Abstract

We provide a systematic comparison of two numerical methods to solve the widely used nonlinear Schrödinger equation. The first one is the standard second order split-step (SS2) method based on operator splitting approach. The second one is the Hamiltonian integration method (HIM), originally proposed in Ref. [1]. It allows the exact conservation of the Hamiltonian at the cost of requiring the implicit time stepping. We found that numerical error for HIM method is systematically smaller than the SS2 solution for the same time step. At the same time, one can take orders of magnitude larger time steps in HIM compared with SS2 still ensuring numerical stability. In contrast, SS2 time step is limited by the numerical stability threshold.

Keywords: nonlinear Schrödinger equation, numerical methods, pseudospectral methods, computational physics

1. Introduction

A nonlinear Schrödinger equation (NLSE) is one of the most generic nonlinear partial differential equation in numerous branches of mathematical and theoretical physics is [2]. NLSE naturally appears if one considers envelope dynamics of a quasi–monochromatic nonlinear wave [3]. In quantum mechanics a version of NLSE is called a Gross–Pitaevskii equation [4] which describes a Bose-Einstein condensate for short-range interactions of particles.

Preprint submitted to Journal of Computational Physics August 11, 2020
A typical NLSE application is the dynamics of optical pulses in an optical fiber. The time evolution of the envelope of an optical pulse in a fiber is well approximated by NLSE, including the description of very long, transoceanic optical communication lines, see e.g. [5, 6]. The Langmuir waves in plasmas are described by NLSE as well, see e.g. Ref. [7, 8]. Dynamics of quasi-monochromatic oceanic waves (which is typical e.g. for ocean swell) is reduced to NLSE or its modifications [9]. For example, the analysis of NLSE offers a possible explanation to the mystery of appearance of the rogue waves [10]. All these and numerous other applications of NLSE and its modification require efficient numerical simulation.

Many techniques can be used in simulation of NLSE: the Crank-Nicholson scheme, the hopscotch method, the Ablowitz–Ladik scheme, the pseudo–spectral split-step method, the Hamiltonian preserving method, and many others (see Refs [11], [12], [13]). One of the most popular method of integration of NLSE was proposed by F. Tappert [14], and its performance was studied in the article [11]. The split-step method can be considered as a version of the Strang’s operator splitting approach [15] combined with pseudo-spectral method. The split-step method can be constructed to any order of accuracy, in this work we consider the second order symmetrized split-step (SS2) method. A recent study of stability of the split-step method can be found in the work [16] and references therein.

In 1992 a novel method for simulation of NLSE has been proposed in the paper [1]. It has been successful to study turbulence in two–dimensional NLSE, however it passed largely unnoticed by a wide audience. Perhaps, that is the reason why it was not mentioned in the recent papers such as [17], [18], that describe somewhat similar numerical methods. This numerical method, which we call the Hamiltonian integration method (HIM), conserves the numerical Hamiltonian and the optical power exactly (in exact arithmetic), and it is based on discrete Hamilton’s equations. In finite digit arithmetic, the error in conservation of Hamiltonian is due to round-off errors inherent to floating point representation.

By using the discrete Hamilton’s equations in other systems one may derive Hamiltonian–preserving numerical schemes. As an example, we refer the reader to the recent work [19] on numerical simulations of nonlinear water waves. One can trace similarities with the symplectic methods [20], whereas HIM is a completely self–contained ad hoc method which can be derived for other Hamiltonian systems having canonical symplectic structure.

We compare the two numerical methods by performing a set of simulations with various initial conditions. In these experiments we observe that in some scenarios HIM method can outperform SS2 when very high accuracy is not essential. The SS2 method requires a stringent condition on time step for stability, whereas HIM is an implicit method and as such allows the time step to be a hundred times larger. Our observations illustrate that HIM method can be the method of choice for efficient simulations of interaction of solitons, where a tight balance between nonlinearity and dispersion occurs.

The paper is organized as follows: we describe the mathematical problem in section 2. The description of numerical methods is given in section 3. The section 4
discusses the relation between the dimensionless NLSE and the physical units relevant to optical fibers communications; the section 5 describes the set of simulations and discusses obtained results; and in section 6 we summarize our observations and discuss the applicability of both methods. The derivation of HIM method is placed in Appendix A and the convergence conditions are discussed in Appendix B.

2. Problem Formulation

Let us consider NLSE in its simplest form (rescaling of coordinate, time, and amplitude can bring NLSE into this form without loss of generality):

$$i\Phi_t + \Phi_{xx} + \gamma|\Phi|^2 \Phi = 0,$$

(1)

where $\Phi(x,t)$ is a complex function, $\gamma = \pm 1$ denotes focusing and defocusing NLSE respectively, and subscript denotes partial derivative with respect to $x$ and $t$. The latter equation is solved on an interval $x \in [-L,L]$ subject to periodic boundary conditions, and $t \in [0,T]$. For the sake of simplicity, we consider NLSE in one spatial dimension, although both methods are applicable to any dimensions (for example, HIM was originally formulated for 2D problem [1]).

2.1. Constants of Motion

The Hamiltonian, $\mathcal{H}$, and the number of particles, $\mathcal{N}$, given by:

$$\mathcal{H} = \int \left( |\Phi_x|^2 - \frac{\gamma}{2} |\Phi|^4 \right) dx \quad \text{and} \quad \mathcal{N} = \int |\Phi|^2 dx,$$

(2)

are conserved quantities for (1). Here and further we integrate over one spatial period $[-L,L]$ and drop the integration limits for brevity. The NLSE is an integrable system [21], and it has infinitely many nontrivial integrals of motion, that may be used to track accuracy of numerical simulation. We consider first two nontrivial integrals of motion, that are given by [21, 22]:

$$C_4 = \int \left[ \Phi \Phi_{xxx} + \frac{3\gamma}{2} |\Phi|^2 \Phi_{x} \right] dx,$$

(3)

$$C_5 = \int \left[ \Phi_{xx}^2 + \frac{\gamma^2}{2} |\Phi|^6 - \frac{\gamma}{2} (|\Phi|^2)^2 - 3\gamma |\Phi|^2 |\Phi_x|^2 \right] dx.$$  

(4)

We denote them $C_4$ and $C_5$ because the first three are so called trivial integrals of motion: the number of particles $\mathcal{N}$ and the Hamiltonian $\mathcal{H}$ [2], and the momentum.

2.2. Exact Solutions of NLSE

The equation (1), has soliton solutions [21], and when NLSE is considered on infinite spatial interval, it may be solved by means of the inverse scattering
transform (IST). Some solutions of NLSE that decay at \( x \to \pm \infty \), such as \( N \)-soliton solutions may be used on a periodic interval when the magnitude of \(|\Phi|\) is close enough to zero at the endpoints \( x = \pm L \).

The one-soliton solution (here and further we use \( \gamma = 1 \)) is given by the formula:

\[
\Phi = \sqrt{2\lambda}e^{i\left(\frac{1}{2}vx + (\lambda - \frac{1}{4}v^2)t + \Phi_0\right)} \cosh \left(\sqrt{\lambda} (x - vt - x_0)\right),
\]

(5)

where \( x_0 \) and \( v \) are the constants that determine initial position and the propagation speed of the soliton, and the constants \( \lambda \) and \( \Phi_0 \) determine the soliton amplitude and the initial phase respectively.

Another exact solution of (1) on infinite line is the two-soliton solution which can be obtained by dressing method [23], given by the formula:

\[
\Phi = \left[ 1 + \frac{e^{\eta_2 + \hat{\eta}_2}(p_1 - p_2)^2}{2(p_1 + \hat{p}_2)^2(p_2 + \hat{p}_2)^2} \right] e^{\eta_1} + \left[ 1 + \frac{e^{\eta_1 + \hat{\eta}_1}(p_1 - p_2)^2}{2(\hat{p}_1 + p_2)^2(p_1 + \hat{p}_1)^2} \right] e^{\eta_2} \frac{D}{D},
\]

(6)

where \( D \) is the following expression:

\[
D = 1 + \frac{e^{\eta_1 + \hat{\eta}_1}}{2(p_1 + \hat{p}_1)^2} + \frac{e^{\eta_2 + \hat{\eta}_2}}{2(p_2 + \hat{p}_2)^2} + \frac{e^{\eta_1 + \hat{\eta}_2}}{2(p_1 + \hat{p}_2)^2} + \frac{e^{\eta_1 + \eta_2}}{2(\hat{p}_1 + p_2)^2} + \frac{e^{\eta_1 + \eta_2 + \eta_1 + \eta_2}}{4(p_1 + \hat{p}_1)(p_2 + \hat{p}_2)(p_1 + \hat{p}_2)(p_2 + \hat{p}_2)}\]

(7)

and \( \eta_1, \eta_2 \) are determined by the expression:

\[
\eta_{1,2} = p_{1,2} x + i p_{1,2}^2 t + a_{1,2},
\]

(8)

here \( p_{1,2} \) and \( a_{1,2} \) are complex constants. The width and the propagation speed of solitons are defined by the real and the imaginary parts of \( p_{1,2} \) respectively. The initial positions of each soliton are defined by \( a_{1,2} \).

2.3. Numerical Solution on Periodic Interval

It is natural to use Fourier series to approximate \( \Phi(x,t) \) on the periodic interval \( x \in [-L, L] \) using a pseudo spectral approach by the means of the discrete Fourier transform (DFT) that is computed using the fast Fourier transform library FFTW [24]. In physical space we use a uniform grid,

\[
x_j = \frac{2L}{N} j - L \quad \text{where } j = 0, \ldots, N - 1
\]

(9)

to discretize the interval \([-L, L]\). We introduce a grid function, \( \Phi^n_j = \Phi(x_j, n\Delta t) \), where \( \Delta t \) is an elementary time step.
3. Description of Numerical Methods

3.1. The SS2 Method

In the SS2 method, the linear and nonlinear terms of (1) are treated separately in a style of Strang splitting \(^{15}\).

Let \(\hat{L} = i\partial^2/\partial x^2\) represent the operator for the linear term and \(\hat{N} = i\gamma|\Phi|^2\) represent the operator for the nonlinear term of (1), then \(\Phi_t(x,t) = (\hat{L} + \hat{N})\Phi(x,t)\). This equation has the formal solution \(\Phi(x,t+\Delta t) = e^{(\hat{L}+\hat{N})\Delta t}\Phi(x,t)\) on a time step \(\Delta t\). In the SS2 method \(^{11}\) we approximate the exponential term by the product of separate exponents:

\[
e^{(\hat{L}+\hat{N})\Delta t} = e^{\hat{L}\Delta t}e^{\hat{N}\Delta t} + \frac{\Delta t^3}{12}\{[\hat{L},[\hat{N},\hat{L}]] + \frac{1}{2}[\hat{N},[\hat{N},\hat{L}]]\} + \ldots, \tag{10}\]

that is accurate up to third order in time. This is a special case of application of Campbell-Baker-Hausdorff formula \(^{25}\). By doing this, the evolution of the linear part and nonlinear part on the step \(\Delta t\) can be carried out separately.

In the context of NLSE this is particularly attractive because both evolutions can be carried out analytically. Note that the linear PDE \(i\Phi_t = -\Phi_{xx}\), can be solved exactly in the Fourier domain:

\[
\Phi_k(t+\Delta t) = e^{-ik^2\Delta t}\Phi_k(t), \tag{11}\]

where \(\Phi_k(t)\) denotes the Fourier coefficient, corresponding to wavenumber \(k\), of \(\Phi(x,t)\). The nonlinear part of (1) given by \(i\Phi_t = -\gamma|\Phi|^2\Phi\) is an ODE, and can be solved exactly:

\[
\Phi(x,t+\Delta t) = e^{i\gamma|\Phi|^2\Delta t}\Phi(x,t). \tag{12}\]

Equations (11) and (12) give us explicit expressions for \(e^{\hat{L}}\) and \(e^{\hat{N}}\) correspondingly. The only complexity is that these two exact solutions are given in Fourier and coordinate spaces which requires switching between them in order to represent \(e^{\hat{L}\Delta t}e^{\hat{N}\Delta t}e^{\hat{L}\Delta t}\) in (10) consecutively.

In a similar manner one may construct higher order split step methods, by alternating linear and nonlinear steps. The SS2 method is stable if the condition,

\[
\Delta t \leq \frac{\Delta x^2}{\pi} \tag{13}\]

described in \(^{26}\) is satisfied. However, one can violate this condition when the highest Fourier coefficients are small enough.

One can note that both steps (linear and nonlinear one) in SS2 methods are performing only rotation of phase, so conservation of number of particle \(\mathcal{N}\) is an intrinsic property of the method.
3.2. Hamiltonian Integration Method

The main feature of the HIM method (introduced in [1]) is its exact conservation of the Hamiltonian, $H$, and number of particles, $N$. This is achieved by requiring that the difference in $H$ (and $N$) on subsequent time steps vanishes, the details of derivation of HIM are given in the Appendix A. HIM is an implicit scheme:

$$i \frac{\Phi^{n+1}_j - \Phi^n_j}{\Delta t} = -\frac{1}{2} \left( \frac{\Phi^{n+1}_j + \Phi^n_j}{\Delta t} \right)_{xx} - \frac{1}{4} \frac{\left( \Phi^{n+1}_j + \Phi^n_j \right) \left( |\Phi^{n+1}_j|^2 + |\Phi^n_j|^2 \right)}{\left( \Phi^{n+1}_j + \Phi^n_j \right)}.$$

(14)

that is solved by means of fixed point iterations on every time step Equation (14) implicitly defines the solution at the subsequent time steps. In the Fourier space the formula (14) becomes the following:

$$\hat{\Phi}^{n+1}_k - \hat{\Phi}^n_k = -\frac{i k^2 \Delta t}{2} \left( \hat{\Phi}^{n+1}_k + \hat{\Phi}^n_k \right) + \frac{i \Delta t}{4} \hat{F} \left[ \left( \Phi^{n+1} + \Phi^n \right) \left( |\Phi^{n+1}|^2 + |\Phi^n|^2 \right) \right],$$

(15)

where $\hat{\Phi}^n_k = \hat{F} \left[ \Phi^n \right]$ is the $k$-th Fourier coefficient of the grid function $\Phi^n$. Following the work [19], the linear part of the equation (15) can be resolved for $\hat{\Phi}^{n+1}_k$ which yields:

$$\hat{\Phi}^{n+1}_k = 1 - \frac{i k^2 \Delta t}{4(1 + i k^2 \Delta t)} \hat{\Phi}^n_k + i \frac{\Delta t}{4(1 + i k^2 \Delta t)} \hat{F} \left[ \left( \Phi^{n+1} + \Phi^n \right) \left( |\Phi^{n+1}|^2 + |\Phi^n|^2 \right) \right].$$

(16)

The equation (16) can be solved by a fixed point iterations:

$$\hat{\Phi}^{n+1, s+1}_k = 1 - \frac{i k^2 \Delta t}{4(1 + i k^2 \Delta t)} \hat{\Phi}^n_k + i \frac{\Delta t}{4(1 + i k^2 \Delta t)} \hat{F} \left[ \left( \Phi^{n+1, s} + \Phi^n \right) \left( |\Phi^{n+1, s}|^2 + |\Phi^n|^2 \right) \right],$$

(17)

where $s$ denotes the iteration number and $\hat{\Phi}^{n+1, 0}_k = \hat{\Phi}^n_k$. We iterate (17) until the residual condition is satisfied:

$$\left\| \hat{\Phi}^{n+1, s+1}_k - \hat{\Phi}^{n+1, s}_k \right\|_2 \leq \varepsilon,$$

(18)

where $\|\cdot\|_2$ denotes the $l_2$ norm on $[-L, L]$, and $\varepsilon$ is the tolerance for fixed point iterations. The initial values $\Phi^{n, 0}$ are computed by using one step of Forward Euler. Following [1], the fixed point iterations of HIM converge for

$$\Delta t < \frac{2}{3 \max(\Phi^n_j)}.$$

(19)

Derivation of this condition is given in Appendix B.

For the time step that satisfies the above condition, the fixed point iterations typically converge in 4 to 6 steps with the tolerance $\varepsilon \leq 10^{-11}$. 

4. Physical Units Relevant to Optical Fiber

Before the investigation of the performance of the two methods on a long time scale, we would like to estimate the characteristic time of simulation that corresponds to the dynamics of a pulse in a physically realistic fiber. In order to do so we consider a trans–Atlantic fiber described in the reference paper [6] subject to:

\[ iA_z - \frac{1}{2} \beta_2 A_{\tau\tau} + \sigma_1 |A|^2 A = 0. \] (20)

We use the values for \( \beta_2 = -20 \text{ ps}^2 \text{ km}^{-1} \), the group velocity dispersion (GVD), and \( \sigma_1 = 1.3 \times 10^{-3} \text{ km}^{-1} \text{ mW}^{-1} \), the strength of nonlinearity for a fiber, provided therein.

The dimensionless NLSE given by (1) must be rewritten in the original dimensional units. We transform the dimensionless NLSE to dimensional units as follows:

\[ z = lt, \quad \tau = \frac{x}{\omega_0}, \quad \text{and} \quad A = A_0 \Phi \] (21)

The derivatives with respect to \( t \) and \( x \) are given by:

\[ \partial_t = l \partial_z \text{ and } \partial_x = \frac{1}{\omega_0} \partial_\tau. \] (22)

The resulting equation transforms into:

\[ iA_z + \frac{1}{\omega_0^2 l} A_{\tau\tau} + \frac{|A|^2 A}{A_0^2 l} = 0. \] (23)

Comparison of two equations (20) and (23) reveals that:

\[ \beta_2 \left[ \frac{\text{ps}^2}{\text{km}} \right] = -\frac{2}{\omega_0^2 l}, \] (24)

\[ \sigma_1 \left[ \frac{1}{\text{km mW}} \right] = \frac{1}{A_0^2 l}, \] (25)

where \( A_0 = 1 \text{ mW}^{1/2} \). By using the parameters \( \beta_2 \) and \( \sigma_1 \) from the reference paper [6], we find that \( l \approx 769 \text{ km} \), \( \omega_0^2 = 1.3 \times 10^{-4} \text{ ps}^{-2} \) from the equations (24)–(25). We find that it is necessary to simulate the fiber until the dimensionless time \( t_{max} \approx 13 \) in order to mimic a \( 10^4 \text{ km} \) fiber. The nonlinear time is then given by \( t_{NL} = \frac{\tau}{|\Phi|^2} = \frac{\pi}{2|\lambda|} \) which in physical units corresponds to \( z_{NL} = l t_{NL} \).

5. Numerical Methods Performance

5.1. Stationary One-Soliton Solution

In this simulation we check the convergence rate of HIM and SS2 by running a sequence of simulations with various time steps. As the initial condition we consider a one-soliton solution (5) with the following parameters:

\[ \lambda = 2, \quad \text{and} \quad \Phi_0 = x_0 = v = 0. \] (26)
Figure 1: (Stationary one-soliton solution on a fully resolved grid) (Left) Convergence rate of numerical methods, HIM (green) and SS2 (red). Both methods have second order convergence, but $L_\infty$ error in solution is about one order smaller for HIM compared to SS2 for the same time steps. (Right) Error in conserved quantities: number of particles $N$ (solid), Hamiltonian $\mathcal{H}$ (dotted), and $C_5$ (dash-dotted) for various time steps. When time step is larger than the stability condition of SS2, errors in $\mathcal{H}$ and $C_5$ start to grow. For HIM, the error is dominated by accumulation of round-off errors and is smaller by several orders of magnitude compared with SS2.

We run the simulation on a fully resolved (highest harmonics are of round-off level) uniform grid of $N = 2048$ grid points, and $L = 25\pi$. The tolerance for HIM iterations is set to $\varepsilon = 10^{-15}$ and simulation time is $T = 5$. The convergence of both methods is demonstrated in Figure 1. We omit the $C_4$ in the Figure 1 because this quantity is identically zero for a stationary one-soliton solution. The error in the integrals of motion for SS2 method is dominated by accumulation of round-off errors for small $\Delta t$, and by the order of method for large $\Delta t$ as shown in the Figure 1. The critical value of $\Delta t$ for which the transition occurs is close to the stability condition of SS2 method.

5.2. Moving One-Soliton Solution

In these simulations we investigate how the traveling speed $v$ of the one-soliton solution (5) affects the accuracy of both numerical methods. It is known that dispersion of waves by SS2 method is identical to the dispersion of NLSE, while from (16) it follows that the dispersion of HIM is only accurate up to third order in $k^2\Delta t$. We expect that for sufficiently large time step the travel speed of soliton will deviate from its true value. We show the results of the simulations with various travel speeds in Figure 2. The initial data for these simulations is given by (5) with parameters:

$$\lambda = 2, \quad \Phi_0 = x_0 = 0, \quad \text{and} \quad v \in [0, 5].$$

The computational box size is $L = 25\pi$ and the number of grid points is $N = 2048$. The tolerance for HIM iterations is $\varepsilon = 10^{-14}$ and the simulation time is $T = 100$. Time step for both methods is set to be $\Delta t = \frac{9.5\Delta x^2}{\pi}$.

It should be noted, that soliton velocity is given in dimensionless units. In the left panel of Figure 2 we observe that the error in the solution has no
dependence on travel speed of the soliton for SS2 method. For HIM, the error in the solution depends on travel speed which is due to inexact dispersion relation of HIM method:

$$\omega_{HIM}(k) = \frac{i}{\Delta t} \ln \frac{1 - i k^2 \Delta t/2}{1 + i k^2 \Delta t/2} = k^2 \left( 1 - \frac{k^4 \Delta t^2}{12} + \ldots \right),$$

where $\omega_{HIM}(k)$ is the angular frequency of the $k$-th Fourier harmonic.

In the center panel, we look at the absolute error in integral quantities, $N$ and $H$. It is about seven orders of magnitude smaller than the error in the solution. On the right panel, we consider the absolute error in integral quantities, $C_4$ (solid), and $C_5$ (dotted) is about seven orders of magnitude smaller than the error in the solution. For travel speed $v \leq 3$ HIM and SS2 give comparable accuracy in $C_4$ and $C_5$, but HIM behaves worse as soon as $v$ is larger than 3. Note that the error in the solution does not always correlate with the error in integral quantities.

5.3. Stationary Two-Soliton Solution

In this simulation we demonstrate the difference between SS2 and HIM when the initial data is a two-soliton solution with the following set of parameters:

$$p_1 = 2.0 \text{ and } p_2 = 1.9$$

$$a_1 = 60 + i = -\bar{a}_2.$$  \hspace{1cm} (29)

The simulation time is $T = 5$, the solution is underresolved on a grid with $N = 1024$ points. The computation box is $x \in [-L, L]$ where $L = 25\pi$. The time
step is $\Delta t = \frac{0.5 \Delta x^2}{\pi}$. It is typical to have solution not resolved to round-off error in long and/or multichannel simulations of light pulses propagating in optical fibers. A smaller number of Fourier harmonics implies faster computations. For this experiment, the smallest amplitudes were of the order $10^{-8}$. We present the results of the simulation in Figures 3 - 4.

In the course of simulation we observe that the error in $H$ and $C_5$ is one to two orders of magnitude smaller in HIM than in SS2. The number of particles is better conserved by SS2 and the error is two orders of magnitude smaller.

5.4. Interaction of Two-Solitons

In this section, we study the dynamics of the two-soliton solution (6). We present parameters of simulations in sections 5.4.1 - 5.4.3 and discuss results of simulations in the section 5.4.4. We use periodic box with $L = 25\pi$ and $N = 4096$ grid points for fully resolved simulations and $N = 1024$ for unresolved simulations. The time step is $\Delta t = \frac{0.8 \Delta x^2}{\pi} < \frac{\Delta x^2}{\pi}$ to satisfy the stability condition (13) in all three simulations. The HIM iterations tolerance is $\epsilon = 10^{-12}$.

5.4.1. Collision with Stationary Soliton

The initial condition is given by the two-soliton solution formula (6) where one of the solitons is moving towards the other soliton which is at rest. The simulation time is $T = 50$, and over the course of simulation two solitons interact once. We present the results of the simulation in the Figures 5 - 7.

The parameters for this two-soliton solution are given by:

$$p_1 = 1.2 \text{ and } p_2 = 1.3 + i$$
$$a_1 = 2.5 + i \text{ and } a_2 = 65 + i.$$

(30)
Figure 4: (Stationary two-soliton solution on underresolved grid) Conserved integrals in a simulation with initial data (29). (Left) The number of particles (solid) and the Hamiltonian (dotted) computed via SS2 (red) and HIM (green). (Right) The integrals $\Delta C_4$ (solid) and $\Delta C_5$ (dotted) via SS2 (red) and HIM (green).

Figure 5: (Collision with stationary soliton) (Top) Numerical solution for HIM (left) and SS2 (right) methods on a fully resolved grid $N = 4096$. (Bottom) Numerical solution for HIM (left) and SS2 (right) methods on an underresolved grid with $N = 1024$. 
Figure 6: (Collision with stationary soliton on a fully resolved grid) (Left) Error in the solution in $L_\infty$-norm as a function of time step in double-logarithmic scale shows second order convergence in $\Delta t$. (Right) Absolute error as a function of time, the solitons interact at approximately $t = 25$. The error vs time is close to a straight line before and after the collision. Its slope, $m$, changes from $m = 6.35 \times 10^{-7}$ to $m = 7.00 \times 10^{-7}$ for HIM method, and from $m = 8.85 \times 10^{-7}$ to $m = 1.10 \times 10^{-6}$ for SS2.

Figure 7: (Collision with stationary soliton on a fully resolved grid) The conserved quantities plotted as a function of time over the course of the simulation, note that SS2 demonstrates a strong peak in error in $H$ at the time of solitons interaction. After the moment of interaction the $C_4$, and the $C_5$ exhibit jump and increase in error with in SS2 and HIM.
5.4.2. Headon Collision of Solitons

The initial condition is given by the two-soliton solution formula \( (6) \) with solitons moving toward each other. The final time of simulation is \( T = 45 \), and two solitons interact once. We present the results of the simulation in Figures 8 - 10. The parameters for this simulation are the following:

\[
p_1 = 1.2 - 0.5i \quad \text{and} \quad p_2 = 1.3 + i
\]
\[
a_1 = -20 + i \quad \text{and} \quad a_2 = 60 + i.
\]  

\( (31) \)

5.4.3. Collision with Pursuing Soliton

The initial condition is given by the two-soliton solution formula \( (6) \) with one soliton pursuing another soliton. The final time of simulation is \( T = 54 \). The pursuing soliton overtakes and interacts with the slower soliton once. The results of this simulation are presented in the Figures 11 - 13 and parameters of the initial condition are as follows:

\[
p_1 = 1.7 + 0.5i \quad \text{and} \quad p_2 = 1.9 + i
\]
\[
a_1 = 50 + i \quad \text{and} \quad a_2 = 110 + i.
\]  

\( (32) \)

5.4.4. Results of the Simulations

In the latter sequence of three simulations involving two-soliton collision, we found that the radiation level in SS2 simulation has been consistently higher.
Figure 9: (Headon collision of solitons on a fully resolved grid) Error in $L_\infty$-norm of the solution vs time computed for SS2 (red) and HIM (green) methods. The collision occurs at the time approximately $t = 21$ where we observe a spike in the error. The error vs time is close to a straight line before and after collision. Its slope, $m$, changes from $m = 8.85 \times 10^{-7}$ to $m = 1.5 \times 10^{-6}$ for SS2 method, and from $m = 6.3 \times 10^{-7}$ to $m = 8.3 \times 10^{-7}$ for HIM method.

Figure 10: (Headon collision of solitons on a fully resolved grid) The conserved quantities (left) $\Delta N$ (solid), $\Delta H$ (dotted), and (right) $\Delta C_4$ (solid), and $\Delta C_5$ (dotted) as a function of time over the course of the simulation with HIM (green) and SS2 (red). Note that SS2 demonstrates a strong peak in error in $H$ at the time of soliton interaction. After the interaction time the $C_4$, and the $C_5$ exhibit large error with both SS2 and HIM.
Figure 11: (Collision with pursuing soliton) (Top) Numerical solution for HIM (left) and SS2 (right) methods on a fully resolved grid with $N = 4096$ points. (Bottom) Numerical solution for HIM (left) and SS2 (right) methods on an underresolved grid with $N = 1024$ points.

Figure 12: (Collision with pursuing soliton on a fully resolved grid) Error in the solution vs time for SS2 (red) and HIM (green) methods in the simulation with one soliton pursuing the other. The time of collision is approximately $t = 28$. We observe that the slope, $m$, of the straight line of error vs time changes at the collision for both methods. In SS2 it changes from $m = 1.26 \times 10^{-5}$ to $m = 1.5 \times 10^{-6}$, and in HIM the slope changes from $m = 6.3 \times 10^{-6}$ to $m = 7.12 \times 10^{-6}$. 
than in simulations with HIM method. In both methods we observe that conservation of integrals of motion $H, N, C_4$ and $C_5$ does not imply highly accurate solution in $L_\infty$-norm. In all the cases we found that HIM method gives smaller $L_\infty$ error in the solution by a factor of at least 1.5-2 with the same time step. In order to compute the $L_\infty$ error we use the exact solution given by the formula (6). The simulation time is chosen so that there is a single collision in the periodic box $[-L, L]$. The formula (6) gives a solution on an infinite line, whereas the simulation is performed on a periodic box and thus the simulation time must not exceed the time it takes the solitons to reach the boundary of the box. Moreover, the soliton must still be exponentially small near the end of the box, so that the comparison with the exact formula is applicable.

Despite the $L_\infty$ error of the solution not being smaller than $10^{-5}$, we observe that the integrals of motion $H, N$ are conserved up to $5 \times 10^{-10}$. Nevertheless, at the time of collision we found that $\Delta H$ experiences a jump up to 5 orders of magnitude in SS2 method, while in HIM it is conserved by construction of the method. Both methods exactly conserve $N$ aside from accumulation of round-off errors over the course of simulations. The two nontrivial integrals of motion, $C_4$ and $C_5$ are not conserved exactly, nevertheless we observe that until the time of collision these quantities vary only in 9-th decimal place. After the collision these values demonstrate a large jump (up to four orders of magnitude) in both methods. Unlike the Hamiltonian, $H$, in SS2 method, these integrals do not revert to their original values after the collision.
5.5. Three Solitons Interactions Simulation

It is known that solitons of the NLSE interact as particles, and interchange momenta during collision [22]. The details of the process can be complicated, but once the solitons move sufficiently far from each other, they behave like separate pulses propagating without change of shape.

In dimensionless units the one–soliton solution is given by (5). For this simulation, the initial condition is the sum of three distinct one–soliton solutions:

\[ \Phi(x, t = 0) = \Phi_1 + \Phi_2 + \Phi_3, \tag{33} \]

where \( \Phi_{1,2,3} \) are given by (5) with the following set of parameters:

\[
\begin{align*}
\lambda_1 &= 2.4, \quad \lambda_2 = 2.9, \quad \lambda_3 = 3.2, \\
v_1 &= 0, \quad v_2 = 0, \quad v_3 = \frac{2}{3}, \\
x_{0,1} &= 40, \quad x_{0,2} = -20, \quad x_{0,3} = -60,
\end{align*}
\]

and zero initial phases. This set of parameters gives us two stationary solitons and one moving. To make sure that we use approximation of a three-soliton solution on a periodic boundary, we make the overlap between solitons is about \(10^{-16}\) and at the boundary \(|\Phi(x, t = 0)| \approx 10^{-16}\).

After using the formulas (21), we translate this initial data to dimensional units. In the dimensional units the characteristic widths, \(\tau_c\), and amplitudes, \(A\), are given by:

\[
\tau_c = \frac{1}{\omega_0 \sqrt{\lambda}} \approx 50 \text{ ps},
\]

\[
A = \sqrt{2\lambda A_0} \approx 2.5 \text{ mW}^{1/2}
\]

and the value of \(\lambda\) varies from approximately is 2.4 to 3.2. Whereas in the original paper [6] the parameters of Gaussian pulses at the end of the fiber vary in amplitude from approximately \(1.0 - 2.2 \text{ mW}^{1/2}\) and have characteristic widths \(10 - 20 \text{ ps}\).

The nonlinear time is given by \(t_{NL} = \frac{\pi}{|\Phi|^2} = \frac{\pi}{2|\lambda|} \approx 0.5\) which in physical units corresponds to \(z_{NL} = t_{NL} l \approx 377\) km. If transatlantic fiber is considered, this amounts to approximately \(26t_{NL}\). We will illustrate the performance of HIM and SS2, on time scale of \(400t_{NL} \approx 200\) which is still physically relevant.

The solution is computed on a grid of \(N = 4096\) points (which corresponds to fully resolved spectrum of solution) with \(L = 25\pi\). The fixed point iterations tolerance is \(\varepsilon = 10^{-12}\) for HIM method. The time step for the split step method is chosen to be \(\Delta t_{SS2} = \frac{0.8\Delta x^2}{\pi}\). During simulation time 200 the numerical solitons interact two times.

In this simulation the results are presented in the Figure 14, we take \(\Delta t_{HIM} = 64\Delta t_{SS2}\), and due to larger time step HIM computation time is approximately 5.76 times smaller. It takes 27.15 seconds for HIM, and 156.45 seconds for SS2.
to complete the computation on Intel Core i7-6700HQ CPU with frequency 2.6 GHz and 8 GB RAM in Matlab on a single thread.

The amplitude of radiation in the tails of solitons is about $10^{-7}$ for SS2, and $10^{-4}$ for HIM while the time step for HIM is 64 times larger than for SS2. This time step allows HIM to accurately depict the positions of the interacting solitons: at the final time the discrepancy in the location of stationary solitons was less than $\Delta x$. Moreover, if the time step for HIM is increased to $128\Delta t_{SS2}$ then the discrepancy in the location is still below $2\Delta x$ and CPU time is 21.30 seconds on a single thread (7.35 times faster than SS2). We note that the amplitude of radiation in the tails of solitons scales as $\Delta t^2$ for both methods. In exact arithmetic and infinitely small $\Delta t$ the magnitude of the solution in these regions is exponentially small.

In the Figure 15, we illustrate the conservation of integrals of motion by showing the difference between the Hamiltonian, the number of particles, and the integrals $C_4$ and $C_5$ at time $t$ and its value at initial time. We note that the number of particles varies no more than $10^{-7}$ for HIM, and less than $10^{-8}$ for SS2. The value of Hamiltonian varies no larger than $10^{-7}$ for HIM, however for SS2 it varies significantly at the time of soliton interaction. We note however, that the accuracy of actual solution is not representative of these number, and the pointwise error of the numerical solution can be much larger. The integral $C_4$ is equal to zero in this example, and is not presented in the figure, but the integral $C_5$ is not zero. It experiences jumps at the time of soliton interactions, and is conserved up to $10^{-2}$ in HIM method due to the much larger time step, $\Delta t_{HIM} = 64\Delta t_{SS2}$.
6. Conclusion

We performed detailed comparison of two algorithms for simulation of NLSE: Hamiltonian integration, proposed in [1] and the widely used split-step method. In all cases Hamiltonian integration demonstrates better conservation of Hamiltonian at the time of soliton collision even for very large time steps. The other constants of motion $N$, $C_4$ and $C_5$ are conserved better by HIM when the time step is the same or slightly larger than for split-step method. However, if the time step is increased several orders of magnitude, the accuracy of conservation of integrals of motion in HIM may become lower. On the other hand, the point-wise error between the numerical solution and analytic formula is significantly larger than the variation of conserved quantities, and thus reflects the quality of the solution rather poorly. In experiments we observed this error to be about $10^{-2}$–$10^{-3}$ in the maximum norm. For this reason a criterion on convergence of fixed iterations by the number of particles that was used in the original paper [1] is suboptimal, and it is more accurate to control convergence by the residual (18) as it was proposed in this paper.

However, if the primary goal is to accurately portray the interaction of solitons over the physically relevant time such as propagation distance in optical fiber, it is significantly more advantageous to use the HIM method with large time step rather than SS2 method which requires smaller time step to satisfy the stability criterion. In our simulations for 400 nonlinear times, the time step for HIM is about 64–128 times larger than the instability criterion for SS2. However, in a simulation for significantly longer time it may lead to accumulation
of errors in positioning of the solitons (jitter). For example if one simulates for 4000 nonlinear times, the inaccuracy in the soliton position is about $10\Delta x$, and in order to keep the accuracy at $\Delta x$ one would need to decrease the time step for HIM which results in smaller gains in computation time.

The accurate portrayal of soliton interactions is crucial for the simulation of interactions in soliton gas [27, 28, 29, 30], or the fast–developing field of integrable turbulence [3], both methods are well-suited for this. At the same time one should mention that split-step is simpler to implement and is more efficient memory–wise. The split-step method is explicit, whereas HIM is an implicit method.

As a summary, we would recommend to use Hamiltonian integration method for simulations requiring accurate description of soliton-soliton interactions or other subtle phenomena in Hamiltonian systems especially when computation time is of the essence. Relevance of fast computational algorithms for optical problems can be illustrated by paper [6, 31] where massively parallel algorithm for modification of NLSE was proposed and implemented. For multidimensional turbulence (see for instance [32]), or for high accuracy short term dynamics, the split-step scheme of the order two, and higher order split step method [20, 33] can be the methods of choice.

Acknowledgments

The work of PML was supported by the National Science Foundation, grant DMS-1814619. Simulations were performed at the Texas Advanced Computing Center using the Extreme Science and Engineering Discovery Environment (XSEDE), supported by NSF Grant ACI-1053575. Also authors would like to thank developers of FFTW [24] for this useful and free software.

Appendix A. Derivation of HIM method

Let $\mathcal{H}^n = \int \left( |\Phi_x^n|^2 - \frac{\gamma}{2} |\Phi^n|^4 \right)$ be the discretized in time Hamiltonian at the n-th time step. We consider change of Hamiltonian after one time step $\Delta t$:

$$\Delta \mathcal{H} = \mathcal{H}^{n+1} - \mathcal{H}^n = I_1 + I_2,$$

where $I_1 := \int \left( |\Phi_x^{n+1}|^2 - |\Phi_x^n|^2 \right) dx$ and $I_2 := \gamma \int \left( \frac{1}{2} |\Phi^n|^4 - \frac{1}{2} |\Phi^{n+1}|^4 \right) dx$. We consider $I_1$ and $I_2$ separately.

By addition and subtraction to $I_1$ of the following terms, $\frac{1}{2} \Phi_x^n \Phi_x^{n+1}$ and $\frac{1}{2} \Phi_x^{n+1} \Phi_x^n$, under the integral sign, combining terms and using integration by parts, one gets:

$$I_1 = -\frac{1}{2} \int \left( \Phi_x^{n+1} \Delta \Phi + \Phi_x^n \Delta \Phi + \Phi_x^{n+1} \Delta \Phi + \Phi_x^n \Delta \Phi \right) dx,$$
here we have introduced $\Delta \Phi = \Phi^{n+1} - \Phi^n$.

By addition and subtraction to $I_2$ of the four following terms, $\frac{\gamma}{2}|\Phi^{n+1}|^2|\Phi^n \Phi^{n+1}|$, $\frac{\gamma}{2}|\Phi^{n+1}|^2|\Phi^n \Phi^{n+1}|$, $\frac{\gamma}{2}|\Phi^n|^2|\Phi^n \Phi^{n+1}|$, and $\frac{\gamma}{2}|\Phi^n|^2|\Phi^n \Phi^{n+1}|$, under the integral sign and combining terms, we arrive at

$$I_2 = -\frac{\gamma}{4} \int (\Delta \Phi (\Phi^{n+1} + \Phi^n) (|\Phi^{n+1}|^2 + |\Phi^n|^2) + \Delta \Phi (\Phi^{n+1} + \Phi^n) (|\Phi^{n+1}|^2 + |\Phi^n|^2)) dx.$$  

After combining the like terms, we arrive at the formula

$$\Delta \mathcal{H} = \frac{1}{2} \int |\Delta \Phi (\Phi^{n+1} + \Phi^n) (|\Phi^{n+1}|^2 + |\Phi^n|^2)| dx.$$  

If we divide (A.2) by $\Delta t$ and require that the first and second expressions in square brackets are equal to $\frac{i\Delta \Phi}{\Delta t}$ and $-\frac{i\Delta \Phi}{\Delta t}$ correspondingly, then $\Delta \mathcal{H}$ vanishes.

We note that:

$$i \Phi_t = \frac{\delta \mathcal{H}}{\delta \Phi},$$

$$i \bar{\Phi}_t = -\frac{\delta \mathcal{H}}{\delta \Phi}.$$

We get the following numerical scheme in time:

$$i \frac{\Phi^{n+1} - \Phi^n}{\Delta t} = -\frac{[\Phi^{n+1} + \Phi^n]_{xx}}{2} - \frac{\gamma(\Phi^{n+1} + \Phi^n)(|\Phi^{n+1}|^2 + |\Phi^n|^2)}{4}.$$  

(A.3)

Appendix B. Derivation of the stability condition

We consider $\Phi^{n+1,s+1} = \Phi_0^{n+1} + \delta \Phi^{s+1}$ and $\Phi^{n+1,s} = \Phi_0^{n+1} + \delta \Phi^s$ where $\Phi_0^{n+1}$ is the exact solution at the $(n+1)$-st time step. The iteration scheme is the following:

$$\Phi_k^{n+1,s+1} = 1 - \frac{ik^2 \Delta t}{1 + ik^2 \Delta t} \Phi_k^n + \frac{i\Delta t \gamma}{4} \hat{F} \left( |\Phi^{n+1,s}|^2 + |\Phi^n|^2 \right) \Phi_k^n.$$  

(B.1)

Let’s keep only terms linear in $\delta \Phi^{s+1}$ and neglect terms with small scale perturbations $\delta \Phi^s$:

$$\delta \Phi_k^{s+1} = \frac{i\Delta t \gamma}{4} \left[ 2|\Phi_0^{n+1}|^2 + |\Phi^n|^2 \right] \delta \Phi_k^n +$$

$$+ \frac{i\Delta t \gamma}{4} \left[ (\Phi_0^{n+1})^2 + \phi^n \phi_0^{n+1} \right] \delta \Phi_k^n.$$  

(B.2)
Therefore, we can compose the following system of linear equations:

\[
\begin{bmatrix}
\delta \Phi_{s}^{k+1} \\
\delta \bar{\Phi}_{s}^{k+1}
\end{bmatrix} = 
\begin{bmatrix}
 c \left[ 2|\Phi_{0}^{n+1}|^2 + |\Phi^{n}|^2 + \Phi^{n} \bar{\Phi}^{n+1}_{0} \right] \\
\bar{c} \left[ (\Phi_{0}^{n+1})^2 + \bar{\Phi}^{n} \Phi_{0}^{n+1} \right]
\end{bmatrix} 
\begin{bmatrix}
 c \left[ (\Phi_{0}^{n+1})^2 + \Phi^{n} \Phi_{0}^{n+1} \right] \\
\bar{c} \left[ 2|\Phi_{0}^{n+1}|^2 + |\Phi^{n}|^2 + \Phi^{n} \bar{\Phi}^{n+1}_{0} \right]
\end{bmatrix} 
\begin{bmatrix}
\delta \Phi_{s}^{k} \\
\delta \bar{\Phi}_{s}^{k}
\end{bmatrix}
\]  

(B.3)

where \( c = \frac{i \gamma \Delta t}{1 + \frac{ik^2}{2} \Delta t} \). We need the matrix on the right hand side of (B.3) (let’s name it \( A \)) to be a contracting map. As a result, we require its determinant to be smaller than 1. From \( |\det(A)| < 1 \), we can get the condition for iterations convergence of HIM:

\[ \Delta t < \frac{2}{|\gamma| \sqrt{3} \max(\Phi^n)^2} \]
