On Quasi-Einstein Sequential Warped Product Manifolds

Fatma KARACA and Cihan ÖZGÜR

Abstract. We find the necessary conditions for a sequential warped product manifold to be a quasi-Einstein manifold. We also investigate the necessary and sufficient conditions for a sequential standard static space-time and a sequential generalized Robertson-Walker space-time to be a manifold of quasi-constant curvature.

Mathematics Subject Classification. 53C25, 53C50, 53B20.

Keywords and phrases. Warped product, sequential warped product, quasi-Einstein manifold, Einstein manifold.

1. Introduction

A Riemannian manifold \((M, g)\), \(n \geq 2\), is said to be an Einstein manifold \([17]\) if its Ricci tensor \(Ric\) is the form of \(Ric = \alpha g\), where \(\alpha \in C^\infty(M)\). It is well-known that if \(n > 2\) then \(\alpha\) is a constant. Let \((M, g), n \geq 2\), be a Riemannian manifold, then the manifold \((M, g)\) is defined to be a quasi-Einstein manifold \([5]\) if the condition

\[
Ric(X, Y) = \alpha g(X, Y) + \beta A(X)A(Y)
\]

is satisfied on \(M\), where \(\alpha\) and \(\beta\) are some differentiable functions on \(M\) with \(\beta \neq 0\) and \(A\) is a non-zero 1-form such that

\[g(X, U) = A(X),\]

for every vector field \(X\) and \(U \in \chi(M)\) being a unit vector field. If \(\beta = 0\), then the manifold turns into an Einstein manifold. The notion of quasi-Einstein manifolds arose during the study of exact solutions of the Einstein field equations as well as during considerations of quasi-umbilical hypersurfaces of conformally flat spaces \([15]\).

Let \((M, g), n \geq 2\), be a Riemannian manifold, then the manifold \((M, g)\) is defined to be a quasi-constant curvature \([6]\) if its curvature tensor field \(R\) satisfies

\[
R(X, Y, Z, W) = a[g(Y, Z)g(X, W) - g(X, Z)g(Y, W)] + b[g(X, W)A(Y)A(Z) - g(X, Z)A(Y)A(W) + g(Y, Z)A(X)A(W) - g(Y, W)A(X)A(Z)]
\]

where \(a, b\) are real valued functions on \(M\) such that \(b \neq 0\) and \(A\) is a 1-form defined by (1.2). If \(b = 0\), then \(M\) is a space of constant curvature. It is easy to see that every Riemannian manifold of quasi-constant curvature is a quasi-Einstein manifold.

The notion of a warped product was introduced by Bishop and O’Neill in \([3]\) to construct Riemannian manifolds with negative sectional curvature. Warped products have remarkable applications in differential geometry as well as in mathematical physics, especially in general relativity.

Warped products have some generalizations like doubly warped products and multiply warped products. A new generalization of warped products is named as sequential...
warped product \cite{[11]} where the base factor of the warped product is itself a new warped product manifold. Let \((M_i, g_i)\) be \(m_i\)-dimensional Riemannian manifolds, respectively, where \(i \in \{1, 2, 3\}\) and also \(\overline{M} = (M_1 \times_f M_2) \times_h M_3\) be an \(m = m_1 + m_2 + m_3\) dimensional Riemannian manifold. Let \(f : M_1 \to (0, \infty)\) and \(h : M_1 \times M_2 \to (0, \infty)\) be two smooth positive functions on \(M_1\) and \(M_1 \times M_2\), respectively. The sequential warped product manifold is the triple product manifold \(\overline{M} = (M_1 \times_f M_2) \times_h M_3\) equipped with the metric tensor

\[
\overline{g} = g_1 \oplus f^2 g_2 \oplus h^2 g_3, \tag{1.3}
\]

where \(f : M_1 \to (0, \infty)\) and \(h : M_1 \times M_2 \to (0, \infty)\) are warping functions \cite{[11]}. Taub-Nut and stationary metrics, Schwarzschild and generalized Riemannian anti de Sitter \(\mathbb{T}^2\) black hole metrics are non-trivial examples of sequential warped products \cite{[11]}.

We shall denote \(\overline{\nabla}, \overline{\nabla}^1, \overline{\nabla}^2, \overline{\nabla}^3, \overline{\text{Ric}}, \overline{\text{Ric}}^1, \overline{\text{Ric}}^2, \overline{\text{Ric}}^3, \overline{\text{scal}}, \overline{\text{scal}}_1, \overline{\text{scal}}_2\) and \(\overline{\text{scal}}_3\) the Levi-Civita connections, the Ricci curvatures and the scalar curvatures of the \(\overline{M}\), \(M_1\), \(M_2\) and \(M_3\), respectively.

Now, we give the following lemmas:

**Lemma 1.1.** \cite{[11]} Let \(\overline{M} = (M_1 \times_f M_2) \times_h M_3\) be a sequential warped product with metric \(\overline{g} = g_1 \oplus f^2 g_2 \oplus h^2 g_3\). If \(X_i, Y_i, Z_i \in \chi (M_i)\) for \(i \in \{1, 2, 3\}\) then

i) \(\nabla_{X_i} Y_i = \nabla_{X_i} Y_1\),

ii) \(\nabla_{X_i} X_2 = \nabla_{X_2} X_1 = X_1 (\ln f) X_2\),

iii) \(\nabla_{X_i} Y_2 = \nabla_{X_2} Y_2 - f g_2 (X_2, Y_2) \text{grad}^1 f\),

iv) \(\nabla_{X_i} X_1 = \nabla_{X_1} X_3 = X_1 (\ln h) X_3\),

v) \(\nabla_{X_i} X_2 = \nabla_{X_i} X_3 = X_2 (\ln h) X_3\),

vi) \(\nabla_{X_i} Y_3 = \nabla_{X_i} Y_2 - h g_3 (X_3, Y_3) \text{grad} h\).

**Lemma 1.2.** \cite{[11]} Let \(\overline{M} = (M_1 \times_f M_2) \times_h M_3\) be a sequential warped product with metric \(\overline{g} = g_1 \oplus f^2 g_2 \oplus h^2 g_3\). If \(X_i, Y_i, Z_i \in \chi (M_i)\), then

i) \(\overline{R}(X_1, Y_1) Z_1 = R^1 (X_1, Y_1) Z_1\),

ii) \(\overline{R}(X_2, Y_2) Z_2 = R^2 (X_2, Y_2) Z_2 - \|\text{grad}^1 f\|^2 [g_2 (X_2, Z_2) Y_2 - g_2 (Y_2, Z_2) X_2]\),

iii) \(\overline{R}(X_1, Y_2) Z_1 = - \frac{1}{f} H^1 (X_1, Z_1) Y_2\),

iv) \(\overline{R}(X_1, Y_2) Z_2 = f g_2 (Y_2, Z_2) \nabla_{X_2} \text{grad}^1 f\),

v) \(\overline{R}(X_1, Y_2) Z_3 = 0\),

vi) \(\overline{R}(X_i, Y_j) Z_j = 0 \text{ for } i \neq j\),

vii) \(\overline{R}(X_i, Y_3) Z_j = - \frac{1}{h} H^i (X_i, Z_j) Y_3 \text{ for } i, j = 1, 2,\)

viii) \(\overline{R}(X_i, Y_3) Z_3 = h g_3 (Y_3, Z_3) \nabla_{X_i} \text{grad} h\) for \(i = 1, 2\),

ix) \(\overline{R}(X_3, Y_3) Z_3 = R^3 (X_3, Y_3) Z_3 - \|\text{grad} h\|^2 [g_3 (X_3, Z_3) Y_3 - g_3 (Y_3, Z_3) X_3]\).

**Lemma 1.3.** \cite{[11]} Let \(\overline{M} = (M_1 \times_f M_2) \times_h M_3\) be a sequential warped product with metric \(\overline{g} = g_1 \oplus f^2 g_2 \oplus h^2 g_3\). If \(X_i, Y_i \in \chi (M_i)\), then

i) \(\overline{\text{Ric}}(X_1, Y_1) = \text{Ric}^1 (X_1, Y_1) - \frac{m_2}{m_1} H^1 (X_1, Y_1) - \frac{m_3}{m_1} H^2 (X_1, Y_1)\),

ii) \(\overline{\text{Ric}}(X_2, Y_2) = \text{Ric}^2 (X_2, Y_2) - \left( f \Delta^1 f + (m_2 - 1) \|\text{grad}^1 f\|^2 \right) g_2 (X_2, Y_2) - \frac{m_2}{m_1} H^1 (X_2, Y_2)\),

iii) \(\overline{\text{Ric}}(X_3, Y_3) = \text{Ric}^3 (X_3, Y_3) - (h \Delta h + (m_3 - 1) \|\text{grad} h\|^2) g_3 (X_3, Y_3)\),
In [5], Chaki and Maity introduced the notion of quasi-Einstein manifolds. In [7], De and Ghosh studied some properties of quasi Einstein manifolds and considered quasi-Einstein hypersurfaces of Euclidean spaces. In [20], Sular and the second author studied quasi-Einstein warped product manifolds for arbitrary dimension \( n \geq 3 \). In [13], Dumitru studied the expressions of the Ricci tensors and scalar curvatures for the bases and fibres on quasi-Einstein warped product manifolds. For further developments about quasi-Einstein manifolds; see [1], [8], [10], [14] and [19]. In [11], De, Shenawy and "Unal defined sequential warped product manifolds. In [18], Pahan and Pal studied the Einstein sequential warped product space with negative scalar curvature and gave an example of the Einstein sequential warped space. In [21], Sahin introduced sequential warped product submanifolds of Kaehler manifolds and obtained some examples. Motivated by the above studies, in the present paper, we consider quasi-Einstein sequential warped product manifolds. Firstly, we obtain that the sequential warped product manifolds are product manifolds if \( \alpha < 0 \). Then, we investigate the necessary and sufficient conditions for a sequential standard static space-time and a sequential generalized Robertson-Walker space-time to be quasi-constant curvature.

2. The quasi-Einstein sequential warped products

In this section, we give some results on quasi-Einstein sequential warped product manifolds. Using Lemma 1.3, we obtain the following proposition:

**Proposition 2.1.** Let \( \overline{M} = (M_1 \times_f M_2) \times_h M_3 \) be a quasi-Einstein sequential warped product manifold whose Ricci tensor is of the form \( \overline{\text{Ric}} = \alpha \overline{g} + \beta A \otimes A \). When \( U \) is a vector field on \( \overline{M} \), then the Ricci tensors of \( M_1, M_2 \) and \( M_3 \) satisfy the following equalities:

\[
\text{Ric}^1(X_1, Y_1) = \alpha g_1(X_1, Y_1) + \beta g_1(X_1, U_1) g_1(Y_1, U_1) + \frac{m_2}{f} H^f(X_1, Y_1) + \frac{m_3}{h} H^h(X_1, Y_1),
\]

(2.1)

\[
\text{Ric}^2(X_2, Y_2) = \left( \alpha f^2 + f \Delta^f + (m_2 - 1) \| \text{grad} f \|^2 \right) g_2(X_2, Y_2) + \beta f^4 g_2(X_2, U_2) g_2(Y_2, U_2) + \frac{m_2}{h} H^h(X_2, Y_2)
\]

(2.2)

and

\[
\text{Ric}^3(X_3, Y_3) = \left( \alpha h^2 + h \Delta h + (m_3 - 1) \| \text{grad} h \|^2 \right) g_3(X_3, Y_3) + \beta h^4 g_3(X_3, U_3) g_3(Y_3, U_3).
\]

(2.3)

**Proof.** Assume that \( \overline{M} = (M_1 \times_f M_2) \times_h M_3 \) is a quasi-Einstein sequential warped product and its Ricci tensor is \( \overline{\text{Ric}} = \alpha \overline{g} + \beta A \otimes A \). Decomposing the vector field \( U \) uniquely into its components \( U_1, U_2 \) and \( U_3 \) on \( M_1, M_2 \) and \( M_3 \), respectively, we can write

\[
U = U_1 + U_2 + U_3.
\]

(2.4)
Using Lemma 1.3, the equations (1.1), (1.3) and (2.4), we obtain the equations (2.1), (2.2) and (2.3). This completes the proof. □

For the scalar curvatures, using Proposition 2.1, we have the following corollary:

**Corollary 2.1.** Let $M = (M_1 \times_f M_2) \times_h M_3$ be a quasi-Einstein sequential warped product manifold. When $U$ is a vector field on $M$, then the scalar curvature of $M_1$, $M_2$ and $M_3$ satisfy the following conditions:

\[
\text{scal}_1 = \alpha m_1 + \beta g_1(U_1, U_1) + \frac{m_2}{f} \Delta^1 f + \frac{m_3}{h} \Delta h,
\]

\[
\text{scal}_2 = \left( \alpha f^2 + f \Delta^1 f + (m_2 - 1) \| \text{grad}^1 f \|^2 \right) m_2 + \beta f^4 g_2(U_2, U_2) + \frac{m_3}{h} \Delta h
\]

and

\[
\text{scal}_3 = \left( \alpha h^2 + h \Delta h + (m_3 - 1) \| \text{grad} h \|^2 \right) m_3 + \beta h^4 g_3(U_3, U_3).
\]

**Lemma 2.1.** [16] Let $f$ be a smooth function on $M_1$. Then the divergence of the Hessian tensor $H^f$ satisfies

\[
\text{div} \big( H^f \big) (X) = \text{Ric} \big( \text{grad}^1 f, X \big) - \Delta \big( df \big) (X),
\]

where $\Delta$ denotes the Laplacian on $M_1$.

Using Proposition 2.1 and Lemma 2.1 we can state the following proposition:

**Proposition 2.2.** Let $(M_1, g_1)$ be a compact Riemannian manifold with $m_1 \geq 2$. Suppose that $f$ is a nonconstant smooth function on $M_1$ satisfying equation (2.1) for constants $\alpha, \beta \in \mathbb{R}$, $m_2 \geq 2$ and $U \in \chi (M)$. If the condition

\[
\frac{m_2}{f} g_1(\text{grad}^1 f, U_1) g_1(U_1, U_1) + \frac{m_2 m_3}{h} H^h(\text{grad}^1 f, X) + m_3 \text{div} \left( \frac{H^h}{h} \right) (X)
\]

\[
= \frac{m_3}{2} d(\frac{\Delta h}{h}) (X) + \frac{2m_2}{f} d \left( \Delta^1 f \right) (X)
\]

holds, then $f$ satisfies

\[
\lambda = \alpha f^2 + f \Delta^1 f + (m_2 - 1) \| \text{grad}^1 f \|^2
\]

for a constant $\lambda \in \mathbb{R}$.

**Proof.** Assume that $U \in \chi (M)$. By Corollary 2.1 we have

\[
\text{scal}_1 = \alpha m_1 + \beta g_1(U_1, U_1) + \frac{m_2}{f} \Delta^1 f + \frac{m_3}{h} \Delta h.
\]

By the use of the second Bianchi identity, we have

\[
d(\text{scal}_1) = 2 \text{div} \big( \text{Ric}^1 \big).
\]

From the equations (2.7) and (2.8), we get

\[
\text{div} \big( \text{Ric}^1 \big) = \frac{m_2}{2f^2} \left[ - (\Delta^1 f) (df) + f d(\Delta^1 f) \right] + \frac{m_3}{2h^2} \left[ - (\Delta h) (dh) + h d(\Delta h) \right].
\]
It is well known from the definition that
\[ \text{div}\left( \frac{1}{f} H^f_1 \right)(X) = -\frac{1}{f^2} H^f_1 (\text{grad}^3 f, X) + \frac{1}{f } \text{div} H^f_1 (X) \] (2.10)
for any vector field \( X \) on \( M_1 \). Since \( H^f_1 (\text{grad}^3 f, X) = \frac{1}{2} d(\| \text{grad}^3 f \|^2)(X) \), the equation (2.10) turns into
\[ \text{div}\left( \frac{1}{f} H^f_1 \right)(X) = -\frac{1}{2f^2} d(\| \text{grad}^3 f \|^2)(X) + \frac{1}{f } \text{div} H^f_1 (X). \] (2.11)
Using Lemma 2.1 and equation (2.1) in (2.11), we find
\[ \text{div}\left( \frac{1}{f} H^f_1 \right)(X) = \frac{1}{2f^2} \left[ (m_2 - 1) d(\| \text{grad}^3 f \|^2)(X) + (2\alpha f) d f(X) - (2f) d (\Delta^1 f)(X) \right] \]
\[ + \frac{\beta}{f} g_1(\text{grad}^3 f, U_1) g_1(X, U_1) + \frac{m_3}{f h} H^h(\text{grad}^3 f, X). \] (2.12)
From equation (2.11), we can write
\[ \text{div}(\text{Ric}^1)(X) = m_2 \text{div}\left( \frac{1}{f} H^f_1 \right)(X) + m_3 \text{div}\left( \frac{1}{h} H^h \right)(X). \] (2.13)
Using the equation (2.12) into (2.13), we obtain
\[ \text{div}(\text{Ric}^1)(X) = \frac{m_2}{2f^2} \left[ (m_2 - 1) d(\| \text{grad}^3 f \|^2)(X) + (2\alpha f) d f(X) - (2f) d (\Delta^1 f)(X) \right] \]
\[ + m_2 \frac{\beta}{f} g_1(\text{grad}^3 f, U_1) g_1(X, U_1) + \frac{m_2 m_3}{f h} H^h(\text{grad}^3 f, X) + m_3 \text{div}\left( \frac{1}{h} H^h \right)(X). \] (2.14)
From the equations (2.9) and (2.14), we get
\[ m_2 \frac{d}{2f^2} \left[ (m_2 - 1) (\| \text{grad}^3 f \|^2) + (\alpha f^2) + f \Delta^1 f \right](X) \]
\[ + m_2 \frac{\beta}{f} g_1(\text{grad}^3 f, U_1) g_1(X, U_1) - 2m_2 f d(\Delta^1 f)(X) + \frac{m_2 m_3}{f h} H^h(\text{grad}^3 f, X) \]
\[ + m_3 \text{div}\left( \frac{1}{h} H^h \right)(X) - \frac{m_3}{2} d \left( \frac{\Delta h}{h} \right)(X) = 0. \] (2.15)
Using the condition (2.5), we have
\[ d \left[ (m_2 - 1) (\| \text{grad}^3 f \|^2) + \alpha f^2 + f \Delta^1 f \right](X) = 0. \]
Therefore, we obtain the equation (2.6). This completes the proof. \( \Box \)

From [18], we have the following lemma:

**Lemma 2.2.** Let \( h \) be a smooth function on \( M_1 \times M_2 \). Then the divergence of the Hessian tensor \( H^h \) satisfies
\[ \text{div}\left( H^h \right)(X) = \text{Ric}(\text{grad}^h, X) - \Delta (dh)(X), \]
where \( \Delta \) denotes the Laplacian on \( M_1 \times M_2 \).
Using the same method in the proof of Proposition 2.2, we can state the following proposition:

**Proposition 2.3.** Let \((M_1, g_1)\) and \((M_2, g_2)\) be two compact Riemannian manifold with \(m_1 \geq 2\) and \(m_2 \geq 2\). Suppose that \(h\) is a nonconstant smooth function on \(M_1 \times M_2\) satisfying

\[
Ric^2 = \lambda g_2(X_2, Y_2) + \beta f^4 g_2(X_2, U_2) g_2(Y_2, U_2) + \frac{m_3}{h} H^h(X_2, Y_2) \tag{2.16}
\]

for a constant \(\lambda \in \mathbb{R}\) and \(U \in \chi(\overline{M})\). If the condition

\[
\frac{m_3}{h} (\lambda - \alpha) dh + \beta \text{div}(f^4) g_2(X_2, U_2) g_2(Y_2, U_2) + \frac{m_3}{h} f^4 g_2(\text{grad} h, U_2) g_2(X_2, U_2) = \frac{2m_3}{h} d(\Delta h) + 2\beta f^3 df g_2(U_2, U_2) \tag{2.17}
\]

holds, then \(h\) satisfies

\[
\nu = \alpha h^2 + h \Delta h + (m_3 - 1) \|\text{grad} h\|^2 \tag{2.18}
\]

for a constant \(\nu \in \mathbb{R}\). Hence for compact quasi-Einstein spaces \((M_3, g_3)\) of dimension \(m_3 \geq 2\) with \(Ric^3 = \nu g_3 + \beta A \otimes A\), we can make a quasi-Einstein sequential warped product space \(\overline{M} = (M_1 \times f M_2) \times_h M_3\) with \(\overline{Ric} = \alpha \overline{g} + \beta A \otimes A\).

**Proof.** Assume that \(U \in \chi(\overline{M})\). By taking the trace of both sides of the equation (2.16), we get

\[
\text{scal}_2 = \lambda m_2 + \beta f^4 g_2(U_2, U_2) + \frac{m_3}{h} \Delta h. \tag{2.19}
\]

Using the same method with Proposition 2.2 with the help of Lemma 2.2, we have the equation (2.18) for a constant \(\nu \in \mathbb{R}\) if the condition (2.17) holds. Thus the first part of the proposition is proved. For a compact quasi-Einstein manifold \((M_3, g_3)\) of dimension \(m_3 \geq 2\) with \(Ric^3 = \nu g_3 + \beta A \otimes A\), we can generate a quasi-Einstein sequential warped product \(\overline{M} = (M_1 \times f M_2) \times_h M_3\) with \(\overline{Ric} = \alpha \overline{g} + \beta A \otimes A\) by using of Proposition 2.2 for \(U \in \chi(\overline{M})\). This completes the proof.

Now, we have the following theorem:

**Theorem 2.1.** Let \(\overline{M} = (M_1 \times f M_2) \times_h M_3\) be a compact quasi-Einstein sequential warped product space whose Ricci tensor is of the form \(\overline{Ric} = \alpha \overline{g} + \beta A \otimes A\) with \(U \in \chi(\overline{M})\). If \(\alpha < 0\), then the sequential warped product becomes a product manifold.

**Proof.** The equation (2.6) gives us

\[
\lambda = \alpha f^2 + \text{div}(f \Delta f) + (m_2 - 2) \|\text{grad}^1 f\|^2. \tag{2.20}
\]

By integrating over \(M_1\), we have

\[
\lambda = \frac{\alpha}{\vartheta(M_1)} \int_{M_1} f^2 + \frac{(m_2 - 2)}{\vartheta(M_1)} \int_{M_1} \|\text{grad}^1 f\|^2, \tag{2.21}
\]

where \(\vartheta(M_1)\) denotes the volume of \(M_1\).
Case I: Assume that \( m_2 \geq 3 \). Let \( p \) be a maximum point of \( f \) on \( M_1 \). Hence, we have \( f(p) > 0, \) \( \text{grad}^1 f(p) = 0 \) and \( \Delta^1 f(p) \geq 0 \). Using the equations (2.6) and (2.21), we can write

\[
0 \leq f(p) \Delta^1 f(p) = \alpha f(p)^2 - \lambda
\]

\[
= \frac{(2 - m_2)}{\vartheta(M_1)} \int_{M_1} ||\text{grad}^1 f||^2 + \frac{\alpha}{\vartheta(M_1)} \int_{M_1} (f(p))^2 - f^2 \leq 0.
\]

If \( \alpha < 0 \), then \( f \) is a constant.

Case II: Assume that \( m_2 = 2 \). Let \( q \) be a minimum point of \( f \) on \( M_1 \). Hence, we have \( f(q) > 0, \) \( \text{grad}^1 f(q) = 0 \) and \( \Delta^1 f(q) \leq 0 \). Thus, we can write

\[
0 \geq f(q) \Delta^1 f(q) = \alpha f(q)^2 - \lambda
\]

\[
= \frac{(2 - m_2)}{\vartheta(M_1)} \int_{M_1} ||\text{grad}^1 f||^2 + \frac{\alpha}{\vartheta(M_1)} \int_{M_1} (f(q))^2 - f^2 \geq 0.
\]

If \( \alpha < 0 \), then \( f \) is a constant.

Similarly, the equation (2.18) gives us

\[
\nu = \alpha h^2 + \text{div}(h\Delta h) + (m_3 - 2) \|\text{grad} h\|^2.
\]

(2.22)

By integrating over \( M_1 \times M_2 \), we have

\[
\nu = \frac{\alpha}{\vartheta(M_1 \times M_2)} \int_{M_1 \times M_2} h^2 + \frac{(m_3 - 2)}{\vartheta(M_1 \times M_2)} \int_{M_1 \times M_2} \|\text{grad} h\|^2,
\]

(2.23)

where \( \vartheta(M_1 \times M_2) \) denotes the volume of \( M_1 \times M_2 \).

Case I: Assume that \( m_3 \geq 3 \). Let \((p_1, p_2)\) be a maximum point of \( h \) on \( M_1 \times M_2 \). Hence, we have \( h(p_1, p_2) > 0, \) \( \text{grad} h(p_1, p_2) = 0 \) and \( \Delta h(p_1, p_2) \geq 0 \). Using the equations (2.18) and (2.23), we get

\[
0 \leq h(p_1, p_2) \Delta h(p_1, p_2) = \alpha h(p_1, p_2)^2 - \nu
\]

\[
= \frac{(2 - m_3)}{\vartheta(M_1 \times M_2)} \int_{M_1 \times M_2} ||\text{grad} h||^2 + \frac{\alpha}{\vartheta(M_1 \times M_2)} \int_{M_1 \times M_2} (h(p_1, p_2))^2 - h^2 \leq 0.
\]

If \( \alpha < 0 \), then \( h \) is a constant.

Case II: Assume that \( m_3 = 2 \). Let \((q_1, q_2)\) be a minimum point of \( h \) on \( M_1 \times M_2 \). Hence, we have \( h(q_1, q_2) > 0, \) \( \text{grad} h(q_1, q_2) = 0 \) and \( \Delta h(q_1, q_2) \leq 0 \). Thus, we get

\[
0 \geq h(q_1, q_2) \Delta h(q_1, q_2) = \alpha h(q_1, q_2)^2 - \nu
\]
\[
\frac{(2 - m_3)}{\vartheta(M_1 \times M_2)} \int_{M_1 \times M_2} \|\text{grad}h\|^2 + \frac{\alpha}{\vartheta(M_1 \times M_2)} \int_{M_1 \times M_2} (h(q_1, q_2)^2 - h^2) \geq 0.
\]

If \(\alpha < 0\), then \(h\) is a constant. This completes the proof. \(\square\)

Using Corollary 2.1, we have the following theorem:

**Theorem 2.2.** Let \(\mathcal{M} = (M_1 \times f M_2) \times_h M_3\) be a quasi-Einstein sequential warped product space, where \(M_1\) and \(M_2\) are two compact spaces and \(M_3\) is a compact quasi-Einstein space. Then the following conditions hold for \(U \in \chi(\mathcal{M})\):

i) If \(\text{scal}_3 \leq 0, \alpha, \beta > 0\) and \(\Delta h \geq 0\), then \(h\) is a constant.

ii) If \(m_2 = 1\) and \((\lambda > \alpha f^2 \text{ or } \lambda < \alpha f^2)\), then \(f\) is a constant. Thus, \(h\) is a constant when \(\alpha, \beta > 0\) and \(\Delta h > 0\). Hence, it is a Riemannian product.

iii) If \(\|\text{grad}^1 f\| \geq \sqrt{\frac{\lambda}{m_2 - 1}}, \|\text{grad}h\| \geq \sqrt{\frac{\nu}{m_3 - 1}}\) and \(\alpha > 0\), then \(f\) and \(h\) are constants. Hence, it is a Riemannian product.

**Proof.** Assume that \(U \in \chi(\mathcal{M})\). From Corollary 2.1, we have

\[
\text{scal}_1 = \alpha m_1 + \beta g_1(U_1, U_1) + \frac{m_2}{f} \Delta^1 f + \frac{m_3}{h} \Delta h,
\]

\[
\text{scal}_2 = \lambda m_2 + \beta f^4 g_2(U_2, U_2) + \frac{m_3}{h} \Delta h
\]

and

\[
\text{scal}_3 = \nu m_3 + \beta h^4 g_3(U_3, U_3).
\]

i) Using the equation (2.26), if \(\text{scal}_3 \leq 0\) and \(\beta > 0\), then \(\nu \leq 0\). From the Proposition 2.3, we can write

\[
\alpha h^2 + h \Delta h = \nu - (m_3 - 1) \|\text{grad}h\|^2 \leq 0.
\]

If \(\alpha > 0\) and \(\Delta h \geq 0\) then, we have

\[
0 \leq h \Delta h \leq -\alpha h^2 \leq 0.
\]

Therefore, we obtain that \(h\) is a constant.

ii) From the Proposition 2.2 and \(m_2 = 1\), we have

\[
\lambda - \alpha f^2 = f \Delta^1 f.
\]

Using the above equation, if \(\lambda > \alpha f^2\text{ or }\lambda < \alpha f^2\), then we find that \(f\) is a constant. So we can write

\[
\lambda = \alpha f^2.
\]

By the use of the equations (2.25), (2.27) and \(m_2 = 1\), we get

\[
\alpha f^2 + \beta f^4 g_2(U_2, U_2) + \frac{m_3}{h} \Delta h = 0.
\]

From equation (2.28), \(\alpha, \beta > 0\) and \(\Delta h > 0\), we obtain that \(h\) is a constant.

iii) From the Proposition 2.2 and 2.3, we have

\[
\alpha f^2 + f \Delta^1 f = \lambda - (m_2 - 1) \|\text{grad}^1 f\|^2
\]
\( \alpha h^2 + h \Delta h = \nu - (m_3 - 1) \| \text{grad} h \|^2. \)  
(2.30)

Using the conditions \( \| \text{grad} f \| \geq \sqrt{\frac{\lambda}{m_2 - 1}}, \| \text{grad} h \| \geq \sqrt{\frac{\nu}{m_3 - 1}} \) and \( \alpha > 0 \) for equations (2.29) and (2.30) respectively, we get

\[
0 \leq \alpha f^2 \leq -f \Delta f \leq 0
\]

and

\[
0 \leq \alpha h^2 \leq -h \Delta h \leq 0.
\]

Therefore, we deduce that \( f \) and \( h \) are constants. This completes the proof. \( \square \)

### 3. Applications

The warped products have attracted great attention in differential geometry and physics because exact solutions to Einstein’s equation are obtained with the help of warped product space-time models [2], [3]. Generalized Robertson-Walker space-times and standard static space-times are two well known solutions to Einstein’s field equations. The standard static space-times can be considered as a generalization of the Einstein static universe [12]. In addition, the Robertson-Walker models in general relativity describe a simply connected homogeneous isotropic expanding or contracting universe. Then, generalized Robertson–Walker space-times extend the Robertson–Walker space-times [9]. Sequential generalized Robertson-Walker and sequential standard static space-times are introduced in [11].

Let \((M_i, g_i)\) be \(m_i\)-dimensional Riemannian manifolds, where \(i \in \{1, 2, 3\}\). Let \(f : M_1 \rightarrow (0, \infty)\) and \(h : M_1 \times M_2 \rightarrow (0, \infty)\) be two smooth positive functions. Then \((m_1 + m_2 + 1)\)-dimensional product manifold \(\overline{M} = (M_1 \times_f M_2) \times_h I\) equipped with the metric tensor

\[
\overline{g} = (g_1 \oplus f^2 g_2) \oplus h^2 (-dt^2)
\]

is a sequential standard static space-time, where \(I\) is an open, connected subinterval of \(\mathbb{R}\) and \(dt^2\) is the Euclidean metric tensor on \(I\) [11]. In addition, \((m_2 + m_3 + 1)\)-dimensional product manifold \(\overline{M} = (I \times_f M_2) \times_h M_3\) equipped with the metric tensor

\[
\overline{g} = (-dt^2 \oplus f^2 g_2) \oplus h^2 g_3
\]

is a sequential generalized Robertson-Walker space-time, where \(I\) is an open, connected subinterval of \(\mathbb{R}\) and \(dt^2\) is the Euclidean metric tensor on \(I\) [11].

**Theorem 3.1.** Let \(\overline{M} = (M_1 \times_f M_2) \times_h I\) be a sequential standard static space-time with metric \(\overline{g} = (g_1 \oplus f^2 g_2) \oplus h^2 (-dt^2)\). Then \((\overline{M}, \overline{g})\) is a manifold of quasi-constant curvature if and only if the following conditions are satisfied

i) \(\alpha = \beta h^2 - \frac{\Delta h}{h}\),

ii) \((M_1, g_1)\) is a quasi-Einstein manifold when the Hessian tensors \(H^f_1\) and \(H^h\) satisfy the following forms with \(U = U_1 + \partial_t\)

\[
H^f_1(X_1, Y_1) = af g_1(X_1, Y_1) + bf g_1(X_1, U_1)g_1(Y_1, U_1)
\]
Using Theorem 4.8 in [11], we obtain

\[ H^h(X_1, Y_1) = (-a + h^2)hg_1(X_1, Y_1) - bhg_1(X_1, U_1)g_1(Y_1, U_1), \]

where \( a, b \in \mathcal{C}^\infty(\widetilde{M}, \mathbb{R}) \) and \( b \neq 0 \).

iii) \((M_2, g_2)\) is an Einstein manifold when the Hessian tensor \( H^h \) satisfies the following form with \( U = U_1 + \partial_t \)

\[ H^h(X_2, Y_2) = (-a + h^2)f^2hg_2(X_2, Y_2) \]

where \( a, b \in \mathcal{C}^\infty(\widetilde{M}, \mathbb{R}) \) and \( b \neq 0 \).

**Proof.** From [11], we have

\[
\overline{Ric}(X_1, Y_1) = \overline{Ric}^t(X_1, Y_1) - \frac{m_2}{f}H^t_1(X_1, Y_1) - \frac{1}{h}H^h(X_1, Y_1), \tag{3.3}
\]

\[
\overline{Ric}(X_2, Y_2) = \overline{Ric}^t(X_2, Y_2) - \left( f\Delta^1 f + (m_2 - 1) \|\text{grad}^1 f\|^2 \right) g_2(X_2, Y_2) - \frac{1}{h}H^h(X_2, Y_2), \tag{3.4}
\]

\[
\overline{Ric}(\partial_t, \partial_t) = h\Delta h. \tag{3.5}
\]

Let \((\widetilde{M}, \overline{g})\) be a manifold of quasi-constant curvature. Thus, \((\widetilde{M}, \overline{g})\) is a quasi-Einstein manifold. Using the equations (1.1) and (1.2), we have

\[
\overline{Ric}(\partial_t, \partial_t) = -\alpha h^2 + \beta h^4. \tag{3.6}
\]

From the equations (3.5) and (3.6), we find

\[
\alpha = \beta h^2 - \frac{\Delta h}{h}.
\]

Using Theorem 4.8 in [11], we obtain

\[
H^h(X_1, Y_1) = (-a + h^2)hg_1(X_1, Y_1) - bhg_1(X_1, U_1)g_1(Y_1, U_1) \tag{3.7}
\]

and

\[
H^t_1(X_1, Y_1) = afg_1(X_1, Y_1) + bg_1(X_1, U_1)g_1(Y_1, U_1) \tag{3.8}
\]

with \( U = U_1 + \partial_t \). By the use of the equations (1.1), (3.7) and (3.8) into (3.3), we obtain

\[
Ric^t(X_1, Y_1) = (\alpha + (m_2 - 1)a + h^2)g_1(X_1, Y_1) + (\beta + (m_2 - 1)b)g_1(X_1, U_1)g_1(Y_1, U_1).
\]

Hence, \((M_1, g_1)\) is a quasi-Einstein manifold.

Using Theorem 4.8 in [11], we calculate

\[
H^h(X_2, Y_2) = (-a + h^2)f^2hg_2(X_2, Y_2), \tag{3.9}
\]

with \( U = U_1 + \partial_t \). Using the equations (1.1) and (3.9) into (3.4), we find

\[
Ric^t(X_2, Y_2) = \left( \alpha f^2 + f\Delta^1 f + (m_2 - 1) \|\text{grad}^1 f\|^2 - \alpha f^2 + f^2h^2 \right) g_2(X_2, Y_2).
\]

Thus, we obtain that \((M_2, g_2)\) is an Einstein manifold. The converse is trivial. This completes the proof. \(\square\)
Theorem 3.2. Let $\overline{M} = (I \times f M_2) \times h M_3$ be a sequential generalized Robertson-Walker space-time with metric $\overline{\eta} = (-dt^2 \oplus f^2 g_2) \oplus h^2 g_3$. Then $(\overline{M}, \overline{\eta})$ is a manifold of quasi-constant curvature if and only if the following conditions are satisfied

i) $\beta - \alpha = \frac{m_2}{f} f'' - \frac{m_3}{h} \frac{\partial^2 h}{\partial t^2}$,

ii) $(M_2, g_2)$ is a quasi-Einstein manifold when the Hessian tensor $H^h$ satisfies the following form with $U = \partial_t + U_2$,

$$H^h(X_2, Y_2) = ahf^2 g_2(X_2, Y_2) + bhf^4 g_2(X_2, U_2) g_2(Y_2, U_2),$$

where $a, b \in C^\infty(\overline{M}, \mathbb{R})$ and $b \neq 0$.

iii) $(M_3, g_3)$ is an Einstein manifold with $U = \partial_t + U_2$.

Proof. From [11], we have

$$\overline{\text{Ric}}(\partial_t, \partial_t) = \frac{m_2}{f} f'' + \frac{m_3}{h} \frac{\partial^2 h}{\partial t^2}, \tag{3.10}$$

$$\overline{\text{Ric}}(X_2, Y_2) = \text{Ric}^2(X_2, Y_2) - \left(-ff'' - (m_2 - 1)(f')^2\right) g_2(X_2, Y_2)$$

$$- \frac{m_3}{h} H^h(X_2, Y_2), \tag{3.11}$$

$$\overline{\text{Ric}}(X_3, Y_3) = \text{Ric}^3(X_3, Y_3) - (h \Delta h + (m_3 - 1) \|\text{grad} h\|^2) g_3(X_3, Y_3). \tag{3.12}$$

Let $(\overline{M}, \overline{\eta})$ be a manifold of quasi-constant curvature. Thus, $(\overline{M}, \overline{\eta})$ is a quasi-Einstein manifold. Using the equations (1.1) and (1.2), we get

$$\overline{\text{Ric}}(\partial_t, \partial_t) = -\alpha + \beta. \tag{3.13}$$

Using the equations (3.10) and (3.13), we obtain

$$\beta - \alpha = \frac{m_2}{f} f'' + \frac{m_3}{h} \frac{\partial^2 h}{\partial t^2}. \tag{3.14}$$

Using Proposition 4.2 in [11], we obtain

$$H^h(X_2, Y_2) = ahf^2 g_2(X_2, Y_2) + bhf^4 g_2(X_2, U_2) g_2(Y_2, U_2) \tag{3.14}$$

with $U = \partial_t + U_2$. In view of the equations (1.1) and (3.14) into (3.11), it follows that

$$\text{Ric}^2(X_2, Y_2) = \left(af^2 - ff'' - (m_2 - 1)(f')^2 + m_3af^2\right) g_2(X_2, Y_2)$$

$$+ (\beta + m_3b)f^4 g_2(X_2, U_2) g_2(Y_2, U_2).$$

Hence, $(M_2, g_2)$ is a quasi-Einstein manifold. Using the equations (1.1) into (3.12), we find

$$\text{Ric}^3(X_3, Y_3) = (ah^2 + h \Delta h + (m_3 - 1) \|\text{grad} h\|^2) g_3(X_3, Y_3).$$

Thus, $(M_3, g_3)$ is an Einstein manifold with $U = \partial_t + U_2$. The converse is trivial. This completes the proof. \qed
