Abstract

We prove that a random \(d\)-regular graph, with high probability, is a cut sparsifier of the clique with approximation error at most \(\frac{2\sqrt{\pi} + o(n,d)}{\sqrt{d}}\), where \(2\sqrt{\pi} = 1.595\ldots\) and \(o(n,d)\) denotes an error term that depends on \(n\) and \(d\) and goes to zero if we first take the limit \(n \to \infty\) and then the limit \(d \to \infty\).

This is established by analyzing linear-size cuts using techniques of Jagannath and Sen \[JS17\] derived from ideas from statistical physics and analyzing small cuts via martingale inequalities.

We also prove that every spectral sparsifier of the clique having average degree \(d\) and a certain high “pseudo-girth” property has an approximation error that is at least the “Ramanujan bound” \(\frac{2 - o(n,d)}{\sqrt{d}}\), which is met by \(d\)-regular Ramanujan graphs, generalizing a lower bound of Srivastava and Trevisan \[ST18\].

Together, these results imply a separation between spectral sparsification and cut sparsification. If \(G\) is a random log \(n\)-regular graph on \(n\) vertices, we show that, with high probability, \(G\) admits a (weighted subgraph) cut sparsifier of average degree \(d\) and approximation error at most \(\frac{2\sqrt{\pi} + o(n,d)}{\sqrt{d}}\), while every (weighted subgraph) spectral sparsifier of \(G\) having average degree \(d\) has approximation error at least \(\frac{2 - o(n,d)}{\sqrt{d}}\).

1 Introduction

If \(G = (V, E_G, w_G)\) is a, possibly weighted, undirected graph, a cut sparsifier of \(G\) with error \(\epsilon\) is a weighted graph \(H = (V, E_H, w_H)\) over the same vertex set of \(G\) and such that

\[
\forall S \subseteq V \quad (1 - \epsilon) \text{ cut}_G(S) \leq \text{ cut}_H(S) \leq (1 + \epsilon) \text{ cut}_G(S) \tag{1}
\]

where \(\text{cut}_G(S)\) denotes the number of edges in \(G\) with one endpoint in \(S\) and one endpoint in \(V - S\), or the total weight of such edges in the case of weighted graphs. This definition is due to Benczur and Karger \[BK96\].

Spielman and Teng \[ST11\] introduced the stronger definition of spectral sparsification. A weighted graph \(H = (V, E_H, w_H)\) is a spectral sparsifier of \(G = (V, E_G, w_G)\) with error \(\epsilon\) if

\[
\forall x \in \mathbb{R}^V \quad (1 - \epsilon) x^T L_G x \leq x^T L_H x \leq (1 + \epsilon) x^T L_G x \tag{2}
\]

where \(L_G\) is the Laplacian matrix of the graph \(G\). If \(A_G\) is the adjacency matrix of \(G\) and \(D_G\) is the diagonal matrix of weighted degrees, then the Laplacian matrix is \(L_G = D_G - A_G\) and it has the property that, for every vector \(x \in \mathbb{R}^V\),

\[
x^T L_G x = \sum_{(u,v) \in E_G} w_{u,v} \cdot (x_u - x_v)^2
\]

The definition of spectral sparsifier is stronger than the definition of cut sparsifier because, if \(x = 1_S\) is the 0/1 indicator vector of a set \(S\), then we have \(x^T L_G x = \text{cut}_G(S)\). So we see that the definition in \[1\] is equivalent to the specialization of the definition of \[2\] to the case of Boolean vectors \(x \in \{0, 1\}^V\).
In all the known constructions of sparsifiers, the edge set $E_{H}$ of the sparsifier is a subset of the edge set $E_{G}$ of the graph $G$. We will take this condition to be part of the definition of sparsifier.

A cut sparsifier $H$ of a graph $G$ has, approximately, the same cut structure of $G$, so that, if we are interested in approximately solving a problem involving cuts or flows in $G$, we may instead solve the problem on $H$ and be guaranteed that an approximate solution computed for $H$ is also an approximate solution for $G$.

As the name suggests, for every graph $G$ it is possible to find a cut sparsifier $H$ of $G$ which is very sparse, and running an algorithm on a sparse graph yields a faster running time than running it on $G$, if $G$ is not sparse itself.

A spectral sparsifier $H$ of $G$ has all the properties of a cut sparsifier, and, furthermore, it can be substituted for $G$ in some additional applications. For example, if we approximately solve the Laplacian linear system $L_{H}x = b$, and $H$ is a good spectral sparsifier of $G$, then the resulting solution will also be an approximate solution to the Laplacian linear system $L_{G}x = b$. If the matrix $L_{H}$ is sparser than the matrix $L_{G}$, solving $L_{H}x = b$ will be faster than solving $L_{G}x = b$.

Benczur and Karger [BK99] showed that, for every graph $G$, a cut sparsifier with error $\epsilon$ having $O(\epsilon^{-2} n \log n)$ edges can be computed in nearly linear time. Spielman and Teng [ST11] proved that a spectral sparsifier with error $\epsilon$ having $O(\epsilon^{-2} n (\log n)^{O(1)})$ edges can be computed in nearly linear time. Spielman and Srivastava [SS11] improved the number of edges that suffice to construct a spectral sparsifier to $O(\epsilon^{-2} n \log n)$, and Batson, Spielman and Srivastava [BSS09] reduced it to $O(\epsilon^{-2} n)$. Up to the constant in the big-Oh notation, the $O(\epsilon^{-2} n)$ bound is best possible, because every $\epsilon$ cut sparsifier of the clique (and, for a stronger reason, every $\epsilon$ spectral sparsifier of the clique) requires $\Omega(\epsilon^{-2} n)$ edges [ACK+16]. While the construction of Batson, Spielman and Srivastava does not run in nearly linear time, there have been subsequent faster constructions with $O(\epsilon^{-2} n)$ edges running in nearly quadratic time [AZLO15] and nearly linear time [LS17].

In this paper we focus on the combinatorial problem of understanding the minimum number of edges that suffice to achieve cut and spectral sparsification, regardless of the efficiency of the construction. In particular, we aim to understand the best possible constant in the $\Theta(\epsilon^{-2} n)$ bound mentioned above.

Currently, the construction (or even non-constructive existence proof) of cut sparsifiers for general graphs with the smallest number of edges is the one due to Batson, Spielman and Srivastava, which also achieves spectral sparsification with the same parameters. In particular, prior to this work, there was no evidence that cut sparsification is “easier” than spectral sparsification, in the sense of requiring a smaller number of edges. In this paper we show that random $\log n$-regular graphs, with high probability, can be cut-sparsified with better parameters than they can be spectrally-sparsified, if one requires the sparsifier to use a subset of the edges of the graph to be sparsified. Under a conjecture of Srivastava and Trevisan, the same separation would apply to sparsifiers of the clique.

In the following, instead of referring to the number of edges in the sparsifier as a function of the error parameter $\epsilon$ and of the number of vertices $n$, it will be cleaner to refer to the error parameter $\epsilon$ as a function of the average degree $d$ of the sparsifier (that is, we call $dn/2$ the number of edges of the sparsifier).

The construction of Batson, Spielman and Srivastava achieves error $(2\sqrt{d})/\sqrt{d}$ with a sparsifier of average degree $d$, for general graphs. Batson, Spielman and Srivastava also show that every sparsifier of the clique of average degree $d$ has error at least $1/\sqrt{d}$. Srivastava and Trevisan [ST18] prove that every sparsifier of the clique of average degree $d$ and girth $\omega_{n}(1)$ (that is, with girth that grows with the number of edges) that spectrally sparsifies the clique has error at least $(2 - o_{n,d}(1))/\sqrt{d}$. An appropriately scaled $d$-regular Ramanujan graph is a spectral sparsifier of the clique with error $(2 + o_{n,d}(1))/\sqrt{d}$, so we will refer to $2/\sqrt{d}$ as the Ramanujan bound for sparsification. Srivastava and Trevisan conjecture that the Ramanujan bound is best possible for all graphs that sparsify the clique.

**Conjecture 1** (Srivastava and Trevisan). Every family of weighted graphs of average degree $d$ that are $\epsilon$ spectral sparsifiers of the clique satisfy $\epsilon > (2 - o_{d}(1))/\sqrt{d}$.
1.1 Our Results

Our main result is that it is possible to do better than the Ramanujan bound for cut sparsification of the clique.

In the following, we use \( G_{n,d}^{\text{reg}} \) to denote the distribution over random \( d \)-regular multigraphs on \( n \) vertices created by taking the disjoint union of \( d \) random perfect matchings. We will always assume that \( n \) is even.

**Theorem 2** (Main). With \( 1 - o_n(1) \) probability, a random regular graph drawn from \( G_{n,d}^{\text{reg}} \), in which all edges are weighted \((n-1)/d\), is a \((2\sqrt{\frac{2}{\pi}} + o_n(d)) / \sqrt{d} \) cut sparsifier of the clique, where \( 2\sqrt{\frac{2}{\pi}} = 1.595... \)

Together with Conjecture 1, the above theorem gives a conditional separation between the error-density tradeoffs of cut sparsification versus spectral sparsification of the clique.

In order to achieve an unconditional separation, we prove a generalization of the result of Srivastava and Trevisan to families of graphs that satisfy a property that is weaker than the property of having large girth (it is enough that most vertices, rather than all vertices, see no cycles within a certain distance) which we then use to prove the following result.

**Theorem 3.** If \( G \) is a random regular graph drawn from \( G_{n,\log n}^{\text{reg}} \), then the following happens with high probability over the choices of \( G \): for all graphs \( H \) of average degree \( d \) which are weighted edge-subgraphs of \( G \), if \( H \) is an \( \epsilon \)-spectral sparsifier of \( G \) then \( \epsilon \geq (2 - o_n(d)) / \sqrt{d} \).

Using the fact that a random log \( n \)-regular graph is, with high probability, a \( O(1/\sqrt{\log n}) \) spectral sparsifier of the clique, and that a random log \( n \)-regular graph contains a random \( d \)-regular graph as a subgraph, we have our separation.

**Theorem 4.** Let \( G \) be a random regular graph drawn from \( G_{n,\log n}^{\text{reg}} \). Then with probability \( 1 - o_n(1) \) over the choice of \( G \) the following happens for every \( d \):

1. There is a weighted subgraph \( H \) of \( G \) with \( dn/2 \) edges such that \( H \) is an \( \epsilon \) cut sparsifier of \( G \) with \( \epsilon \leq (2 - o_n(d)) / \sqrt{d} \);
2. For every weighted subgraph \( H \) of \( G \) with \( dn/2 \) edges, if \( H \) is an \( \epsilon \) spectral sparsifier of \( G \) then \( \epsilon \geq (2 - o_n(d)) / \sqrt{d} \).

1.2 Techniques

Our main result, Theorem 2, is established by analyzing cuts of linear size using rigorous techniques that have been derived from statistical physics \[JS17\] and by analyzing sublinear size cuts using martingale concentration bounds.

For a fixed set \( S \) of \( k = \alpha n \leq n/2 \) vertices, the average number of edges that leave \( S \) in a random \( d \)-regular graph is \( \frac{n-1}{n} \cdot k \cdot (n-k) \) and we are interested in showing that for every such set the deviation from the expectation is at most \( \epsilon \cdot \frac{d}{n-1} \cdot k \cdot (n-k) \), for \( \epsilon \leq 1.595.../\sqrt{d} \).

1.2.1 Bound for small sets

One approach is to set up a martingale and apply an Azuma-like inequality. In this approach, it is better to study the deviation from the expectation of the number of edges that are entirely contained in \( S \). This is because, in a regular graph, the deviation from the expectation of the number of edges crossing the cut \((S, V - S)\) is entirely determined by the deviation from the expectation of the number of edges entirely contained in \( S \), and the latter can be written as a sum of fewer random variables (that is, \( \binom{n}{2} \) versus \( k \cdot (n-k) \)), especially for small \( k \). After setting up the appropriate Doob martingale, we can prove that the probability that the cut \((S, V - S)\) deviates from the expectation by more than \( 1.595.../\sqrt{d} \) times the expectation is at most \( e^{-\Omega(n)} \) if \( k \geq \Omega(n/\sqrt{d}) \) and at most \( e^{-\Omega(dk \log (n/d))} \) for \( k \leq O(n/\sqrt{d}) \). In particular, there is an \( \alpha_0 > 0 \) such that for all \( k \leq \alpha_0 n \) the probability of having a large deviation is much smaller than \( 1/\binom{n}{k} \), in a way that enables a union bound. These calculations are carried out in Section 4.
Unfortunately, such “first moment” calculations cannot be pushed all the way to $\alpha_0 = 1/2$. This is because our calculations with deviation bounds and union bounds are equivalent to estimating the average number of cuts that have a relative error bigger than $1.595.../\sqrt{d}$, with the goal of showing that such average number is much smaller than one. Unfortunately, the average number of balanced cuts that have a relative error bigger than $2/\sqrt{d}$ is bigger than one, so we cannot hope to get a separation from the spectral bounds with first moment calculations.

1.2.2 Bound for large sets

We then turn to techniques derived from statistical physics in order to analyze large cuts. To illustrate this approach, consider the classical problem of bounding the typical value of the max cut optimum in Erdős-Rényi random graphs $G_{n,1/2}$, up to $o(n^{1.5})$ error terms. This is equivalent to the problem of understanding the typical value of

$$\max_{\sigma \in \{\pm 1\}^n} \sigma^T M \sigma$$

where $M$ is a random symmetric matrix with independent uniform $\pm 1$ entries off the diagonal and zero diagonal.

A first step is to prove, by an interpolation argument, that, up to lower order $o(n^{1.5})$ additive error, the optimum of (3) is the same as the optimum of

$$\max_{\sigma \in \{\pm 1\}^n} \sigma^T W \sigma$$

where $W$ is a Wigner matrix, a random symmetric matrix with zero diagonal and independent and standard normally distributed off-diagonal entries.

Finding the optimum of (4) up to an additive error $o(n^{1.5})$ is a standard problem in statistical physics: it is the problem of determining the zero-temperature free energy of a spin-glass model called the Sherrington-Kirkpatrick model, or SK model for short.

Parisi [Par80] defined a family of differential equations, and presented a heuristic argument according to which the infimum of the solutions of those differential equations, would give the free energy of the SK model. That infimum is now called the Parisi formula. Parisi’s approach was extremely influential and widely generalized. Guerra [Gue03] rigorously proved that a solution to each of the differential equations gives an upper bound on the free energy, and, in a monumental work, Talagrand [Tal06] rigorously proved the stronger claim that the Parisi formula is equal to the free energy of the SK model. Talagrand’s work was further generalized by Panchenko [Pan14].

Dembo, Montanari and Sen [DMS17] proved an interpolation result showing that the solution to (4) can also be used to bound the max cut in random sparse graphs of constant average degree $d$, including both random $d$-regular graphs $G_{n,d}^{\text{reg}}$ and Erdős-Rényi random graphs $G_{n,d/n}$. Jagannath and Sen [JS17] proved interpolation theorems for the problem of determining the max cut out of sets of size $\alpha n$, for fixed constant $\alpha$, in $G_{n,d/n}$ and in $G_{n,d}^{\text{reg}}$ graph, and they proved that the two models have different asymptotic bounds when $0 < \alpha < 1/2$.

In particular, to find the maximum (and the minimum) over all sets $S$ of cardinality $\alpha n$ of cut$_G(S)$ in a random $d$-regular graph, Jagannath and Sen prove that one has to study

$$\max_{\sigma \in S_n(\alpha)} \sigma^T \Pi^T W \Pi \sigma$$

where $S_n(\alpha)$ is the subset of vectors $\sigma \in \{\pm 1\}^n$ that contain exactly $\alpha n$ ones, and $\Pi = I - \frac{1}{\alpha} J$ is the matrix that projects on the space orthogonal to $(1,1,\ldots,1)$. The restriction to $S_n(\alpha)$ models the restriction to cuts $(S,V-S)$ where $|S| = \alpha n$, and the projection defines a matrix $\Pi^T W \Pi$ such that all rows and all columns sum to zero, in analogy to the fact that, in a regular graph, all rows and all columns of the adjacency matrix have the same sum.

Jagannath and Sen also define a Parisi-type family of differential equations and they rigorously prove that a solution to any of those equations provides an upper bound to (5). Since their goal is to compare cuts
in regular graphs to cuts in Erdős-Rényi graphs, rather than bounding cut sizes in random regular graphs, they do not provide solutions to their Parisi-type equations. In Section 2 we compute the replica-symmetric solution and get an explicit bound.

From the bound, we get that, for every fixed $\alpha$, with high probability, sets of size $\alpha n$ in a random $d$-regular graph satisfy the definition of $\epsilon$ cut sparsification of the clique with

$$\epsilon \leq \left( 2 \sqrt{\frac{2}{\pi}} + o_{n,d}(1) \right) \cdot \frac{1}{\sqrt{d}} = \frac{1.595 \ldots + o_{n,d}(1)}{\sqrt{d}}$$

A tight upper bound on $\epsilon$, which would come from an exact solution of [4], is likely to be $2/\sqrt{d}$ times the value of the Parisi formula evaluated at zero temperature and no external field (approximately $1.5264/\sqrt{d}$ [CR02]), although we have not attempted to prove this.

1.2.3 Lower bound for spectral sparsification

As discussed above, we established that a random $d$-regular graph is an $\epsilon$ cut sparsifier with $\epsilon \leq (1.595... + o(1))/\sqrt{d}$. Under Conjecture [1] this gives a conditional separation between the error-vs-density tradeoff for cut sparsification of the clique compared to spectral sparsification of the clique.

If we consider sparsifiers that are weighted edge-subgraphs of the graph to sparsify, we can obtain an unconditional separation if we can find a random family of graphs that:

- Contain random $d$-regular graphs as edge-induced subgraphs
- Are, with high probability, $o_{n,d}(1/\sqrt{d})$ spectral sparsifiers of the clique
- Are such that, with high probability, no weighted edge-induced subgraph of average degree $d$ can be a spectral sparsifier of the clique with error smaller than $(2 + o_{n,d}(1))/\sqrt{d}$

Then, if we consider the graphs $G_n$ in this family, and let $H_n$ be a random $d$-regular graph contained in $G_n$, we have that the following happens with high probability: $H_n$ is a graph of average degree $d$ that is a $(1.595... + o_{n,d}(1))/\sqrt{d}$ cut sparsifier of the clique and also a $(1.595... + o_{n,d}(1))/\sqrt{d}$ cut sparsifier of $G_n$, but every edge-weighted subgraph of $G_n$ of average degree $d$ which is an $\epsilon$ spectral sparsifier of $G_n$ is also an $\epsilon + o_{n,d}(1/\sqrt{d})$ spectral sparsifier of the clique and hence satisfies $\epsilon \geq (2 - o_{n,d}(1))/\sqrt{d}$.

Srivastava and Trevisan prove that the Ramunajan bound is optimal for families of graphs of growing girth, but it is not possible to use this property in the above plan because a family of random graphs cannot, with high probability, both contain random $d$-regular graphs and have large girth. To overcome this difficulty, we generalize the result of Srivastava and Trevisan to graphs that have a large "pseudo-girth" $g$, that is, that are such that for a $1 - o(1)$ fraction of the nodes $v$ there is no cycle in the ball centered at $v$ of radius $g/2$. We define test vectors for every graph, and show that, if the graph satisfies the pseudogirth condition with $g = d^{1/4}$, then the test vectors show that, if the graph is an $\epsilon$ spectral sparsifier of the clique then $\epsilon \geq 2/\sqrt{d} - O(d^{-3/4}) - o_n(1)$.

The pseudogirth condition is satisfied by several families of random regular graphs and Erdős-Rényi random graphs. In particular, random $\Delta_n$-regular graphs, for any choice of the degree $\Delta_n$ in the range $d^{1.5} \leq \Delta_n \leq n^{1/nd}$ satisfies the three conditions above and can be used to establish the separation. For concreteness, we have stated our result for $\Delta_n = \log n$.

1.3 Additional Remarks and Open Problems

The notions of cut sparsifier and of spectral sparsifier of the clique are interesting generalizations of the notion of expander graph, and they allow graphs that are possibly weighted and irregular. As with expander graphs, it seems worthwhile to study sparsifiers as fundamental combinatorial objects, beyond their applications to the design of efficient graph algorithms.

A proof of Conjecture [1] would give us a significant generalization of the Alon-Boppana theorem, and it would be a very interesting result.
It is plausible that the clique is the hardest graph to sparsify, both for cut sparsification and for spectral sparsification. This would mean that the error in the construction of Batson, Spielman and Srivastava can be improved from $2\sqrt{2}/\sqrt{d}$ to $2/\sqrt{d}$, up to lower order terms, and that there is a construction (or perhaps a non-constructive existence proof) of cut sparsifiers of general graphs with error smaller than $1.6/\sqrt{d}$, up to lower error terms. At present, unfortunately, there is no promising approach to construct (or non-constructively prove existence) of cut sparsifiers of general graphs error below $2/\sqrt{d}$, or even below $2\sqrt{2}/\sqrt{d}$.

2 Linear-sized cuts

We show that random regular graphs are good cut sparsifiers of the clique over cuts with vertex set $S$ of linear size, so that $|S| = \alpha n$ for constant $\alpha$.

Theorem 5 (Linear Set Regime for Cut Sparsification). For every constant $\alpha \in (0, 1)$, almost always over $H \sim G_{n,d}^\text{reg}$,

$$\left| \frac{\text{cut}_{H}(S)}{E_{S' \in S_{\alpha}} \text{cut}_{H}(S')} - 1 \right| \leq \frac{1}{\sqrt{d}} \left( 2\sqrt{\frac{2}{\pi}} + o_{n,d}(1) \right),$$

where $S_{\alpha} = \{ S \subseteq V \mid |S| = \alpha n \}$ and $2\sqrt{\frac{2}{\pi}} = 1.595 \ldots$.

First we refer to a lemma showing that the maximum cut with relative cut volume $\alpha$ concentrates around its expectation, so that we reduce the problem to understanding the expected value of the maximum cut. We also state its version for minimum cuts, derived by flipping signs and using sign symmetries in the statement and proof of the lemma, in accordance with [JS17, Remark 1].

Lemma 6 (Lemma 2.1 of [JS17]).

$$\Pr_{H \sim G_{n,d}^\text{reg}} \left[ \max_{S \in S_{\alpha}} \frac{1}{n} \text{cut}_{H}(S) - \frac{1}{E_{H' \sim G_{n,d}^\text{reg}} \left[ \max_{S' \in S_{\alpha}} \frac{1}{n} \text{cut}_{H'}(S') \right]} > \varepsilon \right] \leq 2e^{-n\varepsilon^{2}/d},$$

$$\Pr_{H \sim G_{n,d}^\text{reg}} \left[ \min_{S \in S_{\alpha}} \frac{1}{n} \text{cut}_{H}(S) - \frac{1}{E_{H' \sim G_{n,d}^\text{reg}} \left[ \min_{S' \in S_{\alpha}} \frac{1}{n} \text{cut}_{H'}(S') \right]} > \varepsilon \right] \leq 2e^{-n\varepsilon^{2}/d}.$$

As discussed in Section 1.2.2, we now invoke techniques of statistical mechanics developed in the study of spin glasses, specifically the SK model and its generalizations.

After the Parisi formula was proven to solve the SK model, Denbo, Montanari, and Sen [DMS*17] used interpolation techniques to show that the free energy of the SK model corresponds to the maximum or minimum bisection (equivalently, balanced cut) on random sparse graphs. Sen [Sen18] generalized that interpolation to a family of combinatorial problems, including unbalanced cuts $\text{cut}(S)$ where $|S|$ is a constant times $n$, as we study here, relating these problems to a generalization of the SK model.

The SK model has internal energy $\sigma^{T}W\sigma/\sqrt{n}$ for $W \in \mathbb{R}^{n \times n}$ a symmetric Wigner matrix with standard Gaussian entries on the off-diagonal and zero on the diagonals, to be optimized over configurations $\sigma \in \{\pm 1\}^{n}$. The generalization studies the optimization problem with the same matrix $W$ and the same configuration space $\{\pm 1\}^{n}$ but with internal energy

$$H_{W}^{(1)}(\sigma) = \frac{1}{\sqrt{n}}\sigma^{T}\Pi W \Pi \sigma,$$

where $\Pi$ is the orthogonal projection away from the all-ones vector. In this model, finding the extremal cuts of a given relative vertex density $\alpha$ corresponds to optimizing that energy over the restricted set of configurations

$$S_{n}(\alpha) = \left\{ \sigma \in \{\pm 1\}^{n} : \sum_{i} \sigma_{i} = n(2\alpha - 1) \right\}.$$

1 This definition corresponds to that used in [JS17], and is larger by a factor of 2 than a convention used in some other places.
We may formulate this equivalently as optimizing
\[ H_W^{(0)}(\sigma) = \frac{1}{\sqrt{n}} \sigma^T W \sigma \]
over a different alphabet \( \sigma \in \{ \pm 1 - (2\alpha - 1) \} \), with graph cuts of relative vertex density \( \alpha \) corresponding to the set of configurations
\[
A_n(T(\alpha), \varepsilon_n) = \left\{ \sigma \in \{ \pm 1 - (2\alpha - 1) \} : \left| \sum_i \sigma_i^2 - T(\alpha) \right| < \varepsilon_n \right\},
\]
with \( T(\alpha) = 4\alpha(1 - \alpha) \) and setting \( \varepsilon_n = 0 \) to achieve the equivalence.

Finally, Jagannath and Sen [JS17] used an analytical annealing approach to solve this generalized model, yielding the generalization of the Parisi formula stated here:

**Definition 7.** Let \( \nu \) be a measure over \([0, T]\) of the form \( \nu = m(t) dt + \delta_T \) with \( m(t) \) non-negative, non-decreasing, and everywhere right-continuous with left limits (cadlag), where \( dt \) is the uniform measure and \( \delta_T \) is the Dirac delta function at \( t = T \). Then for \( \lambda \in \mathbb{R} \) and \( T(\alpha) = 4\alpha(1 - \alpha) \), we define the ground state energy functional
\[
\mathcal{P}_{T(\alpha)}^1(\nu, \lambda) = u_{\nu, \lambda}(0, 0) - \lambda T(\alpha) - 2 \int_0^{T(\alpha)} s d\nu(s)
\]
where \( u_{\nu, \lambda} \) is the solution to the differential equation with boundary condition
\[
\left\{ \begin{array}{l}
\frac{\partial u}{\partial t} + 2 \frac{\partial^2 u}{\partial x^2} + m(t) \left( \frac{\partial u}{\partial x} \right)^2 = 0, \\
u(x, T(\alpha)) = \max_{\zeta \in \{ \pm 1 - M \}} \zeta x + (\lambda + 2c)\zeta^2,
\end{array} \right.
\]
where \( M = 2\alpha - 1 \).

This definition reduces to the original Parisi formula at zero temperature and external field in the case that \( T = 1 \) and \( M = 0 \) and when the infimum over \( \nu \) is taken.

This generalized Parisi formula relates to average extremal cuts on random regular graphs in the following way.

**Theorem 8** (Combination of Theorem 1.2 and Lemma 2.2 of [JS17]). Let \( T(\alpha) = 4\alpha(1 - \alpha) \). As \( n \to \infty \),
\[
\mathbb{E} \max_{H \sim G_{n,d}^{\text{reg}}} \max_{S \subseteq S_n} |\text{cut}_H(S) - \alpha(1 - \alpha)| \leq \frac{\sqrt{d}}{4n} \inf_{\nu, \lambda} \mathcal{P}_{T(\alpha)}^1(\nu, \lambda) + o_d(1/\sqrt{d}).
\]

**Proof.** By [JS17] Lemma 2.2, almost always over the randomness of \( W \) as \( n \to \infty \),
\[
\mathbb{E} \max_{S' \subseteq S_n} \frac{1}{n} \text{cut}_H(S') = \alpha(1 - \alpha) + \frac{1}{4} \sqrt{d} \mathbb{E} \max_{\sigma \in S_n(\alpha)} \frac{1}{n} H_W^{(1)}(\sigma) + o_d(\sqrt{d}).
\]
As alluded to in [JS17] Remark 1], Lemma 2.2 of [JS17] holds also for minimum cuts: this requires only changing some signs and invoking a few instances of sign-flip symmetry in the proof.
\[
\mathbb{E} \min_{S' \subseteq S_n} \frac{1}{n} \text{cut}_H(S') = \alpha(1 - \alpha) - \frac{1}{4} \sqrt{d} \mathbb{E} \max_{\sigma \in S_n(\alpha)} \frac{1}{n} H_W^{(1)}(\sigma) - o_d(\sqrt{d}).
\]

By the equivalence described earlier in this section and the fact that \( A_n(T(\alpha), 0) \subseteq A_n(T(\alpha), \varepsilon_n) \) for any sequence of \( \varepsilon_n > 0 \),
\[
\max_{\sigma \in S_n(\alpha)} \frac{1}{n} H_W^{(1)}(\sigma) \leq \max_{\sigma \in A_n(T(\alpha), \varepsilon_n)} \frac{1}{n} H_W^{(0)}(\sigma)
\]
\[
= \max_{\sigma \in A_n(T(\alpha), \varepsilon_n)} \frac{1}{n} H_W^{(0)}(\sigma)
\]
By [IS17] Theorem 1.2, for $\varepsilon_n \to 0$ slowly enough as $n \to \infty$, it holds almost surely over $W$ that

$$\lim_{n \to \infty} \max_{\sigma \in A_n(T(\alpha), \varepsilon_n)} \frac{1}{n} H_1^{(0)}(\sigma) = \inf_{\nu, \lambda} \mathcal{P}_{T(\alpha)}^1(\nu, \lambda).$$

Combining the above equations yields the theorem statement.

It is not yet known how to efficiently compute the exact value of the Parisi formula or its generalization. We circumvent this issue by providing an upper bound, by choosing a particularly simple measure $\nu$ to bound the infimum $\inf_{\nu, \lambda} \mathcal{P}_{T(\alpha)}^1(\nu, \lambda)$. Specifically, the choice of $\nu = c\delta_T$ with $m(t) = 0$ is known as the replica-symmetric ansatz [Mal19 Chapter 2], corresponding to the first of Parisi’s original sequence of estimates.

**Lemma 9.**

$$\inf_{\nu, \lambda} \mathcal{P}_{T(\alpha)}^1(\nu, \lambda) \leq 8\sqrt{\alpha(1 - \alpha)} \cdot \frac{1}{\sqrt{2\pi}} e^{-(\text{erf}^{-1}(2\alpha - 1))^2},$$

where erf is the Gauss error function $\text{erf}(x) = \frac{1}{\sqrt{\pi}} \int_{-x}^{x} e^{-t^2} dt$.

**Proof.** First we express $\int_0^T s \nu(s) = cT + \int_0^T tm(t) dt$ and reparameterize $\tilde{\lambda} = \lambda + 2c$ so that we can write

$$\inf_{\nu, \lambda} \mathcal{P}_{T(\alpha)}^1(\nu, \lambda) = \inf_{\nu, \lambda} \tilde{\mathcal{P}}_{T(\alpha)}^1(\nu, \lambda)$$

where $\tilde{\mathcal{P}}_{T(\alpha)}^1(\nu, \lambda)$ is the solution to

$$\begin{cases}
\frac{\partial u}{\partial t} + 2\frac{\partial^2 u}{\partial x^2} + m(t) \left(\frac{\partial u}{\partial x}\right)^2 = 0, & (t, x) \in [0, T) \times \mathbb{R}, \\
u(x, T) = \max_{\zeta \in \{\pm 1\}} \zeta x + \tilde{\zeta}^2,
\end{cases}$$

with $M = 2\alpha - 1$.

By taking $\nu(t) = c\delta_T$ so that $m(t) = 0$, we can upper-bound the infimum over $\nu$, so that

$$\inf_{\nu, \lambda} \mathcal{P}_{T(\alpha)}^1(\nu, \lambda) \leq \inf_{\tilde{\lambda}} \tilde{\mathcal{P}}_{T(\alpha)}^1(\tilde{\lambda}, \lambda) - \tilde{\lambda}T$$

and $\tilde{\mathcal{P}}_{T(\alpha)}^1(\tilde{\lambda}, \lambda)$ is the solution to

$$\begin{cases}
\frac{\partial u}{\partial t} + 2\frac{\partial^2 u}{\partial x^2} = 0, & (t, x) \in [0, T) \times \mathbb{R}, \\
u(x, T) = \max_{\zeta \in \{\pm 1\}} \zeta x + \tilde{\zeta}^2.
\end{cases}$$

By reparameterizing $t$ as $-t$ here, we can see that $u(x, 0)$ is simply the result of evolving $u(x, T)$ according to the heat equation with diffusivity constant 2 for a time of $T$. Evolution of the heat equation with diffusivity $k$ over a time of $T$ is equivalent to convolution with the Gaussian heat kernel $\exp(-x^2/(4kT)) / \sqrt{4\pi kT}$ [Eva10 Chapter 2.3], so

$$\tilde{\mathcal{P}}_{T(\alpha)}^1(\tilde{\lambda}, \lambda) = \frac{1}{\sqrt{8\pi T}} \int_{-\infty}^{\infty} e^{-z^2/(8T)} \left(\max_{\zeta \in \{\pm 1\}} \zeta (z + \tilde{\zeta}^2)\right) dz.$$ 

Thus

$$\inf_{\nu, \lambda} \mathcal{P}_{T(\alpha)}^1(\nu, \lambda) \leq \inf_{\lambda, \tilde{\lambda}} \frac{1}{\sqrt{8\pi T}} \int_{-\infty}^{\infty} e^{-z^2/(8T)} \left(\max_{\zeta \in \{\pm 1\}} \zeta z + \tilde{\zeta}^2\right) dz - \tilde{\lambda}T.$$
Now we calculate
\[
\begin{align*}
\max_{\zeta \in \{\pm 1\}^M} \zeta z + \hat{\lambda}^2 & = \max \left( -z - Mz + \hat{\lambda}(1 + 2M + M^2), z - Mz + \hat{\lambda}(1 - 2M + M^2) \right) \\
& = -Mz + \hat{\lambda}(1 + M^2) + \max(-z + 2M\hat{\lambda}, z - 2M\hat{\lambda}) \\
& = -Mz + \hat{\lambda}(1 + M^2) + |z - 2M\hat{\lambda}|,
\end{align*}
\]
so that
\[
\inf_{\nu,\lambda} P_{T(\alpha)}^1(\nu, \lambda) \leq \inf_{\lambda} \frac{1}{\sqrt{8\pi T}} \int_{-\infty}^{\infty} e^{-z^2/(8T)} \left( -Mz + \hat{\lambda}(1 + M^2) + |z - 2M\hat{\lambda}| \right) dz - \hat{\lambda}T.
\]
Partially evaluating the integral using the facts that a Gaussian probability density function integrates to 1 and, by oddness of the integrand, \(\int_{-\infty}^{\infty} ze^{-z^2/(8T)} dz = 0,\)
\[
\begin{align*}
\inf_{\nu,\lambda} P_{T(\alpha)}^1(\nu, \lambda) & \leq \inf_{\lambda} \frac{1}{\sqrt{8\pi T}} \int_{-\infty}^{\infty} e^{-z^2/(8T)} \left| z - 2M\hat{\lambda} \right| dz + \hat{\lambda}(1 - T + M^2).
\end{align*}
\]
Employing a change of variables \(z \to 2\sqrt{T}z\) to write the integral in terms of the normal Gaussian probability density \(\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-z^2/2}\) and also applying the identity \(1 - T = 1 + 4\alpha^2 - 4\alpha = M^2,\)
\[
\begin{align*}
\inf_{\nu,\lambda} P_{T(\alpha)}^1(\nu, \lambda) & \leq \inf_{\lambda} \int_{-\infty}^{\infty} \phi(z) \left| 2\sqrt{T}z - 2M\hat{\lambda} \right| dz + 2\hat{\lambda}M^2.
\end{align*}
\]
Focusing now on the integral,
\[
\begin{align*}
\int_{-\infty}^{\infty} \phi(z) \left| 2\sqrt{T}z - 2M\hat{\lambda} \right| dz & = \int_{M\hat{\lambda}/\sqrt{T}}^{\infty} \phi(z) \left( 2\sqrt{T}z - 2M\hat{\lambda} \right) dz + \int_{-\infty}^{M\hat{\lambda}/\sqrt{T}} \phi(z) \left( -2\sqrt{T}z + 2M\hat{\lambda} \right) dz \\
& = \int_{-\infty}^{-M\hat{\lambda}/\sqrt{T}} \phi(z) \left( -2\sqrt{T}z - 2M\hat{\lambda} \right) dz + \int_{-\infty}^{M\hat{\lambda}/\sqrt{T}} \phi(z) \left( -2\sqrt{T}z + 2M\hat{\lambda} \right) dz,
\end{align*}
\]
where we negated and flipped the limits of the first integral, which is equivalent to negating the odd part of the integrand while preserving the even part. Continuing to integrate, letting \(\Phi(z)\) denote the Gaussian cumulative density function,
\[
\begin{align*}
& = \int_{-\infty}^{-M\hat{\lambda}/\sqrt{T}} -2\sqrt{T}z \phi(z) dz + \int_{-\infty}^{M\hat{\lambda}/\sqrt{T}} -2\sqrt{T}z \phi(z) dz + 2M\hat{\lambda} \int_{-\infty}^{M\hat{\lambda}/\sqrt{T}} \phi(z) dz, \\
& = \left[ 2\sqrt{T} \phi(z) \right]_{-\infty}^{-M\hat{\lambda}/\sqrt{T}} + \left[ 2\sqrt{T} \phi(z) \right]_{-\infty}^{M\hat{\lambda}/\sqrt{T}} + 2M\hat{\lambda} \left( \Phi(M\hat{\lambda}/\sqrt{T}) - \Phi(-M\hat{\lambda}/\sqrt{T}) \right) \\
& = 4\sqrt{T} \phi(M\hat{\lambda}/\sqrt{T}) + 2M\hat{\lambda} \text{erf}(M\hat{\lambda}/\sqrt{2T}),
\end{align*}
\]
where we used evenness of \(\phi\) and the fact that \(\Phi(x) - \Phi(-x) = \text{erf}(x/\sqrt{2})\) in the last step. So, putting this evaluation of the integral into our previous expression,
\[
\begin{align*}
\inf_{\nu,\lambda} P_{T(\alpha)}^1(\nu, \lambda) & \leq \inf_{\lambda} 4\sqrt{T} \phi(M\hat{\lambda}/\sqrt{T}) + 2M\hat{\lambda} \text{erf}(M\hat{\lambda}/\sqrt{2T}) + 2\lambda M^2.
\end{align*}
\]
By finding the critical point of this expression with respect to \(\hat{\lambda}\), we find a value of \(\hat{\lambda} = -\sqrt{2T} \text{erf}^{-1}(M)/M\). Using this value for \(\hat{\lambda}\),
\[
\begin{align*}
\inf_{\nu,\lambda} P_{T(\alpha)}^1(\nu, \lambda) & \leq 4\sqrt{T} \phi(-\sqrt{2} \text{erf}^{-1}(M)) - 2M\lambda M + 2\lambda M^2 \\
& = 4\sqrt{T} \phi(\sqrt{2} \text{erf}^{-1}(M)).
\end{align*}
\]
\[
\Box
\]
We calculate the largest concrete value attained by the upper bound of the preceding lemma:

**Lemma 10.** For all $\alpha \in (0, 1)$,

$$\inf_{\nu, \lambda} \frac{\mathcal{P}_T^1(\nu, \lambda)}{4\alpha(1 - \alpha)} \leq 2\sqrt{\frac{2}{\pi}} = 1.595...$$

**Proof.** By Lemma 9 for $\alpha \in (0, 1)$,

$$\inf_{\nu, \lambda} \frac{\mathcal{P}_T^1(\nu, \lambda)}{4\alpha(1 - \alpha)} \leq \frac{2}{\sqrt{\alpha(1 - \alpha)}} \cdot \frac{1}{\sqrt{2\pi}} e^{-\left((\text{erf}^{-1}(2\alpha - 1))^2\right)} = f(\alpha).$$

Evaluated at $\alpha = 1/2$, this is equal to $2\sqrt{2/\pi}$, so we just need to show that the upper bound $f(\alpha)$ is maximized at $\alpha = 1/2$.

First we reparameterize $g(M) = f(\alpha)$ with $M = 2\alpha - 1$ so that

$$g(M) = \frac{1}{\sqrt{2\pi(1 - M^2)}} e^{-\left((\text{erf}^{-1}(M))^2\right)}$$

and we want to show that $g$ is maximized at 0. Using the product rule to take the derivative of $g$, since

$$\frac{d}{dM} \frac{1}{\sqrt{1-M^2}} = \frac{M}{(1-M^2)^{3/2}}$$

and

$$\frac{d}{dM} e^{-\left((\text{erf}^{-1}(M))^2\right)} = -\sqrt{\pi} \text{erf}^{-1}(M),$$

$$g'(M) = \frac{1}{\sqrt{2\pi(1 - M^2)}} \left( \frac{Me^{-\left((\text{erf}^{-1}(M))^2\right)}}{1 - M^2} - \sqrt{\pi} \text{erf}^{-1}(M) \right).$$

We take another monotonic reparameterization, introducing $\text{erf}(x)$ for $M$:

$$g'(\text{erf}(x)) = \frac{1}{\sqrt{2\pi(1 - \text{erf}(x)^2)}} \left( \frac{\text{erf}(x)e^{-x^2}}{1 - \text{erf}(x)^2} - \sqrt{\pi}x \right).$$

By Polya [P-45], $\text{erf}(x) < \sqrt{1 - e^{-4x^2/\pi}}$ so that $1 - \text{erf}(x)^2 \geq e^{-4x^2/\pi}$, so that, for $x < 0$ when $\text{erf}(x) < 0$,

$$g'(\text{erf}(x)) \geq \frac{1}{\sqrt{2\pi(1 - \text{erf}(x)^2)}} \left( \text{erf}(x)e^{(4/\pi - 1)x^2} - \sqrt{\pi}x \right).$$

And by Neuman [Neu13], $\text{erf}(x) \geq \frac{2x}{\sqrt{\pi}} e^{-x^2/3}$, so when $x < 0$,

$$g'(\text{erf}(x)) \geq \frac{1}{\sqrt{2\pi(1 - \text{erf}(x)^2)}} \left( \frac{2x}{\sqrt{\pi}} e^{(4/\pi - 4/3)x^2} - \sqrt{\pi}x \right).$$

And as $e^{(4/\pi - 4/3)x^2} \leq 1$, this makes it clear that $g'(\text{erf}(x))$ is positive when $x$ is negative, which means that $g$ is increasing on the negative part of its domain, which by evenness of $g$ means that $g$ is maximized at 0.

This gives us all the ingredients necessary to prove the main theorem of this section.

**Proof of Theorem** Combine Lemma 6, Corollary 8, and Lemma 10 with the fact that $E_{S \in \mathcal{S}_a \text{ cut}_H(S')} = n\alpha(1 - \alpha).$
3 Analysis for small cuts

In this section, we demonstrate that the number of edges crossing a cut \((S, V - S)\) deviates no more from its expectation than by a \(\frac{1}{\sqrt{d}}\) factor with high probability when \(|S|\) is small.

**Theorem 11** (Small Set Regime for Cut Sparsification). There exists sufficiently large \(n \geq 0\) and constant \(d \geq 0\) such that, for any \(S \subset V\) where \(|S| = \alpha_0 n\) and \(\alpha_0 \leq \frac{1}{100}\), a sample \(H \sim \mathcal{G}_{n,d}^\text{reg}\) admits with probability 
\[
1 - o_n(1) 
\]

\[
\frac{\text{cut}_H(S)}{\mathbb{E}_{H \sim \mathcal{G}_{n,d}^\text{reg}}[\text{cut}_H(S)]} - 1 \leq \frac{1.5}{\sqrt{d}}
\]

Our analysis will require the use of a Doob martingale.

**Definition 12.** Given random variables \(A\) and \((Z_\ell)_{\ell=1}^N\) sampled from a common probability space, their associated Doob martingale is given by random variables \((X_\ell)_{\ell=0}^N\) where \(X_0 = \mathbb{E}[A]\) and 
\[
X_\ell = \mathbb{E}[A \mid Z_1, \ldots, Z_\ell]
\]

We note that \((Z_\ell)\) is often called the filtration that \((X_\ell)\) is defined with respect to. For a Doob martingale \((X_\ell)_{\ell=0}^N\), we denote its martingale difference sequence by \((Y_\ell)\) where 
\[
Y_\ell = X_\ell - X_{\ell-1}
\]

and its quadratic characteristic sequence by \((\langle X \rangle_\ell)\) where 
\[
\langle X \rangle_\ell = \sum_{r=1}^{\ell} \mathbb{E}[Y_r^2 \mid Z_1, \ldots, Z_{r-1}]
\]

As mentioned previously, the small cuts analysis will quantify the number of edges contained entirely within a cut and use the fact that, in a regular graph, the number of edges across a cut is uniquely determined by the number of edges within the cut. For a graph \(H\), we will denote \(e_H(S)\) by the number of edges \(e \in E_H\) with both endpoints contained within \(S \subseteq V\). When \(H\) is sampled from a distribution, it is understood that \(e_H(S)\) is a random variable.

3.1 Martingale Construction

Consider \(H\) a random regular graph drawn from \(\mathcal{G}_{n,d}^\text{reg}\). Enumerate its vertices by \(i \in [n]\), and its constituent matchings by \(m \in [d]\). For \(S \subset V\) of size \(|S| = k\), we will assume without loss of generality that \(S = \{1, \ldots, k\}\). Next, consider the sequence of matching-vertex pairs \(\{(m_\ell, i_\ell)\}_{\ell=1}^N\) enumerating each \((m, i) \in [d] \times [k - 1]\) where \(N = d \cdot (k - 1)\). Let us now define the sequence of random variables \((Z_\ell)_{\ell=1}^N\) where \(Z_\ell = Z_{(m_\ell, i_\ell)} \in V\) is the vertex that matching \(m_\ell\) matches \(i_\ell\) in \(V\) to in \(H\). Note that 
\[
e(S) = \sum_{\ell=1}^{N} 1\{Z_\ell \in [k]\ \text{and} \ Z_\ell > i_\ell\}
\]

We now construct the Doob martingale on \(e(S)\) using \((Z_\ell)\) as a filtration. The matched edge-vertex reveal martingale \((X_\ell)_{\ell=0}^N\) is given by 
\[
X_\ell = \mathbb{E}[e(S) \mid Z_1, \ldots, Z_\ell].
\]

One should think of this martingale as counting the number of edges contained within \(S\). As an increasing number of \(Z_\ell\) are conditioned on, information regarding what edges exist in \(H\) is revealed in an ordered way. The order in which an edge is revealed is given by the enumeration of the vertices adjacent to the edge, and the matching the edge belonged to when \(H\) was first sampled from \(d\) random matchings. Additionally, notice that vertex \(k\) is excluded from such pairs \((m_\ell, i_\ell)\). This is because \(m_\ell\) can only match \(k\) to \(i_\ell < k\) for the edge to be contained in \(S\). Consequently, revealing edges adjacent to \(\{1, \ldots, k - 1\}\) suffices to uniquely determine \(e(S)\).

Our analysis of \((X_\ell)\) will now proceed as follows. We first determine bounds on the martingale difference and quadratic characteristic of \((X_\ell)\). These bounds are then used by a standard martingale concentration result to argue that the number of edges contained within \(S\) cannot deviate far from its expectation. Finally, we complete the proof of Theorem 11 by using the fact that concentration in the number of edges within \(S\) immediately implies concentration in the number of edges in \(\text{cut}_H(S)\) when \(H\) is a random \(d\) regular graph.
3.2 Properties of the Martingale

To bound the martingale difference and quadratic characteristic of \((X_t)\), we examine how \(e(S)\) behaves as an increasing number of \(Z_t\) are conditioned on. We say that \(\{z_1, \ldots, z_t\} \subseteq [n]\) is a valid realization of \(Z_t\) if there exists a \(d\) regular graph \(H\) such that each \((i_t, z_t) \in E_H\). When \(z_1, \ldots, z_t\) are deterministically provided, we can define the following quantities.

1. \(a_t = a_t(z_1, \ldots, z_t)\) is the number of remaining vertices in \(S\) that remain unmatched as a function of \(z_1, \ldots, z_t\). We denote \(a_0 = |S| = k\).

2. \(b_t = b_t(z_1, \ldots, z_t)\) is the number of remaining vertices in \(V\) that remain unmatched as a function of \(z_1, \ldots, z_t\). We denote \(b_0 = |V| = n\).

We will also consider \(a_t(z_1, \ldots, z_{t-1}, Z_t)\) and \(b_t(z_1, \ldots, z_{t-1}, Z_t)\) where \(Z_t\) is sampled according to the filtration specified in \(X_t\). In this case, \(a_t\) and \(b_t\) are random variables distributed according to that of the random variable \(Z_t\). When \(z_1, \ldots, z_t\) are a valid realization, we can demonstrate a bound on the ratio \(\frac{a_t}{b_t}\).

**Lemma 13.** Let \(H \sim G_{n,d}^{\text{reg}}\) be a random regular graph, \(S \subseteq V\) such that \(|S| = k < \frac{n}{2}\), and \(N = d \cdot (k - 1)\). For any \(0 \leq \ell \leq N\) and valid realization \(z_1, \ldots, z\ell\), it happens that

\[
\frac{a_\ell}{b_\ell} \leq \frac{k}{n}
\]

**Proof.** We proceed via induction on \(\ell\). For the base case, \(\ell = 0\) implies we have \(\frac{a_0}{b_0} = \frac{k}{n}\). Let us now assume the lemma holds for \(\ell - 1\). Notice that any choice of \(z_\ell\) admits one of three cases.

1. \(z_\ell \in [k]\) and \(z_\ell > i_{\ell}\). This corresponds to \(z_\ell\) revealing the existence of an edge not previously known to be in \(S\) when considering only \(z_1, \ldots, z_{\ell-1}\). Hence \(a_\ell = a_{\ell-1} - 2\) and \(b_\ell = b_{\ell-1} - 2\) and

\[
\frac{a_\ell}{b_\ell} = \frac{a_{\ell-1} - 2}{b_{\ell-1} - 2} \leq \frac{a_{\ell-1}}{b_{\ell-1}} \leq \frac{k}{n}
\]

with the last inequality following by the inductive hypothesis.

2. \(z_\ell \in [k]\) however \(z_\ell < i_{\ell}\). This corresponds to \(i_{\ell}\) having already been matched to \(j \in [k]\) as revealed by \(z_j\) for \(j < \ell\). Thus, \(a_\ell = a_{\ell-1}\) and \(b_\ell = b_{\ell-1}\) and the inductive hypothesis is maintained.

3. \(z_\ell \notin [k]\) however \(z_\ell > i_{\ell}\). This corresponds to \(m_\ell\) matching \(i_{\ell}\) to a vertex not in \(S\). Thus \(a_\ell = a_{\ell-1} - 1\) and \(b_\ell = b_{\ell-1} - 2\) and so

\[
\frac{a_\ell}{b_\ell} = \frac{a_{\ell-1} - 1}{b_{\ell-1} - 2} \leq \frac{a_{\ell-1} - 1}{b_{\ell-1} - n/k} = \frac{a_{\ell-1} - k/n \cdot n/k}{b_{\ell-1} - n/k} < \frac{n}{k}
\]

where the second inequality follows as \(k \leq \frac{n}{2}\) and the last inequality follows by the following principle:

\[
\frac{p}{q} < r \implies \frac{p - rw}{q - w} < r \quad \text{for all } p, q, r, w \in \mathbb{Z}_{\geq 0} \quad \text{and we choose } p = a_{\ell-1}, q = b_{\ell-1}, r = \frac{k}{n}, \text{ and } w = \frac{n}{k}.
\]

In all cases, we have that the lemma holds for \(\ell\), thus completing the induction. \(\Box\)

We now bound the martingale difference of \((X_\ell)\).

**Lemma 14.** Let \(H \sim G_{n,d}^{\text{reg}}\) be a random regular graph, \(S \subseteq V\) such that \(|S| = k < \frac{n}{2}\), and \(N = d \cdot (k - 1)\). Then \(Y_\ell\) associated with \((X_\ell)_{\ell=0}^N\) admits \(|Y_\ell| \leq 1\) for all \(i \in [N]\).

**Proof.** As the \(d\) constituent matchings of \(H\) are sampled independently and uniformly at random, it suffices to assume \(d = 1\), and hence \(N = k - 1\). Now let \(\phi(a, b)\) be the expected number of edges contained inside a subset of \(a\) vertices in a uniformly sampled perfect matching on \(b\) vertices. \(\phi(a, b)\) is the quantity

\[
\phi(a, b) = \binom{a}{2} \cdot \frac{1}{b - 1}
\]
For a given \( \ell \), we begin by fixing a valid realization of random variables \( Z_1 = z_1, \ldots, Z_\ell = z_\ell \) and observe that \( X_{\ell-1} \) can be computed as

\[
X_{\ell-1} = \mathbb{E}[e(S) \mid Z_1 = z_1, \ldots, Z_{\ell-1} = z_{\ell-1}]
\]

\[
= \mathbb{E} \left[ \sum_{r=1}^{N} \mathbf{1}\{Z_r \in [k] \text{ and } Z_r > r\} \mid Z_1 = z_1, \ldots, Z_{\ell-1} = z_{\ell-1} \right]
\]

\[
= \sum_{r=1}^{\ell-1} \mathbf{1}\{z_r \in [k] \text{ and } z_r > r\} + \phi(a_{\ell-1}, b_{\ell-1})
\]

where we have used linearity of expectations to separate terms of \( e(S) \) that have been conditioned to be \( z_r \), and those that remain random. \( X_{\ell} \) is similarly given by the following.

\[
X_{\ell} = \sum_{r=1}^{\ell} \mathbf{1}\{z_r \in [k] \text{ and } z_r > r\} + \phi(a_{\ell}, b_{\ell})
\]

We can now compute \( Y_{\ell} \) as

\[
Y_{\ell} = X_{\ell} - X_{\ell-1} = \mathbf{1}\{z_\ell \in [k] \text{ and } z_\ell > \ell\} + (\phi(a_{\ell}, b_{\ell}) - \phi(a_{\ell-1}, b_{\ell-1}))
\]

Let us denote \( w_\ell = \mathbf{1}\{z_\ell \in [k] \text{ and } z_\ell > \ell\} \). It is either the case that \( w_\ell = 1 \) or \( w_\ell = 0 \). Assuming \( w_\ell = 1 \), we first demonstrate that \( Y_{\ell} \leq 1 \). In this case vertex \( \ell \) is adjacent to \( z_\ell \in S \). Consequently, \( a_\ell = a_{\ell-1} - 2 \) and \( b_\ell = b_{\ell-1} - 2 \) and we have

\[
Y_{\ell} = w_\ell + (\phi(a_{\ell-1} - 2, b_{\ell-1} - 2) - \phi(a_{\ell-1}, b_{\ell-1}))
\]

\[
= 1 + \left( \frac{a_{\ell-1} - 2}{2} \right) \cdot \frac{1}{b_{\ell-1} - 3} - \left( \frac{a_{\ell-1}}{2} \right) \cdot \frac{1}{b_{\ell-1} - 1}
\]

\[
= 1 + \left( \frac{a_{\ell-1} - 2}{2} \right) \cdot \left( \frac{1}{b_{\ell-1} - 3} - \frac{1}{b_{\ell-1} - 1} \right) - \frac{2a_{\ell-1} - 3}{b_{\ell-1} - 1}
\]

\[
\leq 1 + \frac{2a_{\ell-1} - 3}{b_{\ell-1} - 1} - \frac{2a_{\ell-1} - 3}{b_{\ell-1} - 1}
\]

\[
= 1
\]

as required. Completing the analysis for \( w_\ell = 1 \), we demonstrate that \( Y_{\ell} \geq 0 \).

\[
Y_{\ell} = 1 + \left( \frac{a_{\ell-1} - 2}{2} \right) \cdot \left( \frac{1}{b_{\ell-1} - 3} - \frac{1}{b_{\ell-1} - 1} \right) - \frac{2a_{\ell-1} - 3}{b_{\ell-1} - 1}
\]

\[
\geq 1 - \frac{2a_{\ell-1}}{b_{\ell-1}}
\]

\[
\geq 1 - \frac{2k}{n}
\]

The last inequality follows from an application of Lemma \( \text{[13]} \). Suppose now that \( w_\ell = 0 \). Since \( (X_\ell)_\ell = 1 \) is a Doob martingale, \( \mathbb{E}[Y_{\ell}] = 0 \) for all \( \ell \). This implies that \( Y_{\ell} < 0 < 1 \) since in fact \( Y_{\ell} > 0 \) whenever \( w_\ell = 1 \). All that remains to demonstrate is that \( Y_{\ell} > -1 \). Observe that \( w_\ell = 0 \) implies one of two cases.

1. \( z_\ell \in [k] \) however \( z_\ell < \ell \). Then \( a_\ell = a_{\ell-1} \) and \( b_\ell = b_{\ell-1} \) implying \( Y_{\ell} = 0 \).
2. \( z_\ell \notin [k] \) however \( z_\ell > \ell \). Then \( a_\ell = a_{\ell-1} - 1 \) and \( b_\ell = b_{\ell-1} - 2 \). We then compute \( Y_{\ell} \) as

\[
Y_{\ell} = w_\ell + (\phi(a_{\ell-1} - 1, b_{\ell-1} - 2) - \phi(a_{\ell-1}, b_{\ell-1}))
\]
Pr \left[ X_\ell \right] = \frac{a_\ell - 1}{b_\ell - 1} \cdot \frac{1}{b_\ell - 3} + \frac{a_\ell - 1}{b_\ell - 1} - \frac{2}{b_\ell - 1 - 1}

\geq - \frac{k}{n}

where the last inequality follows from Lemma 13.

In both cases, \( Y_\ell > -1 \) since \( k \leq \frac{n}{2} \), thus completing the proof.

Lemma 14 precisely computes how \( X_\ell \) behaves as \( \ell \) increases. If it is revealed that \( m_\ell \) matches \( Z_\ell \) to \( i_\ell < Z_\ell \) (thus within \( S \)), then \( X_\ell \) increases by some amount in the interval \( [1 - \frac{2k}{n}, 1] \). Otherwise \( X_\ell \) decreases by an amount in \( [-\frac{2k}{n}, 0] \). Using this enables us to bound the quadratic characteristic, and understand how the variance of \( e(S) \) accumulates as subsequent \( Z_\ell \) are conditioned on.

Lemma 15. Let \( H \sim \mathcal{G}_{n,d}^{\text{reg}} \) be a random regular graph, \( S \subseteq V \) such that \( |S| = k < \frac{n}{2} \).\( N = d \cdot (k-1) \). For \( (X_\ell)_{\ell=0}^N \), we have \( \langle X \rangle_N \leq \frac{k(k-1)d}{n-2k} \) with probability 1.

Proof. It is sufficient to demonstrate \( \langle X \rangle_\ell - \langle X \rangle_{\ell-1} \leq \frac{k}{n-2k} \) for all \( \ell \in [N] \) as we would have

\[
\langle X \rangle_N = \sum_{\ell=2}^N (\langle X \rangle_\ell - \langle X \rangle_{\ell-1}) \leq N \cdot \frac{k}{n-2k} \leq \frac{k(k-1)d}{n-2k}
\]

Assume without loss of generality that \( d = 1 \) and fix \( \ell \) along with a valid realization \( Z_1 = z_1, \ldots, Z_{\ell-1} = z_{\ell-1} \). One can calculate the following fact

\[
\langle X \rangle_\ell - \langle X \rangle_{\ell-1} = \text{Var}[1 \{Z_\ell \in [k] \text{ and } Z_\ell > \ell\} = 1]
\]

Denote the indicator random variable \( W_\ell = 1 \{Z_\ell \in [k] \text{ and } Z_\ell > \ell\} \). To bound the variance of the indicator, we seek to determine \( \text{Pr}[W_\ell = 1] \) with randomness taken over choice of \( Z_\ell \). Recall that

\[
Y_\ell = W_\ell + (\phi(a_\ell, b_\ell) - \phi(a_{\ell-1}, b_{\ell-1}))
\]

Note \( Y_\ell \) is a random quantity since \( W_\ell, a_\ell = a_{\ell}(z_1, \ldots, z_{\ell-1}, Z_\ell), b_\ell = b_{\ell}(z_1, \ldots, z_{\ell-1}, Z_\ell) \) each depend on a sample \( Z_\ell \). It remains however that \( \mathbb{E}[Y_\ell] = 0 \) implying

\[
0 = \text{Pr}[W_\ell = 1] + \mathbb{E}[(\phi(a_\ell, b_\ell) - \phi(a_{\ell-1}, b_{\ell-1}))]
\]

and hence

\[
\text{Pr}[W_\ell = 1] = \mathbb{E}[(\phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_\ell, b_\ell))]
\]

Let us condition the expectation as follows.

\[
\text{Pr}[W_\ell = 1] = \text{Pr}[W_\ell = 0] \cdot \mathbb{E}[(\phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_\ell, b_\ell) \mid W_\ell = 0] + \text{Pr}[W_\ell = 1] \cdot \mathbb{E}[(\phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_\ell, b_\ell) \mid W_\ell = 1]
\]

\[
\leq \mathbb{E}[(\phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_\ell, b_\ell) \mid W_\ell = 0] + \text{Pr}[W_\ell = 1] \cdot \mathbb{E}[(\phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_\ell, b_\ell) \mid W_\ell = 1]
\]

Implies

\[
\text{Pr}[W_\ell = 1] \leq \frac{\mathbb{E}[(\phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_\ell, b_\ell) \mid W_\ell = 0] + \mathbb{E}[(\phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_\ell, b_\ell) \mid W_\ell = 1]}{1 - \mathbb{E}[(\phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_\ell, b_\ell) \mid W_\ell = 1]}
\]
Recall from the proof of Lemma 14 that $Y_{\ell} \geq 1 - \frac{2k}{n}$ if $W_{\ell} = 1$, while $Y_{\ell} \geq -\frac{k}{n}$ if $W_{\ell} = 0$. This means

$$
\mathbb{E} \left[ \phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_{\ell}, b_{\ell}) \mid W_{\ell} = 0 \right] \leq \frac{k}{n} \\
\mathbb{E} \left[ \phi(a_{\ell-1}, b_{\ell-1}) - \phi(a_{\ell}, b_{\ell}) \mid W_{\ell} = 1 \right] \geq \frac{2k}{n}
$$

and thus we have

$$\Pr \left[ W_{\ell} = 1 \right] \leq \frac{k}{n - 2k}$$

Finally, as $W_{\ell}$ is an indicator random variable, its variance is at most that given by a Bernoulli random variable with success probability $\frac{k}{n - 2k}$. We conclude with

$$\langle X \rangle_{\ell} - \langle X \rangle_{\ell-1} = \text{Var}[W_{\ell}] \leq \Pr[W_{\ell} = 1] \leq \frac{k}{n - 2k}$$

as required.

3.3 Concentration Analysis

We now determine how $(X_{\ell})$ concentrates. In [FGL12], the following Azuma-like inequality is proven for martingales.

**Theorem 16** (Remark 2.1 combined with equations (11) and (13) of [FGL12]). Let $(X_{\ell})_{\ell=0}^N$ be a martingale with martingale differences $(Y_{\ell})$ satisfying $Y_{\ell} \leq 1$ for all $0 \leq \ell \leq N$. For every $0 \leq x \leq N$ and $\nu \geq 0$, we have

$$
\Pr \left[ \left| X_N - X_0 \right| \geq x \right. \text{ and } \langle X \rangle_N \leq \nu^2 \left. \right] \leq 2 \exp \left\{ -\frac{\nu^2}{x + \nu^2} \left( \frac{x+\nu^2}{x+\nu^2} \right)^{x+\nu^2} \right\}
$$

The concentration inequalities of [FGL12] are one-sided inequalities as they are stated for supermartingales. We use the double-sided version, incurring an additional factor of 2 after taking a union bound with the negative of $(X_{\ell})$. We start with a generic application of Theorem 16 to fit our setting.

**Lemma 17.** For $H$ a random regular graph drawn from $G_{n,d}^{\text{reg}}$, $S \subseteq V$ such that $|S| = k < \frac{n}{3}$, and $\delta > 0$, we have the following.

$$
\Pr \left[ \left| e(S) - \mathbb{E}[e(S)] \right| \geq \delta \cdot \mathbb{E}[e(S)] \right] \leq 2 \exp \left\{ -\mathbb{E}[e(S)] \cdot \left( \delta + C \cdot \ln \left( \frac{\delta}{C} + 1 \right) - \delta \right) \right\}
$$

where $C = \frac{2(n-1)}{n-2k}$

**Proof.** Let $x$ and $\nu^2$ be given by the following.

$$x = \delta \cdot \mathbb{E}[e(S)] = \delta \cdot \left( \frac{k}{2} \right) \frac{d}{n-1}$$

$$\nu^2 = \frac{k(k-1)d(n-k)}{n-2k} = \left( \frac{k}{n} \right) \frac{d}{n-1} \cdot \frac{2(n-1)}{n-2k}$$

By Lemma 15, we have that $\langle X \rangle_N \leq \nu^2$ with probability one. Hence

$$
\Pr \left[ |X_0 - X_N| \geq x \text{ and } \langle X \rangle_n \right] = \Pr \left[ |X_0 - X_N| \geq x \right] = \Pr \left[ |e(S) - \mathbb{E}[e(S)]| \geq \delta \mathbb{E}[e(S)] \right]
$$

Applying Theorem 16 for the choice of $x, \nu^2$ above then concludes with the required bound. 

15
As mentioned previously, the purpose of choosing to study edges contained entirely in a set $S$ is because the number of edges contained entirely within $S$ can be written as a sum of fewer indicator random variables than the number of edges crossing the cut $(S, V - S)$. The difference between $(\binom{n}{k})$ and $k(n-k)$ is not negligible (in particular for $k$ small) and we take advantage by further splitting our analysis of small cuts depending on the size of $k$.

A critical point is that one can apply tighter approximations of the exponentiated term in Lemma 17 depending on the size of $k$. When $k \geq O(n/\sqrt{d})$, applying Lemma 30 yields tighter concentration, while it is better to approximate via Lemma 31 when $k \leq O(n/\sqrt{d})$. We further remark that though we study the number of edges contained entirely in $S$, justifying that $H$ cut sparsifies $G$ still requires us to compute the deviation of the number of edges crossing $(S, V - S)$. Consequently, a $\frac{\delta}{C} - 1$ term will appear in our choice of $\delta$ due to scaling between edges contained within $S$ and crossing $(S, V - S)$. Let us now summarize the concentration bounds we use in each case via the following lemma.

**Lemma 18.** There exists a sufficiently large choice of $n \geq 0$ and $d \geq 0$ constant such that given a random draw $H \sim G_{n,d}^{reg}$ and any $S \subset V$ such that $|S| = k$ where $2 \leq k \leq \frac{n}{100}$, the following statements hold

1. If $\frac{\delta}{C} < 1$, then
   \[
   \Pr \left[ |e(S) - E[e(S)]| \geq \delta \cdot E[e(S)] \right] \leq 2 \exp \left( - \frac{25}{k^2 d n} \cdot \delta^2 \right)
   \] (6)

2. If $\frac{\delta}{C} \geq 1$, then
   \[
   \Pr \left[ |e(S) - E[e(S)]| \geq \delta \cdot E[e(S)] \right] \leq 2 \exp \left( - \frac{49}{800} \cdot \frac{k^2 d}{n} \cdot \delta \ln \delta \right)
   \] (7)

where $C = \frac{2(n-1)}{n-2k}$.

**Proof.** When $\frac{\delta}{C} < 1$, we can apply Lemma 30 to approximate $(\delta + C) \cdot \ln \left( \frac{\delta}{C} + 1 \right)$ in Lemma 17 as follows

\[
\Pr \left[ |e(S) - E[e(S)]| \geq \delta \cdot E[e(S)] \right] \leq 2 \exp \left( - E[e(S)] \cdot \left[ (\delta + C) \cdot \ln \left( \frac{\delta}{C} + 1 \right) - \delta \right] \right)
\]
\[
\leq 2 \exp \left( - E[e(S)] \cdot \left[ \delta + \frac{\delta^2}{3C} - \delta \right] \right)
\]
\[
= 2 \exp \left( - E[e(S)] \cdot \frac{\delta^2}{3C} \right)
\]

Expanding $C$ and the expectation, we derive

\[
\exp \left\{ - E[e(S)] \cdot \frac{\delta^2}{3C} \right\} = \exp \left\{ - \frac{k}{2} \cdot \frac{d}{n-1} \cdot \frac{\delta^2}{3} \cdot \frac{n-2k}{2(n-1)} \right\}
\]
\[
= \exp \left\{ - \frac{k^2 d}{n} \cdot \delta^2 \cdot \frac{1}{12} \cdot \left( 1 - \frac{1}{k} \right) \cdot \left( 1 + \frac{1}{n-1} \right)^2 \cdot \left( 1 - \frac{2k}{n} \right) \right\}
\]

Noticing that with large enough $n$, and as $k \leq \frac{n}{100}$, we have that
\[
\exp \left\{ - \frac{k^2 d}{n} \cdot \delta^2 \cdot \frac{1}{12} \cdot \left( 1 - \frac{1}{k} \right) \cdot \left( 1 + \frac{1}{n-1} \right)^2 \cdot \left( 1 - \frac{2k}{n} \right) \right\}
\]
\[
\leq \exp \left\{ - \frac{k^2 d}{n} \cdot 0.99 \cdot \frac{1}{12} \cdot \frac{98}{100} \right\}
\]
\[
\leq \exp \left\{ - \frac{2}{25} \cdot \frac{k^2 d}{n} \cdot \delta^2 \right\}
\]
as required. If \( \frac{\delta}{C} \geq 1 \), then we can apply Lemma 41 to approximate \((\delta + C) \cdot \ln \left(\frac{1}{\delta} + 1\right)\) as follows

\[
\Pr \left[ |e(S) - \mathbb{E}[e(S)]| \geq \delta \mathbb{E}[e(S)] \right] \leq 2 \exp \left( -\frac{\mathbb{E}[e(S)]}{2C} \cdot \delta \ln \delta \right)
\]

Expanding \( C \) and the expectation, we derive

\[
\exp \left( -\frac{\mathbb{E}[e(S)]}{2C} \cdot \delta \ln \delta \right) = \exp \left\{ -\frac{k}{2} \cdot \frac{d}{n-1} \cdot \frac{n-2k}{2(n-1)} \cdot \delta \ln \delta \cdot \frac{1}{2} \right\}
\]

\[
= \exp \left\{ -\frac{k^2d}{n} \cdot \delta \ln \delta \cdot \left( \frac{k-1}{k} \right) \cdot \left( \frac{n}{n-1} \right)^2 \cdot \left( 1 - \frac{2k}{n} \right) \cdot \frac{1}{8} \right\}
\]

Since \( 2 \leq k \leq \frac{n}{100} \), and for large enough \( n \), we have that

\[
\exp \left\{ -\frac{k^2d}{n} \cdot \delta \ln \delta \cdot \left( \frac{k-1}{k} \right) \cdot \left( \frac{n}{n-1} \right)^2 \cdot \left( 1 - \frac{2k}{n} \right) \cdot \frac{1}{8} \right\} \leq \exp \left\{ -\frac{k^2d}{n} \cdot \delta \ln \delta \cdot \frac{1}{2} \cdot \frac{98}{100} \cdot \frac{1}{8} \right\}
\]

\[
= \exp \left( -\frac{49}{800} \cdot \frac{k^2d}{n} \cdot \delta \ln \delta \right)
\]

as required. \( \square \)

We now compute the probability that the number of edges contained within \( S \) deviates far from its expectation. We remark that our choice of \( C \) and \( \delta = (\frac{k}{n} - 2) \cdot \frac{1}{\sqrt{d}} \) imply that \( \frac{\delta}{C} \) grows approximately as \( \frac{n}{k \sqrt{d}} \). In the subsequent proof of Lemma 19 the case of \( \frac{\delta}{C} < 1 \) is analogous to when \( k \geq \Omega(n/\sqrt{d}) \) while \( \frac{\delta}{C} \leq 1 \) corresponds to \( k \leq O(n/\sqrt{d}) \).

**Lemma 19.** There exists a sufficiently large choice of \( n \geq 0 \) and \( d \geq 0 \) constant such that for \( H \sim G_{n,d}^{\text{reg}} \) and any \( S \subset V \) such that \( |S| = k \) where \( 2 \leq k \leq \frac{n}{100} \), we have

\[
\Pr \left[ |e(S) - \mathbb{E}[e(S)]| \geq \delta \mathbb{E}[e(S)] \right] \leq 2 \left( \frac{n}{k} \right)^{1.01}
\]

where \( \delta = (\frac{k}{n} - 2) \cdot \frac{1}{\sqrt{d}} \)

**Proof.** With \( C = \frac{2(n-1)}{n-2k} \), suppose \( \frac{\delta}{C} < 1 \), expanding \( \delta \) in the bound given by equation 6, we have

\[
\Pr \left[ |e(S) - \mathbb{E}[e(S)]| \geq \delta \mathbb{E}[e(S)] \right] \leq 2 \exp \left( -\frac{2}{25} \cdot \frac{k^2d}{n} \cdot \delta^2 \right) = 2 \exp \left\{ -\frac{2}{25} \cdot \frac{k^2d}{n} \cdot \left( \frac{n}{k} - 2 \right)^2 \cdot \frac{1.5^2}{d} \right\}
\]

We now demonstrate how to upper bound this quantity by \( \left( \frac{n}{k} \right)^{1.01} \). It is equivalent to demonstrate

\[
\left( \frac{n}{k} \right)^{1.01} \leq \exp \left\{ \frac{2}{25} \cdot \frac{k^2d}{n} \cdot \left( \frac{n}{k} - 2 \right)^2 \cdot \frac{1.5^2}{d} \right\}
\]

Taking the natural logarithm of both sides, and performing a change of variables \( \alpha = \frac{k}{n} \), we have that

\[
1.01 \ln \left( \left( \frac{n}{\alpha n} \right) \right) \leq \frac{2}{25} \cdot \frac{1.5^2}{n} \cdot \alpha^2 \left( \frac{1}{\alpha} - 2 \right)^2
\]

As \( \ln \left( \left( \frac{n}{\alpha n} \right) \right) \leq n \cdot H(\alpha) \) where \( H \) denotes the binary entropy function, it is sufficient to demonstrate

\[
H(\alpha) \leq 0.18 \cdot (1 - 2\alpha)^2
\]
which holds for $\alpha \leq \frac{1}{100}$. Now suppose $\frac{d}{n} \geq 1$. Expanding $\delta$ in equation 7, we have the following

$$\Pr \left[ |e(S) - \mathbb{E}[e(S)]| \geq \delta \mathbb{E}[e(S)] \right] \leq 2 \exp \left\{ - \frac{49}{800} \cdot \frac{k^2 d}{n} \cdot \delta \ln \delta \right\}$$

$$= 2 \exp \left\{ - \frac{49}{800} \cdot \frac{k^2 d}{n} \cdot \frac{n}{k} \cdot \frac{1.5}{\sqrt{d}} \cdot \ln \left( \frac{n}{k} - 2 \cdot \frac{1.5}{\sqrt{d}} \right) \right\}$$

Notice that since $k \leq \frac{n}{100}$, we have that $1 - \frac{2k}{n} \geq \frac{98}{100}$ meaning the expression can be upper bounded by

$$\exp \left\{ - \frac{49}{800} \cdot \frac{k^2 d}{n} \cdot \frac{n}{k} \cdot \frac{1.5}{\sqrt{d}} \cdot \ln \left( \frac{n}{k} - 1 \cdot \frac{1.5}{\sqrt{d}} \right) \right\} \leq \exp \left\{ - \frac{49}{800} \cdot \frac{98}{100} \cdot \frac{1.5}{k^2 d} \cdot \ln \left( \frac{1.5n}{k^2 d} \cdot \frac{98}{100} \right) \right\}$$

We next claim the following intermediate upper bound.

$$\exp \left\{ - \frac{49}{800} \cdot \frac{98}{100} \cdot \frac{1.5}{k^2 d} \cdot \ln \left( \frac{1.5n}{k^2 d} \cdot \frac{98}{100} \right) \right\} \leq \left( \frac{n}{\sqrt{k^2 d} \cdot 1.5 \cdot 1.5 - 5} \right)^{-1.01}$$

It is again equivalent to demonstrate the following

$$1.01 \cdot \ln \left( \left( \frac{n}{\sqrt{k^2 d} \cdot 1.5 \cdot 1.5 - 5} \right) \right) \leq \frac{49}{800} \cdot \frac{98}{100} \cdot \frac{1.5}{k^2 d} \cdot \ln \left( \frac{1.5n}{k^2 d} \cdot \frac{98}{100} \right)$$

However, because $\ln \left( \frac{n}{k} \right) \leq k \ln \left( \frac{n}{k} \right)$, it suffices to demonstrate

$$1.01 \cdot \frac{\sqrt{k^2 d}}{1.5 \cdot 100} \cdot \frac{98}{150} \cdot \ln \left( 150 \cdot \frac{1.5n}{k^2 d} \cdot \frac{98}{100} \right) \leq \frac{49}{800} \cdot \frac{98}{100} \cdot \frac{1.5}{k^2 d} \cdot \ln \left( \frac{1.5n}{k^2 d} \cdot \frac{98}{100} \right)$$

which is equivalent to

$$\ln \left( 150 \cdot \frac{1.5n}{k^2 d} \cdot \frac{98}{100} \right) \leq \frac{49}{800} \cdot \left( \frac{98}{100} \right)^2 \cdot 1.5^2 \cdot \frac{150}{1.01} \cdot e \cdot \ln \left( \frac{1.5n}{k^2 d} \cdot \frac{98}{100} \right)$$

Because 7 lower bounds the constant on the right hand side, it is enough to show

$$\ln \left( 150 \cdot \frac{1.5n}{k^2 d} \cdot \frac{98}{100} \right) \leq 7 \cdot \ln \left( \frac{1.5n}{k^2 d} \cdot \frac{98}{100} \right)$$

As $\frac{1.5n}{k^2 d} \cdot \frac{98}{100} \geq \delta \geq C \geq 1$, we can choose a large enough $n$ such that the above holds. Finally, we show

$$\left( \frac{n}{\sqrt{k^2 d} \cdot 1.5 \cdot 1.5 - 5} \right)^{-1.01} \leq \left( \frac{n}{k} \right)^{-1.01}$$

by choosing a $d$ large enough since $\frac{d}{n} \geq 1$. A choice of $d \geq \left( \frac{1.5 \cdot 150}{100} \right)^2$ suffices.

### 3.4 Completing the Proof

Finishing the analysis of the small cuts regime, we now show that the number of edges crossing $(S, V - S)$ deviates no more from its expectation than by a $\frac{d}{\sqrt{n}}$ factor with high probability.
Proof of Theorem 11. Denote \(|S| = k\). If \(k = 1\), then \(\text{cut}_H(S) = d\) for any random \(d\) regular graph \(H\) thus \(\text{cut}_H(S) - \mathbb{E}[\text{cut}_H(S)] = 0\). Now consider any \(2 \leq k \leq \frac{n}{\Delta}\). Because \(H\) is \(d\) regular, we have

\[
\text{cut}_H(S) = kd - 2 \cdot e_H(S)
\]

Thus the event \(\{|\text{cut}_H(S) - \mathbb{E}[\text{cut}_H(S)]| \geq \frac{1}{\sqrt{d}} \cdot \mathbb{E}[\text{cut}_H(S)]\}\) occurs if and only if

\[
|\text{cut}_H(S) - \mathbb{E}[\text{cut}_H(S)]| \geq \frac{1.5}{\sqrt{d}} \cdot \mathbb{E}[\text{cut}_H(S)]
\]

\[
|kd - 2 \cdot e_H(S) - \mathbb{E}[kd - 2 \cdot e_H(S)]| \geq \frac{1.5}{\sqrt{d}} \cdot \mathbb{E}[kd - 2 \cdot e_H(S)]
\]

\[
|\mathbb{E}[e_H(S)] - e_H(S)| \geq \frac{1.5}{\sqrt{d}} \cdot \mathbb{E}[e_H(S)] \cdot \frac{kd}{2 \mathbb{E}[e_H(S)] - 1}
\]

\[
|e_H(S) - \mathbb{E}[e_H(S)]| \geq \frac{1.5}{\sqrt{d}} \cdot \mathbb{E}[e_H(S)] \cdot \frac{n - 1}{k - 1 - 1}
\]

Now, \(\frac{n - 1}{k - 1} - 1 = \frac{n}{k} - (1 + \frac{1}{k - 1}) \geq \frac{n}{k} - 2\) since \(k \geq 2\). The probability of the above occurring is at most

\[
\mathbb{Pr}
\left[
|\text{cut}_H(S) - \mathbb{E}[\text{cut}(S)]| \geq \frac{1.5}{\sqrt{d}} \cdot \mathbb{E}[\text{cut}(S)]
\right]
\leq \mathbb{Pr}
\left[
|e_H(S) - \mathbb{E}[e_H(S)]| \geq \frac{1.5}{\sqrt{d}} \cdot \frac{n}{k} - 2\right]
\]

Applying Lemma 19 using \(\delta = \frac{1.5}{\sqrt{d}} \cdot (\frac{n}{k} - 2)\) implies that the right hand side is at most \(o_{n,d}(\binom{n}{k})^{-1}\). Performing a union bound over at most \(\binom{n}{k}\) cuts of size \(k\) then completes the proof. \(\square\)

4 Lower Bound for Spectral Sparsification

In the following, if \(H = (V, E_H, w_H)\) is an undirected weighted graph and \(v \in V\) is a vertex, we call the combinatorial degree of \(v\) the number of edges incident on \(v\), and we call the weighted degree of \(v\) the sum of the weights of the edges incident on \(v\). A random walk in a graph is a process in which we move among the vertices of a graph and, at every step, we move from the current node \(u\) to a neighbor \(v\) of the \(u\) with probability proportional to the weight of the edge \((u, v)\). A non-backtracking random walk is like the above process except that if at a certain step we move from \(u\) to \(v\), then at the subsequent step it is not allowed to go from \(v\) to \(u\). For example, a non-backtracking walk in a cycle is a process that, after the first step, moves deterministically around the cycle, either always clockwise or always counterclockwise.

In this section we prove the following result.

Theorem 20 (Lower Bound for Spectral Sparsification). Let \(H = (V, E, w)\) be a weighted graph on \(n\) vertices and with \(dn/2\) edges, so that \(H\) has average combinatorial degree \(d\). Let \(K_n\) be a clique on \(V\) with every edge weighted \(1/n\). Suppose that \(H\) is an \(\epsilon\) spectral sparsifier of \(K_n\) and make the following definition:

- Let \(B\) be a bound such that for every vertex \(v \in V\), at most \(B\) vertices of \(H\) are reachable from \(v\) via paths of combinatorial length at most \(g\);
- Call \(V'\) the set of vertices \(r\) such that the subgraph induced by the vertices at combinatorial distance at most \(g\) from \(r\) contains no cycle. Call \(V''\) the set of vertices \(r\) such that the same property holds for the vertices at combinatorial distance at most \(2g\). Call \(n - F\) the cardinality of \(V''\).

Then

\[
\epsilon \geq \frac{2}{\sqrt{d}} - O \left( \frac{1}{g \sqrt{d}} + \frac{g(B + F)}{d} + \frac{g(B + F)}{n} \right)
\]

For example, if the girth of the graph is at least \(4g + 1\) and the graph has maximum degree \(\Delta\), then \(B \leq \Delta^{g+1}\) and \(F = 0\). If \(g = d^{1/4}\), and \(B\) and \(F\) are of size \(o(n)\), then the bound on \(\epsilon\) is \(\epsilon \geq \frac{2}{\sqrt{d}} - O(d^{-3/4}) - o(1)\).
4.1 The Test Vectors

The condition that $H$ is an $\epsilon$ spectral sparsifier of $L_{K_n}$ can be written as

$$\forall x \in \mathbb{R}^V \quad (1 - \epsilon) \ x^T L_{K_n} x \leq x^T L_H x \leq (1 + \epsilon) \ x^T L_{K_n} x$$

which can be written as

$$\forall x \in \mathbb{R}^V \quad (1 - \epsilon) \ (x \cdot x^T) \bullet L_{K_n} \leq (x \cdot x^T) \bullet L_H \leq (1 + \epsilon) \ (x \cdot x^T) \bullet L_{K_n}$$

where $A \bullet B = \sum_{i,j} A_{i,j} B_{i,j}$ is the Frobenius inner product between real-valued square matrices. The above condition is equivalent to

$$\forall X \succeq 0 \quad (1 - \epsilon) \ X \bullet L_{K_n} \leq X \bullet L_H \leq (1 + \epsilon) \ X \bullet L_{K_n}$$

because all positive semidefinite matrices $X \succeq 0$ are convex combinations of rank-1 symmetric matrices of the form $xx^T$. We will then be looking for positive semidefinite matrices $X$ for which $X \bullet L_{K_n}$ is noticeably different from $X \bullet L_H$. This approach is equivalent to the approach of considering probability distributions over test vectors $x$ which is taken in [ST18].

As in [ST18], we will make a number of assumptions on the structure of $H$. Such assumptions can be made without loss of generality, because if they fail then there are simple proofs (given in [ST18] of the conclusion of Theorem 20). The assumptions are the following:

1. Every vertex of $H$ has combinatorial degree at least $d/4$;
2. Every vertex of $H$ has weighted degree between $1 - 4/\sqrt{d}$ and $1 + 4/\sqrt{d}$;
3. Every edge $(u, v)$ of $H$ has weight at most $4/\sqrt{d}$.

Under all the above assumptions, we will construct two PSD matrices $X$ and $Y$ such that

$$\frac{1 + \epsilon}{1 - \epsilon} \geq \frac{X \bullet L_H}{X \bullet L_{K_n}} \cdot \frac{Y \bullet L_{K_n}}{Y \bullet L_H} \geq 1 + \frac{4}{\sqrt{d}} + O \left( \frac{1}{g} + \frac{g}{d} + \frac{g(B + F)}{n} \right)$$

which will imply the conclusion of the Theorem.

For every two vertices $r$ and $v$, let $\Pr[r \rightarrow_{\ell} v]$ be the probability that a non-backtracking $\ell$-step random walk in $H$ (performed by following edges with probability proportional to their weight) reaches $v$ in the last step. For every $r$, define the vectors $f_r, h_r$ as

$$f_r(v) = \sum_{\ell=0}^{g} (-1)^\ell \sqrt{\Pr[r \rightarrow_{\ell} v]}$$

$$h_r(v) = \sum_{\ell=0}^{g} \sqrt{\Pr[r \rightarrow_{\ell} v]}$$

Our two PSD matrices are

$$X = \sum_{r \in V} f_r f_r^T, \quad Y = \sum_{r \in V} h_r h_r^T$$

To understand the intuition of the above definition, if $r \in V'$ then, for every $v$, there can be at most one way to reach $v$ from $r$ with a non-backtracking walk of length $\leq g$, because otherwise we would see a cycle in the subgraph induced by the nodes at distance $\leq g$ from $v$ contradicting the definition of $V'$. This means that $f_r(v) = h_r(v) = 0$ if $v$ is at distance more than $g$ from $r$. If $v$ is at distance $\ell \leq g$ from $r$ then $f_r(v) = (-1)^\ell \sqrt{\Pr[r \rightarrow_{\ell} v]}$ and $h_r(v) = \sqrt{\Pr[r \rightarrow_{\ell} v]}$, so that, in particular, $f_r^2(v) = h_r^2(v)$.

We collect some properties that will be useful.
Fact 21. If \( r \in V' \), then \( ||f_r||^2 = ||h_r||^2 = g + 1 \).

Proof. If \( r \in V' \), then for every \( v \), we have

\[
f_r^2(v) = h_r^2(v) = \sum_{\ell=0}^{g} \Pr[r \xrightarrow{n_{\ell}} v]
\]

and

\[
||f_r||^2 = ||h_r||^2 = \sum_{v} \sum_{\ell=0}^{g} \Pr[r \xrightarrow{n_{\ell}} v] = g + 1
\]

because, for every fixed \( \ell \), we have

\[
\sum_{v} \Pr[r \xrightarrow{n_{\ell}} v] = 1
\]

Fact 22. If \( r \notin V' \), then

\[
0 \leq ||f_r||^2 \leq (g + 1)^2
\]

\[
0 \leq ||h_r||^2 \leq (g + 1)^2
\]

Proof. We have

\[
||h_r||^2 = \sum_{v} \left( \sum_{\ell=0}^{g} h_r(v) \right)^2 \leq \sum_{v} (g + 1) \cdot \sum_{\ell=0}^{g} h_r(v)^2 = (g + 1)^2
\]

where we used Cauchy-Schwarz. The same calculation applies to \( f_r \).

Fact 23.

\[
1 - \frac{F}{n} \leq \frac{I \cdot X}{n \cdot (g + 1)} \leq 1 + \frac{gF}{n}
\]

and

\[
1 - \frac{F}{n} \leq \frac{I \cdot Y}{n \cdot (g + 1)} \leq 1 + \frac{gF}{n}
\]

Proof. We have

\[
I \cdot Y = \sum_{r} ||h_r||^2 \geq \sum_{r \in V'} ||h_r||^2 \geq (n - F) \cdot (g + 1)
\]

\[
I \cdot Y = \sum_{r} ||h_r||^2 = \sum_{r \in V'} ||h_r||^2 + \sum_{r \notin V'} ||h_r||^2 \leq (n - F) \cdot (g + 1) + F \cdot (g + 1)^2
\]

and the same calculation for the \( f_r \).

Fact 24.

\[
0 \leq Y \cdot J \leq (g + 1)^2 Bn
\]

Proof.

\[
Y \cdot J = \sum_{r} (f_r, 1)^2 = \sum_{r} \left( \sum_{v} \sum_{\ell=0}^{g} \sqrt{Pr[r \xrightarrow{n_{\ell}} v]} \right)^2
\]

\[
\leq (g + 1)B \sum_{r} \sum_{v} \sum_{\ell=0}^{g} Pr[r \xrightarrow{n_{\ell}} v]
\]

\[
= (g + 1)^2 Bn
\]

where we used Cauchy-Schwarz and the fact that, for every \( r \), there are at most \( B \) vertices \( v \) that are reachable with non-zero probability from \( r \) using walks of lengths \( \leq g \).
4.2 Outline of the Proof

We will show that:

1. both $X \cdot L_{\bar{K}_n}$ and $Y \cdot L_{\bar{K}_n}$ are $(1 \pm o(1))ng$;
2. $Y \cdot D_H \leq (1 + o(1))ng$;
3. $X \cdot L_H / Y \cdot L_H \geq 1 + (1 - o(1)) \cdot (Y - X) \cdot A_H / Y \cdot D_H$;
4. $(Y - X) \cdot A_H \geq (1 - o(1))^4 ng / \sqrt{d}$.

So that:

$$X \cdot L_H \cdot Y \cdot L_{\bar{K}_n} \cdot Y \cdot L_{\bar{K}_n} \cdot Y \cdot L_H \geq 1 + 4 \cdot (1 - o(1)) \cdot (1 - o(1))^4 ng / \sqrt{d}$$

as in (8), where the “$o(1)$” notation refers to terms that are at most an absolute constant times $1/d^{1/4}$ provided that $g = d^{1/4}$ and $B$ and $F$ are at most $n/d$.

The claims 1, 2 and 3 above are proved using simple properties of the functions $f_r$ and $h_r$ mentioned above, and the crux of the argument is the fourth claim, which will follow by showing

$$(Y - X) \cdot A_H \geq (1 - o(1))^4 ng / \sqrt{d}$$

where $w_{a,b}$ is the weight of edge $(a, b)$ in the graph $H$. We know that $\sum_{a,b} w_{a,b} = (1 \pm o(1))n$ and that there are $dn$ pairs $a, b$ such that the edge $(a, b)$ has non-zero weight. The convexity of the function $x \rightarrow x^{1.5}$ can then be used to deduce that the expression is minimized when all the non-zero weights are the same

$$\sum_{a,b} w_{a,b}^{1.5} \geq d \cdot \left( \frac{\sum_{a,b} w_{a,b}}{dn} \right)^{1.5}$$

from which the fourth claim above will follow.

4.3 Proof of the Lower Bound

We will now prove the four claims that we made in the previous section.

Lemma 25.

$$\frac{Y \cdot L_{\bar{K}_n}}{X \cdot L_{\bar{K}_n}} \geq 1 - O\left( \frac{g \cdot (F + B)}{n} \right)$$

Proof. Recall that

$L_{\bar{K}_n} = I - \frac{1}{n}J$

where $J = 1 \cdot 1^T$ is the matrix that is one everywhere. This means that

$$Y \cdot L_{\bar{K}_n} = Y \cdot I - \frac{1}{n} Y \cdot J \geq n(g + 1) \cdot \left( 1 - \frac{F}{n} - \frac{(g + 1)B}{n} \right)$$

$$X \cdot L_{\bar{K}_n} = X \cdot I - \frac{1}{n} X \cdot J \leq X \cdot I \leq n(g + 1) \cdot \left( 1 + \frac{gF}{n} \right)$$

Lemma 26.

$$\left( 1 - \frac{4}{\sqrt{d}} \right) \cdot \left( 1 - \frac{F}{n} \right) \leq \frac{Y \cdot D_H}{n \cdot (g + 1)} \leq \left( 1 + \frac{4}{\sqrt{d}} \right) \cdot \left( 1 + \frac{gF}{n} \right)$$
Proof. Follows from a previous claim on $Y \cdot I$ and on the fact that the degree condition on $H$ can be expressed as

$$\left(1 - \frac{4}{\sqrt{d}}\right) \cdot I \preceq D_H \preceq \left(1 + \frac{4}{\sqrt{d}}\right) \cdot I$$

\[\square\]

Lemma 27.

$$\frac{X \cdot L_H}{Y \cdot L_H} \geq 1 + \frac{(Y - X) \cdot A_H}{Y \cdot D_H} - O\left(\frac{gF}{n}\right)$$

Proof.

$$\frac{X \cdot L_H}{Y \cdot L_H} - 1 = \frac{(X - Y) \cdot L_H}{Y \cdot L_H}$$

$$= \frac{(Y - X) \cdot A_H - (Y - X) \cdot D_H}{Y \cdot D_H - Y \cdot A_H}$$

$$\geq \frac{(Y - X) \cdot A_H - (Y - X) \cdot D_H}{Y \cdot D_H}$$

so that

$$\frac{X \cdot L_H}{Y \cdot L_H} \geq 1 + \frac{(Y - X) \cdot A_H}{Y \cdot D_H} - \frac{(Y - X) \cdot D_H}{Y \cdot D_H}$$

We have

$$(Y - X) \cdot D_H = \sum_r \sum_v w(v) \cdot (h_r^2(v) - f_r^2(v))$$

$$= \sum_{r \notin V'} \sum_v w(v) \cdot (h_r^2(v) - f_r^2(v))$$

$$\leq \sum_{r \notin V'} \sum_v w(v) \cdot h_r^2$$

$$\leq \left(1 + \frac{4}{\sqrt{d}}\right) \sum_{r \notin V'} \sum_v h_r^2$$

$$\leq \left(1 + \frac{4}{\sqrt{d}}\right) \cdot F \cdot (g + 1)^2$$

where we used the facts, proved above, that $h_r^2(v) = f_r^2(v)$ when $r \in V'$, that all weighted degrees are at most $1 + 4/\sqrt{d}$, and that $||h_r||^2 \leq (g + 1)^2$.

On the other hand,

$$Y \cdot D_H \geq \left(1 - \frac{4}{\sqrt{d}}\right) \cdot Y \cdot I \geq \left(1 - \frac{4}{\sqrt{d}}\right) \left(1 - \frac{F}{n}\right) n \cdot (g + 1)$$

\[\square\]

Lemma 28 (Main).

$$(Y - X) \cdot A_H \geq \left(1 - O\left(\frac{g}{\sqrt{d}} + \frac{gF\sqrt{d}}{n}\right)\right) 4gn \cdot \frac{1}{\sqrt{d}}$$

23
Proof. Finally we come to the main argument. We have

\[(Y - X) \cdot A_H = \]

\[\sum_{r \in V'} h_r^T A_H h_r - f_r^T A_H f_r + \sum_{r \notin V'} h_r^T A_H h_r - f_r^T A_H f_r\]

where

\[\sum_{r \notin V'} h_r^T A_H h_r - f_r^T A_H f_r \geq -\sum_{r \notin V'} \|f_r\|^2 \cdot \|A_H\| \geq -|F|(g + 1)^2 \left(1 + \frac{4}{\sqrt{d}}\right)\]

so that it remains to study \(\sum_{r \in V'} h_r^T A_H h_r - f_r^T A_H f_r\).

\[= \sum_{r \in V'} \sum_{a,b} w_{a,b} \cdot (h_r(a) h_r(b) - f_r(a) f_r(b)) \]

\[= 2 \sum_{r \in V'} \sum_{a,b} w_{a,b} h_r(a) h_r(b)\]

To motivate the last step, we note that \(w_{a,b} h_r(a) h_r(b)\) is non-zero iff there is some \(\ell \leq g - 1\) such that \(a\) is at distance \(\ell\) from \(r\) and \(b\) is at distance \(\ell + 1\) from \(r\) (or vice versa) and so

\[h_r(a) h_r(b) = \sqrt{\Pr[r \rightarrow_{\ell} a] \sqrt{\Pr[r \rightarrow_{\ell+1} b]}}\]

and

\[f_r(a) f_r(b) = (-1)^\ell \sqrt{\Pr[r \rightarrow_{\ell+1} a] \sqrt{\Pr[r \rightarrow_{\ell+1} b]}} = -h_r(a) h_r(b)\]

Let us call \(T_r\) the BFS tree rooted at \(r\) and of depth \(g\), and assume that its edges are directed from parent to child. Then we can rewrite

\[\sum_{r \in V'} h_r^T A_H h_r - f_r^T A_H f_r \]

\[= 4 \sum_{r \in V'} \sum_{(a,b) \in T_r} w_{a,b} h_r(a) h_r(b)\]

\[= 4 \sum_{r \in V'} \sum_{\ell=0}^{g-1} \sum_{(a,b) \in T_r : \text{dist}(r,a) = \ell} w_{a,b} \sqrt{\Pr[r \rightarrow_{\ell} a] \sqrt{\Pr[r \rightarrow_{\ell+1} b]}}\]

\[\geq 4 \sum_{r \in V'} \sum_{\ell=0}^{g-1} \sum_{(a,b) \in T_r : \text{dist}(r,a) = \ell} w_{a,b} \sqrt{\Pr[r \rightarrow_{\ell} a] \sqrt{\Pr[r \rightarrow_{\ell+1} b]}}\]
where \( \Pr[u \to_t v] \) denotes the probability that a \( t \)-step standard random walk (in which edges are followed with probability proportional to their weight) started at \( u \) ends at \( v \). We have used the fact that if there is a unique shortest path from \( u \) to \( v \) and the length of such path is \( t \), then we have \( \Pr[u \to_t v] \geq \Pr[u \to_t v] \).

Another observation is that, in the particular circumstance in which \( r \in V' \), \( (a, b) \in T_r \), and \( a \) has distance \( \ell \) from \( r \) and \( b \) has distance \( \ell + 1 \) from \( r \), we have

\[
\Pr[r \to_{\ell+1} b] = \Pr[r \to_\ell a] \cdot \frac{w_{a,b}}{w(a)}
\]

and, together with our assumptions on the degrees of the vertices,

\[
\sum_{r \in V'} h^T_r A_H h_r - f^T_r A_H f_r \\
\geq 4 \left( 1 - O \left( \frac{1}{d^{3/4}} \right) \right) \sum_{r \in V', \ell=0}^{g-1} \sum_{(a,b) \in T_r, dist(r,a)=\ell} w_{a,b} \Pr[r \to_\ell a]
\]

where \( dist(r,a) \) is the length (number of edges) of a shortest path from \( r \) to \( a \). Now let us consider the above inner summation over all pairs \( a, b \) such that \( a \) is at distance \( \ell \) from \( r \) and the edge \( (a, b) \) exists in \( T_r \), meaning that \( b \) is further from \( r \) than \( a \) is. If \( p \) is the predecessor of \( a \) in the unique path of length \( \ell \) from \( r \) to \( a \), then we have

\[
\sum_{b \neq p} w_{a,b} \geq 1 - O \left( \frac{1}{d^{3/4}} \right) \sum_b w_{a,b}
\]

because \( \sum_b w_{a,b} \geq \Omega(1) \) and \( w_{a,p} \leq O(1/d^{3/4}) \).

We can thus conclude that

\[
\sum_{r \in V'} h^T_r A_H h_r - f^T_r A_H f_r \\
\geq 4 \left( 1 - O \left( \frac{1}{d^{3/4}} \right) \right) \sum_{\ell=0}^{g-1} \sum_{a:dist(a,r)=\ell} \Pr[r \to_\ell a] \sum_b w_{a,b}
\]

The next observation is that if \( a \) is in \( V'' \) and \( r \) is at distance \( \leq g - 1 \) from \( a \), then \( r \) is in \( V' \), so we have

\[
\sum_{r \in V''} \sum_{\ell=0}^{g-1} \sum_{a:dist(a,r)=\ell} \Pr[r \to_\ell a] \sum_b w_{a,b} \\
\geq \sum_{a \in V''} \sum_{\ell=0}^{g-1} \sum_{r:dist(a,r)=\ell} \Pr[r \to_\ell a] \sum_b w_{a,b} \\
\geq \left( 1 - O \left( \frac{g}{\sqrt{d}} \right) \right) \sum_{a \in V''} \sum_{\ell=0}^{g-1} \sum_{r:dist(a,r)=\ell} \Pr[a \to_\ell r] \sum_b w_{a,b} \\
\geq \left( 1 - O \left( \frac{g}{\sqrt{d}} \right) \right) \cdot g \cdot \sum_{a \in V''} \sum_b w_{a,b}
\]

By a convexity argument mentioned above,

\[
\sum_{a,b} w_{a,b}^{1.5} \geq dn \left( \frac{\sum_{a,b} w_{a,b}}{dn} \right)^{1.5} \geq \left( 1 - O \left( \frac{1}{\sqrt{d}} \right) \right) \frac{n}{\sqrt{d}}
\]

and

\[
\sum_{a \notin V''} \sum_b w_{a,b} \leq O(F)
\]
so

$$\sum_{a \in V'} \sum_{b} w_{a,b}^{1.5} \geq \left(1 - O\left(\frac{g}{\sqrt{d}} + \frac{gF}{n}\right)\right) \frac{n}{\sqrt{d}}$$

and putting everything together

$$\sum_{r \in V'} h_r^T A_H h_r - f_r^T A_H f_r \geq \left(1 - O\left(\frac{g}{\sqrt{d}} + \frac{gF}{n}\right)\right) 4 gn \cdot \frac{1}{\sqrt{d}}$$

and

$$(Y - X) \cdot A_H \geq \left(1 - O\left(\frac{g}{\sqrt{d}} + \frac{gF}{n}\right)\right) 4 gn \cdot \frac{1}{\sqrt{d}}$$

4.4 Completing the Proof

We can now prove Theorem 20.

Proof of Theorem 20. Given a graph $H$ that satisfies the assumptions of the Theorem and that is an $\epsilon$ spectral sparsifier of $\overline{K}_n$, define PSD matrices $X$ and $Y$ as in Section 4.1. We have

$$\frac{X \cdot L_H}{X \cdot L_{\overline{K}_n}} \cdot \frac{Y \cdot L_{\overline{K}_n}}{Y \cdot L_H} \leq \frac{1 + \epsilon}{1 - \epsilon} \leq 1 + 2\epsilon + O(\epsilon^2)$$

If $\epsilon > 2/\sqrt{d}$ there is nothing else left to prove. If $\epsilon \leq 2/\sqrt{d}$, then

$$\epsilon \geq \frac{1}{2} \left(\frac{X \cdot L_H}{X \cdot L_{\overline{K}_n}} \cdot \frac{Y \cdot L_{\overline{K}_n}}{Y \cdot L_H} - 1\right) - O\left(\frac{1}{d}\right)$$

Now, from Lemma 26 and Lemma 27 we have

$$\frac{X \cdot L_H}{X \cdot L_{\overline{K}_n}} \cdot \frac{Y \cdot L_{\overline{K}_n}}{Y \cdot L_H} \geq \left(1 + \frac{(Y - X) \cdot A_H}{Y \cdot D_H} - O\left(\frac{gF}{n}\right)\right) \cdot \left(1 - O\left(\frac{g \cdot (F + B)}{n}\right)\right)$$

From Lemma 26 and Lemma 28 we have

$$\frac{(Y - X) \cdot A_H}{Y \cdot D_H} \geq \left(1 - O\left(\frac{g}{\sqrt{d}} + \frac{gF}{n}\right)\right) 4 gn \cdot \frac{1}{\sqrt{d}} \geq \frac{4}{\sqrt{d}} \left(1 - O\left(\frac{1}{g} + \frac{g}{\sqrt{d}} + \frac{gF}{n}\right)\right)$$

Putting everything together,

$$\epsilon \geq \frac{1}{2} \cdot \frac{4}{\sqrt{d}} \cdot \left(1 - O\left(\frac{1}{g} + \frac{g}{\sqrt{d}} + \frac{gF}{n}\right)\right)$$

5 Separation Between Cut and Spectral Sparsification

We will now show a separation between cut and spectral sparsification of random log $n$-regular graphs.

First, we demonstrate that a random log $n$ regular graph satisfies the “pseudo-girth” conditions required by Theorem 20.
Theorem 29. If $G$ is a random regular graph drawn from $G_{n,\log n}^{\text{reg}}$, and $g$ is a fixed constant then the following occur.

1. With probability 1, for every vertex $v$ of $G$, the number of vertices of $G$ reachable from $v$ via paths of length at most $g$ is $O((\log n)^g)$.

2. If we call $V''$ the set of vertices $v$ such that there is no cycle in the vertex-induced subgraph of $G$ induced by the vertices at distance at most $2g$ from $v$, then with probability $1-o_n(1)$ over the choice of $G$, $|V''| \geq n - O((\log n)^{4g+1})$.

Proof. The first property immediately follows from the fact that the combinatorial degree is at most $\log n$. For the second part, fix a vertex $v$ and consider the probability, over the choice of $G$, that $v \not\in V''$. By applying the principle of deferred decision, we first generate the $\log n$ neighbors of $v$, then the additional neighbors of those neighbors, and so on. Every time we make a decision about how to match a particular vertex $x$ in one of the $\log n$ matchings, the probability of hitting a previously seen vertex is at most $O((\log n)^{2g}/n)$ and so the probability that we create a cycle is at most $O((\log n)^{4g}/n)$. The conclusion of the theorem follows by applying Markov’s inequality.

We now prove the separation between cut and spectral sparsification. We restate Theorem 4 from the introduction.

Theorem 4. Let $G$ be a random regular graph drawn from $G_{n,\log n}^{\text{reg}}$. Then with probability $1-o_n(1)$ over the choice of $G$ the following happens for every $d$:

1. There is a weighted subgraph $H$ of $G$ with $dn/2$ edges such that $H$ is an $\epsilon$ cut sparsifier of $G$ with $\epsilon \leq (1.595... + o_n(1))/\sqrt{d}$.

2. For every weighted subgraph $H$ of $G$ with $dn/2$ edges, if $H$ is an $\epsilon$ spectral sparsifier of $G$ then $\epsilon \geq (2-o_n(1))/\sqrt{d}$.

Proof. Let us fix $d$. If $G$ is a random $\log n$-regular graph drawn from $G_{n,\log n}^{\text{reg}}$, then, for every fixed $d$ there is a $1-o_n(1)$ probability that there are $o_n(n)$ nodes that see a cycle within distance $d^{1/4}$ and there are $o_n(n)$ nodes in the ball of radius $d^{1/4}$ around each node. Note that the above properties will also hold for any edge-subgraph $H$ of $G$.

From Theorem 29 we have that, with $1-o_n(1)$ probability over the choice of $G$, if a weighted edge-induced subgraph $H$ of $G$ of average degree $d$ is an $\epsilon$-spectral sparsifier of the clique, then $\epsilon \geq (2-O(d^{-3/4})-o_n(1))/\sqrt{d}$.

From Hor19 we have that with $1-o_n(1)$ probability the graph $G$ is an $O(1/\log n)$ spectral sparsifier (and also cut sparsifier) of the clique, and so if a weighted edge-induced subgraph $H$ of $G$ of average degree $d$ is an $\epsilon$-cut sparsifier of the $G$, then again $\epsilon \geq (2-O(d^{-3/4})-o_n(1))/\sqrt{d}$.

Since we constructed $G$ as the union of $\log n$ random matchings, $G$ contains, for large enough $n$, a random $d$-regular graph from $G_{n,d}^{\text{reg}}$ as an edge-induced subgraph (for example, consider the first $d$ of the $\log n$ matchings used to construct $G$). We can deduce from Theorem 29 that, with $1-o_n(1)$ probability, $G$ contains as a weighted edge-induced subgraph a graph $H$ that has average degree $d$ and is a $(1.595... + o_n,d)/\sqrt{d}$ cut sparsifier of the clique.

We conclude that with $1-o_n(1)$ probability over the choice of $G$, there is a weighted edge-induced subgraph $H$ of $G$ such that $H$ has average degree $d$ and is a $(1.595... + o_n,d)/\sqrt{d}$ cut sparsifier of $G$.

6 Acknowledgments

The work of JS and LT on this project has received funding from the European Research Council (ERC) under the European Union’s Horizon 2020 research and innovation programme (grant agreement No. 834861). Most of this work was done while AC was a visiting student at Bocconi University. The authors would like to thank Andrea Montanari for pointing us to JS17, and the Physics and Machine Learning group at Bocconi, particularly Enrico Malatesta, for patiently explaining the Parisi equations and the replica method to us.

A Analytic Inequalities

In this section, we prove two analytic inequalities required by our martingale concentration analysis. The first lemma is used to approximate the exponent in the concentration bound provided by Lemma 17 in the case where $\frac{\delta}{C}$ is small.

**Lemma 30.** For any $\delta, C \geq 0$ such that $\frac{\delta}{C} \leq 1$, we have that

$$(\delta + C)\ln\left(\frac{\delta}{C} + 1\right) \geq \delta + \frac{\delta^2}{3C}$$

**Proof.** Proceed by expanding $\delta \ln\left(\frac{\delta}{C} + 1\right)$ via its Taylor approximation:

$$\delta \ln\left(\frac{\delta}{C} + 1\right) = \delta \cdot \sum_{t=1}^{\infty} (-1)^{t+1} \frac{\delta^t}{C^t t}$$

similarly for $C \ln\left(\frac{\delta}{C} + 1\right)$, we have

$$C \cdot \ln\left(\frac{\delta}{C} + 1\right) = C \cdot \sum_{t=1}^{\infty} (-1)^{t+1} \frac{\delta^t}{C^t t} = \delta + \sum_{t=1}^{\infty} (-1)^{t+1} \frac{\delta^t}{C^t(t+1)}$$

Combining the two expansions, we derive

$$(\delta + C)\ln\left(\frac{\delta}{C} + 1\right) = \delta + \sum_{t=1}^{\infty} (-1)^{t+1} \left(\frac{\delta^t}{C^t} \left(\frac{1}{t} - \frac{1}{t+1}\right)\right) \geq \delta + \frac{\delta^2}{3C}$$

The second lemma is used to approximate the exponent in Lemma 17 when $\frac{\delta}{C}$ is large.

**Lemma 31.** For any $\delta \geq C \geq 1$, we have

$$(\delta + C)\ln\left(\frac{\delta}{C} + 1\right) - \delta \geq \frac{1}{2C} \cdot \delta \ln \delta$$

**Proof.** Denote $f(C, \delta) = (\delta + C)\ln\left(\frac{\delta}{C} + 1\right) - \delta - \frac{1}{2C} \cdot \delta \ln \delta$. It suffices to demonstrate $f(C, \delta) \geq 0$ for all $\delta \geq C \geq 1$. To see this, first note $f(C, \delta) \geq 0$ for all $\delta = C \geq 1$ as we have

$$f(C, \delta) = (\delta + C)\ln\left(\frac{\delta}{C} + 1\right) - \delta - \frac{1}{2C} \cdot \delta \ln \delta = 2\delta \cdot \ln (2\delta) - \delta - \frac{\ln \delta}{2}$$

which is true for any $\delta \geq 1$. We next compute $\frac{\partial f}{\partial \delta}$ as follows.

$$\frac{\partial f}{\partial \delta} = \ln\left(\frac{\delta}{C} + 1\right) - \frac{1}{2C} \cdot (\ln \delta + 1) = \ln\left(\frac{\delta/C + 1}{\delta^{1/2C}}\right) - \frac{1}{2C}$$

If we can show that $\frac{\partial f}{\partial \delta} \geq 0$ for all $\delta \geq C \geq 1$, then we would have that $f$ is non-negative along $\delta = C$, and non-decreasing along the positive $\delta$ direction past the $\delta = C$ line. It must then be that $f$ is non-negative for all $\delta \geq C \geq 1$. Towards this, observe it is equivalent to demonstrate

$$\left(\frac{\delta}{C} + 1\right)^{2C} \geq \delta e$$

With $g(C, \delta) = \left(\frac{\delta}{C} + 1\right)^{2C} - \delta e$, we notice that for all $\delta = C \geq 1$ we have

$$g(C, \delta) = \left(\frac{\delta}{C} + 1\right)^{2C} - \delta C = 2^{2\delta} - \delta e \geq 1$$
with the second equality holding via $\frac{\delta}{\psi} \geq 1$. Meanwhile, observe that

$$\frac{\partial g}{\partial \delta} = 2 \left( \frac{\delta}{C} + 1 \right)^{2C-1} - e \geq 2 \cdot 2^{2-1} - e \geq 0$$

Consequently, $g(C, \delta) \geq 0$ implying $\left( \frac{\delta}{\psi} + 1 \right)^{2C} \geq \delta e$ implying $\frac{\partial f}{\partial \psi} \geq 0$ as required. $\square$
