VIETORIS-RIPS HOMOLOGY THEORY FOR SEMI-UNIFORM SPACES

ANTONIO RIESER

Abstract. The Vietoris-Rips complex was first introduced in 1927 by Leopold Vietoris [72], and while it is now widely used in both topological data analysis and the theory of hyperbolic groups, many of the fundamental properties of its homology have remained elusive. In this article, we define the Vietoris-Rips homology for semi-uniform spaces, which generalizes the classical theory for graphs and metric spaces, and provides a natural, general setting for the construction. We then prove a version of the Eilenberg-Steenrod axioms in this setting, giving a natural definition of homotopy for semi-uniform spaces in the process.

1. Introduction

The Vietoris-Rips complex and its homology and cohomology have become indispensable tools in the applications of algebraic topology, particularly to areas with a combinatorial flavor. In topological data analysis, it has become the standard homology theory used to analyze data with persistent homology [1, 13, 14], and before its emergence as a computational tool, it was already widely used in the study of hyperbolic groups [5, 6]. Despite its popularity, however, little is known about even the most basic properties of the Vietoris-Rips homology, except in the limiting case when the defining parameter approaches zero, i.e. the so-called ‘metric cohomology’ studied by Hausmann in [7]. Indeed, the standard properties, i.e. the Eilenberg-Steenrod axioms, fail for the classical Vietoris-Rips homology with a fixed scale parameter \( r > 0 \), even in the form studied in [7] for metric spaces, and to date, no alternative has been proposed.

In this article, we construct a version of the Vietoris-Rips homology by first encoding the scale parameter into the structure of the space, and then constructing a Vietoris-Rips homology theory for such space-scale pairs. Once this is accomplished, we demonstrate that a version of the Eilenberg-Steenrod axioms does, in fact, hold. The encoding of the scale parameter into the space is achieved through the choice of a semi-uniform structure given by the parameter. Indeed, we will develop the Vietoris-Rips theory for general semi-uniform spaces, and we do not actually require the metric for the constructions. As a result, the theory also applies to graphs and other cases of interest in combinatorics as well. In the last section, we show that our construction reduces to the standard Vietoris-Rips complex on graphs, and that the \( \leq \)-version of the Vietoris-Rips complex on finite metric spaces, and

CONACYT-CIMAT, Centro de Investigación en Matemáticas, Calle Jalisco, Colonia Valenciana, C.P. 36023 Guanajuato, GTO, Mexico
the results in Section 4 are new even for the classical Vietoris-Rips homology in these cases. We additionally show that, as in the classical case, the homology of a Riemannian manifold may be recovered by the (semi-uniform) Vietoris-Rips homology of a sufficiently Gromov-Hausdorff close finite metric space.

We remark, too, that studying the Vietoris-Rips theory from this point of view clarifies that there is no essential difference between such ‘topological’ constructions for graphs and those for more general spaces. Indeed, these results give an illustrative example of how considering homotopy and homology in non-topological categories unifies many situations of interest, thus providing significant conceptual and technical advantages over developing the relevant theory in each area separately.

2. Semi-uniform spaces

In this section, we give a brief introduction to semi-uniform spaces, which will be our primary objects of study. Further details may be found in [2].

2.1. Semi-uniform spaces. Semi-uniform spaces and uniformly continuous functions between them generalize the essential aspects of uniform continuity in metric spaces to a wider collection of spaces and maps.

In order to define semi-uniform structures, we will first need the following preliminary definitions.

**Definition 2.1.** For a set \( U \subset X \times X \), we define \( U^{-1} := \{(y, x) \mid (x, y) \in U\} \), and for a subset \( A \subset X \), we define \( U[A] := \{y \in X \mid (a, y) \in U \subset X \times X \text{ for some } a \in A\} \). If \( A = \{x\} \), we write \( U[x] \) for \( U[\{x\}] \), and if \( F \) is a collection of subsets of \( X \times X \) (such as a filter), then we define the collection of sets \( \{F[A] := \{U[A] \mid U \in F\} \).

We also recall the definition of a filter.

**Definition 2.2** (\([2]\) Definition 12.B.2). Let \( X \) be a set, and let \( F \) be a non-empty collection of subsets of \( A \). We say that \( F \) is a filter on \( X \) if

1. \( \emptyset \notin F \)
2. \( A, B \in F \implies A \cap B \in F \)
3. \( A \in F, A \subset B \subset X \implies B \in F \)

A collection \( F \) satisfying the above definition is sometimes called a proper filter in the literature, with filter being reserved for collections \( F \) which only satisfy Items 2 and 3. However, since all of the filters we will encounter do not contain the empty set, we will not make this distinction in this article.

We now proceed to the definition of a semi-uniform space.

**Definition 2.3.** Let \( X \) be a set. A semi-uniform structure on \( X \) is a filter \( F \) on \( X \times X \) such that

1. Each set in \( F \) contains the diagonal \( \Delta \subset X \times X \)
2. If \( U \in F \), then \( U^{-1} \) contains an element of \( F \)

Note that, since \( F \) is a filter, then item 2 above is equivalent to: \((2') U^{-1} \in F\).

A semi-uniform space \((X, F)\) is a pair consisting of a set \( X \) and a semi-uniform structure \( F \) on \( X \).

**Definition 2.4.** We say that a function \( f : (X, F_X) \to (Y, F_Y) \) is uniformly continuous iff, for each \( V \in F_Y \), there exists a \( U \in F_X \) such that \((x, y) \in U \) implies \((f(x), f(y)) \in V \).
Definition 2.5. Let \((X, \mathcal{F})\) be a semi-uniform space. If \(\mathcal{G}\) is a filter base for \(\mathcal{F}\), then we say that \(\mathcal{G}\) is a base for the semi-uniformity \(\mathcal{F}\). Similarly, a subbase for the semi-uniformity \(\mathcal{F}\) is a subbase for the filter \(\mathcal{F}\).

Our principal examples of semi-uniform spaces will be built from semi-pseudometrics, defined here.

Definition 2.6. A semi-pseudometric \(d : X \times X \to \mathbb{R}\) on \(X\) is a map such that

1. \(d(x, x) = 0\) for all \(x\) in \(X\).
2. \(d(x, y) = d(y, x)\) for all \((x, y) \in X \times X\).

Example 2.7. (1) If \(d\) is a semi-pseudometric on \(X\), then the collection of sets
\[ A_r = \{(x, y) \mid d(x, y) < r\}, \]
where \(r > 0\), form a filter base on \(X \times X\) which satisfies conditions 1 and 2 in the definition of a semi-uniform structure. By Theorem 23.4 in [2], this implies that it is a filter base for a semi-uniform structure \(\mathcal{F}\) on \(X\), which we will call the semi-uniformity induced by \(d\).

(2) Suppose that \((X, d)\) is a semi-pseudometric space, and let \(q \geq 0\). Then the function \(d_q : X \times X \to \mathbb{R}\) defined by
\[
d_q(x, y) = \begin{cases} d(x, y) - q & d(x, y) > q \\ 0 & d(x, y) \leq q \end{cases}
\]
is also a semi-pseudometric on \(X\). Denote by \(\mathcal{F}_q\) the semiuniformity induced by \(d_q\) constructed in example 1 above. We will refer to \(\mathcal{F}_q\) as the semi-uniformity induced by \(d\) at scale \(q\).

(3) As above, let \((X, d)\) be a metric space, and suppose that \(q > 0\). Define the function \(d_{\leq q} : X \times X \to \mathbb{R}\) by
\[
d_{\leq q}(x, y) = \begin{cases} d(x, y) & d(x, y) > q \\ 0 & d(x, y) \leq q \end{cases}
\]
and note that \(d_q\) is a semi-pseudometric on \(X\). Denote by \(\mathcal{F}_{\leq q}\) the semi-uniformity induced by \(d_{\leq q}\) constructed in Example 1 above. We will say that \(\mathcal{F}_q\) is the closed semi-uniformity induced by \(d\) at scale \(q\). Note that the main difference between this structure and the structure \(\mathcal{F}_q\) in Example 2 is that
\[
\bar{A}_q := \{(x, y) \mid d(x, y) \leq q\} \in \mathcal{F}_{\leq q},
\]
whereas \(\bar{A}_q \notin \mathcal{F}_q\).

There is a particularly nice characterization of uniformly continuous functions between semi-uniform spaces induced by metrics as in Example 2 above.

Definition 2.8. Let \((X, d_X)\) and \((Y, d_Y)\) be metric spaces. We say that a function \(f : X \to Y\) is \((p, q)\)-continuous iff \(\forall \epsilon > 0, \exists \delta > 0\) such that, for every \(x, y \in X\) we have
\[
d_X(x, y) < p + \delta \implies d_Y(f(x), f(y)) < q + \epsilon.
\]

Proposition 2.9. Let \((X, d_X)\) and \((Y, d_Y)\) be metric spaces, and let \(p, q \geq 0\). A function \(f : X \to Y\) is \((p, q)\)-continuous iff it is uniformly continuous as a function \(f : (X, \mathcal{F}_p) \to (Y, \mathcal{F}_q)\) between semi-uniform spaces.

Proof. First, suppose \(f : X \to Y\) is \((p, q)\)-continuous, and let \(V \in \mathcal{F}_q\). Then, by definition of \(\mathcal{F}_q\), \(\exists r > q\) such that
\[
V_r := \{(y, y') \in Y \times Y \mid d_Y(y, y') < r\} \subset V.
\]
Choose $0 < \epsilon < r - q$. Since $f$ is $(p, q)$-continuous, there exists a $\delta > 0$ such that $d_X(x, y) < p + \delta \implies d_Y(f(x), f(y)) < q + \epsilon$. Therefore, $f(U_{p+\delta}) \subset V_r \subset V$, where

$$U_{p+\delta} := \{(x, x') \in X \times X \mid d(x, x') < p + \delta\}.$$ 

However, $U_{p+\delta} \in \mathcal{F}_p$ by definition of $\mathcal{F}_p$. Since $V \in \mathcal{F}_q$ was arbitrary, it follows that $f$ is uniformly continuous.

Now suppose that $f$ is uniformly continuous as a map between the semi-uniform spaces $(X, \mathcal{F}_p) \to (Y, \mathcal{F}_q)$, and let $\epsilon > 0$. Define

$$V_\epsilon := \{(y, y') \in Y \times Y \mid d(y, y') < q + \epsilon\}.$$ 

Since $f$ is uniformly continuous, and each $V_\epsilon \in \mathcal{F}_p$, there exists a $U \in \mathcal{F}_p$ such that $f(U) \subset V_\epsilon$. However, $\mathcal{F}_p$ is generated by sets of the form

$$U_\delta := \{(x, x') \in X \times X \mid d(x, x') < p + \delta\},$$

where $\delta > 0$. Therefore, there exists a $\delta > 0$ such that $U_\delta \subset U$, so we have $f(U_\delta) \subset f(U) \subset f(V_\epsilon)$, and it follows that $f$ is $(p, q)$-continuous. \hfill $\square$

### 2.2. Semi-uniform spaces from a Čech closure space

We examine in this section a special class of semi-uniform spaces which are constructed from the interior of a Čech closure space, and, in the case of a topological space, from its open covers. We will show in Section 3 how the so-called “Vietoris homology” and “Alexander cohomology” studied in [3] are the Vietoris-Rips complexes with respect to this semi-uniform structure. We begin by giving a short introduction to Čech closure spaces. For more details, see [2] and [10].

**Definition 2.10.** Let $X$ be a set, and let $c : \mathcal{P}(X) \to \mathcal{P}(X)$ be a function on the power set of $X$ which satisfies

1. $c(\emptyset) = \emptyset$
2. $A \subset c(A)$ for all $A \subset X$
3. $c(A \cup B) = c(A) \cup c(B)$ for all $A, B \subset X$

The function $c$ is called a Čech closure operator (or closure operator) on $X$, and the pair $(X, c)$ is called a Čech closure space (or closure space).

**Example 2.11.** (1) Let $X$ be a topological space with $A \subset X$, and denote by $\bar{A}$ the (topological) closure of $A$. Then $c(A) = \bar{A}$ is a Čech closure operator. Note that, in this case, $c^2(A) = c(A)$. For such closure operators (i.e. with $c^2 = c$), it is known that the collection

$$\mathcal{O} := \{X \setminus c(A) \mid A \subset X\}$$

forms the open sets of a topology on $X$ [2]. We will refer to closure operators with the property $c^2 = c$ as topological or Kuratowski closure operators.

(2) Let $(X, d)$ be a metric space, and $r > 0$ a positive real number. For any $A \subset X$, define

$$c_r(A) := \{x \in X \mid d(x, A) \leq r\}.$$ 

Then $c_r$ is a closure operator on $X$.

**Definition 2.12.** Let $(X, c)$ be a closure space, and suppose $A \subset X$. We define the interior of $A$, $i(A)$, by

$$i(A) = X - c(X - A).$$
Furthermore, we say that $U \subset X$ is a neighborhood of $A$ iff $A \subset i(U)$. A collection $\mathcal{U}$ of subsets of $X$ is an interior cover of $X$ iff

$$X = \bigcup_{U \in \mathcal{U}} i(U).$$

**Proposition 2.13.** Let $(X, c)$ be a Čech closure space, and suppose that $B \subset A \subset X$. Then $i(B) \subset i(A)$.

**Proof.** Since $X - A \subset X - B$, the axioms of the closure structure give $c(X - A) \subset c(X - B)$, and therefore

$$i(B) = X - c(X - B) \subset X - c(X - A) = i(A),$$

as desired. □

**Proposition 2.14.** Let $(X, c)$ be a Čech closure space. For any two neighborhoods $U$ and $V$ of a point $x \in X$, the intersection $U \cap V$ is also a neighborhood of $x$.

**Proof.** Since $x \in i(U) \cap i(V)$, we have

$$x \in (X - c(X - U)) \cap (X - c(X - V)) = X - (c(X - U) \cup c(X - V))$$

$$= X - c((X - U) \cup (X - V))$$

$$= X - c(X - (U \cap V)),$$

by the properties of $c$ and de Morgan’s laws. Therefore, $x \in i(U \cap V)$. □

**Corollary 2.15.** Suppose that $\mathcal{U}$ and $\mathcal{V}$ are interior covers of a Čech closure space $(X, c)$. Then the collection

$$\mathcal{U} \cap \mathcal{V} := \{U \cap V \mid U \in \mathcal{U}, V \in \mathcal{V}\}$$

is an interior cover of $(X, c)$.

**Proof.** Since $\mathcal{U}$ and $\mathcal{V}$ are interior covers of $(X, c)$, there exist $U_x \in \mathcal{U}$ and $V_x \in \mathcal{V}$ which are both neighborhoods of $x$. By Proposition 2.14, $U_x \cap V_x$ is a neighborhood of $x$ as well. Since $U_x \cap V_x \in \mathcal{U} \cap \mathcal{V}$ and $x \in X$ is arbitrary, the conclusion follows. □

**Remark 2.16.** Note that Corollary 2.15 implies that the collection $\mathcal{I}$ of interior covers of $X$ is a directed system with partial order $\mathcal{V} < \mathcal{U}$ iff $\mathcal{U}$ refines $\mathcal{V}$.

We now begin the construction of two semi-uniform structures associated to a Čech closure space. We begin by constructing a relations from a cover.

**Definition 2.17.** Let $(X, c)$ be a Čech closure space, and let $\mathcal{U}$ be an interior cover of $(X, c)$. We define the relation $V_{\mathcal{U}}$ associated to $\mathcal{U}$ by

$$V_{\mathcal{U}} = \{(x, y) \mid \exists U \in \mathcal{U}: x, y \in U\}.$$

We further define the relation $R_{\mathcal{U}}$ associated to $\mathcal{U}$ by

$$R_{\mathcal{U}} = \{(x, y) \mid \exists U \in \mathcal{U}: (x \in i(U) \text{ and } y \in U) \text{ or } (y \in i(U) \text{ and } x \in U)\}.$$

We now show that these relations can be assembled into semi-uniform structures on $X$. We shall require the following lemma.

**Lemma 2.18.** Let $\mathcal{U}$ and $\mathcal{U}'$ be interior covers of the Čech closure space $(X, c)$. If $\mathcal{U} < \mathcal{U}'$ (i.e. if $\mathcal{U}'$ refines $\mathcal{U}$), then $V_{\mathcal{U}'} \subset V_{\mathcal{U}}$ and $R_{\mathcal{U}'} \subset R_{\mathcal{U}}$. 
Proof. We first show that $R_{\mathcal{U}'_c} \subset R_{\mathcal{U}_c}$. Suppose $(x, y) \in R_{\mathcal{U}'_c}$. Then there exists a $U' \in \mathcal{U}'$ such that, without loss of generality, $x \in i(U')$ and $y \in U'$. However, since $\mathcal{U}'$ refines $\mathcal{U}$, there exists a set $U \in \mathcal{U}$ with $U' \subset U$. By Proposition 2.13, $i(U') \subset i(U)$ as well. It follows that $x \in i(U)$ and $y \in U$, and therefore $(x, y) \in R_{\mathcal{U}_c}$, as desired.

Now suppose that $(x, y) \in V_{\mathcal{U}'_c}$. Then there exists a $U' \in \mathcal{U}'$ with $x, y \in U'$. As above, since $\mathcal{U}'$ refines $\mathcal{U}$, there exists a $U \in \mathcal{U}$ with $U' \subset U$, and therefore $x, y \in U$, which gives $(x, y) \in V_{\mathcal{U}_c}$, proving the result. □

Proposition 2.19. Suppose $(X, c)$ is a Čech closure space, let $\mathcal{I}_c$ denote the collection of interior covers of $(X, c)$, and let $\mathcal{V}_c$ be the filter on $X \times X$ generated by the collection $\{V_{\mathcal{I}}\}_{\mathcal{I} \in \mathcal{I}_c}$, from Definition 2.17. Then $(X, \mathcal{V}_c)$ is a semi-uniform space.

Proof. By 23.A.4 in [2], we must show that

1. Every element $V_{\mathcal{U}_c} \in \mathcal{V}_c$ contains the diagonal in $X \times X$, and
2. For any element $V_{\mathcal{U}_c} \in \mathcal{V}_c$, the inverse $V_{\mathcal{U}_c}^{-1}$ contains an element of $\mathcal{V}_c$.

Let $V_{\mathcal{U}_c} \in \mathcal{V}_c$. Then, by construction, for every $x \in X$ exists $U \in \mathcal{U}$ such that $x \in U$. It follows that $(x, x) \in V_{\mathcal{U}_c}$, proving Item (1). Furthermore, $(x, y) \in V_{\mathcal{U}_c}$ iff there exists a $U \in \mathcal{U}$ with $x, y \in U$, which implies that $(y, x) \in V_{\mathcal{U}_c}$ as well, proving Item (2).

Similarly, for the filter $\mathcal{R}_c$, we have

Proposition 2.20. Suppose $(X, c)$ is a Čech closure space such that, for any two points $x, y \in X$, $x \in c(y)$ iff $y \in c(x)$. Let $\mathcal{I}_c$ denote the collection of interior covers on the Čech closure space $(X, c)$, and let $\mathcal{A}_c$ and $\mathcal{S}_c$ be the filter on $X \times X$ generated by the collection $\{R_{\mathcal{I}}\}_{\mathcal{I} \in \mathcal{I}_c}$, from Definition 2.17. Then $(X, \mathcal{R}_c)$ is a semi-uniform space.

Proof. By 23.A.4 in [2], we must show that

1. Every element $R_{\mathcal{U}_c} \in \mathcal{R}_c$ contains the diagonal in $X \times X$, and
2. For any element $R_{\mathcal{U}_c} \in \mathcal{R}_c$, the inverse $R_{\mathcal{U}_c}^{-1}$ contains an element of $\mathcal{R}_c$.

Let $R_{\mathcal{U}_c} \in \mathcal{R}_c$. Then, as above, for any $x \in X$, there is a $U \in \mathcal{U}$ with $x \in i(U)$, and therefore $(x, x) \in R_{\mathcal{U}_c}$, fulfilling Item (1) above. Also, by construction, $R_{\mathcal{U}_c}^{-1} = R_{\mathcal{U}_c}$, and so Item (2) is satisfied as well. □

Definition 2.21. Given a Čech closure space $(X, c)$ and an interior cover $\mathcal{U}$ of $(X, c)$ we say that the relation $V_{\mathcal{U}}$ is the Vietoris relation of the cover $\mathcal{U}$, and that the pair $(X, V_{\mathcal{U}})$ is the Vietoris semi-uniform space induced by $c$. Similarly, we say that the relation $R_{\mathcal{U}}$ is the interior-inclusion relation of the cover $\mathcal{U}$, and that the pair $(X, R_{\mathcal{U}})$ is the interior-inclusion (or I-I) semi-uniform space induced by $c$. When $(X, c)$ is topological (i.e. whe $c^2 = c$), we have that $\mathcal{V}_c = \mathcal{R}_c$, and we call the resulting semi-uniform structure the topological semi-uniform structure induced by $c$, which we denote by $\mathcal{F}_\tau$. We call the semi-uniform space $(X, \mathcal{F}_\tau)$ the topological semi-uniform space induced by $c$.

3. The Vietoris-Rips Complex and Vietoris-Rips Homology

Let $(X, \mathcal{F})$ be a semi-uniform space. For every element $U \in \mathcal{F}$, we now define a simplicial complex from the pair $(X, U)$, which we denote $\Sigma^X_U$. We proceed as
follows. First, we construct the graph $G(X, U) = (V, E)$ by:

$$V = \{x \mid x \in X\}$$

$$E = \{(x_0, x_1) \mid (x_0, x_1) \in U\}$$

Note that a priori, this gives a directed graph. If, for ever $(x_0, x_1)$, the edge $(x_1, x_0)$ also exists, then we replace the directed graph with an undirected graph, which we still denote $G(X, U)$. If $G(X, U)$ is undirected, we let $\Sigma^X_U$ be the clique complex of $G(X, U)$. If $G(X, U)$ is directed, then we let $\Sigma^X_U$ be the directed clique complex of $G(X, U)$. That is, in the directed case, we say that a finite set $\{x_0, \ldots, x_q\}$ is a $q$-simplex in $\Sigma^X_U$ iff there exists a permutation of the indices $\gamma: \{0, \ldots, q\} \to \{0, \ldots, q\}$ such that $(x_{\gamma(i)}, x_{\gamma(j)}) \in E$ if $\gamma(i) < \gamma(j)$. Note that we do not assume a global ordering of the vertices, and so all possible orderings of the vertices $\{x_0, \ldots, x_n\}$ are considered when determining whether the collection forms a simplex in the directed flag complex. If there exists such a permutation, then for any subset of $\{x_{\gamma(0)}, \ldots, x_{\gamma(q)}\}$ the condition $(x_{\gamma(i)}, x_{\gamma(j)}) \in E$ if $\gamma(i) < \gamma(j)$ is also fulfilled, and so $\Sigma^X_U$ is indeed a simplicial complex.

**Definition 3.1.** We call the simplicial complex $\Sigma^X_U$ the Vietoris-Rips complex of the pair $(X, U)$.

### 3.1. Vietoris-Rips homology and cohomology

Let $(X, F)$ be a semi-uniform space. For $A \subset X$ and $U \in F$, define

$$U_A := U \cap (A \times A).$$

We further define the relatization of $F$, written $F_A$, to be the collection of sets

$$F_A := \{U_A \mid U \in F, U_A \neq \emptyset\}.$$

**Proposition 3.2.** The collection of sets $F_A$ forms a semi-uniform structure on $A$. 

**Proof.** Immediate from the definitions. \qed

**Definition 3.3.** Let $A \subset X$. We write $(X, A, F)$ to denote the pair of semi-uniform spaces $((X, F), (A, F_A))$, which we will call a *semi-uniform pair*.

The relation between the Vietoris-Rips complexes $\Sigma^A_{U_A}$ and $\Sigma^X_U$ is given by the following proposition.

**Proposition 3.4.** Let $(X, F)$ be a semi-uniform space. Suppose that $A \subset X$, and $U \in F$. Then $\Sigma^A_{U_A}$ is a subcomplex of $\Sigma^X_U$.

**Proof.** Let $\sigma := (x_0, \ldots, x_n) \in \Sigma^A_{U_A}$, and without loss of generality suppose that $(x_i, x_j) \in U_A$ for all $i < j$. Then, in particular, $(x_i, x_j) \in U$ for all $i < j$, and therefore $\sigma \in \Sigma^X_U$, as desired. \qed

**Definition 3.5.** Let $(X, F)$ be a semi-uniform space, $A \subset X, U \in F$, and let $\Sigma^X_U$ and $\Sigma^A_{U_A}$ be the respective Vietoris-Rips complexes. We denote the homology and cohomology of the simplicial pair $(\Sigma^X_U, \Sigma^A_{U_A})$ with coefficients in the abelian group $G$ by

$$H_*^{VR}(X, A; U; G) := H_*(\Sigma^X_U, \Sigma^A_{U_A}; G)$$

$$H^*_R(X, A; U; G) := H^*(\Sigma^X_U, \Sigma^A_{U_A}; G)$$

which we call the Vietoris-Rips homology and the Vietoris-Rips cohomology of $(X, A, U)$, respectively. When $A = \emptyset$, we will simply write $H_*^{VR}(X; U; G)$ and
8 VIETORIS-RIPS HOMOLOGY FOR SEMI-UNIFORM SPACES

\( H^*_V(X; U; G) \). Additionally, when \( G = \mathbb{Z} \), we write \( H^*_V(X, A; U) \) and \( H^*_V(X, A; U) \) for \( H^*_V(X, A; U; \mathbb{Z}) \) and \( H^*_V(X, A; U; \mathbb{Z}) \), respectively.

**Lemma 3.6.** Let \((X, A, \mathcal{F})\) be a semi-uniform pair, and let \( U, U' \in \mathcal{F} \) with \( U \subset U' \). Then there is a simplicial embedding

\[
\iota_{U':U}: (\Sigma^X_U, \Sigma^A_U) \to (\Sigma^X_{U'}, \Sigma^A_{U'})
\]

which induces homomorphisms on the simplicial homology and cohomology groups

\[
\iota^*_U: H^*_V(X, A; U) \to H^*_V(X, A; U')
\]

\[
\iota_{U':U}^*: H^*_V(X, A; U') \to H^*_V(X, A; U).
\]

**Proof.** Define \( \iota_{U':U} \) by

\[
\iota_{U':U}(x_0, \ldots, x_n) = (x_0, \ldots, x_n)
\]

Since \( U \subset U' \), any simplex \( \sigma \in \Sigma^X_U \) is also in \( \Sigma^X_{U'} \), it follows that \( \iota_{U':U} \) is a simplicial embedding. Restriction of \( \iota_{U':U} \) to \( \Sigma^A_U \) gives the corresponding injection, and the homomorphisms on simplicial homology and cohomology are produced by the functoriality of homology and cohomology of simplicial complexes. \( \square \)

Define a partial order \( < \) on \( \mathcal{F} \) by: \( U < U' \) iff \( U \subset U' \). Since \( \mathcal{F} \) is closed under finite intersections by definition, \( (\mathcal{F}, <) \) is a directed set, and Lemma 3.6 makes the homology and cohomology groups \( H^*_V(X, A; U) \) and \( H^*_V(X, A; U) \) into inverse and directed systems, respectively. This observation leads to the following definitions.

**Definition 3.7.** We define the **Vietoris-Rips homology** of \((X, A, \mathcal{F})\) with coefficients in \( G \) by

\[
H^*_V(X, A, \mathcal{F}; G) = \lim_{\longrightarrow} H^*_V(X, A; U; G).
\]

The **Vietoris-Rips cohomology** of \((X, A, \mathcal{F})\) is given by

\[
H^*_V(X, A, \mathcal{F}; G) = \lim_{\longleftarrow} H^*_V(X, A; U; G)
\]

where the respective limits are taken over the elements of \( \mathcal{F} \).

**Remark 3.8.** Note that, since \( U \) and \( U^{-1} \) are in \( \mathcal{F} \), and since \( \mathcal{F} \) is a (proper) filter, we have that \( \emptyset \neq U \cap U^{-1} \in \mathcal{F} \), and so the subcollection of symmetric elements of \( \mathcal{F} \) is cofinal in \( \mathcal{F} \). This allows us to compute the Vietoris-Rips homology and cohomology of \((X, A, \mathcal{F})\) solely from the clique complexes of undirected graphs.

**Remark 3.9.** Let \((X, c)\) be a We recall that, by results in [9], the Vietoris-Rips cohomology of \((X, \mathcal{V}_c)\) is isomorphic to the Čech cohomology of \((X, c)\), i.e. the limit of the cohomologies of the nerve complexes of the interior covers, ordered by refinement. (See [9] for more details on the Čech cohomology of a Čech closure space.)

4. THE EILENBERG-STENROD AXIOMS

The Eilenberg-Steenrod axioms form the essential elements of a homology theory on topological spaces. In this section, we give a version of the Eilenberg-Steenrod axioms for semi-uniform spaces, and we show that they are satisfied by the Vietoris-Rips homology and cohomology defined in Section 3 above.
4.1. Functoriality. We first construct the homomorphisms on homology and cohomology induced by uniformly continuous maps of the pair \( f: (X, A, F_X) \rightarrow (Y, B, F_Y) \), i.e. where \( f: (X, F_X) \rightarrow (Y, F_Y) \) is uniformly continuous and \( f(A) \subset B \). We begin with the following lemma.

**Lemma 4.1.** Let \( f: (X, A, F_X) \rightarrow (Y, B, F_Y) \) be a uniformly continuous map of pairs. Then, for every \( V \in F_Y \), there exists a \( U \in F_X \) and an induced simplicial map of simplicial pairs

\[
\tilde{f}_{UV}: (\Sigma^X_U, \Sigma^A_{U_A}) \rightarrow (\Sigma^Y_V, \Sigma^B_{U_B}).
\]

**Proof.** We first note that, since \( f \) is uniformly continuous, then, by definition, for every \( V \in F_Y \), there exists a \( U \in F_X \) such that \( f(U) \subset V \). We construct the induced map \( \tilde{f}: \Sigma^X_U \rightarrow \Sigma^Y_V \). First, without loss of generality, let \( \sigma = (x_0, \ldots, x_n) \in \Sigma^X_U \) be such that \((x_i, x_j) \in U \) for all \( i < j \). Then define

\[
\tilde{f}(\sigma) := (f(x_0), \ldots, f(x_n)).
\]

Since \( f(U) \subset V \), it follows that \((f(x_i), f(x_j)) \in V \) for any \( i < j \), and therefore \( \tilde{f}(\sigma) \in \Sigma^Y_V \), making \( \tilde{f} \) a simplicial map. Furthermore, since \( f(A) \subset B \), \( \tilde{f}(\Sigma^A_{U_A}) \subset \Sigma^B_{U_B} \), and therefore \( \tilde{f} \) is a simplicial map of pairs, as desired. \( \square \)

**Lemma 4.2.** Let \( (X, F_X) \) and \( (Y, F_Y) \) be semi-uniform spaces and suppose the map \( f: (X, F_X) \rightarrow (Y, F_Y) \) is uniformly continuous. Let \( V, V' \in F_Y \) with \( V \subset V' \), and let \( U, U' \in F_X \) be such that \( f(U) \subset V \) and \( f(U') \subset V' \), respectively. Then the induced maps on homology and cohomology make the diagrams

\[
\begin{align*}
\vcenter{\xymatrix{ H_*(X, A; U; G) & H_*(Y, B; V; G) \\
\downarrow & \downarrow \\
H_*(X, A; U'; G) & H_*(Y, B; V'; G) }} \quad \text{and} \quad \begin{align*}
\vcenter{\xymatrix{ H^*(X, A; U; G) & H^*(Y, B; V; G) \\
\downarrow & \downarrow \\
H^*(X, A; U'; G) & H^*(Y, B; V'; G) }}
\end{align*}
\end{align*}
\]

commute.

**Remark 4.3.** Note that the existence of \( U, U' \in F_X \) is guaranteed by the uniform continuity of \( f \).

**Proof.** We first consider the diagram of simplicial complexes

\[
\begin{align*}
\vcenter{\xymatrix{ \Sigma^X_U & \Sigma^Y_V \\
\downarrow & \downarrow \\
\Sigma^X_{U'} & \Sigma^Y_{V'} }}
\end{align*}
\]

where the \( \iota_* \) are as defined in Lemma 4.1 and the \( \tilde{f}_* \) are the simplicial maps from Lemma 4.1. Let \( \sigma = (x_0, \ldots, x_n) \in \Sigma^X_U \). By construction, \( \iota_{U,V}(\sigma) = \sigma \), and \( \tilde{f}_{U',V'}(\sigma) = (\tilde{f}(x_0), \ldots, \tilde{f}(x')) \). Similarly, we have that \( f_{V,U}(\sigma) = (f(x_0), \ldots, f(x_n)) \), and \( \iota_{U,V'}(f(x_0), \ldots, f(x_n)) = (f(x_0), \ldots, f(x_n)) \). Since the simplex \( \sigma \in \Sigma^X_U \) was
arbitrary, the diagram commutes. Applying the homology and cohomology functors to this diagram, and the result follows. □

**Theorem 4.4.** Let \((X, A, c)\) be a closure space pair, where \((X, c)\) is semi-uniformizable. The Vietoris-Rips homology \(H^\ast_{VR}(X, A, c)\) and cohomology \(H^\ast_{VR}(X, A, c)\) are functorial with respect to uniformly continuous maps.

**Proof.** The theorem follows from Lemmas 4.1 and 4.2. □

4.2. Exactness.

**Theorem 4.5.** Let \((X, A, F)\) be semi-uniform pair, and \(G\) an abelian group. Then there is a functorial long-exact sequence of pairs

\[
\cdots \to H^\ast_{VR}(X, A; G) \to H^\ast_{VR}(X; G) \to H^\ast_{VR}(A; G) \to H^{\ast+1}_{VR}(X, A; G) \to \cdots
\]

and a functorial sequence of order two

\[
\cdots \to H^\ast_{VR}(A; G) \to H^\ast_{VR}(X; G) \to H^\ast_{VR}(A, G) \to H^{\ast-1}_{VR}(A; G) \to \cdots
\]

**Proof.** For each element \(U \in F\), one has the corresponding long exact sequences from simplicial homology and cohomology. Since exactness is preserved by direct limits, and exactness is of order two for indirect limits, it follows the sequence of pairs is exact for \(H^\ast_{VR}(X, A; G)\) and of order two for \(H^\ast_{VR}(X, A; G)\). □

4.3. The Dimension Axiom.

**Theorem 4.6.** Let \((p, F_p)\) denote the one point semi-uniform space. Then

\[
H^n_{VR}(p; G) \cong H^0_{VR}(p; G) \cong \begin{cases} G & n = 0 \\ 0 & n > 0, \end{cases}
\]

**Proof.** Since the one-point set only has a single point, the dimension axiom follows from the corresponding result for simplicial complexes. □

4.4. The Excision axiom. For the excision axiom, we first note that the simplicial homology and cohomology groups of a combinatorial simplicial complex are isomorphic to the homology and cohomology groups of its geometric realization. We first quote the following results from [11], which we will use in the proof of the lemma which follows.

**Lemma 4.7.** ([11], Proposition 7.5). If the CW-complex \(\Sigma\) is the union of subcomplexes \(\Sigma_1\) and \(\Sigma_2\), then the inclusion \(i : (\Sigma_1, \Sigma_1 \cap \Sigma_2) \hookrightarrow (\Sigma, \Sigma_2)\) induces an isomorphism

\[
i_n : H_n(\Sigma_1, \Sigma_1 \cap \Sigma_2) \xrightarrow{\cong} H_n(\Sigma, \Sigma_2).
\]

for all \(n \in \mathbb{Z}\).

**Remark 4.8.** As mentioned on page 125 of [11], the dual of the above result also holds, by dualizing its proof. Therefore, we also have that \(i\) induces an isomorphism in cohomology

\[
i^n : H^n(\Sigma, \Sigma_2) \xrightarrow{\cong} H^n(\Sigma_1, \Sigma_1 \cap \Sigma_2)
\]

for every \(n \in \mathbb{Z}\) as well.
Theorem 4.9 (Excision). Let $(X, \mathcal{F})$ be a semi-uniform space, and let $B \subset A \subset X$. Suppose that there exists an element $W \in \mathcal{F}$ such that, for every $U \subset W$, $U \in \mathcal{F}$, 
\[ U[B] \subset A. \]

Then 
\[ H_{VR}^*(X - B, A - B : \mathcal{F}; G) \cong H_{VR}^*(X, A : \mathcal{F}; G) \]
and 
\[ H_{VR}^*(X - B, A - B : \mathcal{F}; G) \cong H_{VR}^*(X, A : \mathcal{F}; G). \]

Proof. Let $A \subset B \subset X$, and let $U' \subset W, U' \in \mathcal{F}'$. Let $U = U' \cap (U')^{-1}$, and note that $U$ is symmetric, i.e. $U = U^{-1}$. We first show that 
\[ \Sigma_U^X = \Sigma_U^A \cup \Sigma_U^{(X-B)}. \]

Let $\sigma = (x_0, \ldots, x_n) \in \Sigma_U^X$ and suppose that $\sigma \notin \Sigma_U^{(X-B)}$. Then there must be at least one $x_i \in \{x_0, \ldots, x_n\}$ with $x_i \in B \subset A$. However, since $U$ is symmetric, this implies that $x_i \in U[x_i] \subset U[B] \subset A$ for all $x_j \in \sigma$. It follows that $(x_j, x_k) \in U \cap (A \times A)$ for all $x_j, x_k \in \{x_0, \ldots, x_n\}$, and therefore 
\[ \sigma \notin \Sigma_U^A. \]

Now suppose that $\sigma \notin \Sigma_{U[A]}^A$. Then there exists $x_i \in \{x_0, \ldots, x_n\}$ such that 
\[ x_i \in X - A. \]
Suppose there exists a $j$ where $x_j \in B$. Then $x_i \in U(B) \subset X - A$, a contradiction, and therefore, $x_j \in X - B$ for all $x_j$. Furthermore, we have $(x_j, x_k) \in U \cap (X-B) \times (X-B)$ for all $x_j, x_k \in \{x_0, \ldots, x_n\}$, and therefore 
\[ \sigma \notin \Sigma_U^{(X-B)}. \]

Taking $\Sigma_1 = X - B$ and $\Sigma_2 = A$ in Lemma 4.17 and Remark 4.8, we have 
\[ H_{VR}^*(X - B, A - B : U; G) \cong H_{VR}^*(X, A : U; G) \]
and 
\[ H_{VR}^*(X - B, A - B : U; G) \cong H_{VR}^*(X, A : U; G). \]

Since the set of symmetric controlled sets $U$ is cofinal in $\mathcal{F}$, the result follows. \qed

4.5. The Homotopy axiom. For the Homotopy axiom, we will follow the general line of proof in the proof of the corresponding axioms for Čech homology and cohomology in [4]. Before we begin, we define several terms.

Definition 4.10. Let $I := [0, 1]$, and let $\mathcal{F}_\tau$ be the topological semi-uniform structure induced by the standard topology on $I$ as in Definition 2.21. Let $(X, \mathcal{F}_X)$ be a semi-uniform space. We write $(X \times I, \mathcal{F}_Y)$ for the product semi-uniform space of $(X, \mathcal{F}_\tau)$ and $(I, \mathcal{F}_\tau)$.

Definition 4.11. Suppose that $(X, \mathcal{F}_X)$ and $(Y, \mathcal{F}_Y)$ are semi-uniform spaces. We say that two uniformly continuous maps $f, g : (X, \mathcal{F}_X) \to (Y, \mathcal{F}_Y)$ are homotopic, or $f \simeq g$, if there exists a uniformly continuous map 
\[ H : (X \times I, \mathcal{F}_Y) \to (Y, \mathcal{F}_Y) \]
such that 
\[
\begin{align*}
H(x, 0) &= f(x) \\
H(x, 1) &= g(x)
\end{align*}
\]
for all $x \in X$. If

we say that two semi-uniform spaces $(X, \mathcal{F}_X)$ and $(Y, \mathcal{F}_Y)$ are homotopy equivalent, or $(X, \mathcal{F}_X) \simeq (Y, \mathcal{F}_Y)$, if and only if there exist uniformly continuous maps $f : (X, \mathcal{F}_X) \to (Y, \mathcal{F}_Y)$ and $g : (Y, \mathcal{F}_Y) \to (X, \mathcal{F}_X)$ such that $g \circ f \simeq 1_X$ and $f \circ g \simeq 1_Y$.

We show that the topological semi-uniform structure on the interval $I = [0, 1]$ has a more convenient form, which will be useful in the following.

**Proposition 4.12.** Let $(X, d)$ be a compact metric space with topological closure operator $\tau$ (i.e. $\tau^2 = \tau$) induced by the metric. Then $F_0 = \mathcal{F}_\tau$, where $\mathcal{F}_\tau$ is the topological semi-uniform structure induced by $\tau$, and $F_0$ is the semi-uniform structure generated by the sets $\{(x, y) \mid d(x, y) > r\}$ for some $r > 0$, as in Example 2.7(1).

**Proof.** We claim that $\mathcal{F}_\tau$ is generated by the collection of sets of the form $U_r := \{(x, y) \mid d(x, y) < r\}$, where $r > 0$ ranges over the positive real numbers. We first show that every $U_r \in \mathcal{F}_\tau$. Fix $r > 0$ and consider the open cover $\mathcal{B}_r := \{B_x(r) \mid x \in X\}$, where $B_x(r)$ denotes the open ball centered at $x$ with radius $r$. Then the Vietoris relation $V_\mathcal{B}_r \subset U_{2r}$. Since $V_\mathcal{B}_r \in \mathcal{F}_\tau$ and $\mathcal{F}_\tau$ is a filter, we have that $U_{2r} \in \mathcal{F}_\tau$, and since $r > 0$ was arbitrary, $U_r \in \mathcal{F}_\tau$ for every $r > 0$.

Now suppose that $U$ is an open cover of $X$, and let $V_U$ denote the corresponding Vietoris relation. Since $X$ is compact by hypothesis, $\mathcal{U}$ has a Lebesgue number $\lambda$, and therefore the collection $\mathcal{B}_\lambda := \{B_x(\lambda) \mid x \in X\}$ is an open cover of $X$ which refines $V_U$. Since $V_U \subset V_{\mathcal{B}_\lambda}$, from Proposition 2.18 we have that $V_{\mathcal{B}_\lambda} \subset V_U$, proving the claim.

Since both filters $\mathcal{F}_\tau$ and $F_0$ are generated by the same collection of sets, it follows that $\mathcal{F}_\tau = F_0$.

In this section, we wish to prove the homotopy invariance of the Vietoris-rips homology and cohomology, i.e.

**Theorem 4.13.** Let $(X, \mathcal{F}_X)$ and $(Y, \mathcal{F}_Y)$ be semi-uniform spaces, and suppose $f_0, f_1 : (X, \mathcal{F}_X) \to (Y, \mathcal{F}_Y)$ are uniformly continuous maps with $f_0 \simeq f_1$. Then

$$f_0^* = f_1^* : H^Y_R(X, A, \mathcal{F}_X) \to H^Y_R(Y, B, \mathcal{F}_Y), \quad f_0^* = f_1^* : H^+_R(Y, B, \mathcal{F}_Y) \to H^+_R(X, A, \mathcal{F}_X)$$

We first show that it will be sufficient to prove the following theorem.

**Theorem 4.14.** Let $g_0, g_1 : (X, \mathcal{F}_X) \to (X, \mathcal{F}_X) \times (I, \tau)$ be defined by $g_0(x) = (x, 0)$, $g_1(x) = (x, 1)$. Then $g_{0*} = g_{1*}$ and $g_0^* = g_1^*$.

**Lemma 4.15.** Theorem 4.14 is equivalent to Theorem 4.13.

**Proof.** Theorem 4.13 $\implies$ Theorem 4.14: $g_0$ and $g_1$ are homotopic by the homotopy $H : (X, \mathcal{F}_X) \times (I, \tau) \to (X, \mathcal{F}_X) \times (I, \tau)$ defined by $H(x, t) = (x, t)$, which is uniformly continuous, since the identity from a semi-uniform space to itself is uniformly continuous.

Theorem 4.14 $\implies$ Theorem 4.13: Suppose $H : (X, \mathcal{F}_X) \times (I, \tau) \to (Y, \mathcal{F}_Y)$ is a homotopy for $f_0, f_1 : (X, \mathcal{F}_X) \to (Y, \mathcal{F}_Y)$. Then $f_1 = H \circ g_1$. By functoriality, we have $f_{1*} = H_* g_{1*}$ and $f_{1*} = g_{1*}^* H^*$. Since $g_{0*} = g_{1*}$ and $g_{0*}^* = g_{1*}^*$, by hypothesis, the result follows.
4.5.1. Acyclic carriers. Before proceeding with the proof of Theorem 4.14, we will first review some terminology and results on common acyclic carriers in simplicial complexes that we need for the proof. The following section is summarized §4, VI, section 5. More details may be found there.

**Definition 4.16.** Let $K$ be a simplicial complex and $G$ an abelian group, let $C_0(K; G)$ denote the 0-th dimensional simplicial chain complex, generated by the vertices of $K$, and let $c := \sum g_i v_i \in C_0(K; G)$ be an arbitrary element of $C_0(K; G)$.

We define the index map $\text{Ind} : C_0(K; G) \to G$ by $\text{Ind}(c) = \text{Ind}(\sum g_i v_i) := \sum g_i$.

**Definition 4.17.** We say that a map $f : K \to K'$ between simplicial complexes is a *chain map* if the induced map $f_* : C_*(K) \to C_*(K')$ satisfies $df = fd$. We say that $f$ is an *algebraic map* if $f$ is a chain map and $\text{Ind}(f(c)) = \text{Ind}(c)$ for all $c \in C_0(K)$.

**Definition 4.18.** A function which maps simplices $\sigma$ of a simplicial complex $\Sigma$ to subcomplexes $S(\sigma) \subset \Sigma'$ of a simplicial complex $\Sigma'$ is called a *carrier function* if, for every face $\gamma \subset \sigma$, $S(\gamma)$ is a subcomplex of $C(\sigma)$. If $f : \Sigma \to \Sigma'$ is an algebraic map such that $\alpha \subset \sigma \in \Sigma$ implies $f(\alpha) \subset C(\sigma)$, then $C$ is called the carrier of $f$.

**Definition 4.19.** We say that a simplicial complex $K$ is *acyclic* if $\bar{H}_*(K) = 0$, where $\bar{H}_*(K)$ is the reduced simplicial homology of the simplicial complex $K$. We say that a carrier function $C$ is *acyclic* if, for each simplex $\sigma$, the simplicial complex $C(\sigma)$ is acyclic.

**Proposition 4.20** ([4], Theorem 5.8). Suppose $K$ and $K'$ be simplicial complexes and that suppose $f, g : K \to K'$ are algebraic maps with common acyclic carrier function $C$. Then $f_* = g_*$ and $f^* = g^*$.

4.5.2. Proof of the homotopy axiom. In this section, we will give the proof of Theorem 4.14. We begin with the following definition.

**Definition 4.21.** Let $(X, d)$ be a metric space. For every $r \in (0, 1)$, let $U_r \subset I \times I$ be the set

$$U_r := \{(x, y) \in I \times I \mid d(x, y) < r\}$$

**Definition 4.22.** Let $(X, d)$ be a metric space. We denote by $\tau$ the semi-uniform structure generated by the collection $\{U_r \mid r > 0\}$.

**Lemma 4.23.** For any $r > 0$, the Vietoris-Rips complex of $(I, U_r)$, $\Sigma^I_{U_r}$, is acyclic.

*Proof.*** This follows directly from [7], Lemma 2.2. \qed

**Lemma 4.24.** Let $X$ be a set with relation $R \subset X \times X$. Consider $I$ with the Euclidean metric and the relation $U_r \subset I \times I$ defined above, and let $\sigma = \{v_0, \ldots, v_k\}$ be a simplex of $\Sigma^X_R$. Suppose $S(\sigma)$ is the subcomplex of $\Sigma^X_{R \times U_r}$, which consists of all of the simplices in $\Sigma^X_{R \times U_r}$, whose vertices are of the form $(v_i, t)$, $v_i \in \sigma$, $t \in I$. Then $S(\sigma)$ is acyclic.

*Proof.*** Consider a simplex $\gamma = ((v_0, t_0), \ldots, (v_n, t_n))$ in $S$. We note that $\gamma$ is a simplex in $S$ iff $(t_0, \ldots, t_n) \in \Sigma^I_{U_r}$. Since $\sigma \in \Sigma^X_R$, however, this implies that the map $f : S \to S$ induced by the map $(v_i, t) \mapsto (v_0, t)$ is contiguous with the identity, and therefore the homology and cohomology of $S$ are equal to that of $I \times \{v_0\} = I$.

Since $I$ is acyclic by Lemma 4.23, the result follows. \qed
Lemma 4.25. Let $(X, F_X)$ be a semi-uniform space, $(I, \tau) = ([0,1], F_0)$, and consider the continuous maps $g_0, g_1 : (X, A) \to (X, F_X) \times (I, \tau)$ given by

$$g_0(x) := (x, 0),$$
$$g_1(x) := (x, 1).$$

Then, for every $V \in \tau$ and $U \in F_X$, there exists a $\tilde{U} \in F_X$ be such that $f_i(\tilde{U}) \subset U \times V$ for $i \in \{0,1\}$, and

$$g_0\tilde{U}_* = g_1\tilde{U}_* : H^V_R(X; \tilde{U}) \to H^V_R(X \times I; U \times V)$$
$$g_0^* = g_1^* : H^*_R(X \times I; U \times V) \to H^*_R(X; \tilde{U})$$

Proof. Since each $g_i$, $i = 0,1$ is continuous, there exists a $U_i \in F_X$ such that $g_i(U_i) \subset V$. Define $\tilde{U} = U_0 \cap U_1$, and note that $\tilde{U} \in F_X$ by definition of a semi-uniform structure. Now, for each simplex $\sigma$ of $\Sigma^{X \times I}_\tilde{U}$, consider the subcomplex $C(\sigma)$ of $\Sigma^{X \times I}_U$ consisting of all simplices with vertices of the form $(x_i, t)$, where $x_i$ is a vertex of $\sigma$ and $t \in I$. By Lemma 4.24, $C(\sigma)$ is acyclic. Note that, if $\gamma$ is a face of $\sigma$, then $C(\gamma) \subset C(\sigma)$, and, furthermore, if $c$ is a chain built on $\sigma$, then $\tilde{g}_i(c) \subset C(\sigma)$ for $i \in \{0,1\}$. Since $\sigma \in \Sigma^X_U$ is arbitrary, we have that $C(\sigma)$ is a common acyclic carrier for the maps $\tilde{g}_0$ and $\tilde{g}_1$, and the conclusion follows from Proposition 4.20. \hfill \Box

5. Isomorphism Theorems

In this section, we give a number of results which aid in the calculation of the Vietoris-Rips homology and cohomology groups. We begin by giving a simple alternative proof of Theorem 5.1 in [7], using results in [3].

Theorem 5.1. For the category of compact metric pairs (i.e. pairs of metric spaces $(X, A)$ with $X$ and $A$ compact and $A \subset X$), $H^*_R(X, A, F_0) \cong H^*(X, A)$, where $H^*(X, A)$ is the Čech cohomology of the pair $(X, A)$.

Proof. By Proposition 4.12, $F_0 = F_\tau$, and therefore $H^*_R(X, A, F_0) \cong H^*_R(X, A, F_\tau)$. However, the groups $H^*_R(X, A, F_\tau)$ are the Alexander cohomology groups from [3]. By Theorem 2 in [3], then, we have $H^*_R(X, A, F_\tau) \cong H^*(X, A)$. \hfill \Box

We continue with several situations where the semi-uniform structure has a maximal element, facilitating the calculation of the Vietoris-Rips homology and cohomology groups.

Theorem 5.2. Let $(X, d)$ be a finite semi-pseudometric space and suppose that $q > 0$ is a positive real number. Let $U_{\leq q} = \{(x, y) \mid d(x, y) \leq q\}$. Then

$$H^*_R(X, F_q) \cong H_* \left( \Sigma^X_{U_{\leq q}} \right), \text{ and}$$
$$H^*_R(X, F_q) \cong H^* \left( \Sigma^X_{U_{\leq q}} \right).$$
Proof. For every $\epsilon > 0$, define 
\[ V_{q+\epsilon} := \{(x, y) \in X \times X \mid d(x, y) < q + \epsilon \}. \]
Since $X$ is finite, there is an $\epsilon_0 > 0$ such that, for any $0 < \epsilon < \epsilon_0$, $V_{q+\epsilon} = U_{\leq q}$. Since the collection of sets $\{V_{q+\epsilon} \mid 0 < \epsilon < \epsilon_0\}$ is cofinal in $\mathcal{F}$ and, for each such $0 < \epsilon < \epsilon_0$, we have 
\[ H^*_{VR}(X, V_{q+\epsilon}) \cong H^*(\Sigma_{U_{\leq q}}), \quad \text{and} \]
\[ H^*_{VR}(X, V_{q+\epsilon}) \cong H^*(\Sigma_{U_{\leq q}}), \]
the result follows. \[\square\]

Remark 5.3. Recall that, in the classical Vietoris-Rips complex $\Sigma_{VR}(X)$ defined at a scale $q > 0$, the set $\{x_0, \ldots, x_q\}$ is a simplex in $\Sigma_{VR}(X)$ iff, for every pair $(x_i, x_j)$, $d(x_i, x_j) < q$. The above theorem shows that the classical Vietoris-Rips homology and the one defined here are the same for finite pseudo-metric spaces $X$ and all $q > 0$ such that $d(x, x') \neq q$ for any $x, x' \in X$.

Theorem 5.4. Let $M$ be a closed Riemannian manifold, and let $d_{GW}$ denote the Gromov-Hausdorff distance. There exists an $\epsilon_0 > 0$ such that, for any $0 < \epsilon < \epsilon_0$, there exists a $\delta > 0$ where, if $(X, d)$ is a finite metric space with $d_{GW}(M, X) < \delta$, then $H^*(X, V_{\epsilon}) \cong H^*(M)$ and $H^*_{VR}(X, V_{\epsilon}) \cong H^*(M)$.

Proof. By Theorem 1.1 in [8] there exists an $\epsilon_0 > 0$ such that for any $0 < \epsilon < \epsilon_0$, $H^*_V(X, U_\epsilon) \cong H^*_V(M)$ and $H^*_VR(X, U_\epsilon) \cong H^*(M)$, where $U_\epsilon$ is defined by 
\[ U_\epsilon := \{(x, y) \in X \times X \mid d(x, y) < \epsilon \}. \]
Now fix an $0 < \epsilon < \epsilon_0$, and let $0 < \epsilon' < \epsilon_0 - \epsilon$. Then $H^*_V(X, U_{\epsilon+\epsilon'}) \cong H^*_V(M)$ and $H^*_VR(X, U_{\epsilon+\epsilon'}) \cong H^*(M)$. Since the $U_{\epsilon+\epsilon'}$ are cofinal in $\mathcal{F}$, the result follows. \[\square\]

Theorem 5.5. Let $G = (V, E)$ be an undirected graph, and let $(V, \mathcal{F}_E)$ be the associated semi-uniform space, i.e. mathcal{F}_E is the filter generated by $E \in V \times V$. Then $H^*_V(V, cE)$ and $H^*_VR(V, cE)$ are equal to the homology and cohomology, respectively, of the clique complex of $G$.

Proof. By construction, $E$ is a maximal element of $\mathcal{F}_E$ and therefore the single-element family $\{E\}$ is cofinal in $\mathcal{F}_E$. The result follows. \[\square\]
