ON THE BRAID MONODROMY GROUP OF A POLYNOMIAL IN ONE VARIABLE

VIK.S. KULIKOV

Abstract. It is proved that the braid monodromy group \( \Gamma_P(z) \subset \text{Br}_n \) of a polynomial \( P(z) \in \mathbb{C}[z] \), \( \deg P(z) = n \), is the braid group \( \text{Br}_n \) if the polynomial \( P(z) \) has \( n-1 \) distinct critical values.

0. Introduction

Let \( K \subset \Pi \) be a subset of the complex plane \( \Pi = \mathbb{C} \) consisting of \( n \) distinct points. Denote by \( \text{Br}_n = \text{Br}_n[\Pi, K] \) the braid group of the plane \( \Pi \) with \( n \) strings and \( \sigma : \text{Br}_n \to \mathbb{S}_n \) the natural epimorphism to the symmetric group \( \mathbb{S}_n \).

Let \( P(z) = z^n + c_{n-1}z^{n-1} + \cdots + c_1z + c_0 \in \mathbb{C}[z] \) be a polynomial in one variable, \( \deg P(z) = n > 1 \). The polynomial \( P(z) \) defines a finite morphism \( p_P(z) : \Pi := \mathbb{C} \to \mathbb{C} \) of degree \( n \) given by \( w = P(z) \). Denote by \( C_{P(z)} = \{ z \in \Pi \mid P'(z) = 0 \} \) the set of critical points of \( P(z) \) and \( B_{P(z)} = p_P(z)(C) \subset \mathbb{C} \) the branch locus of morphism \( p_P(z) \), so that \( p_P(z) : \Pi \setminus p^{-1}_P(B_{P(z)}) \to \mathbb{C} \setminus B_{P(z)} \) is an unramified finite cover of degree \( n \).

Let us choose a point \( w_0 \in \mathbb{C} \setminus B_{P(z)} \) and consider a loop \( \lambda : [0, 1] \to \mathbb{C} \setminus B_{P(z)} \) that starts and ends at the point \( w_0 \). The inverse image \( p^{-1}_P(\lambda) \subset \Pi \) of the loop \( \lambda \) is the \( n \) paths \( \{ b_1(t), \ldots, b_n(t) \} \), \( b_j(t) \neq b_{j'}(t) \) for \( j \neq j' \), that start and end at the points lying in \( K = p^{-1}_P(w_0) = \{ q_1, \ldots, q_n \} \) which define a geometric braid \( b(\lambda) \).

If \( \lambda_1 \) and \( \lambda_2 \) are homotopic loops, then it is easy to see that the braids \( b(\lambda_1) \) and \( b(\lambda_2) \) are isotopic. Therefore the lift of loops defines a braid monodromy homomorphism \( \beta_P(z) : \pi_1(\mathbb{C} \setminus B_{P(z)}, w_0) \to \text{Br}_n = \text{Br}_n[\Pi, K] \). The image \( \text{Im} \beta_P(z) := \Gamma_P(z) \subset \text{Br}_n \) is called the braid monodromy group of polynomial \( P(z) \). The composition \( \mu_P(z) = \sigma \circ \beta_P(z) : \pi_1(\mathbb{C} \setminus B_{P(z)}, w_0) \to \mathbb{S}_n \) is called the monodromy homomorphism of \( P(z) \) and its image \( \text{Im} \mu := G_P(z) \subset \mathbb{S}_n \) is called the monodromy group of \( P(z) \).

Obviously, a necessary condition for \( \beta_P(z) \) to be an epimorphism is the equality \( G_P(z) = \mathbb{S}_n \). Note that this condition is not always met. For example, if \( P(z) = z^n \) then \( G_P(z) \) is a cyclic group of order \( n \), and it is easy to see that if \( P(z) = z^n - z^2 \) then \( G_P(z) = D_4 \subset \mathbb{S}_n \) is the dihedral group of order 8. Therefore, the following question is of interest, which subgroups of \( \text{Br}_n \) can be realized as the braid monodromy groups of polynomials.

The aim of this paper is to prove the following
Theorem 1. If $B_{P(z)}$ consists of $n - 1$ distinct points, then $\Gamma_{P(z)} = Br_n$.

The proof of Theorem 1 is given in Section 2 and in Section 1, we remind several definitions and well-known results related to the theory of braid groups (see details, for example, in [1]) and introduce notations which are used in the proof of Theorem 1.

1. The braid groups

1.1. As an abstract group, the group $Br_n$ has the following presentation. It is generated by elements $\{a_1, \ldots, a_{n-1}\}$ being subject to the relations

$$
\begin{align*}
    a_ja_{j+1}a_j &= a_{j+1}a_ja_{j+1}, & 1 \leq j \leq n - 1, \\
    a_ja_k &= a_ka_j, & |j - k| \geq 2
\end{align*}
$$

(such generators of $Br_n$ are called standard).

Below in this section, we remind the well-known realization of the braid group $Br_n$ as a geometric braid group.

1.2. Let $S$ be either the complex plane $\Pi$ or a disk $D_r(z_0) = \{z \in \Pi \mid |z - z_0| < r\}$ in $\Pi$.

Let us fix a set $K = \{q_1, \ldots, q_n\} \subset S$ consisting of $n$ distinct points. The elements $b$ of the geometric braid group $Br_n[S, K]$ are $n$ pairwise nonintersecting paths

$$
\{(b_j(t), t) \in S \times \mathbb{R} \mid t \in [0, 1]\}, \quad j = 1, \ldots, n,
$$

(considered up to continuous isotopy) the start points of which are $(b_j(0), 0) = (q_j, 0)$ and the end points of which belong to the set $K \times \{1\}$.

A braid $b$ defines a permutation $\sigma(b) \in S_n$ acting on the set $\{1, \ldots, n\}$, $\sigma(b)(j) = k$ if $b_j(1) = q_k$.

The product of braids

$$
b_1 = \{b_{1,1}(t), \ldots, b_{1,n}(t), t\} \text{ and } b_2 = \{b_{2,1}(t), \ldots, b_{2,n}(t), t\}
$$

is the braid $b = b_1b_2 = \{(b_1(t), \ldots, b_{n}(t), t)\}$, where

$$
b_j(t) = \begin{cases}
    b_{1,j}(2t), & \text{if } 0 \leq t \leq \frac{1}{2}, \\
    b_{2,\sigma(b)(j)}(2t - 1), & \text{if } \frac{1}{2} \leq t \leq 1,
\end{cases} \quad j = 1, \ldots, n.
$$

Let $l_j \subset S$ be a smooth path connecting the point $q_j$ with the point $q_{j+1}$ such that $l_j \cap K = \{q_j, q_{j+1}\}$ and let $U \subset S$ be a sufficiently small neighborhood of the path $l_j$ such that $K \cap U = \{q_j, q_{j+1}\}$ and there is a diffeomorphism $\psi : D_{1+\varepsilon}(0) = \{z \in \mathbb{C} \mid |z| < 1 + \varepsilon\} \to U$ preserving the "complex" orientation and such that $\psi([-1, 1]) = l_j$, where $[-1, 1] = \{z \in \mathbb{C} \mid \text{Re} z \in [-1, 1], \text{Im}z = 0\}$, and $\psi(1) = q_j$, $\psi(-1) = q_{j+1}$. The braid $b(t) = \{(b_1(t), \ldots, b_{n}(t), t)\}$, where

$$
b_k(t) = \begin{cases}
    q_k & \text{for } k \neq j, j + 1, \\
    \psi(e^{\pi i t}) & \text{for } k = j, \\
    \psi(e^{\pi i (t+1)}) & \text{for } k = j + 1,
\end{cases}
$$
is called a half-twist associated with the path $l_j$. (Below, we will assume that $\psi : D_{1+\varepsilon}(0) \to U$ is a bi-holomorphic isomorphism.)

Let us choose $n - 1$ smooth paths $l_j \subset S$, $j = 1, \ldots, n - 1$, that start at the points $q_j$ and end at $q_{j+1}$, and such that the path $l = l_1 \cup \cdots \cup l_{n-1}$ is a simple path without self-intersections (such collection of the paths $l_j$ is called a frame of the group $\text{Br}_n[S, K]$). Then the set \{a_1, \ldots, a_{n-1}\} $\in \text{Br}_n[S, K]$ of the half-twists associated with the paths $l_j$ defines an isomorphism between $\text{Br}_n[S, K]$ and the abstract braid group $\text{Br}_n$.

1.3. Let $n = 2$. The abstract braid group $\text{Br}_2$ is generated by the standard generator $a_1$.

Consider a geometric braid $b = \{(b_1(t), t), (b_2(t), t)\}$. Let $q_2 - q_1 = |q_2 - q_1|e^{i \pi}$, then there is a continuous function $\text{arg} b : [0, 1] \to \mathbb{R}$ such that $\text{arg} b(0) = \varphi$ and $q_2(t) - q_1(t) = |b_2(t) - b_1(t)|e^{i \text{arg} b(t)}$. The number

$$N_b = \frac{1}{\pi} (\text{arg} b(1) - \text{arg} b(0)) \in \mathbb{Z}$$

is called the number of half-twists of $b$. Obviously, if braids $b_1$ and $b_2$ are isotopic, then $N_{b_1} = N_{b_2}$. In addition, we have $N_{b_1b_2} = N_{b_1} + N_{b_2}$. Therefore the map $N : \text{Br}_2[S, K] \to \mathbb{Z}$ sending braids $b$ to $N_b$ is a homomorphism of groups.

**Lemma 1.** Let $l \subset S$ be a frame of $\text{Br}_2[S, K]$ and $b$ a half-twist associated with the path $l$. Then $N_b = 1$ and, in particular, $b$ is a standard generator of $\text{Br}_2[S, K]$.

**Proof.** The bi-holomorphic map $\psi : D_{1+\varepsilon}(0) \to U$, involved in the definition of the half-twist $b$, defines a holomorphic function $w(z) = \psi(z) - \psi(-z)$ on $D_{1+\varepsilon}(0)$ such that $w(z) = -w(-z)$. Denote by $\text{arg} w(z)$ a continuous branch along the path $\gamma = \{e^{i \pi}t\}_{t \in [0, 2]}$ of the function $\text{Arg} w(z)$. Obviously, $N_b = \frac{1}{\pi} (\text{arg} w(e^{i \pi}) - \text{arg} w(e^{0i}))$.

We have

$$\text{arg} w(e^{2i}) - \text{arg} w(e^{i}) = \text{arg} w(e^{1i}) - \text{arg} w(e^{0i}),$$

since $w(z) = -w(-z)$. It is easy to see that $w(z) = 0$ only if $z = 0$ and the order of zero of the function $w(z)$ at $z = 0$ is equal to 1. Therefore, by the argument principle,

$$\text{arg} w(e^{2i}) - \text{arg} w(e^{0i}) = (\text{arg} w(e^{2i}) - \text{arg} w(e^{1i})) + (\text{arg} w(e^{1i}) - \text{arg} w(e^{0i})) = 2\pi$$

and hence $\text{arg} w(e^{1i}) - \text{arg} w(e^{0i}) = \pi$. \hfill $\square$

2. **Proof of Theorem**

2.1. Consider a polynomial $P(z) = z^n + c_{n-1}z^{n-1} + \cdots + c_1z + c_0$. First of all, note that after the coordinate change $\tilde{w} = w - c_0$ in $\mathbb{C}$, the morphism $p_{P(z)} : \Pi \to \mathbb{C}$ is given by $\tilde{w} = z^n + c_{n-1}z^{n-1} + \cdots + c_1z$. So, without loss of generality, we can assume that $c_0 = 0$.

Denote by $\mathcal{P} \simeq \mathbb{C}_{n-1}$ the affine space of polynomials $P(z)$, deg $P(z) = n$, of the form $z^n + c_{n-1}z^{n-1} + \cdots + c_1z$ and let $\mathcal{C} \subset \mathcal{P}$ be the set of polynomials $P(z)$ such that $B_{P(z)}$ consists of $n - 1$ distinct points.
Let us show that the set $\mathcal{C}$ is everywhere dense Zariski open subvariety in $\mathcal{P}$ and, in particular, $\mathcal{C}$ is a connected set.

Consider in $\mathcal{P} \times \Pi \simeq \mathbb{C}^n$ the smooth hypersurface $\mathcal{P}'$ given by

$$nz^{n-1} + (n-1)c_{n-1}z^{n-2} + \cdots + c_1 = 0.$$ 

Obviously, the restriction $h : \mathcal{P}' \to \mathcal{P}$ of the projection $pr : \mathcal{P} \times \Pi \to \mathcal{P}$ to $\mathcal{P}'$ is a finite morphism of degree $n-1$. Note that the morphism $h$ can be considered as the composition of two dominant morphisms $h_1$ and $h_2$, where $h_1 : \mathcal{P}' \to \mathcal{P} \times \mathbb{C}$ is the restriction to $\mathcal{P}'$ of morphism $id \times p : \mathcal{P} \times \Pi \to \mathcal{P} \times \mathbb{C}$ given by

$$(c_{n-1}, \ldots, c_1, z) \mapsto (c_{n-1}, \ldots, c_1, z + c_{n-1}z^{n-1} + \cdots + c_1z)$$

and $h_2 : \mathcal{V} = h_1(\mathcal{P}') \to \mathcal{P}$ is the restriction to $\mathcal{V}$ of the projection $pr : \mathcal{P} \times \mathbb{C} \to \mathcal{P}$.

It is easy to check that for the polynomial $P_0 = z^n - nz \in \mathcal{P}$ the preimage $h_2^{-1}(P_0)$ consists of $n-1$ distinct points. Therefore $\deg h_2 \geq n-1$ and hence, $\deg h_2 = n-1$, and $h_1 : \mathcal{P}' \to \mathcal{V}$ is a bi-rational morphism such that $h_1 : \mathcal{P}' \setminus h_1^{-1}(\text{Sing } \mathcal{V}) \to \mathcal{V} \setminus \text{Sing } \mathcal{V}$ is a bi-regular morphism, where $\text{Sing } \mathcal{V}$ is the set of singular points of $\mathcal{V}$. Consequently, $\mathcal{C} = \mathcal{P} \setminus (\mathcal{D} \cup h_2(\text{Sing } \mathcal{V}))$ is an everywhere dense Zariski open subvariety (here $\mathcal{D}$ is the hypersurface in $\mathcal{P}$ given by $\Delta_{n-1} = 0$, where $\Delta_{n-1}$ is the discriminant of the polynomial $nz^{n-1} + (n-1)c_{n-1}z^{n-2} + \cdots + c_1$).

2.2. Let us show that it suffices to prove Theorem 1 for a particular polynomial $P_0(z) \in \mathcal{C}$. Indeed, let $P_1(z)$ and $P_2(z) \in \mathcal{C}$ be two very close to each other polynomials. Then the sets $B_{P_1(z)}$ and $B_{P_2(z)}$ are very close to each other, and the sets $p^{-1}_{P_1(z)}(w_0)$ and $p^{-1}_{P_2(z)}(w_0)$ are also very close to each other for a point $w_0 \in \Pi \setminus (B_{P_1(z)} \cup B_{P_2(z)})$. Therefore we can identify the groups $\text{Br}_n[\Pi, p^{-1}_{P_1(z)}(w_0)]$ and $\text{Br}_n[\Pi, p^{-1}_{P_2(z)}(w_0)]$ and identify the groups $\pi_1(\mathbb{C}\setminus B_{P_1(z)}, w_0)$ and $\pi_1(\mathbb{C}\setminus B_{P_2(z)}, w_0)$ which are isomorphic to the free group $\mathbb{F}_{n-1}$ generated by elements represented by simple loops $\lambda_j$ around the very close points $w_{1,j} \in B_{P_1(z)}$ and $w_{2,j} \in B_{P_2(z)}$, $j = 1, \ldots, n-1$. These identifications imply that the groups $\Gamma_{P_1(z)}$ and $\Gamma_{P_2(z)}$ are isomorphic, since the geometric braids $p^{-1}_{P_1(z)}(\lambda_j)$ and $p^{-1}_{P_2(z)}(\lambda_j)$ are also very close to each other for each $j = 1, \ldots, n-1$. Therefore the isomorphisms of the groups $\Gamma_{P(z)}$ for all $P(z) \in \mathcal{C}$ follows from connectedness of $\mathcal{C}$.

2.3. Consider the polynomial $P_0(z) = z^n - nz$. We have

$$C_{P_0(z)} = \{e^{2\pi(j-1)i/n-1}\}_{j=1,\ldots,n-1} \text{ and } B_{P_0(z)} = \{w_j = (1-n)e^{2\pi(j-1)i/n-1}\}_{j=1,\ldots,n-1}.$$ 

Let $w_0 = 0$ and

$$K = p^{-1}_{P_0(z)}(0) = \{q_1 = 0, q_2 = n^{-1}\sqrt{n}e^{2\pi(2-2i)/n-1}, \ldots, q_n = n^{-1}\sqrt{n}e^{2\pi(n-2)i/n-1}\}.$$ 

Denote by $D_r(w_1) = \{w \in \mathbb{C} \mid |w - w_1| < r\}$ the disk of radius $r > 0$ with center at $w_1$.

The set $p^{-1}_{P_0(z)}(w_1)$ consists of $n-1$ points $z_1 = 1-n, z_2, \ldots, z_{n-1}$ and there is $\varepsilon_0$ such that
We can assume that there is a bi-holomorphic map \( \varphi: W_j \rightarrow D_{\varepsilon_0}(w_1) \) for \( j > 1 \) (denote by \( \phi_j: D_{\varepsilon_0}(w_1) \rightarrow W_j \) the inverse maps),

3) \( p_{P(z_0)}w_i: W_1 \rightarrow D_{\varepsilon_0}(w_1) \) is a holomorphic map of degree 2.

In addition, we can assume that there is a bi-holomorphic map \( \varphi_1: D_{\sqrt{\varepsilon_0}} = \{ \tilde{z} \in \mathbb{C} \mid |\tilde{z}| \leq \sqrt{\varepsilon_0} \} \rightarrow W_1 \) such that \( p_{P(z_0)}w_i \circ \varphi_1: D_{\sqrt{\varepsilon_0}} \simeq W_1 \rightarrow D_{\varepsilon_0}(w_1) \) is given by \( w = w_1 + \tilde{z}^2 \).

Let us choose \( \varepsilon < \varepsilon_0 \) such that \( \varphi_1(\overline{D_{\sqrt{\varepsilon}}}) \subset \{ z \in \Pi \mid |z - \frac{n-\sqrt{n}}{2}| \leq \frac{n-\sqrt{n}}{2} \} \) and put \( V_j = W_j \cap p_{P_{(z)}}^{-1}(\overline{D_{\varepsilon}(w_1)}) \), where \( \overline{D_{\varepsilon}(w_1)} \) is the closure of \( D_{\varepsilon}(w_1) \) in \( D_{\varepsilon_0}(w_1) \).

Consider a loop \( \lambda_1 \) around the point \( w_0 \) that begins and ends at the point \( w_0 \),

\[
\lambda_1(t) = \begin{cases} 
\lambda_{1,1}(t) = 3(1 - n + \varepsilon)t & \text{for } t \in [0, 1/3], \\
\lambda_{1,2}(t) = 1 - n + \varepsilon e^{2\pi(3t-1)i/3} & \text{for } t \in [1/3, 2/3], \\
\lambda_{1,3}(t) = -3(1 - n + \varepsilon)(t - 1) & \text{for } t \in [2/3, 1]. 
\end{cases}
\]

**Proposition 1.** The geometric braid \( b_1 = p_{p_{(z)}}^{-1}(\lambda_1) = \{ b_{1,1}, \ldots, b_{1,n} \} \) is isotopic to a half-twist associated with the path \( \Lambda_1 = \{ z = x + iy \in \Pi \mid x \in [0, n-\sqrt{n}], y = 0 \} \).

**Proof.** Each strand \( b_{1,j} \) of the braid \( b_1 \) is the union of three paths, \( b_{1,j} = \bigcup_{l=1}^{3} b_{1,j,l} \), where

\[
b_{1,j,l} = \{ (b_{1,j}(t), t) \mid p_{p_{(z)}}(b_{1,j}(t)) = \lambda_1(t), t \in [(l-1)/3, l/3] \}, \ l = 1, 2, 3.
\]

Note that \( b_{1,j,1}(t) = b_{1,j,3}(1-t) \) for each \( j > 2 \) and \( t \in [0, 1/3] \).

To describe the functions \( b_{1,j}(t), \ j = 1, 2 \), consider the graph of the function \( \tau = P_0(x), x \in [0, n-\sqrt{n}] \), depicted in Fig. 2. The parts of this graph from \((0,0)\) to \( A \) and from \((n-\sqrt{n},0)\) to \( B \) define two functions \( x = f_1(\tau) \) and \( x = f_2(\tau), \tau \in [1-n+\varepsilon, 0] \).

![Graph of function \( \tau = x^n - nx, x \in [0, n-\sqrt{n}] \).](image.png)
Then
\[
\begin{align*}
b_{1,1}(t) &= f_1(3(1 - n + \varepsilon)t) & \text{if } t \in [0, 1/3], \\
b_{1,2}(t) &= \varphi_1(\sqrt{e^{\pi(3t-1)n}}) & \text{if } t \in [1/3, 2/3], \\
b_{1,3}(t) &= f_2(3(1 - n + \varepsilon)(1-t)) & \text{if } t \in [2/3, 1]
\end{align*}
\]
and
\[
\begin{align*}
b_{1,2}(t) &= f_2(3(1 - n + \varepsilon)t) & \text{if } t \in [0, 1/3], \\
b_{1,2}(t) &= \varphi_1(\sqrt{e^{3\pi ti}}) & \text{if } t \in [1/3, 2/3], \\
b_{1,3}(t) &= f_1(3(1 - n + \varepsilon)(1-t)) & \text{if } t \in [2/3, 1].
\end{align*}
\]

Denote by \(U_1 = b_{1,1}(t) \cup b_{1,2} \cup V_1\) and \(U_j = b_{1,j+1} \cup V_j\) for \(j = 2, \ldots, n - 1\). It is easy to see that \(U_{j_1} \cap U_{j_2} = \emptyset\) if \(j_1 \neq j_2\).

Consider the map \(h : [1/3, 2/3] \times [0, 1] \to D_\varepsilon(w_1)\) given by the rule
\[
h(t, \tau) = 1 - n + \varepsilon(e^{2\pi(3t-1)n/3}(1-\tau) + \tau).
\]
The map \(h\) defines the continuous family of braids \(\beta_\tau = \{(\beta_{1,\tau}(t), t), \ldots, (\beta_{n,\tau}(t), t)\}\), where \(\beta_{j,\tau}(t) \equiv b_{1,j}(t)\) if \(j = 1, 2\), \(\beta_{j,\tau}(t) \equiv b_{1,j}(t)\) if \(t \notin (1/3, 2/3)\), and \(\beta_{j,\tau}(t) = \phi_{j-1}(h(t, \tau))\) for \(\tau \in [1/3, 2/3]\) and \(j > 2\). The family of braids \(\beta_\tau\) defines an isotopy in \(\Pi \times \mathbb{R}\) between the braids \(b_1 = \beta_0\) and \(\beta_1\), since \(U_{j_1} \cap U_{j_2} = \emptyset\) if \(j_1 \neq j_2\) and \(\beta_{j,\tau}(t) \in U_{j-1}\) for \(j > 2\) and \((t, \tau) \in [0, 1] \times [0, 1]\).

Note that \(\beta_{j,1}(t) = \beta_{j,1}(1-t)\) for \(j > 2\) and \(t \in [0, 1/2]\). Therefore the family of braids \(\tilde{\beta}_\tau = \{(\tilde{\beta}_{1,\tau}(t), t), \ldots, (\tilde{\beta}_{n,\tau}(t), t)\}, \tau \in [0, 1]\), where \(\tilde{\beta}_{j,\tau}(t) \equiv \beta_{j,1}(t)\) for \(j = 1, 2\)

\[
\tilde{\beta}_{j,\tau}(t) = \begin{cases} 
\beta_{j,\tau}(t) & \text{if } 2t \leq 1 - \tau \text{ or } 2t \geq 1 + \tau, \\
\beta_{j,\tau}(1-\tau) & \text{if } 1 - \tau \leq 2t \leq 1 + \tau
\end{cases}
\]

for \(j > 2\).

The family \(\tilde{\beta}_\tau\) defines an isotopy between the braids \(\beta_1 = \tilde{\beta}_0\) and \(\tilde{\beta}_1\). Therefore the braid \(b_1\) is isotopic to the braid \(\tilde{\beta}_1 = \{(b_{1,1}(t), t), (b_{1,2}(t), t), (g_3, t), \ldots, (q_n, t)\}\).

The points \(q_2, \ldots, q_n\) belong to the circle \(\partial D_{n-\sqrt{n}}(0)\). Therefore if a positive \(\delta \ll 1\), then \(q_j \notin D_{n-\sqrt{n}}(n^{-\sqrt{n}}/2)\) for \(j > 2\) and hence, "forgetting" about the strands \((q_3, t), \ldots, (q_n, t)\) of the braid \(\tilde{\beta}_1\), we obtain the braid \(\tilde{\beta}_1' = \{(b_{1,1}(t), (b_{1,2}(t), t) \in Br_2[D_{n-\sqrt{n}}(n^{-\sqrt{n}}/2), \{q_1, q_2\}]\) Applying Lemma [I], we obtain that the geometric braid \(\tilde{\beta}_1'\) is isotopic in \(D_{n-\sqrt{n}}(n^{-\sqrt{n}}/2) \times \mathbb{R}\) to the half twist associated with the path

\[
\Lambda_1 = \{t + (1-t)n^{-\sqrt{n}}\}_{t \in [0, 1]} \subset D_{n-\sqrt{n}}(n^{-\sqrt{n}}/2)
\]

connecting the points \(q_1\) and \(q_2\), since \(N_{\tilde{\beta}_1} = 1\). Therefore the braid \(\tilde{\beta}_1\) (and hence, \(b_1\)) is also isotopic to the half twist \(\tilde{b}_1\) associated with the path \(\Lambda_1\). \(\Box\)
2.4. The fundamental group $\pi_1(\mathbb{C} \setminus B_{p_0(z)}, 0)$ is generated by elements represented by the loops $\lambda_j = e^{2\pi i (j-1)/(n-1)} \lambda_1$, and the subgroup $\Gamma_{p_0(z)} \subset \text{Br}_n[\Pi, K]$ is generated by the braids $b_j = p^{-1}_{p_0(z)}(\lambda_j), j = 1, \ldots, n - 1$. Note that if we take new coordinates $\tilde{w} = e^{2\pi i (1-j)/(n-1)} w$ in $\mathbb{C}$ and $\tilde{z} = e^{2\pi i (1-j)/(n-1)} z$ in $\Pi$, then in the new coordinates, the morphism $p_{p_0(z)} : \Pi \to \mathbb{C}$ is given by the same formula $\tilde{w} = P_0(\tilde{z})$. Therefore the braids $b_j = e^{-2\pi i (j-1)/(n-1)} b_1$ are isotopic to the half-twists $\tilde{b}_j$ associated with the paths $\Lambda_j = e^{2\pi i (1-j)/(n-1)} \Lambda_1$.

2.5. Let us choose a frame $\{l_1, \ldots, l_{n-1}\}$ of $(\Pi, K)$ as follows: $l_1 = \Lambda_1$ and

$$l_j = \{e^{2\pi i (j-1-2t)/(n-1)} \sqrt{n} \}_{t \in [0,1]}, \quad j = 2, \ldots, n - 1,$$

are the circular arcs of the circle $\partial D_{\sqrt{n}/\sqrt{n}}(0)$ between the points $q_j$ and $q_{j+1}$. The half-twists $a_j$, associated with the paths $l_j$, generate the group $\text{Br}_n[\Pi, K]$.

It is easy to see (if to "straighten" the frame (see Fig. 2))

that $\tilde{b}_1 = a_1$ and $\tilde{b}_j = (a_{j-1} \ldots a_1)^{-1} a_j (a_{j-1} \ldots a_1)$ for $j = 2, \ldots, n - 1$ as elements of $\text{Br}_n[\Pi, K]$. Therefore the elements $b_j, j = 1, \ldots, n - 1$, also generate the group $\text{Br}_n[\Pi, K]$. \hfill \Box
