde{f}}, k_g = \tilde{k}_g \).
Remark 3.6. The conditions for synchronization given in Theorem 3.2 and Corollary 3.1 are sufficient conditions, but are not necessary conditions. Hence, sometimes there may be synchronization in the trajectories despite of not complying with the conditions.

Remark 3.7. Note that \( v(1) \) and \( s_1 \) is chosen in such a manner that \( v(1) \) depends on \( u(1) \) and \( v(1) \in H \). This reliance of \( v(1) \) on \( u(1) \) is just to indicate that \( v(1) \) (and hence \( \{v(n)\}_{n \in \mathbb{N}} \)) is not independent from \( \{u(n)\}_{n \in \mathbb{N}} \). Hence there are other choices of \( s_1 \) for which \( v(1) \) depends on \( \{u(n)\}_{n \in \mathbb{N}} \) and \( v(1) \in H \). If we consider the projection \( p \) of the initial state \( u(1) \) on the manifold of synchronization \( H \). then \( p = (p(i))_{i \in \mathbb{N}} \in H \subset \mathbb{R}^{\mathbb{N}} \), where \( p(i) \in \mathbb{R}^k \). As \( p \) is a point on \( H \), all the \( p(i) \) are equal and we can choose \( s_n = p(i) \) for all \( i \in \mathbb{N}_N \). If \( f = g \), then instead of considering \( s_1 = \frac{1}{\mathbb{N}} \sum_{n=1}^{\mathbb{N}} u(1)(i) \), we can take \( s_1 \), as the solution of the uncoupled system \( u(n+1)(i) = f(u(n)(i)) \) (when this solution exists).

Let us recall some rudimentary facts. How do we calculate the shortest distance of a point from a plane in 3D geometry? We draw a perpendicular from the point to the plane and calculate the distance between the given point and the point of intersection of the perpendicular to the plane. It becomes more interesting when the plane is passing through the origin, that is the plane is a 2-dimensional subspace of \( \mathbb{R}^3 \). Now, if we rotate the co-ordinate axes in such a way that the new \( Z \)-axis will be in the direction, perpendicular to the plane, passing through the origin and its positive direction will be on the side of the plane in which the point lies. Clearly \( X \) and \( Y \)-axes will be two mutually perpendicular lines passing through the origin and lie on the plane. Now the distance of the point from the plane is the \( z \)-coordinate of the point with respect to the new coordinate system. Hence the distance is \( \|D \hat{E} X\| \), where \( X = (x_1, x_2, x_3)^T \) is the coordinates of the point with respect to the old coordinate system, \( E \) is the matrix of the coordinate transformation described as above, and the diagonal matrix \( D = \text{diag}(0, 0, 1) \). Now consider another situation, where \( V \) is a \( q \)-dimensional subspace of \( \mathbb{R}^n \) for any \( n > q \in \mathbb{N} \) and we compute the distance of \( p \in \mathbb{R}^n \) from the subspace \( V \) by using the above idea. Let \( B_V \) and \( B_{V^\perp} \) be orthonormal bases of \( V \) and \( V^\perp \), respectively, and \( B = B_V \cup B_{V^\perp} \). Let \( P \) be the coordinate of the point \( p \) with respect to the usual coordinate system and \( E \) be the matrix of the coordinate transformation from usual coordinate system to the coordinate system corresponding to the orthonormal ordered basis \( B \) of \( \mathbb{R}^n \). Let \( D \hat{V} \) be an \( n \times n \) diagonal matrix whose \( i \)-th diagonal entry is 0, if the \( i \)-th member of the order basis \( B \) is from \( V \), 1 otherwise. Then the distance from \( p \) to \( V \) is \( \|D \hat{V} E_V P\| \).

The manifold of synchronization \( H \), defined above, is a \( k \)-dimensional subspace of \( \mathbb{R}^{kN} \). Let \( \|\theta(n)\| \) be the distance of the state \( u(n) \) from \( H \), then \( \theta(n) = D_H E_H u(n) = \Lambda u(n) \), where \( \Lambda = D_H E_H \). If \( \theta(n) \to 0 \) as \( n \to \infty \), then the trajectories of the CDSH converge asymptotically to \( H \) and the synchronization is achieved. Thus in order to obtain condition for global synchronization it would be enough to find the condition of \( \theta(n) \to 0 \). In order to get the condition for \( \theta(n) \to 0 \), which will be one condition for global synchronization, we need a recursive relation between \( \theta(n+1) \) and \( \theta(n) \). If we use the model in Equation (18) then we have

\[
\theta(n+1) = \Lambda u(n+1) \implies \theta(n+1) = \Lambda [g(u(n)) + \epsilon C f(u(n))] \Gamma
\]

In order to get the recursive relation, on the right side of Equation (29) the matrix \( \Lambda \) should have some property to go inside the function \( g \) and \( f \) in some way, so that we get the term \( \Lambda u(n) \). Now we construct a matrix with the desired properties. More precisely, we construct a candidate for being \( \Lambda \).

Lemma 3.5. There exists an orthogonal matrix \( \Delta \), which commutes with the matrix \( C \). Moreover if the functions \( f \) and \( g \) are of the form, as described in Equation (10) with \( f \) and \( g \), where \( \bar{f} \) and \( \bar{g} \) are differentiable, and all of their partial derivatives exist and bounded then \( \|\Delta f(u(n))\|^2 \leq \|\Delta g(u(n))\|^2 + \|\Delta f(u(n))\|^2 \) and \( \|\Delta g(u(n))\|^2 \leq \|\Delta f(u(n))\|^2, \) where \( \|\Delta f\|^2 = \)
(\sum_{p \in \mathcal{N}_k} \| \sup_q (\tilde{f}_p') \|^2) \text{ and } \| \sup_q \tilde{g}' \|^2 = (\sum_{p \in \mathcal{N}_k} \| \sup_q (\tilde{g}_p') \|^2) \), \( \sup_q (\tilde{f}_p') = \sup (\frac{\partial}{\partial x_q} \tilde{f}_p(x)) \) and \( \sup_q (\tilde{g}_p') = \sup (\frac{\partial}{\partial x_q} \tilde{g}_p(x)) \).

**Proof.** By Lemma 3.3, \(-C\) is positive semi-definite. There exists an orthogonal matrix \(Q\) such that

\[
-C = Q^T D(-C)Q = Q^T (D(-C))^{\frac{1}{2}} QQ^T (D(-C))^{\frac{1}{2}} Q = \Delta \Delta,
\]

where \((D(-C))\) is the diagonalization of \(-C\) and \(\Delta = Q^T (D(-C))^{\frac{1}{2}} Q\) is an orthogonal matrix with the following property,

\[
\Delta(-C) = \Delta^3 = (-C)\Delta.
\]

We know \(f(u(n)) = \left( \begin{array}{c} \tilde{f}(u(n)(1)) \\ \vdots \\ \tilde{f}(u(n)(N)) \end{array} \right) = \left( \begin{array}{c} \tilde{f}_1(u(n)(1)) & \cdots & \tilde{f}_k(u(n)(1)) \\ \vdots & \ddots & \vdots \\ \tilde{f}_1(u(n)(N)) & \cdots & \tilde{f}_k(u(n)(N)) \end{array} \right) \). We define

\[
\phi(n)(p) := \Delta \left( \begin{array}{c} \tilde{f}_p(u(n)(1)) \\ \vdots \\ \tilde{f}_p(u(n)(N)) \end{array} \right). \text{ Thus, } \|\phi(n)(p)\|^2 = (\phi(n)(p))^T (\phi(n)(p))
\]

\[
= - \sum_{m=2}^{m_{max}} \frac{m}{m-1} \left( \frac{1}{m!} \sum_{r=1}^{m} \sum_{i_2...i_m} a_{r_i...i_m} \sum_{j=2}^{m} (\tilde{f}_p(u(n))(i_j) - \tilde{f}_p(u(n))(r))^2 \right)
\]

\[
\leq \|\sup(\tilde{f}_p')\| \sum_{m=2}^{m_{max}} \frac{1}{m-1} \sum_{r=1}^{m} \sum_{i_2...i_m} a_{r_i...i_m} \sum_{j=2}^{m} \|u(n)(i_j) - u(n)(r)\|^2.
\]

As the state of each vertex, \(u(n)(i)\) is a \(k\)-component vector, we represent \(u(n)(i)\) as \(\{(u(n)(i))_q\}_{q \in \mathcal{N}_k}\). Thus

\[
\|u(n)(i_j) - u(n)(r)\|^2 = \sum_{q=1}^{k} \|(u(n)(i_j))_q - (u(n)(r))_q\|^2.
\]

Using Equation (33) we get

\[
\|\Delta \left( \begin{array}{c} \tilde{f}_p(u(n)(1)) \\ \vdots \\ \tilde{f}_p(u(n)(N)) \end{array} \right) \|^2 \leq \sum_{q=1}^{k} \|\sup(\tilde{f}_p')\| \|\Delta \left( \begin{array}{c} ((u(n)(1))_q \\ \vdots \\ ((u(n)(N))_q \right) \|^2.
\]

Now after considering the action of \(\Delta\) on the components of \(f(u(n))\) we see the action of \(\Delta\) on \(f(u(n))\). Using Equation (34), we get

\[
\|\Delta f(u(n))\|^2 = \|\Delta \left( \begin{array}{c} \tilde{f}_1(u(n)(1)) & \cdots & \tilde{f}_k(u(n)(1)) \\ \vdots & \ddots & \vdots \\ \tilde{f}_1(u(n)(N)) & \cdots & \tilde{f}_k(u(n)(N)) \end{array} \right) \|^2
\]

\[
= \sum_{p \in \mathcal{N}_k} \|\Delta \left( \begin{array}{c} \tilde{f}_p(u(n)(1)) \\ \vdots \\ \tilde{f}_p(u(n)(N)) \end{array} \right) \|^2
\]

\[
\leq \left( \sum_{p \in \mathcal{N}_k} \|\sup(\tilde{f}_p')\|^2 \right) \left( \sum_{q \in \mathcal{N}_k} \|\Delta \left( \begin{array}{c} ((u(n)(1))_q \\ \vdots \\ ((u(n)(N))_q \right) \|^2 \right) = \|\sup \tilde{g}'\|^2 \|\Delta u(n)\|^2,
\]

(35)
where \( \| \sup \tilde{f} \|^2 = ( \sum_{p \in \mathbb{N}_k} \| \sup(\tilde{f}_p) \|^2 ) \).

Since the same result also holds for \( g \). Thus we have

\[
\| \Delta g(u(n)) \|^2 \leq \| \sup \tilde{g} \|^2 \| \Delta u(n) \|^2,
\]

where \( \| \sup \tilde{g} \|^2 = ( \sum_{p \in \mathbb{N}_k} \| \sup(\tilde{g}_p) \|^2 ) \).

Now we can choose \( \Lambda = \Delta \), that is, \( \theta(n) = \Delta u(n) \).

**Lemma 3.6.** If \( \theta(n) = \Delta u(n) \), then \( \theta(n) \to 0 \) as \( n \to \infty \) implies that the trajectory \( \{ u(n) \}_{n \in \mathbb{N}} \) achieves synchronization asymptotically.

**Proof.** Expanding the term \( \| \Delta u(n) \|^2 \) we have

\[
\| \Delta u(n) \|^2 = \left( \sum_{p \in \mathbb{N}_k} \| \Delta \left( \begin{array}{c}
    (u(n)(1))_p \\
    \vdots \\
    (u(n)(N))_p
  \end{array} \right) \|^2 \right) = \sum_{p \in \mathbb{N}_k} \sum_{m=2}^{m_{\text{max}}} \frac{m}{m-1} \left( \sum_{i} m \sum_{i_2} a_{i_2} \sum_{j=2}^{m} \left( (u(n)(i))_p - (u(n)(i))_p \right)^2 \right).
\]

Hence by Equation (37), \( \lim_{n \to \infty} \theta(n) = 0 \) \( \implies \) \( \lim_{n \to \infty} \sum_{p \in \mathbb{N}_k} \sum_{m=2}^{m_{\text{max}}} \frac{m}{m-1} \left( \sum_{i} m \sum_{i_2} a_{i_2} \sum_{j=2}^{m} \left( (u(n)(i))_p - (u(n)(i))_p \right)^2 \right) = 0 \), that is, \( \lim_{n \to \infty} (u(n)(j)_p - u(n)(i)_p)^2 = 0 \) for all \( i, j \in \mathbb{N}_N \), and \( p \in \mathbb{N}_k \), since the underlying hypergraph is connected. Hence result follows.

**Theorem 3.3.** If the functions \( f \) and \( g \) are of the form given by Equation (10) with \( \tilde{f}, \tilde{g} \) are differentiable functions and \( ( \| \sup \tilde{g} \|^2 + \epsilon \| \Gamma^T \| \| C \| \| \sup \tilde{f} \| ) < 1 \), where \( \| \sup \tilde{f} \|^2 = ( \sum_{p \in \mathbb{N}_k} \| \sup(\tilde{f}_p) \|^2 ) \)

and \( \| \sup \tilde{g} \|^2 = ( \sum_{p \in \mathbb{N}_k} \| \sup(\tilde{g}_p) \|^2 ) \), where \( \sup(\tilde{f}_p) = \sup_{q \in \mathbb{N}_k} (\frac{\partial}{\partial x_q} \tilde{f}_p(x)) \) and \( \sup(\tilde{g}_p) = \sup_{q \in \mathbb{N}_k} (\frac{\partial}{\partial x_q} \tilde{g}_p(x)) \), then any trajectory of the CDSH represented by the model in Equation (18) achieves synchronization asymptotically.

**Proof.** Since by Equation (31) \( \Delta \) and \( C \) commutes, so to find the sequential trajectory of \( \theta(n) \) we consider the recursive relation

\[
\theta(n+1) = \Delta u(n+1) = \Delta [g(u(n)) + \epsilon C f(u(n))] = \Delta g(u(n)) + \epsilon \Delta f(u(n)) \Gamma.
\]

Therefore, \( \| \theta(n+1) \| \leq \| \Delta g(u(n)) \| + \epsilon \| C \| \| \Gamma^T \| \| \Delta f(u(n)) \| \leq ( \| \sup \tilde{g} \|^2 + \epsilon \| C \| \| \Gamma^T \| ) \| \sup \tilde{f} \| \| \theta(n) \| \| \theta(n) \| .
\]

Hence, if \( ( \| \sup \tilde{g} \|^2 + \epsilon \| C \| \| \Gamma^T \| ) \| \sup \tilde{f} \| < 1 \), then \( \theta(n) \to 0 \) as \( n \to \infty \). This completes the proof.

If we consider \( f = g \) and \( \Gamma = I_k \), then the Equation (18) becomes

\[
u(n+1) = (I_N + \epsilon C) f(u(n)).
\]

**Corollary 3.2.** If the function \( f \) is of the form given in Equation (10), with \( \tilde{f} \) is differentiable functions and \( \| I_N + \epsilon C \| < \| \sup \tilde{f} \| \) where \( \| \sup \tilde{f} \|^2 = ( \sum_{p \in \mathbb{N}_k} \| \sup(\tilde{f}_p) \|^2 ) \) and \( \| \sup \tilde{g} \|^2 = ( \sum_{p \in \mathbb{N}_k} \| \sup(\tilde{g}_p) \|^2 ) \), where \( \sup(\tilde{f}_p) = \sup_{q \in \mathbb{N}_k} (\frac{\partial}{\partial x_q} \tilde{f}_p(x)) \) and \( \sup(\tilde{g}_p) = \sup_{q \in \mathbb{N}_k} (\frac{\partial}{\partial x_q} \tilde{g}_p(x)) \) then any trajectory of the CDSH represented by Equation (39) synchronizes asymptotically.

**Proof.** The rule of evolution of the quantity, \( \theta(n) \) is \( \theta(n+1) = \Delta u(n+1) = \Delta [I_N + \epsilon C] f(u(n)) = [I_N + \epsilon C] \Delta f(u(n)) \). Hence, the norm of this quantity must satisfy the following inequality.

\[
\| \theta(n+1) \| \leq \| [I_N + \epsilon C] \| \| \Delta f(u(n)) \| \leq \| I_N + \epsilon C \| \| \sup \tilde{f} \| \| \theta(n) \| .
\]

Thus the result follows.

**Remark 3.8.** Note that the condition of synchronization in Corollary 3.2 is not the same with the condition stated in Theorem 3.3. Since \( \| I_N + \epsilon C \| \leq [1 + \| C \| ] \), a little different condition of synchronization can be obtained by considering \( f = g \) in Theorem 3.3.
**Theorem 3.4.** If $f$ and $g$ are such that $\|f(x)\| \leq k_f \|x\|$, $\|g(x)\| \leq k_g \|x\|$, $\|\Delta(f(x))\| \leq \|f(\Delta x)\|$, $\|\Delta(g(x))\| \leq \|g(\Delta x)\|$, and $\|k_g + \epsilon C\|\|k_f\| < 1$ then any trajectory of CDSH, given by Equation (16), achieves synchronization.

**Proof.** Using the assumed condition of the theorem we have, $\|\theta(n+1)\| \leq \|g(\Delta u(n))\| + \epsilon \|C\|\|f(\Delta u(n))\|$

\[
\leq \|k_g\| + \epsilon \|C\|\|k_f\| \|\Delta u(n)\| = \|k_g\| + \epsilon \|C\|\|k_f\| \|\theta(n)\|. 
\]

Hence the theorem follows. \qed

**Remark 3.9.** A natural question is whether such a function $f$ that satisfies all the conditions in Theorem 3.4 exists or not. We try to find the answer in next two examples.

**Example 3.4.** Let $F$ be an $N \times N$ matrix which commutes with $\Delta$ (for example $F$ can be any power of $\Delta$) and $f$ is defined by $f(u(n)) = Fu(n)$, where $u(n) = \{(u(n))_{ij}\mid i \in \mathbb{N}_k, j \in \mathbb{N}_k \in \mathbb{R}^{Nk}\}$ represents the state of the CDSH at time $n$. Here $(u(n))_{ij}$ is the $j$-th component of the $i$-th vertex at time $n$. Since $f$ is linear and $\Delta(f(u(n))) = F\Delta u(n) = f(\Delta u(n))$, the function $f$ satisfies the conditions of Theorem 3.4.

**Example 3.5.** If we define $f : \mathbb{R}^{Nk} \to \mathbb{R}^{Nk}$ as $f = (\tilde{f} \tilde{f} \ldots \tilde{f})^T$ where $\tilde{f} : \mathbb{R}^k \to \mathbb{R}^k$ and $\tilde{f} = (\tilde{f}_i)_{i \in \mathbb{N}_k}$, where $\tilde{f}_i : \mathbb{R}^k \to \mathbb{R}$ and is defined by $\tilde{f}_i((x)) = \sin(\frac{x_i}{\pi})\|x\|$. Here, $f$ is Lipschitz and $\|\Delta f(u)\| \leq 0 \leq \|f(\Delta u)\|$. Before stating the next theorem on global synchronization we prove the following lemma.

**Lemma 3.7.** Let $R$ be a symmetric matrix, whose row sum is 0 and $\tilde{f}$ be a Lipschitz function. If $f$ is a function of the form given in Equation (10) such that $\|f(x) - \tilde{f}(y)\| \leq k_f \|x - y\|$, then $(f(x))^T R(f(x)) \leq k_f x^T R x$.

**Proof.** This result follows from the following steps.

\[
(f(x))^T R(f(x)) = (f(x))^T (\sum_i R_{ij}(f(x)(j)) = (f(x))^T (\sum_{j \neq i} R_{ij}(f(x)(j)) - (f(x)(i))) = \sum_{i,j} R_{ij}[(f(x)(j))(f(x)(i)) - (f(x)(i))^2] \\
\leq k_f^2 \frac{1}{2} \sum_{i,j} R_{ij}[(x(j)) - (x(i))]^2 = k_f^2 x^T R x.
\]

\qed

**Theorem 3.5.** Let $R$ be a negative semi-definite matrix whose row sum is 0 and $\tilde{f}$ be a Lipschitz function. Let $f$ be a function of the form given in Equation (10) such that $\|f(x) - \tilde{f}(y)\| \leq k_f \|x - y\|$. If there exists a positive real $b > k_f$ such that $(I_N + \epsilon C)^T R(I_N + \epsilon C) - \frac{1}{b} R \geq 0$ then the trajectories of the dynamical system given by Equation (39) synchronize.

**Proof.** Following Equation (30) we claim that there exist a symmetric matrix $S$ such that $R = -S^T S$. If $(\alpha(n)) = Su(n)$ then $\|\alpha(n+1)\|^2 = (\alpha(n+1))^T (\alpha(n+1)) = (u(n+1))^T S^T Su(n+1) = -a(n+1))^T Ru(n+1)$. By using Equation (30) we get, $-\|a(n+1)\|^2 = (f(u(n)))^T [I_N + \epsilon C]^T R[ (I_N + \epsilon C) f(u(n))] \geq \frac{1}{b} (f(u(n))^T R f(u(n))).$ Since $R$ is a symmetric zero-sum matrix, so is $-R$. Hence by Lemma 3.7 we have $\|a(n+1)\|^2 \leq k_f^2 \frac{1}{b} (u(n))^T (-R)(u(n)) = \left(\frac{k_f^2}{b}\right) \|a(n)\|^2.$ Since $k_f < b$, $(\alpha(n)) = Su(n) \to 0$, as $n \to \infty.$ Thus, if $\lim_{n \to \infty} u(n) = u$ then $Su = 0$. Hence, $\|Su\|^2 = 0 \implies (Su)^T(Su) = 0 \implies u^T R u = 0.$ Since $R$ is a symmetric matrix which have 0 row sum,

\[
(40) \quad u^T R u = 0 \implies \frac{1}{2} \sum_{i} R_{ij}(u(i) - u(j))^2 = 0.
\]

Since the underlying hypergraph is connected, from the above Equation (40) we have $u(i) = u(j)$, for all $i, j \in \mathbb{N}_N$. This completes the proof. \qed

3.1.4. **Local stability analysis.** Here we focus on the trajectories of the CDSH, which start from neighboring points of the manifold of synchronization. That is, the initial points of the trajectories are situated in so small neighborhood of a point in the manifold of synchronization that all the nonlinear functions can be replaced by their linearization around the point in the
manifold of synchronization. The main plan in this section is to explore the possibilities of
attracting the trajectories, adjoining to the manifold of synchronization to the manifold itself.
Hence, in a nutshell, this section is on the analysis of the stability of synchronization under
small perturbations using linearization. Hence, it is called linear stability analysis. It is also
known as the study of local synchronization.

Let us have a bird’s-eye view on linearization. Let \( h : \mathbb{R}^n \rightarrow \mathbb{R} \) be a smooth function, \( a \in \mathbb{R}^n \)
be a fixed point and \( x \in \mathbb{R}^n \) be any arbitrary point. The Taylor series of \( f(x) \) about \( a \) is given by,

\[
(41) \quad f(x) = f(a) + \sum_{i \in \mathbb{N}_n} \frac{1}{i!} (x-a)^i \partial f^i(a),
\]

where \( \partial f^i(a) \) is a \( i \)-th order \( n \)-dimensional symmetric tensor (for details see [34, example-1.1
in chapter-1]) given by \( \partial f^i(a)_{j_1j_2...j_i} = \frac{\partial^i f(a)}{\partial x_{j_1}\partial x_{j_2}...\partial x_{j_i}} \). For any \( m \)-order \( n \)-dimensional tensor
\( T = \{(t_{j_1...j_m})_{j_1\in\mathbb{N}_m} \}_{r\in\mathbb{N}_m} \) and \( x \in \mathbb{C}^n \), the product \( T x^m \) (as defined in [34, page-4]) is defined
as \( T x^m = T \times_1 x \times_2 x \times_3 \ldots \times_m x = \sum_{j_1j_2...j_m \in \mathbb{N}_m} t_{j_1j_2...j_m} x(j_1)x(j_2)\ldots x(j_m) \). For \( i = 1, \) \( \partial f^i(a) \)
is called the gradient of \( f \) at \( a \) and for \( i = 2 \) it is the Hessian matrix of \( f \) evaluated at \( a \).

Now if \( x \) is sufficiently neighboring to \( a \), that is, \( x \) is in a sufficiently small neighborhood of \( a \)
then \( (x-a) \) is very small in modulus. The nonlinear terms in Equation (41) involving the
powers of \( (x-a) \) become very small and hence the truncated linear part on the right hand side
of Equation (41) can be treated as a good approximation of \( f(x) \) for any \( x \) sufficiently adjacent
to \( a \). This approximation is called the linearization of \( f \) around \( a \). Hence in compact form, the
linearization of \( f \) around \( a \) is given by

\[
(42) \quad f(x) = f(a) + (\nabla f(a))(x-a).
\]

Expanding it we get, \( f(x) = f(a) + \sum_{i \in \mathbb{N}_n} (x-a)^i \partial f^i(a) \). Note that, if we consider \( x \) and \( a \) as row
vectors then we can assume \( Df(a) = \{(\partial f^i(a))_{j_1j_2...j_i} \} \) as a column vector. In that case Equation (42)
can be rewritten as \( f(x) = f(a) + (x-a).Df(a) \). If we consider \( x \) and \( a \) are column vectors,
respectively and \( Df(a) = \{(\partial f^i(a))_{j_1j_2...j_i} \} \) is a row vector, Equation (42) becomes \( f(x) = f(a) +
Df(a).(x-a) \). Now we consider linearization in the stability analysis of synchronization.

**Lemma 3.8.** The stability of synchronization of a synchronized trajectory and the local syn-
chronizability of a trajectory which started very near to the manifold of synchronization of the
CDSH, given by Equation (18) depends on the local stability of a dynamical system around 0.

**Proof.** Let \( u(1) \in \mathbb{R}^{N_k} \) be a point, very close to the manifold of synchronization, \( H \). That is,
there exist a point \( v(1) \in H \subset \mathbb{R}^{N_k} \) such that \( e(1) = u(1) - v(1) \) and \( \|e(1)\| \) are sufficiently
small. Let \( \{u(n)\}_{n \in \mathbb{N}} \) and \( \{v(n)\}_{n \in \mathbb{N}} \) be two trajectories of the discrete CDSH represented by
Equation (18) with initial points \( u(1) \) and \( v(1) \), respectively and \( \{e(n)\}_{n \in \mathbb{N}} \) is the trajectory
defined by \( e(n) = u(n) - v(n) \). Using Equation (18) we have,

\[
(43) \quad e(n+1) = (g(u(n)) + eC f(u(n)) \Gamma) - (g(u(n)) + eC f(u(n)) \Gamma)
\]

\[
= g(u(n)) - g(v(n)) + eC (f(u(n)) - f(v(n))) \Gamma
\]

By Equation (18), \( v(1) \in H \implies v(n) \in H \) for all \( n \in \mathbb{N} \). If \( e(n) \rightarrow 0 \), as \( n \rightarrow \infty \), then
the local synchronization is achieved by the trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of
the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) is stable under any small perturbation. Our next aim is
to find the equation governing the trajectory \( \{e(n)\}_{n \in \mathbb{N}} \) of the error dynamical system using
Equation (43) and analyse its stability around 0.
Now, using Equation (10) we have, \( f(u(n)) \)

\[
(44) \quad \begin{pmatrix}
\bar{f}_1(u(n)(1)) \\
\vdots \\
\bar{f}_{n}(u(n)) \\
\vdots \\
\bar{f}_k(u(n)(N)) \\
\vdots \\
\bar{f}_{N}(u(n)(N))
\end{pmatrix} = \begin{pmatrix}
\bar{f}_1(u(n)(1)) \\
\vdots \\
\bar{f}_{n}(u(n)) \\
\vdots \\
\bar{f}_k(u(n)(N)) \\
\vdots \\
\bar{f}_{N}(u(n)(N))
\end{pmatrix}
\]

\[
= \begin{pmatrix}
\bar{f}_1(v(n)(1)) + e(n)(1) \\
\vdots \\
\bar{f}_{n}(v(n)) \\
\vdots \\
\bar{f}_k(v(n)(N)) + e(n)(N)
\end{pmatrix} + \begin{pmatrix}
(e(n)(1)).D \bar{f}_1(v(n)(1)) \\
\vdots \\
(e(n)(N)).D \bar{f}_1(v(n)(N))
\end{pmatrix}
\]

As we know \( v(n) \in H \), for all \( n \in \mathbb{N} \), hence \( v(n)(1) = v(n)(2) = \ldots = v(n)(N) = s_n \in \mathbb{R}^k \) and we rewrite Equation (44) as

\[
(45) \quad f(u(n)) = f(v(n)) + \begin{pmatrix}
(e(n)(1)).D \bar{f}_1(s_n) \\
\vdots \\
(e(n)(N)).D \bar{f}_1(s_n)
\end{pmatrix}
\]

where \( e(n) = \begin{pmatrix}
(e(n)(1)) \\
\vdots \\
(e(n)(N))
\end{pmatrix} \) is an \( N \times k \) matrix and \( J_f(n) = \begin{pmatrix} D \bar{f}_1(s_n) & \ldots & D \bar{f}_k(s_n) \end{pmatrix} \) is a \( k \times k \) matrix. Similarly, for the function \( g \), we get

\[
(46) \quad g(u(n)) = g(v(n)) + e(n).J_g(n).
\]

Hence by using Equation (45) and Equation (43) we have,

\[
(47) \quad e(n + 1) = e(n)J_g(n) + \epsilon C e(n) J_f(n) \Gamma.
\]

Clearly the condition for the stability of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) and the condition for the local synchronization of \( \{u(n)\}_{n \in \mathbb{N}} \) is the condition for the local stability of the error system represented in Equation (47).

Since, \( C \) is a symmetric matrix, there exists an orthogonal matrix \( Q \) (the rows of \( Q \) are the eigenvectors of \( C \)) such that \( C = Q^T D_C Q \), where \( D_C \) is the diagonalization of \( C \). Now from Equation (47) we get, \( Qe(n + 1) = Qe(n)J_g(n) + \epsilon QCQ^T Qe(n) J_f(n) \Gamma \). Hence it can be concluded that

\[
(48) \quad \eta(n + 1) = \eta(n)J_g(n) + \epsilon D_C \eta(n) J_f(n) \Gamma,
\]

where \( \eta(n) = Qe(n) \) for all \( n \in \mathbb{N} \). Thus \( \eta(n + 1)(i) = \eta(n)(i)(J_g(n) + \epsilon \lambda_i J_f(n) \Gamma) \). Hence,

\[
(49) \quad \eta(n + 1)(i) = \left\{ \prod_{k=1}^{n} (J_g(k) + \epsilon \lambda_i J_f(k) \Gamma) \right\} \eta(1)(i),
\]

for all \( i \in \mathbb{N}_N \). Here \( \{\lambda_i\}_{i \in \mathbb{N}_N} \) are all the eigenvalues of \( C \). Clearly, as \( n \to \infty \), if \( \eta(n) \to 0 \) then \( e(n) \to 0 \). Hence the condition for local synchronization of \( \{u(n)\}_{n \in \mathbb{N}} \) and the condition for stability of the synchronization of \( \{v(n)\}_{n \in \mathbb{N}} \) are the conditions for stability of \( \{\eta(n)\}_i \) for all \( i \in \mathbb{N}_N \) around the equilibrium point 0. \( \square \)
3.1.5. Construction of Lyapunov function for local synchronization. Let \( A \) be a positive definite \( k \times k \) matrix. Let \( V : \mathbb{R}^N \to \mathbb{R} \) be a function defined by

\[
V(x) = x A x^T. 
\]

Clearly, \( V(x) \geq 0 \) for all row vector \( x \in \mathbb{R}^n \). Now we have

\[
V(\eta(n+1)) \leq \|(\eta(n))(i)\|_A \|(J_g(n) + \epsilon \lambda_i J_f(n) \Gamma)\|_A, 
\]

which implies if \( \|(J_g(n) + \epsilon \lambda_i J_f(n) \Gamma)\|_A < 1 \) then \( \eta(n) \) is stable around 0 for all \( i \in \mathbb{N}_N \). Hence, by using Lemma 3.8, we get our desired result.

Lemma 3.9. If \( \|(J_g(n) + \epsilon \lambda_i J_f(n) \Gamma)\|_A < 1 \) then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of CDSH given by Equation (18) is stable under a small perturbation.

Proof. Writing Equation (51) in with the notation of \( \| \cdot \|_A \) we have

\[
\|(\eta(n+1))(i)\|_A \leq \|(\eta(n))(i)\|_A \|(J_g(n) + \epsilon \lambda_i J_f(n) \Gamma)\|_A, 
\]

which implies if \( \|(J_g(n) + \epsilon \lambda_i J_f(n) \Gamma)\|_A < 1 \) then \( \eta(n) \) is stable around 0 for all \( i \in \mathbb{N}_N \). Hence, by using Lemma 3.8, we get our desired result.

Theorem 3.6. Let \( f = g \) and \( \Gamma = c.I_k \), for some constant \( c \). If the limit, \( \sigma = \lim_{n \to \infty} \frac{1}{n} \sum_{r=1}^{n} \log \|J_f(r)\|_A \)

exists and all the absolute values of the eigenvalues of \( C \) are contained in the interval \([\frac{1-e^{-c \sigma}}{c \sigma}, \frac{1+e^{-c \sigma}}{c \sigma}]\) then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of the discrete dynamical system given by Equation (18) is stable under small perturbation.

Proof. Since \( f = g \), and \( \Gamma = c.I_k \) Equation (52) becomes \( \|(\eta(n+1))(i)\|_A \leq \|(\eta(n))(i)\|_A \|(1 + \epsilon c \lambda_i)\| \|(J_f(r))\|_A, \)

which implies \( \eta(n) \to 0 \) as \( n \to \infty \), if \( \|(1 + \epsilon c \lambda_i)\| \|(\prod_{r=1}^{n} \|J_f(r)\|_A)\|^\frac{1}{n} < 1 \), for all \( i \), that is, if

\[
\|(1 + \epsilon c \lambda_i)\| e^\sigma < 1, 
\]

for all \( i \), where \( \sigma = \lim_{n \to \infty} \log \left( \prod_{r=1}^{n} \|J_f(r)\|_A \right)^\frac{1}{n} = \lim_{n \to \infty} \frac{1}{n} \sum_{r=1}^{n} \log \|J_f(r)\|_A \). Hence the trajectories of the CDSH represented by Equation (18), synchronize locally if \( \frac{1-e^{-c \sigma}}{c \sigma} < -\lambda_i < \frac{1+e^{-c \sigma}}{c \sigma} \) for all \( i = 1, 2, \ldots, N \). In other words, the synchronization is stable under small perturbation if the above condition satisfied. This completes the proof.

In fact from Lemma 3.9, we can conclude a little more than Theorem 3.6 but before that we need the following remark.

Remark 3.10. The rows of \( Q \) are the eigenvectors of \( C \). Hence the eigenvalues of \( C \) has one to one correspondence with the rows of \( Q \). As the \( r \)-th row \( Qe(1) \) is obtained by right multiplication of \( e(1) \) with the \( r \)-th row of \( Q \) (that is with the transpose of an eigenvector of \( C \)), the \( r \)-th row of \( Qe(1) \) also has an one to one correspondence with the eigenvalues of \( C \). That is if \( \lambda_r \) is the \( r \)-th eigenvalue with eigenvector \( v_r \) then \( r \)-th row of \( Q \) is \( Q_r = v_r \) and the \( r \)-th row of \( Qe(1) \) is \( v_r^T e(1) \). We are going to use this correspondence in the next result.

Theorem 3.7. Let \( f = g \), \( \Gamma = c.I_k \), for some constant \( c > 0 \) and the limit, \( \sigma = \lim_{n \to \infty} \frac{1}{n} \sum_{r=1}^{n} \log \|J_f(r)\|_A \)

exists. Let \( e(1) \) be the initial perturbation of synchronized trajectory. If either the \( i \)-th row (component) of the \( Qe(1) = \eta(1) \) is zero or the absolute value of the corresponding \( i \)-th eigenvalue of \( C \) is contained in the interval \([\frac{1-e^{-c \sigma}}{c \sigma}, \frac{1+e^{-c \sigma}}{c \sigma}]\), then the local synchronization is achieved by any
Corollary 3.4. Let \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of the CDSH, given by Equation (18) is stable under small perturbation.

Proof. From Equation (53), it can be concluded that \( \lim_{n \to 0} \eta(n)(i) = 0 \) if either \( \eta(1)(i) = 0 \) or \( \|((1 + c\epsilon\lambda_i))\|e^\sigma < 1 \). Using this fact and proceeding like the proof of Theorem 3.6, this result can be proved easily. \( \square \)

Remark 3.11. The rows of \( Q \) are the eigenvectors of \( C \). Let the \( r \)-th row of \( Q \) (say \( Q_r \)) is the eigenvector of \( C \) corresponding to the eigenvalue 0. So \( Q_r \in \mathbb{R}^N \) with all its components are equal to 1. If we choose \( s_1 \) as defined in Equation (25) and \( V(1) \) accordingly (that is, if we do not choose the other options for \( s_1 \) given in Remark 3.7), then the \( r \)-th component of \( \eta(1) = Q_v(1) \) can be written, by using Equation (25), as \( Q_r.e(1) = Q_r.(u(1) - v(1)) = \sum_{i \in N} u(1)(i) - \sum_{i \in N} v(1)(i) = 0 \). Thus by Theorem 3.7, we have the following result.

Corollary 3.3. Let \( f = g \) and \( \Gamma = c.I_k \), for some constant \( c > 0 \). If the limit, \( \sigma = \lim_{n \to \infty} \frac{1}{n} \sum_{r=1}^{n} \log \|J_f(r)\|_A \) exists and all the absolute values of the nonzero eigenvalues of \( C \) are contained in the interval \( \left[\frac{1-e^{-\sigma}}{c\lambda_{\min}}, \frac{1+e^{-\sigma}}{c\lambda_{\max}}\right] \) then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of the CDSH, given by Equation (18) is stable under small perturbation.

Proof. This result directly follows from Remark 3.11 and Theorem 3.7. \( \square \)

The next corollary easily follows from Theorem 3.6, Remark 3.11.

Corollary 3.4. If \( f = g \), \( \Gamma = c.I_k \) for some constant \( c > 0 \), the limit \( \sigma = \lim_{n \to \infty} \frac{1}{n} \sum_{r=1}^{n} \log \|J_f(r)\|_A \) exists, and the coupling strength \( \epsilon \) is contained in the interval \( \left[\frac{1-e^{-\sigma}}{c\lambda_{\min}}, \frac{1+e^{-\sigma}}{c\lambda_{\max}}\right] \), where \( \lambda_{\max} \) and \( \lambda_{\min} \) are the maximum and minimum of the absolute values of the nonzero eigenvalues of \( C \) respectively then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of the CDSH, given by Equation (18) is stable under small perturbation.

Proof. If \( \epsilon \in \left[\frac{1-e^{-\sigma}}{c\lambda_{\min}}, \frac{1+e^{-\sigma}}{c\lambda_{\max}}\right] \) where \( \lambda_{\max} \) and \( \lambda_{\min} \) are the maximum and minimum of the absolute values of the non zero eigenvalues of \( C \) respectively, then \( \frac{1-e^{-\sigma}}{c\lambda_{\min}} < \lambda_{\min} < \lambda_{\max} < \frac{1+e^{-\sigma}}{c\lambda_{\max}} \). Hence, \( \frac{1-e^{-\sigma}}{c\lambda_{\min}} < \frac{1+e^{-\sigma}}{c\lambda_{\max}} \). This can be written as \( -e^{-\sigma} < 1 + c\epsilon\lambda_i < e^{-\sigma} \), or in terms of absolute value, \( \|(1 + c\epsilon\lambda_i))\|e^\sigma < 1 \). Hence the result follows from Equation (54) and Remark 3.11. \( \square \)

Now we recall some results from [35] and [36].

Lemma 3.10. [36, page-7, equation (2.3), (2.4)] \( \left( \begin{array}{cc} Q(x) & S(x) \\ S^T(x) & R(x) \end{array} \right) > 0 \) is equivalent to \( R(x) > 0 \), \( Q(x) - S(x)R(x)^{-1}S(x)^T > 0 \), where \( Q(x) = Q(x)^T \), \( R(x) = R(x)^T \), and \( S(x) \) depends affinely on \( x \).

Lemma 3.11. [35, Theorem 1.2 (Existence of a Lyapunov function implies stability), page-2] Let \( x = 0 \) be an equilibrium point for the autonomous system \( x(t + 1) = f(x(t)) \) where \( f : D \to \mathbb{R}^n \) is locally Lipschitz in \( D \subset \mathbb{R}^n \) and \( 0 \in D \). Suppose there exists a continuous function \( V : D \to \mathbb{R} \) such that \( V(0) = 0 \) and \( V(x) > 0 \), for all \( x \in D - \{0\} \) and \( V(f(x)) - V(x) \leq 0 \), for all \( x \in D \). Then \( x = 0 \) is stable. Moreover if \( V(f(x)) - V(x) < 0 \), for all \( x \in D - \{0\} \) then \( x = 0 \) is asymptotically stable.

Lemma 3.12. [35, Theorem 1.4 (Existence of a Lyapunov function implies stability), page-2] Let \( x = 0 \) be an equilibrium point for the autonomous system \( x(t + 1) = f(x(t)) \) where \( f : D \to \mathbb{R}^n \) is locally Lipschitz in \( D \subset \mathbb{R}^n \) and \( 0 \in D \). Suppose there exists a continuous
function $V : D \to \mathbb{R}$ such that $V(0) = 0$ and $V(x) > 0$, for all $x \in D - \{0\}$ and $V(x \to 0)$ as 
\[ \|x\| \to \infty \text{ and } V(f(x)) - V(x) < 0, \text{ for all } x \in D - \{0\} \] then $x = 0$ is globally asymptotically stable.

Now we have the following theorem.

**Theorem 3.8.** If there exists a positive definite matrix $A$ such that $[((J_g(n) + \epsilon \lambda_i J_f(n) \Gamma))A((J_g(n) + \epsilon \lambda_i J_f(n) \Gamma))^T - A] < 0$ for all $i$ then local synchronization is achieved by any trajectory $\{u(n)\}_{n \in \mathbb{N}}$ and the synchronization of the synchronized trajectory $\{v(n)\}_{n \in \mathbb{N}}$ of the CDSH given by Equation (18) is stable under small perturbation.

*Proof.*

\begin{align*}
V(\eta(n + 1)i) - V(\eta(n)i) &= (\eta(n)(i)) [((J_g(n) + \epsilon \lambda_i J_f(n) \Gamma))A((J_g(n) + \epsilon \lambda_i J_f(n) \Gamma))^T - A](\eta(n)(i))^T.
\end{align*}

Hence if $[((J_g(n) + \epsilon \lambda_i J_f(n) \Gamma))A((J_g(n) + \epsilon \lambda_i J_f(n) \Gamma))^T - A]$ is negative definite, then $V(\eta(n + 1)i) - V(\eta(n)i) \leq 0$ and the result follows from Lemma 3.11, Lemma 3.12.

Hence by using Lemma 3.10, Lemma 3.12 we have the next corollary.

**Corollary 3.5.** If there exists a positive definite matrix $A$ such that

\[ A > 0 \]

for all $i$ then local synchronization is achieved by any trajectory $\{u(n)\}_{n \in \mathbb{N}}$ and the synchronization of the synchronized trajectory $\{v(n)\}_{n \in \mathbb{N}}$ of the discrete dynamical system given by Equation (18) is stable under small perturbation.

**Remark 3.12.** If we take the maximum edge cardinality, $m_{\text{max}} = 2$, all the underlying hypergraphs of the models, discussed above, become graphs and the corresponding CDSH become dynamical networks. Thus, some of the above results on CDSH can be considered as generalization of the same on dynamical-networks found in [30, 37, 29].

### 3.2. Synchronization in discrete coupled dynamical systems on weighted hypergraphs

Let $G = (V, E, w)$ be a weighted hypergraph with vertex set $V$, edge set $E$, and a weight function $w : E \to \mathbb{R}^+$. The positive real number $w(e)$ is called the weight of the hyperedge $e$ [38]. One may consider the $\mathbb{R}$ as the range of the weight function, but in this work, we restrict the same to $\mathbb{R}^+$. It is quite common to represent the vertex-edge-incidence in a systems on hypergraphs, $G$ by using a bipartite graph, where one of the parts consists of the vertices, and the other consists of the hyper-edges of $G$, respectively. In this bipartite graph, a vertex of $G$ is adjacent to a hyperedge, if and only if, the vertex belongs to that hyperedge in $G$ (see Figure 1). This bipartite graph is known as the incidence graph of the hypergraph.

![Figure 1. Bipartite representation of hypergraph.](image)

In a CDSH, the hyper-edges act as the interactive couplings. It is natural to expect a condition of synchronization governed by hyper-edges. Now for each edge $e = (v_{i_1}, v_{i_2}, \ldots, v_{i_j})$...
with cardinality \(j\), we define a function \(h_e : \mathbb{R}^{Nk} \rightarrow \mathbb{R}^{Nk}\) by

\[
h_e(u)(i) = \begin{cases} \frac{j}{j-1}(u_{i} - u(i)) & \text{if the } i\text{-th vertex } v_i \in e, \\ 0 & \text{otherwise,} \end{cases}
\]

where \(u_{i} = \frac{\sum_{e \in \mathcal{E} \setminus \{i\}} u(e)}{j}\) and \(u(i) \in \mathbb{R}^{Nk}\). The function \(h_e\) can be considered as action of the edge \(e\) on the state of the vertices (or simply, the action of \(e\)). Note that an edge \(e_r\) has a non-zero action on the vertex \(v_j\) only if \((v_j, e_r)\) is an edge in the incidence graph of the systems on hypergraphs.

Now we study the linearity in this action of hyper-edges. We define an \(N \times 1\) matrix \(I_e\) and an \(N \times N\) diagonal matrix \(D_e\) corresponding to a hyper-edge \(e\) by, \((I_e)_{i} = 1\) if \(v_i \in e\), otherwise \((I_e)_{i} = 0\) and \((D_e)_{ii} = 1\) if \(i \in e\), otherwise \((D_e)_{ii} = 0\). It can be easily verified that

\[
h_e(u) = \frac{|e|}{|e| - 1}\left(1 - I_eI_e^T - D_e\right)u = H_e(u), \quad \text{where } H_e := \frac{|e|}{|e| - 1}\left(1 - I_eI_e^T - D_e\right).
\]

We call the \(N \times N\) symmetric matrix \(H_e\) the edge-diffusion matrix of the edge \(e\). Now using Equation (57) we re-write the general model represented in Equation (14) as

\[
u(n + 1)(i) = \bar{g}(u(n))(i) + \epsilon \sum_{m=2}^{m_{max}} \sum_{m-1}^{m} \sum_{e_r \in \mathcal{E}(i); |e_r| = m} (u_{j} - f(u(n))(i))\]

which implies

\[
u(n + 1) = \{u(n + 1)(i)\}_{i \in \mathbb{N}^N} = \{\bar{g}(u(n))(i) + \epsilon \sum_{m=2}^{m_{max}} \sum_{e_r \in \mathcal{E}(i); |e_r| = m} h_{e_r}(f(u(n)))(i)\}_{i \in \mathbb{N}^N}
\]

\[
= g(u(n)) + \epsilon \sum_{e_r \in \mathcal{E}} H_{e_r}(f(u(n)))
\]

\[
= \sum_{e_r \in \mathcal{E}} \left\{ \frac{1}{M} g(u(n)) + \epsilon H_{e_r}(f(u(n))) \right\}.
\]

Now Equation (60) is our model to study the action of edge and its effect on synchronization in discrete CDSH. This model can be generalized further by introducing a \(k \times k\) inner couple matrix \(\Gamma\) as follows.

\[
u(n + 1) = \sum_{e_r \in \mathcal{E}} \left\{ \frac{1}{M} g(u(n)) + \epsilon H_{e_r}(f(u(n)))\Gamma \right\}.
\]

**Remark 3.13.** The model represented by Equation (16) is equivalent to the model given by Equation (60) since both of them are equivalent to the model described in Equation (14). Similarly the model in Equation (18) is equivalent to the model given by Equation (61). It is obvious that any theorem, holds for the trajectories of a CDSH model, will also hold for all its equivalent models.

In the previous sections, we have considered the coupling strength \(\epsilon\) as a constant. Now we are interested in taking different coupling strengths for the couplings, i.e., for the hyperedges. Thus we consider \(\epsilon : E \rightarrow \mathbb{R}^+\) as a function. We denote \(\epsilon(e)\) by \(\epsilon_e\) for all \(e \in E\). One may also choose \(\epsilon(e)\) as a function of \(w(e)\) for a weighted hypergraph \(G = (V, E, w)\). Here, we are considering \(\epsilon(e) = w(e)\) for all \(e \in E\) for our dynamical (weighted) systems on hypergraphs model.

After taking \(\epsilon_e\) in Equation (61) we have the following weighted systems on hypergraphs model.

\[
u(n + 1) = \sum_{e_r \in \mathcal{E}} \left\{ \frac{1}{M} g(u(n)) + \epsilon_e H_{e_r}(f(u(n)))\Gamma \right\}.
\]
From the definition of $e$, Proposition 3.1.

Let $G$ be a weighted hypergraph on $N$ vertices, $M$ edges and $w_e$ be the weight of a hyper-edge $e \in E$. The $(i,j)$-th position of the $N \times N$ matrix $A_w$ is defined as $(A_w)_{ij} = \sum_{e \in E, i \in e} \frac{w_e}{|e|! - 1}$ if $i \sim j$, elsewhere $(A_w)_{ij} = 0$.

Proposition 3.1. Let $G$ be a weighted hypergraph and $w_e$ be the weight of a hyper-edge $e$ of $G$. Then $L_w = A_w - \sum_{e \in E} \epsilon_e D_e$.

Proof. From the definition of $L_w$, we write

$$L_w = \sum_{e \in E} \epsilon_e H_e = \sum_{e \in E} \frac{\epsilon_e}{|e| - 1} (I_e I_e^T - D_e) - \sum_{e \in E} \epsilon_e D_e.$$

Now, $(I_e I_e^T)_{ij} = \begin{cases} 1 & \text{if } i, j(\neq i) \in e, \\ 1 & \text{if } i = j \in e, \\ 0 & \text{otherwise}, \end{cases}$ and $(I_e I_e^T - D_e)_{ij} = \begin{cases} 1 & \text{if } i, j(\neq i) \in e, \\ 0 & \text{otherwise}. \end{cases}$

Hence by Equation (66), we have $L_w = A_w - \sum_{e \in E} \epsilon_e D_e$, where $\epsilon_e$ is the weight of the hyper-edge $e$, for all $e \in E$.

Now we define the matrix $D_w$ as follows

$$D_w := \sum_{e \in E} \epsilon_e D_e.$$

Theorem 3.9. If $f$ and $g$ are Lipschitz functions with Lipschitz constant $k_f$ and $k_g$, respectively, and $(k_g + \|L_w\|k_f\|\Gamma^T\|) < 1$, then any trajectory of the CDSH represented by the model of Equation (61) achieves synchronization asymptotically. If $f = g$ and $\Gamma = I_k$, then the sufficient condition for synchronization becomes $\|I_N + L_w\| < \frac{1}{k_f}$.

Proof. Recall that $s_1 = \frac{1}{N} \sum_{i=1}^{N} u(1)(i)$ and $v(1)$ be an $N \times k$ matrix whose all the $N$ rows be the $N$ copies of $s_1$. The trajectory of $\{v(n)\}$ evolves governed by the CDSH model of Equation (65), that is, by the equation

$$v(n + 1) = g(v(n)) + L_w(f(v(n)))\Gamma.$$
Lemma 3.14. There exists an orthogonal matrix \( \Delta_w \), which commutes with the matrix \( L_w \). Moreover if the functions \( f \) and \( g \), described in Equation (10), are differentiable with all their partial derivatives exist and bounded then \( \|\Delta_w f(u(n))\|^2 \leq \|\sup \tilde{f}^i\|^2 \|\Delta_w u(n)\|^2 \) and \( \|\Delta_w g(u(n))\|^2 \leq \|\sup \tilde{g}^i\|^2 \|\Delta_w u(n)\|^2 \), where \( \|\sup \tilde{f}^i\|^2 = (\sum_{i \in N_k} \|\sup \tilde{f}^i\|)^2 \) and \( \|\sup \tilde{g}^i\|^2 = (\sum_{i \in N_k} \|\sup \tilde{g}^i\|)^2 \).

Proof. The proof is similar to the same of Lemma 3.5.

Now we define \( \theta_w(n) := \Delta_w u(n) \), which acts as a lyapunov function in global analysis of the weighted discrete dynamical system.

Lemma 3.15. If \( \theta_w(n) = \Delta_w u(n) \), then \( \theta_w(n) \to 0 \) as \( n \to \infty \) implies that the trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) achieves synchronization asymptotically.

Proof. The proof is similar to the same of Lemma 3.6.

Theorem 3.10. If \( f \) and \( g \) are differentiable functions and \( [\|\sup \tilde{g}^i\| + \|\Gamma^T\|L_w\|\sup \tilde{f}^i\|] < 1 \) then any trajectory of the CDSH represented by the model of Equation (65) achieves synchronization asymptotically.

Proof. Using Equation (65), we have \( \theta_w(n+1) = \Delta_w [g(u(n)) + L_w(f(u(n)))\Gamma] \). Hence by using Lemma 3.14 and proceeding as the proof of Theorem 3.3, we get \( \|\theta_w(n+1)\|^2 \leq [\|\sup \tilde{g}^i\| + \|\Gamma^T\|L_w\|\sup \tilde{f}^i\|] \|\theta_w(n)\|^2 \). Hence the theorem follows.

Corollary 3.7. If \( f = g \) and \( \Gamma = cI_k \), and \( \|[I_N + cL_w]\| \) is a constant, then the trajectories of the CDSH, given by Equation (65) globally synchronize asymptotically.

Proof. Since \( f = g \) and \( \Gamma = cI_k \), then using Equation (65), we have \( \theta_w(n+1) = \Delta_w [I_N + cL_w f(u(n))] \). Hence by using Lemma 3.14 we have \( \|\theta_w(n+1)\|^2 \leq [\|[I_N + cL_w]\|[\|\sup \tilde{f}^i\|] \|\theta_w(n)\|] \). Hence the result follows.
Now we state the analogue of Theorem 3.5 for the weighted case.

**Theorem 3.11.** Let \( f \) is a function of the form given by Equation (10) with \( \|\tilde{f}(x) - \tilde{f}(y)\| \leq k_f\|x - y\| \), where \( \tilde{f} \) is a Lipschitz function. Let \( f = g \) and \( \Gamma = I_k \). If there exists a negative semidefinite matrix \( R \) whose row sum is 0, and there exists a positive real \( b > k_f \) such that \((I_N + L_w)^T R (I_N + L_w) - \frac{b}{2} R \geq 0 \) then the trajectories CDSH, described in Equation (65) synchronizes.

**Proof.** The proof similar as the same of Theorem 3.5. \( \square \)

3.2.2. Stability analysis of the coupled discrete dynamical systems on weighted hypergraphs.

**Lemma 3.16.** The stability of synchronization of a synchronized trajectory and the local synchronization of a trajectory which starts very near to the manifold of synchronization of the CDSH, given in Equation (65) depend on the local stability of a dynamical system around 0.

**Proof.** Let \( u(1) \in \mathbb{R}^{Nk} \) be a point very close to the manifold of synchronization, \( H \). There exists a point \( v(1) \in H \subset \mathbb{R}^{Nk} \) such that \( e(1) = u(1) - v(1) \) and \( \|e(1)\| \) is sufficiently small. Let \( \{u(n)\}_{n \in \mathbb{N}} \) and \( \{v(n)\}_{n \in \mathbb{N}} \) be two trajectories of the CDSH represented by Equation (65) with the initial points \( u(1) \) and \( v(1) \), respectively, and \( \{e(n)\}_{n \in \mathbb{N}} \) be the trajectory of another dynamical system defined by \( e(n) = u(n) - v(n) \). Using Equation (65) we have,

\[
e(n + 1) = [g(u(n)) + L_w f(u(n))] - [g(v(n)) + L_w f(u(n))]
\]

\[
= g(u(n)) - g(v(n)) + L_w[f(u(n)) - f(v(n))].
\]

Since \( v(1) \in H \), by Equation (65), we get \( v(n) \in H \) for all \( n \in \mathbb{N} \). Now, if \( e(n) \rightarrow 0 \), as \( n \rightarrow \infty \), then the local synchronization is achieved by the trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) is stable under a small perturbation.

Hence Equation (45) and Equation (43) together imply,

\[
e(n + 1) = e(n)J_g(n) + L_w e(n)J_f(n) .
\]

Thus, Equation (70) represents the required dynamical system, whose stability around 0 is equivalent to local stability of synchronization of the synchronized solution of the weighted CDSH, given by Equation (65). \( \square \)

Since \( L_w \) is a symmetric matrix, there exists an orthogonal matrix \( R \) ( The rows of \( R \) are the eigenvectors of \( L_w \)) such that \( L_w = R^TD_{L_w}R \), where \( D_{L_w} \) is the diagonalization of \( L_w \). Multiplying \( R \) on the both sides of Equation (70) we get, \( Re(n + 1) = Re(n)J_g(n) + RL_wR^TRe(n)J_f(n) \). Hence,

\[
\eta_w(n + 1) = \eta_w(n)J_g(n) + D_{L_w}\eta_w(n)J_f(n),
\]

where \( \eta_w(n) = Re(n) \) for all \( n \in \mathbb{N} \). Clearly which implies \( \eta_w(n + 1)(i) = \eta_w(n)(i)J_g(n) + \mu_i \eta_w(n)(i)J_f(n) \)

\[
(72)
\]

Hence,

\[
\eta_w(n + 1)(i) = \left\{ \prod_{k=1}^{n} (J_g(k) + \mu_i J_f(k)) \right\} \eta_w(1)(i)
\]

for all \( i \in \mathbb{N}_N \), where \( \{\mu_i\}_{i \in \mathbb{N}_N} \) are all the eigenvalues of \( L_w \). Clearly \( e(n) \rightarrow 0 \) as \( n \rightarrow \infty \) if \( \eta_w(n) \rightarrow 0 \) as \( n \rightarrow \infty \). Hence the condition of local synchronization of \( \{u(n)\}_{n \in \mathbb{N}} \) and the condition of stability of the synchronization of \( \{v(n)\}_{n \in \mathbb{N}} \) are the condition of stability of \( \{\eta_w(n)\} \), for all \( i \in \mathbb{N}_N \) around the equilibrium point 0.

**Theorem 3.12.** If \( \|(J_g(n) + \mu_i J_f(n))\|_A < 1 \) then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of the CDSH, given by Equation (65), is stable under small perturbation.

**Proof.** The result follows by replacing \( \epsilon \lambda_i \) by \( \mu_i \) in the proof of Lemma 3.9. \( \square \)
Corollary 3.8. If \( g = f, \Gamma = cI_k \) for some \( c > 0 \), the limit \( \sigma = \lim_{n \to \infty} \frac{1}{n} \left( \sum_{k=1}^{n} \log \| J_f(k) \| \right) \) exists, and the absolute values of all the eigenvalues of \( L_w \) are contained in \( \left[ \frac{1-e^{-\sigma}}{c}, \frac{1+e^{-\sigma}}{c} \right] \) then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of the CDSH, given by Equation (65), is stable under small perturbation.

Proof. If \( g = f \) and \( \Gamma = I_k \), then by Equation (72) we have,

\[
\eta_w(n+1)(i) = \left( \prod_{k=1}^{n} (1 + c\mu) J_f(k) \right) \eta_w(1)(i).
\]

Let \( \sigma = \lim_{n \to \infty} \frac{1}{n} \left( \sum_{k=1}^{n} \log \| J_f(k) \| \right) \). Now Equation (73) implies that

\[
\| \eta_w(n+1)(i) \| \leq \| (1 + \mu c) |e^\sigma|^n \| \eta_w(1)(i) \|.
\]

Thus the trajectories synchronize locally if \( ||(1 + \mu c)|e^\sigma| < 1 \) for all \( i \), that is, if \((1 - e^{-\sigma}) < -c\mu < (1 + e^{-\sigma})\). Hence the result follows.

Corollary 3.9. If \( g = f, \Gamma = cI_k \) for some \( c > 0 \), the limit \( \sigma = \lim_{n \to \infty} \frac{1}{n} \left( \sum_{k=1}^{n} \log \| J_f(k) \| \right) \) exists, and the absolute values of all the nonzero eigenvalues of \( L_w \) are contained in \( \left[ \frac{1-e^{-\sigma}}{c}, \frac{1+e^{-\sigma}}{c} \right] \) then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of the CDSH, given by Equation (65), is stable under small perturbation.

Remark 3.14. Recall Remark 3.10, where we have described a correspondence between the rows of \( Qe(1) \) and the eigenvalues of \( C \). Similarly there is a correspondence between the rows of \( Re(1) \) and the eigenvalues of \( L_w \). We are going to use this correspondence in the next result.

Now we will state a result, which is analogous to Theorem 3.7.

Theorem 3.13. Let \( f = g, \Gamma = cI_k \), for some constant \( c(>0) \) and the limit, \( \sigma = \lim_{n \to \infty} \frac{1}{n} \sum_{i=1}^{n} \log \| J_f(r) \|_A \) exists. Let \( e(1) \) be the initial perturbation of synchronized trajectory. If either the \( i \)-th row (component) of the \( Re(1) = \eta_w(1) \) is zero or the absolute value of the corresponding \( i \)-th eigenvalue of \( L_w \) is contained in \( \left[ \frac{1-e^{-\sigma}}{c}, \frac{1+e^{-\sigma}}{c} \right] \), then the local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of CDSH, given by Equation (65), is stable under small perturbation.

Proof. Similar to the proof of Theorem 3.7.

Corollary 3.10. Let \( f = g \) and \( \Gamma = cI_k \), for some constant \( c > 0 \). If the limit, \( \sigma = \lim_{n \to \infty} \frac{1}{n} \sum_{i=1}^{n} \log \| J_f(r) \|_A \) exists and all the absolute values of the nonzero eigenvalues of \( L_w \) are contained in the interval \( \left[ \frac{1-e^{-\sigma}}{c}, \frac{1+e^{-\sigma}}{c} \right] \) then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of the CDSH, given by Equation (65), is stable under small perturbation.

Proof. Similar to the proof of Corollary 3.3.

Theorem 3.14. If there exists a positive definite matrix \( A \) such that \( \| (J_g(n) + \mu_i J_f(n) \Gamma) J_g(n) + \mu_i J_f(n) \Gamma \|^2 - A \| < 0 \) for all \( i \) then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of CDSH, given by Equation (65), is stable under small perturbation.

Proof. The proof follows by replacing \( \epsilon \lambda_i \) by \( \mu_i \) in the proof of Theorem 3.8.
Hence by using Lemma 3.10 and Lemma 3.12 we have the following corollary.

**Corollary 3.11.** If there exists a positive definite matrix $A$ such that
\[
A^{-1} (J_g(n) + \mu_i J_f(n) \Gamma) \geq 0
\]
for all $i$ then local synchronization is achieved by any trajectory $\{u(n)\}_{n \in \mathbb{N}}$ and the synchronization of the synchronized trajectory $\{v(n)\}_{n \in \mathbb{N}}$ of CDSH, given by Equation (18), is stable under a small perturbation.

### 3.3. Structural property of the hypergraph and synchronizability.

First, we recall a lemma from [39].

**Lemma 3.17.** Let $M = (m_{ij})$ be an $N \times N$ symmetric positive semidefinite matrix such that $M \mathbf{1} = 0$. Then the second smallest eigenvalue $\lambda_2$ of $M$ satisfies $\lambda_2 \leq \frac{N}{N-1} \min_i m_{ii}$, where $\mathbf{1} \in \mathbb{R}^N$ is a vector with all its components equal to 1.

We also have a similar lemma as follows.

**Lemma 3.18.** Let $M = (m_{ij})$ be a symmetric positive semidefinite $N$ by $N$ matrix such that $M \mathbf{1} = 0$. Then the largest eigenvalue $\lambda_N$ of $M$ satisfies $\lambda_N \geq \frac{N}{N-1} \max_i m_{ii}$, where $\mathbf{1} \in \mathbb{R}^N$ is a vector with all its components equal to 1.

**Proof.** Let $W = \{\mathbf{1}\}^\perp$. So
\[
\lambda_N = \max_{x \in W; \|x\| = 1} x^T M x.
\]
Let $\tilde{M} = \lambda_N (I_N - \frac{1}{N} \mathbf{1} \mathbf{1}^T) - M$. Any $y \in \mathbb{R}^N$ with $\|y\| = 1$ can be written as $y = q \mathbf{1} + rx$ and hence
\[
y^T \tilde{M} y = r^2 x^T \tilde{M} x \quad [ \text{because } \tilde{M} \mathbf{1} = 0]
\]
\[
= r^2 \lambda_N x^T x - x^T M x \geq 0, \quad [ \text{Using Equation (75).}]
\]
Hence $\tilde{M}$ is positive definite and by Equation (76) all the diagonal entry of $\tilde{M}$ is non negative and hence $\lambda_N \frac{N-1}{N} - \max_i m_{ii} \geq 0$. This completes the proof. \qed

Since $C \mathbf{1} = 0$ and the absolute values of eigenvalues of $C$ are the eigenvalues of the positive semidefinite matrix $-C$ using Lemma 3.17 and Lemma 3.18 we have the following lemma.

**Lemma 3.19.** If $\lambda_{\min}$ and $\lambda_{\max}$ are the minimum and maximum, respectively, of the absolute values of all the non zero eigenvalues of $C$ then $\lambda_{\min} \leq \frac{N}{N-1} (\min_i d(i)) \leq \frac{N}{N-1} (\max_i d(i)) \leq \lambda_{\max}$.

Now using Corollary 3.4 and Lemma 3.19 we have the following theorem.

**Theorem 3.15.** If $f = g$, $\Gamma = c I_k$, for some constant $c$, the limit, $\sigma = \lim_{n \to \infty} \frac{1}{n} \sum_{r=1}^n \log \|J_f(r)\|_A$ exists, and the coupling strength $\epsilon$ is contained in the interval $[\frac{N-1}{N} - \frac{1}{c \min d(i)} - \frac{N-1}{N} \frac{1}{c \min d(i)}]$ then local synchronization is achieved by any trajectory $\{u(n)\}_{n \in \mathbb{N}}$ and the synchronization of the synchronized trajectory $\{v(n)\}_{n \in \mathbb{N}}$ of the CDSH, given by Equation (18), is stable under small perturbation.

Using [28, Theorem 3.7 and corollary 3.8] we get
\[
\lambda_{\min} \leq b_C = \min \left\{ \frac{d_{i_1} + d_{i_2} + \cdots + d_{i_{\epsilon}}}{|\epsilon|} : \epsilon = \{i_1, i_2, \ldots, i_{|\epsilon|} \in E \} \right\} \leq \lambda_{\max}.
\]
Since $[\frac{1-\epsilon^2}{c b_G}, \frac{1 + \epsilon^2}{c b_G}] \subset [\frac{1-\epsilon^2}{c \lambda_{\max}}, \frac{1 + \epsilon^2}{c \lambda_{min}}]$, using Corollary 3.4 and Equation (77) we have the following theorem.
Theorem 3.16. If \( f = g, \Gamma = c.I_k, \) for some constant \( c, \) the limit \( \sigma = \lim_{n \to \infty} \frac{1}{n} \sum_{i=1}^{n} \log \|J_f(r)\|_A \) exists, and the coupling strength \( \epsilon \) is contained in the interval \( [1 \pm \epsilon^{-\sigma}, 1 \pm \epsilon^{-\sigma}] \) then local synchronization is achieved by any trajectory \( \{u(n)\}_{n \in \mathbb{N}} \) and the synchronization of the synchronized trajectory \( \{v(n)\}_{n \in \mathbb{N}} \) of the CDSH, given by Equation (18), is stable under small perturbation.

3.4. Coupled continuous dynamical systems on hypergraphs. While developing the models for coupled discrete dynamical systems on hypergraph, we have used some diffusion matrices of hypergraphs, such as \( C \) and \( L_w. \) Now, using these matrices and following the existing methods for constructing models for continuous-time dynamical networks, we build the same for continuous-time CDSH. We start with weighted case using the matrix \( L_w = \sum_{e_r \in E} \epsilon_{e_r} H_{e_r}. \)

The same for an unweighted systems on hypergraphs will automatically follow by taking the coupling strengths as constant, i.e., \( \epsilon_{e_r} = \epsilon \) for all \( e_r \in E. \) Then \( L_w = \epsilon C. \)

The model of the continuous-time CDSH is given by the equation
\[
\dot{u}(t) = f(u(t)) + L_w g(u(t))\Gamma,
\]
where \( f, g, u \) are as described in Equation (8) and Equation (10), and \( \Gamma \) is described in Equation (18). We use \( t \) to denote the time instead of \( n, \) to distinguish between the discrete and continuous-time cases. Now we start with local stability analysis.

3.4.1. Local stability analysis of coupled continuous-time dynamical systems on hypergraphs. Let \( s_1 = \frac{1}{N} \sum_{i=1}^{N} u(1)(i)(\in \mathbb{R}^k) \) and \( v(1) \) be an \( N \times k \) matrix whose all the \( N \) rows are \( N \) copies of \( s_1. \) Let \( \{v(n)\} \) be a trajectory that evolves by the rules of the CDSH model described in Equation (78). Clearly, the trajectory \( \{v(n)\} \) starts from the manifold of synchronization and confined in this manifold. Hence if any trajectory becomes closer to \( \{v(n)\} \) with the flow of time then that trajectory synchronizes asymptotically. Now, taking \( e(t) = u(t) - v(t) \) we have
\[
\dot{e}(t) = f(u(t)) - f(v(t)) + L_w (g(u(t)) - g(v(t)))\Gamma.
\]

We recall Equation (46). Since the trajectories \( u(t) \) and \( v(t) \) are very close, we use linearized approximation and, thus, we write
\[
g(u(t)) = g(v(t)) + e(t).J_g(t) \quad \text{and} \quad f(u(t)) = f(v(t)) + e(t).J_f(t).
\]
Hence Equation (79) becomes
\[
\dot{e}(t) = e(t).J_f(t) + L_w (e(t).J_g(t))\Gamma.
\]
\( L_w \) is a symmetric matrix. Hence there exists an orthogonal matrix \( R \) such that \( L_w = R^T D L_w R, \) where \( D_{L_w} \) is the diagonalization of \( L_w. \) Multiplying \( R \) on the both sides of Equation (81) we get,
\[
\dot{e}(t) = Re(t).J_f(t) + RL_w R^T Re(t).J_g(t)\Gamma, \quad \text{which implies} \quad \eta_w(t) = \eta_w(t).J_f(t) + D_{L_w}\eta_w(t).J_g(t)\Gamma = e(t)-J_f(t) + \mu_i\eta_i(t).J_g(t)\Gamma.
\]
\[
hence, \quad \dot{e}(t) = \eta_w(t)(i).[J_f(t) + \mu_i J_g(t)]\Gamma
\]
for all \( i \in \mathbb{N}_N. \) Now from the above discussion we have the following theorem.

Theorem 3.17. If the system described in Equation (82) is asymptotically stable around its zero solution, then the synchronization of a synchronized trajectory of the CDSH described in Equation (78) is stable under small perturbation.

Now using the Lyapunov approach, we have some sufficient conditions for ensuring the stability of the synchronization.

Theorem 3.18. If there exists a positive definite \( k \times k \) matrix \( P \) and a positive real \( b \) such that for all \( i, t, \) \( [J_f(t) + \mu_i J_g(t)]\Gamma + bI_k P \) is a negative semidefinite matrix then synchronization in the CDSH given by Equation (78) is stable under small perturbation.
Theorem 3.19. Let us consider a Lyapunov function \( V(t) = \frac{1}{2} \eta_w(t)(i) P \eta_w(t)^T(i) \), where \( P \) is a \( k \times k \) positive definite matrix. Then

\[ \dot{W}_P(t) = \eta_w(t)(i) P \eta_w^T(t)(i) = \eta_w(t)(i) [J_f(t) + \mu_i J_g(t) \Gamma] \eta_w^T(t)(i) \leq -b \eta_w(t)(i) P \eta_w(t)^T(i) = -2b W_P(t). \]

Hence \( W_P(t) \to 0 \) as \( t \to \infty \) for all \( i \), and this completes the proof.

Note that for \( k = 1 \), the condition in Theorem 3.18 becomes as follows: If there exists a \( b > 0 \) such that \( \left[ \frac{df(s(t))}{dt} + \mu_i \frac{dg(s(t))}{dt} + b \right] \leq 0 \). Hence we state the following.

Corollary 3.12. If \( k = 1 \), \( \Gamma = 1 \), and there exists a positive real \( b \) such that for all \( i, t \), \( \left[ \frac{df(s(t))}{dt} + \mu_i \frac{dg(s(t))}{dt} + b \right] \leq 0 \) then synchronization in the CDSH, given by Equation (78) is stable under small perturbation.

Using the vector notation for \( u(t) \) and \( v(t) \) instead of the matrix notation, we can conclude the following result.

Theorem 3.19. The synchronization of a synchronized trajectory of the CDSH given by Equation (78) is stable under small perturbation if \( [J_f(t) \otimes I_N + J_g(t) \otimes D_{Lw}] \) is negative definite, where \( \otimes \) is Kronecker product and \( D_{Lw} \) is the diagonalization of \( L_w \).

Proof. Let us consider a Lyapunov function \( V_I(t) = \frac{1}{2} \sum_{i \in \mathbb{N}_N} (\eta_w(t)(i)) (\eta_w(t)(i))^T \). Differentiating \( V_I(t) \) with respect to \( t \) we get

\[ \dot{V}_I(t) = \sum_{i \in \mathbb{N}_N} (\dot{\eta}_w(t)(i))(\eta_w(t)(i))^T = \sum_{i \in \mathbb{N}_N} \eta_w(t)(i) [J_f(t) + \mu_i J_g(t) \Gamma] (\eta_w(t)(i))^T \]

As \( [J_f(t) \otimes I_N + J_g(t) \otimes D_{Lw}] \) is negative definite, \( \dot{V}_I(t) < 0 \) and hence the result follows.

3.4.2. Global synchronization in continuous-time CDSH. Here, we restrict \( g \) as an identity function. Thus Equation (79) becomes

\[ \dot{e}(t) = f(u(t)) - f(v(t)) + L_w(e(t)) \Gamma. \]

Hence, the evolution of the \( i \)-th vertex is expressed by

\[ \dot{e}(t)(i) = \tilde{f}(u(t)(i)) - \tilde{f}(v(t)(i)) + \sum_{j \in \mathbb{N}_N} L_{wij}(e(t)(j)) \Gamma. \]

Theorem 3.20. If \( \Gamma \) is positive semidefinite diagonal matrix and there exists a \( k \times k \) diagonal positive definite matrix \( P \) such that \( (\tilde{f}(x) - \tilde{f}(y)) (P(x - y))^T \leq (x - y) K(p, f)(x - y)^T \) where \( K(p, f) \) is negative definite, then a trajectory of the dynamical system given by Equation (78) synchronizes asymptotically.

Proof. Let us consider a Lyapunov function \( V_P(t) = \frac{1}{2} \sum_{i \in \mathbb{N}_N} (e(t)(i))^P(e(t)(i))^T \). Now differentiating \( V_P(t) \) with respect to \( t \) and by using Equation (86), we have

\[ \dot{V}_P(t) = \sum_{i \in \mathbb{N}_N} [\tilde{f}(u(t)(i)) - \tilde{f}(v(t)(i)) + \sum_{j \in \mathbb{N}_N} L_{wij}(e(t)(j)) \Gamma] P(e(t)(i))^T \]

\[ \leq \sum_{i \in \mathbb{N}_N} (e(t)(i))^k(P, \tilde{f})(e(t)(i))^T + \sum_{i \in \mathbb{N}_N} \sum_{j \in \mathbb{N}_N} L_{wij}(e(t)(j)) \Gamma P(e(t)(i))^T \]

\[ = \sum_{i \in \mathbb{N}_N} (e(t)(i))^k(P, \tilde{f})(e(t)(i))^T + \sum_{i \in \mathbb{N}_N} \sum_{j \in \mathbb{N}_N} L_{wij} \sum_{r \in \mathbb{N}_k} (e(t)(j))(r) \Gamma_{rr} P_{rr}(e(t)(i)(r)) \]

\[ \leq \sum_{i \in \mathbb{N}_N} (e(t)(i))^k(P, \tilde{f})(e(t)(i))^T + \sum_{r \in \mathbb{N}_k} \Gamma_{rr} P_{rr}(e(t)(\cdot, r))^T L_w(e(t)(\cdot, r)). \]
\[ \dot{V}_P(t) < 0, \text{ since } L_w \text{ is negative semidefinite, } \Gamma \text{ is positive semidefinite, } P \text{ is positive definite, and } k(P, f) \text{ is negative definite. Thus } V_P(t) \to 0 \text{ as } t \to \infty. \text{ Hence the result follows.} \]

**Example 3.6.** Let \( \bar{f} \) be a differentiable function which has bounded partial derivatives. Let \( \sup(f') = \{ \sup \frac{\partial f'(x)}{\partial x} \}_{i,j \in \mathbb{N}^k} \) and there exists a positive definite matrix \( P \) such that \( \sup(f')P \) is negative semidefinite. Now, if we take \( k(P, f) = \sup(f')P \) then the condition given in Theorem 3.20 is satisfied.

**Theorem 3.21.** If \( \Gamma = I_k \) and \((\bar{f}(x) - \bar{f}(y))(x - y)^T \leq (x - y)(k(I, f)(x - y)^T \) where \( K(I, \bar{f}) + L_w \) is negative definite, then the trajectories of the dynamical system given by Equation (78) synchronize asymptotically.

**Proof.** Take \( P = \Gamma = I_k \) in Equation (87) we get

\[
\dot{V}_I(t) \leq \sum_{i \in \mathcal{N}} (e(t)(i))^T k(I, \bar{f})(e(t)(i))^T + \sum_{i \in \mathcal{N}} \sum_{j \in \mathcal{N}} L_{wij}(e(t)(j))(e(t)(i))^T.
\]

If we consider \( e(t) \) in vector form then from Equation (87) we have \( \dot{V}_I(t) \leq e(t)^T k(I, \bar{f}) \otimes I_k e(t)^T + e(t)^T L_w \otimes I_k e(t)^T = e(t)^T [k(I, \bar{f}) + L_w] \otimes I_k e(t)^T. \) Since \((k(I, \bar{f}) + L_w)\) is negative definite, \( \dot{V}_I(t) \) is negative and \( \dot{V}_I(t) \to 0, \) as \( t \to \infty. \) Hence the result follows.

**Remark 3.15.** The results derived from Theorem 3.20 and Theorem 3.21 by taking \( m_{\text{max}} = 2 \) (that is when the underlying hypergraph becomes graph) are similar to what have been reported in [40, 41].

In the next result, we consider \( k = 1. \) Thus \( \Gamma \) is a scalar. For simplicity we assume \( \Gamma = 1. \) Now, Equation (78) becomes

\[
\dot{u}(t) = f(u(t)) + L_w g(u(t)).
\]

Thus Equation (79) becomes

\[
\dot{e}(t) = f(u(t)) - f(v(t)) + L_w (g(u(t)) - g(v(t))).
\]

**Theorem 3.22.** For \( k = 1, \) If there exists an \( N \times N \) positive definite matrix \( P \) such that \((x - y)^T P (f(x) - f(y)) \leq (x - y)^T k_{(P, f)} (x - y) \) and \((x - y)^T P L_w (g(x) - g(y)) \leq (x - y)^T k_{(P, L_w, g)} (x - y), \) for all \( x, y \in \mathbb{R}^N, \) where both \( k_{(P, L_w, g)}, \) and \( k_{(P, f)} \) are \( N \times N \) matrix and \([k_{(P, f)} + k_{(P, L_w, g)} + bP]\) is a negative definite matrix, then any trajectory of the CDSH given by Equation (90) synchronizes.

**Proof.** Let us consider the quantity \( V_w(t) = \frac{1}{2} (e(t))^T P e(t), \) where \( P \) is an \( N \times N \) positive definite matrix. So \( \lim_{t \to 0} V_w(t) = 0 \iff \lim_{t \to 0} e(t) = 0. \) Now, \( \dot{V}_w(t) = (e(t))^T P \dot{e}(t) = (e(t))^T P [f(u(t)) - f(v(t)) + L_w (g(u(t)) - g(v(t)))] \leq (e(t))^T [k_{(P, f)} + k_{(P, L_w, g)}] e(t) \leq -b(e(t))^T P e(t) = -2bV_w(t). \) Hence, \( \lim_{t \to 0} V_w(t) = 0 \) and this completes the proof.

**3.5. CDSH models using normalized matrices.** The use of a normalized Laplacian matrix in a dynamical network model is quite common. We can also construct the same for systems on hypergraphs by using a normalized matrices associated with its underlying hypergraph, for both, discrete-time and continuous-time dynamical systems. It is also common to multiply the Laplacian matrix by the inverse of the degree matrix to obtain the normalized Laplacian matrix (see Definition 2.5). As the hypergraph \( G \) is connected, the matrices, \( D_G, \) and \( D_w \) are positive definite and hence, are invertible. Here \( D_G \) is the degree matrix of \( G \) and \( D_w \) is defined in Equation (67).

Similar to Definition 2.5, we define

\[
\hat{C} := D_G^{-1} C \text{ and } \hat{L} := D_w^{-1} L_w.
\]

As, the row sums of both the matrices, \( \hat{C} \) and \( \hat{L} \) are zero, so the diffusion process in a systems on hypergraphs and the related synchronization can be described using these matrices. Now, if
we replace $C$ and $L_w$ by $\hat{C}$ and $\hat{L}$, respectively, all the models described in the previous sections, become CDSH models involving the normalized matrices.

**Remark 3.16.** In previous sections, we have used the fact that $C$ and $L_w$ are symmetric, but, in general, $\hat{C}$ and $\hat{L}$ are not. Though, both of them are not symmetric with respect to the usual inner product, but, $\hat{C}$ and $\hat{L}$ are symmetric with respect to the inner products $<\cdot,\cdot>_{D_C}$ and $<\cdot,\cdot>_{D_w}$, respectively, where $<x,y>_{D_C}:=x^TD_Gy$ and $<x,y>_{D_w}=x^TD_wy$ for all $x,y\in\mathbb{R}^N$. Thus using these inner products we can derive the similar results by using $\hat{C}$ and $\hat{L}$ in places of $C$ and $L_w$, respectively, in previous sections.

4. Numerical Illustrations

In this section we numerically demonstrate the theoretical results obtained in the previous sections.

4.1. Examples of hypergraphs and simulations of CDSH models. First, we construct some hypergraphs which are used in examples for CDSH in later sections. The results described in previous sections are simulated using the following CDSH.

![Sudoku-grid](image1)

![Hypergraph representation of sudoku grid](image2)

**Figure 2. Sudoku hypergraph.**

**Example 4.1.** In sudoku grid (Figure 2a) there are 9 rows and 9 columns, respectively. So, altogether, a sudoku grid has 81 cells create 9 rows and 9 columns of the grid. We construct a 9-uniform hypergraph $G$ from a sudoku grid, where the 81 cells are considered as the vertices with the following indexing map. The $(i,j)$-th cell of the grid is taken as the vertex $v_i+9x(j-1)$ of $G$. The hyper-edges are (Figure 2b) all the 9 rows, 9 columns, and 9 blocks having $3 \times 3$ cells each. We denote a block as $B_{p,q}$, where $p,q=1,\ldots,3$. Thus the $(i,j)$-th cell belongs to the block $B_{p,q}$, where $p=[i/3]$ and $q=[j/3]$. So, two vertices (cells), $v_i$ and $v_j$ are adjacent if, either they belong to the same column / row or in the same square block. We index the hyper-edges as follows. For $i=1,\ldots,9$, the $i$-th row represents the $i$-th hyper-edge, i.e. $e_i$. For $j=1,\ldots,9$, the $(9+j)$-th hyper-edge, $e_{9+j}$, is represented by the $j$-th column of the grid. For $p,q=1,\ldots,3$ the $(18+p+3\times(q-1))$-th hyper-edge, $e_{18+p+3\times(q-1)}$, is represented by $B_{p,q}$. Hence there are 81 vertices and 27 hyper-edges in $G$. Clearly the incidence matrix $I_G$ is an $81 \times 27$ matrix in which the row corresponding to the vertex $v_{i+9x(j-1)}$ (cell $(i,j)$), that is, the $i+9 \times (j-1)$-th row of $I_G$ has 1 in the $i$-th, $(9+j)$-th, and the $(18+[i/3]+3 \times ([j/3]-1))$-th columns, respectively, and has 0 in rest of the columns.

Clearly for this example, the matrix $B_0$ (defined in Equation (9)) is an $81 \times 81$ matrix whose eigenvalues are $-\frac{27}{8}$, $-\frac{9}{4}$, $-\frac{9}{8}$, and 0 with multiplicity 60, 16, 4, and 1, respectively.
Example 4.2. Consider the graph in Figure 3a. There are 6 vertices. Now we construct a hypergraph (Figure 3b), with same 6 vertices. A hyper-edge of this hypergraph consists of a vertex of the graph (hypergraph) along with its neighbors in the graph. So, two vertices of the graph are adjacent in the hypergraph if either they are adjacent in the graph or they has a common neighbour in the graph.

Thus the number of edges in the hypergraph is equal to the number vertices in the graph, (i.e., 6 in Figure 3a). Two of the hyper-edges have cardinality 4 and the rest have the cardinality 3. The connectedness of this hypergraph follows from the connectedness of the graph. We denote the hyper-edge corresponding to the neighbours of the vertex $v_i$ by $e_i$.

Example 4.3. Let there be a $3 \times 3$ grid, i.e., with 9 cells (as shown in Figure 4a). Now we construct a hypergraph. Consider all the cells as vertices. A hyper-edge $e_i$ corresponding to a cell (vertex) $v_i$ consists of only all of its neighbouring cells, i.e. the cells which share a common side or a corner point with the cell $v_i$ (see Figure 4b). Note that, here $v_i \notin e_i$. We denote the hyper-edge corresponding to the vertex $v_i$ as $e_i$.

Two vertices are adjacent in the hypergraph if the corresponding cells have a common neighbour. The hyperedge $e_5$, has cardinality 8. The four hyperedges $e_4, e_6 ,e_2$, and $e_8$ have the cardinality 5 and the rest of the four hyperedges (i.e., $e_1, e_3 ,e_9$, and $e_7$) are of cardinality 3. The hyperedge $e_5$ contains all the 8 vertices except $v_5$. Thus considering $e_5$ along with any other edge containing $v_5$ shows that the hypergraph is connected.
Example 4.4. This example, which is taken from [42, page-15, figure-13], represents an allylic complex and cyclopropenyl complex. The vertices of the hypergraph are allylic ligands, cyclopropenyl ligands, and metals. Here the hyperedges are the polycentric bonds among the allylic ligands, cyclopropenyl ligands and metals (For detail description of the vertices and hyperedges see [42, Page-14, 15]). The hypergraph contains 9 vertices and 4 hyperedges. This hypergraph is connected because \( e_4 \cup e_2 \) contains all the vertices and \( e_4 \cap e_2 \) is non-empty (see Figure 5). Cardinality of \( e_1, e_2, e_3, \) and \( e_4 \) are 3, 4, 5, and 6 respectively.

**Figure 5.** Chemical hypergraph.

Example 4.5. In a google form, a group of peoples are asked the names of social networking websites or applications among Whatsapp, Facebook, Instagram, and hike, used by them. Eight responses are received. Based on those responses, we construct a hypergraph, whose vertices are websites or applications among Whatsapp, Facebook, Instagram, and hike, used by them. Eight vertices are considered, \( v_1, v_2, v_3, v_4, v_5, v_6, v_7, v_8 \).

Thus the cardinalities of \( e_1, e_2, e_3, \) and \( e_4 \) are 8, 6, 5, and 2 respectively.

Example 4.6. For this example we consider the set \( S = \{2, 3, 4, 5, 6, 8, 9, 10, 12\} \) as the set of vertices of the hypergraph. A hyperedge \( e_i \) is the maximal subset of \( S \) consists of the elements whose greatest common divisor is \( i + 1 \), for \( i = 1, \ldots, 5 \). So, two vertices are adjacent in this hypergraph if they have a common divisor (\( \geq 2 \)). Hence the hyperedges are, \( e_1 = \{2, 4, 6, 8, 10, 12\}, e_2 = \{3, 6, 9, 12\}, e_3 = \{4, 8, 12\}, e_4 = \{5, 10\}, e_5 = \{6, 12\} \). This hypergraph is connected since \( e_1, e_2, e_4 \) cover all the vertices. The incidence matrix of the hypergraph is in the table below.

**Figure 6.** hypergraph of social network

### 4.2. Examples for coupled discrete-time dynamical systems on hypergraphs (un-weighted case).

4.2.1. Simulations on global synchronizability.

Example 4.7. In Example 4.1, the hypergraph is a uniform hypergraph. So here \( C = B \). The maximum modulus of the eigenvalues of \( C \) is \( \frac{27}{8} \). Let us choose \( \epsilon = 0.5, k = 1, \Gamma = 1 \).

With this set up, if we choose \( \tilde{f}(x) = 20 + \frac{1}{2} x \) and \( \tilde{g}(x) = 20 + \frac{1}{2} x \), then \( |k_2 + \epsilon \| C \| k_f \| \Gamma T \| | = [0.5+0.5 \times \frac{27}{8} \times \frac{7}{12}] < 1 \), which is the sufficient condition for synchronization given in Theorem 3.2 and Corollary 3.1 and hence asymptomatic synchronization of the trajectories of the CDSH is observed (see Figure 7a). If we take \( f(x) = g(x) = 1 + 0.99 x \) then the maximum modulus of eigenvalues of \( (I + \epsilon C) = \| I + \epsilon C \| = 1 < \frac{1}{k_f} = \frac{1}{0.99} \), which is the sufficient condition of synchronization when \( f = g \), as given in Theorem 3.2 and Corollary 3.1. Hence the trajectories synchronize with flow of time (Figure 7b).
Example 4.8. Consider a CDSH with the underlying hypergraph mentioned in Example 4.5. Here, $\| [I + \epsilon C] \| = 1.515$, where $\epsilon = 0.5, k = 1, \Gamma = 1$. If we choose $f(x) = g(x) = 2 + \frac{100}{152} \sin x$, then we have $k_f = \frac{100}{152}$ and $\| [I + \epsilon C] \| k_f > 1$. The sufficient conditions for synchronization given in Theorem 3.2 and Corollary 3.1 are not satisfied and the trajectories remain asynchronous (Figure 8a). When we take $f(x) = g(x) = 2 + \frac{100}{152} x$, then we get $\| [I + \epsilon C] \| k_f < 1$, and hence the sufficient conditions for synchronization given in Theorem 3.2 and Corollary 3.1 are satisfied and the trajectories synchronize asymptotically (Figure 8b).

Example 4.9. Consider a CDSH with the underlying hypergraph described in Example 4.4. So here $\| [I + \epsilon C] \| = 1$, where $\epsilon = 0.5, k = 1, \Gamma = 1$. If we choose $f(x) = g(x) = 1 + \frac{1}{3} \cos x$, then $k_f = 1.5$ and $\| [I + \epsilon C] \| k_f > 1$, but, still the trajectories of the system synchronize globally as stated in Remark 3.6 (see Figure 9). Thus it also supports that the conditions stated in Theorem 3.2 and Corollary 3.1 are sufficient but not necessary.

Example 4.10. Consider a CDSH with $k = 2, \Gamma = \frac{1}{3} I_2, \epsilon = 0.5$, the underlying hypergraph is described in Example 4.4. If we take $\bar{f} : \mathbb{R}^2 \to \mathbb{R}^2$ is defined by $\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \mapsto F \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$, and $\bar{g} : \mathbb{R}^2 \to \mathbb{R}^2$ is defined as $\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \mapsto G \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$, where $F = a \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$ and $G = b \begin{pmatrix} 3 & 2 \\ 1 & 4 \end{pmatrix}$. Recall
Theorem 3.2. So, \( k_f = a, \ k_g = 5b, ||C|| = 2.8333, \) and \((k_g + \epsilon ||C||k_f||\Gamma^T||) = (5b + 0.5 \times 2.8333 \times a \times \frac{1}{3})\).

Now if we consider \( a = 1, \) and \( b = \frac{1}{10} \) then \( ||C|| = 2.8333, \) and \((k_g + \epsilon ||C||k_f||\Gamma^T||) \approx 0.9722 < 1. \) Hence the sufficient condition, is satisfied and the trajectories synchronize (Figure 10). Here Figure 10a, and Figure 10b show the evolution of the first and second components, respectively, of the dynamics in all the vertices.

Figure 10. Synchronization with \([k_g + \epsilon ||C||k_f||\Gamma^T||] \approx 0.9722 < 1.\)

Now, if we interchange the functions \( \tilde{f}, \tilde{g} \) and take the other values same, that is, if \( \tilde{f} : \mathbb{R}^2 \to \mathbb{R}^2 \) is defined by \( \left( \begin{array}{c} x_1 \\ x_2 \end{array} \right) \mapsto G \left( \begin{array}{c} x_1 \\ x_2 \end{array} \right) \), and \( \tilde{g} : \mathbb{R}^2 \to \mathbb{R}^2 \) is defined by \( \left( \begin{array}{c} x_1 \\ x_2 \end{array} \right) \mapsto F \left( \begin{array}{c} x_1 \\ x_2 \end{array} \right) \) then we get a new CDSH, where \( k_g = a, \ k_f = 5b, \) and \((k_g + \epsilon ||C||k_f||\Gamma^T||) = (a + 0.5 \times 2.8333 \times 5b \times \frac{1}{3})\). If \( a = 1, \) and \( b = \frac{1}{10} \) then \((k_g + \epsilon ||C||k_f||\Gamma^T||) \approx 1.2 > 1 \) and hence the condition of Theorem 3.2 is not satisfied. So synchronization does not happen (see Figure 11). If we take \( a = 0.77, \) \( b = \frac{1}{10} \) then \((k_g + \epsilon ||C||k_f||\Gamma^T||) \approx 1.006 > 1. \) Although, here, the condition of Theorem 3.2 is also not satisfied, but, synchronization is achieved (see Figure 12). Thus the condition provided by Theorem 3.2 is sufficient but not necessary.

Figure 11. Asynchronous trajectories with \([k_g + \epsilon ||C||k_f||\Gamma^T||] \approx 1.2 > 1.\)

Figure 12. Synchronization with \([k_g + \epsilon ||C||k_f||\Gamma^T||] \approx 1.006 > 1.\)
4.2.2. Simulations for local stability analysis and local synchronizability.

Example 4.11. Consider a CDSH with $k = 1$, the underlying hypergraph is taken from Example 4.1. If we choose $s_1 = 2$ (defined in Equation (25)), and $\bar{f}(x) = \sin x$ then by Equation (45), $J_f(n) = \cos(s_{n-1})$, and hence $\sigma \approx -0.0053$.

Now, if we consider $c = 1$, and $\epsilon = 0.6$ in the condition given in Theorem 3.6, then $[\frac{1-e^{-\sigma}}{ce}, \frac{1+e^{-\sigma}}{ce}] = [-0.0088, 3.3422]$. As the underlying hypergraph is taken from Example 4.1, then minimum of absolute values of the nonzero eigenvalue of $C$ is 1.1250 and the maximum of that is 3.3750. Since, the sufficient conditions given in Corollary 3.3 are satisfied and the required interval is large enough to contain all the absolute values of non zero eigenvalues of $C$, there is synchronization (Figure 13a) if the initial perturbation is small enough but there may not (Figure 13b) be synchronization if the initial perturbation is not sufficiently small.

![Figure 13. Local stability analysis.](image)

Example 4.12. We consider the CDSH with $k = 1$, $s_1 = 2$, and $\bar{f}(x) = \frac{36}{25}x + 5$. Then by Equation (45) we have $J_f(n) = \frac{36}{25}$ and hence $\sigma \approx 0.3646$. Now, if we take $c = 1$ and $\epsilon = 1$ in the conditions of Theorem 3.6, then $[\frac{1-e^{-\sigma}}{ce}, \frac{1+e^{-\sigma}}{ce}] = [0.3056, 1.6944]$. If the underlying hypergraph is taken from Example 4.1, then minimum absolute values of the nonzero eigenvalues of $C$ is 1.1250 and the maximum of the same is 3.3750. Hence, the sufficient conditions described in Lemma 3.9, Theorem 3.6, and Corollary 3.4 are not satisfied and the trajectories remain asynchronous (Figure 14a).

If we consider $\epsilon = 0.5$, then $[\frac{1-e^{-\sigma}}{ce}, \frac{1+e^{-\sigma}}{ce}] = [0.6111, 3.3889]$, and the absolute values of all the nonzero eigenvalues of $C$ contained in this interval and hence the trajectories synchronize (Figure 14b).

Now if we take the coupling strength $\epsilon = 0.15$ in the conditions of Theorem 3.6, then $[\frac{1-e^{-\sigma}}{ce}, \frac{1+e^{-\sigma}}{ce}] = [2.0370, 11.2963]$. This interval becomes larger but not large enough to contain the absolute values of all the nonzero eigenvalues of $C$ and the trajectories remain asynchronous (Figure 14c).

![Figure 14. Change in local synchronizability with different coupling strengths.](image)

4.3. Examples of coupled dynamical systems on weighted hypergraphs. In this section we discuss some examples related to weighted systems on hypergraphs and some matrices associated with those systems on hypergraphs.
Example 4.13. Now we construct a weighted systems on hypergraphs where we consider the function of coupling strength $\epsilon : V \to \mathbb{R}^+$ and the weight function $w : V \to \mathbb{R}^+$ for edges are the same. The coupling strength of all the edges are $\epsilon_1 = w_1 = \frac{1}{2}$, $\epsilon_2 = w_2 = \frac{3}{5}$, $\epsilon_3 = w_3 = \frac{2}{3}$, $\epsilon_4 = w_4 = \frac{3}{10}$, $\epsilon_5 = w_5 = \frac{1}{2}$, $\epsilon_6 = w_6 = \frac{2}{15}$, $\epsilon_7 = w_7 = \frac{5}{7}$, $\epsilon_8 = w_8 = \frac{1}{2}$, and $\epsilon_9 = w_9 = \frac{3}{10}$.

Example 4.14. Let us consider the hypergraph given in Example 4.3.

We take the function of coupling strength $\epsilon : V \to \mathbb{R}^+$ equal to the weight function $w : V \to \mathbb{R}^+$ for edges are the same. The coupling strength of all the edges are $\epsilon_1 = w_1 = \frac{3}{10}$,

$\epsilon_2 = w_2 = \frac{1}{2}$, $\epsilon_3 = w_3 = \frac{3}{10}$, $\epsilon_4 = w_4 = \frac{1}{2}$, $\epsilon_5 = w_5 = \frac{4}{5}$, $\epsilon_6 = w_6 = \frac{1}{2}$, $\epsilon_7 = w_7 = \frac{1}{2}$, $\epsilon_8 = w_8 = \frac{1}{2}$, and $\epsilon_9 = w_9 = \frac{3}{10}$.

Example 4.15. If we consider the hypergraph from Example 4.5,

We fix $\epsilon_1 = w_1 = 0.3$, $\epsilon_2 = w_2 = 0.5$, $\epsilon_3 = w_3 = 0.3$, and $\epsilon_4 = w_4 = 0.5$.

4.3.1. Simulations of global synchronization in coupled discrete dynamical systems on hypergraphs.

Example 4.16. If we consider a weighted discrete CDSH whose underlying hypergraph is the weighted hypergraph considered in Example 4.14. We take $k = 1$, $\Gamma = 1$, $f(x) = 5 + \frac{1}{2} \sin x$, and $g(x) = 5 + \frac{1}{2} \cos x$. Thus $\|L_w\| = \mu_{\text{max}} \approx 3.74$ and $(k_g + \|L_w\|k_f\|\Gamma^T\|) = (k_g + \mu_{\text{max}}k_f\|\Gamma^T\|) \approx 0.97 < 1$. Hence, as stated in Theorem 3.9, the trajectories synchronize (Figure 15a).

(A) Synchronization with $(k_g + \|L_w\|k_f\|\Gamma^T\|) < 1$. (B) Asynchronous trajectories with $(k_g + \|L_w\|k_f\|\Gamma^T\|) > 1$. (C) Synchronization with $(k_g + \|L_w\|k_f\|\Gamma^T\|) \approx 4.74 > 1$.

FIGURE 15. Simulations of effects due the conditions stated in Theorem 3.9 and Corollary 3.6, on synchronization.

(A) Synchronization with $\|I_N + L_w\| \leq \frac{1}{k_f}$. (B) Asynchronous trajectories with $\|I_N + L_w\| \geq \frac{1}{k_f}$.

FIGURE 16. Simulation of effects due the conditions given in Theorem 3.9 and Corollary 3.6, for $f = g$.

If we take $f(x) = 5 + \sin x$ and $g(x) = 5 + \cos x$, then $(k_g + \|L_w\|k_f\|\Gamma^T\|) \approx 4.74 > 1$ and the trajectories remain asynchronous (see Figure 15b).

The conditions given in Theorem 3.9 and Corollary 3.6 are sufficient conditions of synchronization, but not necessary. Hence synchronization may happen without complying with those conditions. As an example, take $f(x) = \frac{1}{2} \sin x$ and $g(x) = \cos x$ in the above example (Figure 15c).
With the above set up, we consider \( f = g \) and \( \tilde{f}(x) = \tilde{g}(x) = a \sin x \). Thus we have \( \|I_N + L_w\| = \omega \approx 2.74 \) and \( k_f = a \). Now if we consider \( a = \frac{1}{3} \), which shows \( \|I_N + L_w\| = \omega \approx 2.74 < 3 = \frac{1}{k_f} \), then the sufficient condition of Theorem 3.9 and Corollary 3.6 is satisfied and synchronization is observed (see Figure 16a). If we take \( a = \frac{1}{2} \), which implies \( \|I_N + L_w\| = \omega \approx 2.74 > 2 = \frac{1}{k_f} \), i.e., there is no synchronization (see Figure 16b).

Example 4.17. If we consider the CDSH, with the underlying weighted hypergraph is chosen from Example 4.13. Take \( k = 1, \Gamma = 1 \), \( f(x) = a \frac{x}{1 + x^2} \), \( \tilde{g}(x) = b \cos x \), which implies \( \|L_w\| = 2.93 \) \( \implies \) \( (\sup \|g\| + ||\Gamma^T\| \|L_w\| \|\sup f\|) \approx (b + 2.93a) \). Now if we consider \( a = \frac{1}{3} \) and \( b = \frac{1}{3} \), then we get \( (\sup \|g\| + ||\Gamma^T\| \|L_w\| \|\sup f\|) \approx 0.92 < 1 \), complying with the sufficient condition of Theorem 3.10 and hence the trajectories synchronize (Figure 17a). If we take \( a = \frac{3}{2} \), \( b = 1 \), then \( (\sup \|g\| + ||\Gamma^T\| \|L_w\| \|\sup f\|) \approx 5.40 > 1 \), is not complying with the sufficient condition and the trajectories remain asynchronous (Figure 17b). If \( a = \frac{1}{2} \) and \( b = 1 \), then \( (\sup \|g\| + ||\Gamma^T\| \|L_w\| \|\sup f\|) \approx 2.46 > 1 \). Although, here, it is not complying with the condition, but trajectories synchronize (see Figure 17c). Hence is indicates that the condition is sufficient but not necessary.

![Figure 17](image)

(A) Synchronization (B) Asynchronous trajectories (C) Synchronization with \( (\sup \|g\| + ||\Gamma^T\| \|L_w\| \|\sup f\|) < 1 \). \( ||\Gamma^T\| \|L_w\| \|\sup f\| > 1 \).

Example 4.18. If we consider an weighted discrete CDSH whose underlying weighted hypergraph is taken from Example 4.14. Choose \( k = 1, \Gamma = 1 \), \( \tilde{g}(x) = \tilde{f}(x) = px + q \sin x \), then we have \( \|\|I_N + L_w\| \| \approx 2.74 \) and \( \frac{1}{\sup \|f\|} = \frac{1}{p+q} \). This shows that the condition given in Corollary 3.7 is satisfied when \( 2.74 < \frac{1}{p+q} \). Now if we take \( p = \frac{5}{27}, q = \frac{1}{27} \), then \( \|\|I_N + L_w\| \| \sup \|f\| \| \approx 2.74 \times \frac{9}{27} = 0.91 < 1 \), complying with the sufficient condition of Corollary 3.7, hence the trajectories synchronize (Figure 18a). If we choose \( p = \frac{5}{27}, q = \frac{6}{27} \), then \( \|\|I_N + L_w\| \| \sup \|f\| \| \approx 2.74 \times \frac{14}{27} \approx 1.11 > 1 \), which does not satisfy the sufficient condition of Corollary 3.7, and hence the trajectories remain asynchronous (Figure 18b).

If we consider \( p = \frac{5}{27} \), and \( q = \frac{5}{27} \), which implies \( \|\|I_N + L_w\| \| \sup \|f\| \| \approx 2.74 \times \frac{10}{27} \approx 1.0155 > 1 \).

Although, it does not comply with the sufficient condition of Corollary 3.7, the trajectories synchronize (Figure 18c), and which shows that the condition is sufficient, but not necessary.

4.3.2. Simulations of the results on local synchronization of coupled discrete dynamical systems on weighted hypergraphs.

Example 4.19. If we consider the CDSH, where the underlying weighted hypergraph is taken from Example 4.15. Choose \( k = 1, \Gamma = 1 \), and \( \tilde{g}(x) = \tilde{f}(x) = e^{\sigma \sin \frac{x}{\sigma}} \). Then for \( p = 1, q = 1 \) we have \( \sigma \approx -1.0578 \) and \( [(1-e^{-\sigma}), (1+e^{-\sigma})] \approx [-1.88, 3.88] \), and hence the maximum and minimum of the absolute values of the eigenvalues of \( L_w \) are 2.1268 and 0, respectively. So the condition given in Corollary 3.8 is satisfied and the trajectories synchronize (Figure 19a) if the perturbation is sufficiently small.
The synchronizability of a CDSH depends on the spectra of these diffusion matrices. We have also seen that the coupling strengths of a CDSH play an important role in the synchronizability.

In Section 3.3, we have observed that lying of some parameters, related to the structure of underlying hypergraph or the dynamical systems on each node, inside the interval $[\lambda_{\text{min}}, \lambda_{\text{max}}]$
provides sufficient conditions of synchronization. In this study, we have always considered that the underlying hypergraph is undirected and hence the diffusion matrices are symmetric and which makes our study simple. The diffusion matrices related to a directed dynamical network may not be symmetric. So the study of synchronization in directed systems on hypergraphs will be interesting.

ACKNOWLEDGEMENTS

The authors would like to show their gratitude to Shirshendu Chowdhury for his constant valuable advice and guidance for studying dynamical systems throughout this work. His constructive comments have enriched this study enormously. The authors are also grateful to Timoteo Carletti for helpful discussions on the terminologies, hyper-networks, and hypergraphs.

The authors are sincerely thankful to Meghna, Chiranjeet Ghosh, Sourav Makhal, Saikat Mondal, Buddhadev Chatterjee, Kausik Das, Arun Sardar for their precious responses in a google form, that help us to construct the hypergraph of Example 4.5. The authors are also thankful to Mrinmay Biswas, Sugata Ghosh, Gargi Ghosh, Avishhek Chatterjee, Shibananda Biswas, and Somnath Basu for fruitful discussions.
