LOCAL SINGULAR CHARACTERISTICS ON $\mathbb{R}^2$

PIERMARCO CANNARSA AND WEI CHENG

ABSTRACT. The singular set of a viscosity solution to a Hamilton-Jacobi equation is known to propagate, from any noncritical singular point, along singular characteristics which are curves satisfying certain differential inclusions. In the literature, different notions of singular characteristics were introduced. However, a general uniqueness criterion for singular characteristics, not restricted to mechanical systems or problems in one space dimension, is missing at the moment. In this paper, we prove that, for a Tonelli Hamiltonian on $\mathbb{R}^2$, two different notions of singular characteristics coincide up to a bi-Lipschitz reparameterization. As a significant consequence, we obtain a uniqueness result for the class of singular characteristics that was introduced by Khanin and Sobolevski in the paper [On dynamics of Lagrangian trajectories for Hamilton-Jacobi equations. Arch. Ration. Mech. Anal., 219(2):861–885, 2016].

1. INTRODUCTION

This paper is devoted to study the local propagation of singularities for viscosity solutions of the Hamilton-Jacobi equations

\begin{align*}
\text{(HJ)} & \quad H(x, Du(x)) = 0, \quad x \in \mathbb{R}^n, \\
\text{(HJ}_{\text{loc}}) & \quad H(x, Du(x)) = 0, \quad x \in \Omega,
\end{align*}

where $H$ is a Tonelli Hamiltonian in (HJ) and $H$ is of class $C^1$ and strictly convex in the $p$-variable in (HJ$_{\text{loc}}$). In (HJ), we assume that 0 on the right-hand side is Mañé’s critical value. The existence of global weak KAM solutions of (HJ) was obtained in [12]. In (HJ$_{\text{loc}}$), we suppose $\Omega \subset \mathbb{R}^n$ is a bounded domain.

Semiconcave functions are nonsmooth functions that play an important role in the study of (HJ) and (HJ$_{\text{loc}}$). For semiconcave viscosity solutions of Hamilton-Jacobi equations, Albano and the first author proved in [1] that singular arcs can be selected as generalized characteristics. Recall that a Lipschitz arc $x : [0, \tau] \to \mathbb{R}^n$ is called a generalized characteristic starting from $x$ for the pair $(H, u)$ if it satisfies the following:

\begin{equation}
\begin{cases}
\dot{x}(s) \in \text{co} H_p \left(x(s), D^+ u(x(s))\right) & \text{a.e. } s \in [0, \tau], \\
\dot{x}(0) = x.
\end{cases}
\end{equation}

If $x \in \text{Sing} (u)$—the singular set of $u$—then [1, Theorem 5] gives a sufficient condition for the existence of a generalized characteristic propagating the singularity of $u$ locally.

The local structure of singular (generalized) characteristics was further investigated by the first author and Yu in [11], where singular characteristics were proved more regular near the starting point than the arcs constructed in [1]. Such additional properties will be crucial for the analysis we develop in this paper.

Date: August 14, 2020.

Key words and phrases. Hamilton-Jacobi equation, viscosity solution, singular characteristics.
For any weak KAM solution $u$ of (HJ), the class of intrinsic singular (generalized) characteristics was introduced in [4] by the authors of this paper, building on properties of the Lax-Oleinik semi-group of positive type. Such a method allowed to construct global singular characteristics, which we now call intrinsic. Moreover, in [5] and [6] such an “intrinsic approach” turned out to be useful for pointing out topological properties of the cut locus of $u$, including homotopy equivalence to the complement of the Aubry set (see also [7] for applications to Dirichlet boundary value problems).

In spite of its success in capturing singular dynamics, it could be argued that the relaxation procedure in the original definition of generalized characteristics—that is, the presence of the convex hull in (1.1)—might cause a loss of information coming from the Hamiltonian dynamics behind. On the other hand, such a relaxation is necessary to ensure convexity of admissible velocities for the differential inclusion in (1.1), since the map $x \mapsto H_p(x, D^+u(x))$ fails to be convex-valued, in general.

The most important example where the above relaxation is unnecessary is probably given by mechanical Hamiltonians of the form

$$H(x, p) = \frac{1}{2} (A(x)p, p) + V(x),$$

where $A(x)$ is a symmetric positive definite $n \times n$-matrix smoothly depending on $x$ and $V(x)$ is a smooth function on $\mathbb{R}^n$. In this case, a much finer theory has been developed, yielding quantitative tools for the analysis of singular characteristics ([2], [9]) and their long time behaviour ([3]). This is mainly due to the fact that, for a mechanical Hamiltonian, (1.1) reduces to the generalized gradient system

$$\begin{cases}
\dot{x}(t) \in A(x(t))D^+u(x(t)) & t > 0 \text{ a.e.} \\
x(0) = x,
\end{cases}$$

the solutions of which, unique for any initial datum, form a Lipschitz semi-flow (see, e.g., [1], [2], and [8]). Unfortunately, such a uniqueness property, which for (1.2) is a simple consequence of the quasi-dissipativity of the set-valued map $x \mapsto \{A(x)D^+u(x)\}$, breaks down for a general Hamiltonian because $x \mapsto H_p(x, D^+u(x))$ is no longer quasi-dissipative (see [11] and [15]).

Recent significant progress in the attempt to develop a more restrictive notion of singular characteristics is due to Khanin and Sobolevski (13). In this paper, we will call such curves strict singular characteristic but in the literature they are also refereed to as broken characteristics, see [16, 17]. We now proceed to recall their definition: given a semiconcave solution $u$ of (HJ)$_{loc}$, a Lipschitz singular curve $x : [0, T] \to \Omega$ is called a strict singular characteristic from $x \in \text{Sing}(u)$ if there exists a measurable selection $p(t) \in D^+u(x(t))$ such that

$$\begin{cases}
\dot{x}(t) = H_p(x(t), p(t)) & a.e. \ t \in [0, T], \\
x(0) = x.
\end{cases}$$

As already mentioned, the existence of strict singular characteristics for time dependent Hamilton-Jacobi equations was proved in [13], where additional regularity properties of such curves were established including right-differentiability of $x$ for every $t$, right-continuity of $\dot{x}$, and the fact that $p(\cdot) : [0, T] \to \mathbb{R}^n$ satisfies

$$H(x(t), p(t)) = \min_{p \in D^+u(x(t))} H(x(t), p) \quad \forall t \in [0, T].$$

In Appendix A, we give a proof of the existence and regularity of strict characteristics for solutions to (HJ)$_{loc}$ for the reader’s convenience.
In view of the above considerations, it is quite natural to raise the following questions:

(Q1) What is the relation between a strict singular characteristic, \( x \), and a singular characteristic, \( y \), from the same initial point?

(Q2) What kind of uniqueness result can be proved for singular characteristics? What about strict singular characteristics?

In this paper, we will answer the above questions in the two-dimensional case under the following additional conditions:

(A) \( n = 2 \) and \( y \) is Lipschitz;

(B) the initial point \( x = y(0) \) of the singular characteristic \( y \) is not a critical point with respect the pair \((H, u)\), i.e., \( 0 \notin H_p(x_0, D^+ u(x)) \);

(C) \( y \) is right differentiable at \( 0 \) and

\[
\dot{y}^+(0) = H(x_0, p_0),
\]

where \( p_0 = \arg\min\{H(x_0, p) : p \in D^+ u(x)\} \);

(D) \( \lim_{t \to 0^+} \text{ess sup}_{s \in [0, t]} |\dot{y}(s) - \dot{y}^+(0)| = 0. \)

Notice that any strict singular characteristic \( x \) and the singular characteristic \( y \) given in [11] (see also Proposition 2.12) satisfy conditions (A)-(D). The intrinsic singular characteristic \( z \) constructed in [4] (see also Proposition 2.13) satisfies just conditions (A)-(C), in general.

The main results of this paper can be described as follows.

- For any pair of singular curves \( x_1 \) and \( x_2 \) satisfying condition (A)-(D), there exists \( \tau > 0 \) and a bi-Lipschitz homeomorphism \( \phi : [0, \tau] \to [0, \phi(\tau)] \) such that, \( x_1(\phi(t)) = x_2(t) \) for all \( t \in [0, \tau] \). In other words, the singular characteristic starting from a noncritical point \( x \) is unique up to a bi-Lipschitz reparameterization (Theorem 3.6).

- In particular, if \( x \) is a strict singular characteristic and \( y \) is a singular characteristic starting from the same noncritical initial point \( x \), then there exists \( \tau > 0 \) and a bi-Lipschitz homeomorphism \( \phi : [0, \tau] \to [0, \phi(\tau)] \) such that \( y(\phi(t)) = x(t) \) for all \( t \in [0, \tau] \) (Corollary 3.8).

- We have the following uniqueness property for strict singular characteristics: let

\[
x_j : [0, T] \to \Omega \quad (j = 1, 2)
\]

be strict singular characteristics from the same noncritical initial point \( x \). Then there exists \( \tau \in (0, T] \) such that \( x_1(t) = x_2(t) \) for all \( t \in [0, \tau] \). (Theorem 3.9)

Finally, we remark that the results of this paper cannot be applied to intrinsic singular characteristics because of the mentioned lack of condition (D). Extra techniques will have to be developed to cover such an important class of singular arcs.

The paper is organized as follows. In section 2, we introduce necessary material on Hamilton-Jacobi equations, semiconcavity, and singular characteristics. In section 3, we answer question (Q1)-(Q2) in the two-dimensional case. In the appendix, we give a full proof of the existence of strict singular characteristics.

2. HAMILTON-JACOBI EQUATION AND SEMICONCAVITY

In this section, we review some basic facts on semiconcave functions and Hamilton-Jacobi equations.

2.1. Semiconcave function. Let $\Omega \subset \mathbb{R}^n$ be a convex open set. We recall that a function $u : \Omega \to \mathbb{R}$ is semiconcave (with linear modulus) if there exists a constant $C > 0$ such that

$$\lambda u(x) + (1 - \lambda)u(y) - u(\lambda x + (1 - \lambda)y) \leq \frac{C}{2}(1 - \lambda)|x - y|^2$$

for any $x, y \in \Omega$ and $\lambda \in [0, 1]$.

Let $u : \Omega \subset \mathbb{R}^n \to \mathbb{R}$ be a semiconcave function and let $p \in D^+(u)(x)$. Then $u$ is semiconcave in $\Omega$ with constant $C$ and $p \in D^+(u)(x)$. Conversely, if $u$ is semiconcave in $\Omega$ with constant $C$, then (2.2) holds for any $x \in \Omega$ and $p \in D^+(u)(x)$.

Let $u : \Omega \to \mathbb{R}$ be locally Lipschitz. We recall that a vector $p \in \mathbb{R}^n$ is called a reachable (or limiting) gradient of $u$ at $x$ if there exists a sequence $\{x_n\} \subset \Omega \setminus \{x\}$ such that $u$ is differentiable at $x_k$ for each $k \in \mathbb{N}$, and

$$\lim_{k \to \infty} x_k = x \quad \text{and} \quad \lim_{k \to \infty} Du(x_k) = p.$$ 

The set of all reachable gradients of $u$ at $x$ is denoted by $D^+(u)(x)$.

The following proposition concerns fundamental properties of semiconcave functions and their gradients (see [10] for the proof).

**Proposition 2.2.** Let $u : \Omega \subset \mathbb{R}^n \to \mathbb{R}$ be a semiconcave function and let $x \in \Omega$. Then the following properties hold.

(a) $D^+(u)(x)$ is a nonempty compact convex set in $\mathbb{R}^n$ and $D^+(u)(x) \subset \partial D^+(u)(x)$, where $\partial D^+(u)(x)$ denotes the topological boundary of $D^+(u)(x)$.

(b) The set-valued function $x \mapsto D^+(u)(x)$ is upper semicontinuous.

(c) If $D^+(u)(x)$ is a singleton, then $u$ is differentiable at $x$. Moreover, if $D^+(u)(x)$ is a singleton for every point in $\Omega$, then $u \in C^1(\Omega)$.

(d) $D^+(u)(x) = \co D^+(u)(x)$.

(e) If $u$ is both semiconcave and semiconvex in $\Omega$, then $u \in C^{1,1}(\Omega)$.

**Definition 2.3.** Let $u : \Omega \to \mathbb{R}$ be a semiconcave function. $x \in \Omega$ is called a singular point of $u$ if $D^+(u)(x)$ is not a singleton. The set of all singular points of $u$ is denoted by $\operatorname{Sing}(u)$. 

Definition 2.4. Let \( k \in \{0, 1, \ldots, n\} \) and let \( C \subset \mathbb{R}^n \). \( C \) is called a \( k\)-rectifiable set if there exists a Lipschitz continuous function \( f : \mathbb{R}^k \to \mathbb{R}^n \) such that \( C \subset f(\mathbb{R}^k) \). \( C \) is called a countably \( k\)-rectifiable set if it is the union of a countable family of \( k\)-rectifiable sets.

Let us recall a result on the rectifiability of the singular set \( \text{Sing}(u) \) of a semiconcave function \( u \) in dimension two.

Proposition 2.5 ([10]). Let \( \Omega \subset \mathbb{R}^2 \) be an open domain, \( u : \Omega \to \mathbb{R} \) be a semiconcave function, and set

\[
\text{Sing}_k(u) = \{ x \in \text{Sing}(u) : \dim(D^+ u(x)) = k \}, \quad k = 0, 1, 2.
\]

Then \( \text{Sing}_k(u) \) is countably \((2 - k)\)-rectifiable for \( k = 0, 1, 2 \). In particular, \( \text{Sing}_2(u) \) is countable.

2.2. Aspects of weak KAM theory. For any \( x, y \in \mathbb{R}^n \) and \( t > 0 \), we denote by \( \Gamma_{x,y}^t \) the set of all absolutely continuous curves \( \xi \) defined on \([0, t]\) such that \( \xi(0) = x \) and \( \xi(t) = y \).

Define

\[
A_t(x, y) = \inf_{\xi \in \Gamma_{x,y}^t} \int_0^t L(\xi(s), \dot{\xi}(s)) \, ds, \quad x, y \in \mathbb{R}^n, \ t > 0.
\]

We call \( A_t(x, y) \) the fundamental solution for the Hamilton-Jacobi equation

\[
D_t u(t, x) + H(x, \frac{\partial u(t, x)}{\partial x}) = 0, \quad t > 0, x \in \mathbb{R}^n.
\]

By classical results (Tonelli’s theory), the infimum in (2.3) is a minimum. Each curve \( \xi \in \Gamma_{x,y}^t \) attaining such a minimum is called a minimal curve for \( A_t(x, y) \).

Definition 2.6. For each \( u : \mathbb{R}^n \to \mathbb{R} \), let and \( T_t u \) and \( \tilde{T}_t u \) be the Lax-Oleinik evolution of negative and positive type defined, respectively, by

\[
T_t u(x) = \inf_{y \in \mathbb{R}^n} \{ u(y) + A_t(y, x) \}, \quad \tilde{T}_t u(x) = \sup_{y \in \mathbb{R}^n} \{ u(y) - A_t(x, y) \}, \quad (x \in \mathbb{R}^n, t > 0).
\]

The following result is well-known.

Proposition 2.7 ([12]). There exists a Lipschitz semiconcave viscosity solution of (HJ). Moreover, such a solution \( u \) is a common fixed point of the semigroup \( \{T_t\} \), i.e., \( T_t u = u \) for all \( t \geq 0 \).

Clearly, (HJ) has no unique solution and we call each solution, given as a fixed point of the semigroup \( \{T_t\} \), a weak KAM solution of (HJ).

Definition 2.8. Let \( u \) be a continuous function on \( M \). We say \( u \) is \( L\)-dominated if

\[
u(\xi(b)) - u(\xi(a)) \leq \int_a^b L(\xi(s), \dot{\xi}(s)) \, ds,
\]

for all absolutely continuous curves \( \xi : [a, b] \to \mathbb{R}^n \) \((a < b)\), with \( \xi(a) = x \) and \( \xi(b) = y \). We say such an absolutely continuous curve \( \xi \) is a \((u, L)\)-calibrated curve, or a \( u\)-calibrated curve for short, if the equality holds in the inequality above. A curve \( \xi : (-\infty, 0] \to \mathbb{R}^n \) is called a \( u\)-calibrated curve if it is \( u\)-calibrated on each compact sub-interval of \((-\infty, 0]\). In this case, we also say that \( \xi \) is a backward calibrated curve (with respect to \( u \)).

The following result explains the relation between the set of all reachable gradients and the set of all backward calibrated curves from \( x \) (see, e.g., [10] or [14] for the proof).
Proposition 2.9. Let $u : \mathbb{R}^n \to \mathbb{R}$ be a weak KAM solution of $-\Delta_p u(x) = f(x)$ and let $x \in \mathbb{R}^n$. Then $p \in D^+ u(x)$ if and only if there exists a unique $C^2$ curve $\xi : (-\infty, 0] \to \mathbb{R}^n$ with $\xi(0) = x$ and $p = L_v(x, \dot{\xi}(0))$, which is a backward calibrated curve with respect to $u$.

2.3. Propagation of singularities. In this paper, we will discuss various types of singular curves describing the propagation of singularities for Lipschitz semiconcave solutions of the Hamilton-Jacobi equations $(H_{loc})$ and $(H_j)$.

Definition 2.10. $x$ is called a critical point with respect to $(H, u)$ if $0 \in H_p(x_0, D^+ u(x))$.

Let $u$ be a Lipschitz semiconcave viscosity solution of $(H_{loc})$ and $x \in \text{Sing}(u)$.

Definition 2.11. A singular characteristic from $x$ is a Lipschitz arc $x : [0, r] \to \Omega \ (r > 0)$ such that:

1. $x$ is a generalized characteristic with $x(0) = x$,
2. $x(t) \in \text{Sing}(u)$ for all $t \in [0, r]$,
3. $\dot{x}(0) = H_p(x_0, p_0)$ where $p_0 = \arg\min\{ H(x_0, p) : p \in D^+ u(x) \}$,
4. $\lim_{t \to 0^+} \sup_{t \in [0, t]} |\dot{x}(s) - \dot{x}(0)| = 0$.

The following existence of singular characteristic is due to [1, 11].

Proposition 2.12. Let $u$ be a Lipschitz semiconcave solution of $(H_{loc})$ and $x \in \text{Sing}(u)$. Then, there exists a singular characteristic $y : [0, T] \to \Omega$ with $y(0) = x$.

Now, suppose $u$ is a Lipschitz semiconcave weak KAM solution of $(H_j)$. In [4], another singular curve for $u$ is constructed as follows. First, it is shown that there exists $\lambda_0 > 0$ such that for any $(t, \lambda) \in \mathbb{R}_+ \times \mathbb{R}^n$ and any maximizer $y$ for the function $u(\lambda) - A_i(x, \lambda)$, we have that $|y - x| \leq \lambda_0 t$. Then, taking $\lambda = \lambda_0 + 1$, one shows that there exists $t_0 > 0$ such that, if $t \in (0, t_0)$, then there exists a unique $y_{t,x} \in B(x, \lambda t)$ of $u(\cdot) - A_i(x, \cdot)$ such that

\begin{equation}
\dot{T}_t u(x) = u(y_{t,x}) - A_i(x, y_{t,x}).
\end{equation}

Moreover, such a $t_0$ is such that $-A_i(x, \cdot)$ is concave with constant $C_2/t$ and $C_1 - C_2/t < 0$ for $0 < t \leq t_0$. We now define the curve

\begin{equation}
z(t) = \begin{cases} x, & t = 0, \\ y_{t,x}, & t \in (0, t_0]. \end{cases}
\end{equation}

Proposition 2.13 ([4]). Let the curve $z$ be defined in (2.5). Then, the following holds:

1. $z$ is a Lipschitz generalized characteristic,
2. if $x \in \text{Sing}(u)$ then $z(t) \in \text{Sing}(u)$ for all $t \in [0, t_0]$,
3. $\dot{z}(0)$ exists and

\begin{equation}
\dot{z}(0) = H_p(x_0, p_0)
\end{equation}

where $p_0 = \arg\min\{ H(x_0, p) : p \in D^+ u(x) \}$.

Hereafter, we will refer to the arc $z$ defined in (2.5) as the intrinsic characteristic from $x$.

3. Singular Characteristic on $\mathbb{R}^2$

We now return to questions (Q1) and (Q2) from the Introduction. So far, we have introduced three kinds of singular arcs issuing from a point $x_0 \in \text{Sing}(u)$, namely

- strict singular characteristics, that is, solutions to (1.3),
- singular characteristics, introduced in Definition 2.11, and
- the intrinsic singular characteristic $z$ given by Proposition 2.13.
In this section, we will compare the first two notions of characteristics when \( \Omega \subseteq \mathbb{R}^2 \).

We begin by introducing the following class of Lipschitz arcs.

**Definition 3.1.** Given \( T > 0 \), we denote by \( \text{Lip}_0(0, T; \Omega) \) the class of all Lipschitz arcs \( x : [0, T] \to \Omega \) such that the right derivative

\[
\dot{x}^+(0) = \lim_{t \downarrow 0} \frac{x(t) - x(0)}{t}
\]

does exist and satisfies

\[
\lim_{t \to 0^+} \text{ess sup}_{s \in [0, t]} |\dot{x}(s) - \dot{x}^+(0)| = 0.
\]

For any \( x \in \text{Lip}_0(0, T; \Omega) \) we set

\[
\omega_x(t) := \text{ess sup}_{s \in [0, t]} |x(s) - x^+(0)|.
\]

Owing to (3.1), we have that \( \omega_x(t) \to 0 \) as \( t \downarrow 0 \).

**Lemma 3.2.** Let \( x \in \text{Lip}_0(0, T; \Omega) \) be such that \( \dot{x}^+(0) \neq 0 \). Then,

\[
|\dot{x}(t_1) - \dot{x}(t_0)| - |t_1 - t_0| - |\dot{x}^+(0)| \leq |t_1 - t_0| \omega_x(t_1 \lor t_0) \quad \forall t_0, t_1 \in [0, T]
\]

and \( x \) is injective on some interval \([0, T_0]\) with \( 0 < T_0 < T \).

**Proof.** Observe that, for any \( 0 \leq t_0 \leq t_1 \leq T \), the identity

\[
x(t_1) - x(t_0) = \int_{t_0}^{t_1} \dot{x}(t) \, dt = (t_1 - t_0) \dot{x}^+(0) + \int_{t_0}^{t_1} (\dot{x}(t) - \dot{x}^+(0)) \, dt
\]

immediately gives (3.3). In turn, (3.3) implies that, if \( \dot{x}(t_1) - \dot{x}(t_0) = 0 \), then

\[
|t_1 - t_0| - |\dot{x}^+(0)| \leq |t_1 - t_0| \omega_x(t_1)
\]

Since \( \dot{x}^+(0) \neq 0 \), we conclude that \( t_1 = t_0 \) if \( t_0, t_1 \in [0, T_0] \) with \( T_0 \) sufficiently small. \( \square \)

Let \( x \in \mathbb{R}^2 \) and let \( \theta \in \mathbb{R}^n \) be a unit vector. For any \( \rho \in (0, 1) \) let us consider the cone

\[
C_{\rho}(x, \theta) = \left\{ y \in \mathbb{R}^2 \mid \langle y - x, \theta \rangle \geq \rho |y - x| \right\}
\]

with vertex in \( x \), amplitude \( \rho \), and axis \( \theta \). Clearly, \( C_{\rho}(x, \theta) \) is given by the union of the two cones

\[
C_{\rho}^+(x, \theta) = \left\{ y \in \mathbb{R}^2 \mid \langle y - x, \theta \rangle \geq \rho |y - x| \right\}
\]

and

\[
C_{\rho}^-(x, \theta) = \left\{ y \in \mathbb{R}^2 \mid \langle y - x, \theta \rangle \leq -\rho |y - x| \right\},
\]

which intersect each other only at \( x \).

**Lemma 3.3.** Let \( x_j \in \text{Lip}_0(0, T; \Omega) \) \((j = 1, 2)\) be such that

(i) \( x_j(0) = x_0(0) =: x_0 \),
(ii) \( \dot{x}_j(0) = \dot{x}_j^+(0) \), and
(iii) \( \dot{x}_j(s) \neq 0 \) \((j = 1, 2)\) for a.e. \( s \in [0, T] \).

Define

\[
\theta_j(s) = \frac{\dot{x}_j(t)}{|\dot{x}_j(t)|} \quad (s \in [0, T] \text{ a.e.})
\]

and fix \( \rho \in (0, 1) \). Then the following holds true:

(a) there exists \( s_\rho \in (0, T) \) such that \( x_0 \in C_{\rho}^{-}(x_1(s), \theta_1(s)) \) for a.e. \( s \in [0, s_\rho] \);
(b) there exists \( \tau_\rho \in (0, T] \) such that for all \( t \in (0, \tau_\rho] \) there exists \( \sigma_\rho(t) \in (0, T] \) such that

\[
|x_2(t) - x_1(s)| \leq \frac{1 + \rho}{2\rho} t|x_1^+(0)| \quad \forall s \in [0, \sigma_\rho(t)]
\]

(3.6)

and (a) follows.

Then

\[ x_2(t) \in C^+_\rho(x_1(s), \theta_1(s)) \quad \text{for a.e. } s \in [0, \sigma_\rho(t)]. \]

Proof. Hereafter, we denote by \( o_i(s) (i \in \mathbb{N}) \) any (scalar- or vector-valued) function such that

\[
\lim_{s \to 0^+} \frac{o_i(s)}{s} = 0.
\]

In view of (3.3) we conclude that

\[
|x_0 - x_1(s)| = s|x_1^+(0)| + o_1(s) \quad \forall s \in [0, T].
\]

Moreover, setting \( \theta_1(0) = x_1^+(0)/|x_1^+(0)| \), for a.e. \( s \in [0, T] \) we have that

\[
\langle x_0 - x_1(s), \theta_1(s) \rangle = \langle x_0 - x_1(s), \theta_1(0) \rangle + \langle x_0 - x_1(s), \theta_1(s) - \theta_1(0) \rangle
\]

(3.9)

\[
= -s|x_1^+(0)| + o_2(s).
\]

Now, having fixed \( \rho \in (0, 1) \) let \( s_\rho \in (0, T_1) \) be such that, for a.e. \( s \in [0, s_\rho] \),

\[
\frac{|o_1(s)|}{s} \leq \frac{1 - \rho}{2\rho} |x_1^+(0)| \quad \text{and} \quad \frac{|o_2(s)|}{s} \leq \frac{1 - \rho}{2} |x_1^+(0)|.
\]

Then \( |x_0 - x_1(s)| \leq \frac{1 + \rho}{2\rho} s|x_1^+(0)| \) by (3.8). From (3.9) it follows that

\[
\langle x_0 - x_1(s), \theta_1(s) \rangle \leq -\frac{1 + \rho}{2} s|x_1^+(0)| \leq -\rho|x_0 - x_1(s)| \quad (s \in [0, s_\rho] \text{ a.e.})
\]

and (a) follows.

The proof of (b) is similar: since \( \dot{x}_2^+(0) = \dot{x}_1^+(0) \) by condition (ii), for all \( t \in [0, T] \) and \( s \in [0, T] \) we have that

\[
x_2(t) - x_1(s) = (t - s)\dot{x}_1^+(0) + o_3(t) + o_3(s).
\]

(3.10)

Hence, for all \( s, t \in (0, T] \) we deduce that

\[
\left| \frac{x_2(t) - x_1(s)}{t|x_1^+(0)|} - \frac{\dot{x}_1^+(0)}{|x_1^+(0)|} \right| \leq \frac{s}{t} + \frac{|o_3(t)| + |o_3(s)|}{t|x_1^+(0)|}.
\]

So,

\[
|x_2(t) - x_1(s)| \leq t|x_1^+(0)| \left( 1 + \frac{s}{t} + \frac{|o_3(t)| + |o_3(s)|}{t|x_1^+(0)|} \right).
\]

(3.11)

Next, take the scalar product of each side of (3.10) with \( \theta_1(s) \) to obtain

\[
\langle x_2(t) - x_1(s), \theta_1(s) \rangle = t\langle \dot{x}_1^+(0), \theta_1(s) \rangle - \langle s\dot{x}_1^+(0) - o_3(t) - o_3(s), \theta_1(s) \rangle
\]

(3.12)

\[ = t\langle \dot{x}_1^+(0) \rangle + t\langle \dot{x}_1^+(0), \theta_1(s) - \theta_1(0) \rangle - \langle s\dot{x}_1^+(0) - o_3(t) - o_3(s), \theta_1(s) \rangle
\]

for all \( t \in [0, T] \) and a.e. \( s \in [0, T] \).

Once again, having fixed \( \rho \in (0, 1) \), we can find \( \tau_\rho \in (0, T] \) satisfying the following: for all \( t \in (0, \tau_\rho] \) there exists \( \sigma_\rho(t) \in (0, T] \) such that

\[
tl|\dot{x}_1^+(0), \theta_1(s) - \theta_1(0)| + |s\dot{x}_1^+(0) - o_3(t) - o_3(s), \theta_1(s)\rangle | \leq \frac{1 - \rho}{2} t|x_1^+(0)|
\]

and

\[
1 + \frac{s}{t} + \frac{|o_3(t)| + |o_3(s)|}{t|x_1^+(0)|} \leq 1 + \frac{\rho}{2\rho}
\]
for all $t \in [0, \tau_1]$ and a.e. $s \in [0, \sigma_1(t)]$. Then, (3.11) leads directly to (3.6). Moreover, returning to (3.12), for all $t \in [0, \tau_1]$ and a.e. $s \in [0, \sigma_1(t)]$ we conclude that

$$
\langle x_2(t) - x_1(s), \theta_1(s) \rangle \geq t|x_1^+(0)| - \frac{1 - \rho}{2} t|x_1^+(0)| = \frac{1 + \rho}{2} t|x_1^+(0)| \geq \rho|x_2(t) - x_1(s)|,
$$

where we have used (3.11) to deduce the last inequality. Hence, (3.7) follows. \[\square\]

Given a semiconcave solution $u$ of (HJloc), we hereafter concentrate on singular arcs for $u$, that is, arcs $x \in \text{Lip}_0(0, T; \Omega)$ such that $x(t) \in \text{Sing}(u)$ for all $t \in [0, T]$. We denote such a subset of $\text{Lip}_0(0, T; \Omega)$ by $\text{Lip}_0^*(0, T; \Omega)$.

**Lemma 3.4.** Let $u$ be a semiconcave solution of (HJloc) and let $x \in \text{Lip}_0^*(0, T; \Omega)$ be such that $\dot{x}^+(0) \neq 0$. Then there exists $T_0 \in (0, T]$ such that the set

$$
S_x = \left\{ s \in [0, T_0] \mid D^+u(x(s)) = [p_s^1, p_s^2] \text{ with } p_s^1, p_s^2 \in D^+u(x(s)), p_s^1 \neq p_s^2 \right\}
$$

has full measure in $[0, T_0]$. Moreover, $\lim_{s \to 0^+} p_s^i = p_0$ with $p_0 \in D^+u(x_0)$ $(i = 1, 2)$ and

$$
\langle \dot{x}(s), p_s^2 - p_s^1 \rangle = 0 \quad \text{for a.e. } s \in [0, T_0]
$$

**Proof.** The structure of the superdifferential of $u$ along $x$ is described by Proposition 2.5 and Proposition 3.13.15 in [10]. \[\square\]

**Lemma 3.5.** Let $u$ be a semiconcave solution of (HJloc) and let $x_0 \in \text{Sing}(u)$ be such that $0 \notin H_p(x_0, D^+u(x_0))$. Let $x \in \text{Lip}_0^*(0, T; \Omega)$ be such that $x(0) = x_0$ and

$$
\dot{x}^+(0) = H_p(x_0, p_0) \quad \text{where } p_0 = \arg \min\{H(x_0, p) : p \in D^+u(x_0)\}. \tag{3.13}
$$

Let $T_0 \in (0, T]$ be given by Lemma 3.4 and, for every $s \in S_x$, let $\xi^1_s$ and $\xi^2_s$ be backward calibrated curves on $(-\infty, 0)$ satisfying

$$
\xi^i_s(0) = x(s) \quad \text{and} \quad \xi^i_s(0) = H_p(x(s), p_s^i) \quad (i = 1, 2) \tag{3.14}
$$

Then there exist constants $r_i > 0$, $s_1 \in [0, T_0]$, and $\delta \in (0, 1)$ and such that

$$
|x(s) - \xi^i_s(-r)| \geq \delta r \quad (i = 1, 2) \tag{3.15}
$$

and, for all $s \in [0, s_1] \cap S_x$ and $r \in [0, r_0]$, $\xi^i_s(-r) \in C^+_\delta(x(s), \theta_2(s))$ and $\xi^2_s(-r) \in C^-_\delta(x(s), \theta_2(s))$ where

$$
\theta_2(s) = \frac{p^2_s - p^1_s}{|p^2_s - p^1_s|} \quad (s \in S_x).
$$

**Proof.** The existence of backward calibrated curves satisfying (3.14) follows from Proposition 2.9. Moreover, for all $r \geq 0$ we have that

$$
x(s) - \xi^i_s(-r) = \xi^i_s(0) - \xi^i_s(-r) = r\xi^i_s(0) + o(r) = rH_p(x(s), p_s^i) + o(r) \quad (i = 1, 2) \tag{3.17}
$$

where $\lim_{r \to 0^+} o(r)/r = 0$ uniformly with respect to $s \in S_x$.

Now, observe that, since $x_0$ is not a critical point with respect to $(u, H)$, by possibly reducing $T_0$ we have that $x(s)$ is also not a critical point for all $s \in [0, T_0]$ due to the upper-semicontinuity of the set-valued map $s \mapsto H_p(x(s), D^+u(x(s)))$. So, for some $r_0 > 0$, $s_0 \in (0, T_1)$, and $\delta_0 \in (0, 1)$, we deduce that

$$
\frac{r}{\delta_0} \geq |x(s) - \xi^i_s(-r)| = r|H_p(x(s), p_s^i)| + o(r) \geq \delta_0 r \quad (i = 1, 2) \tag{3.18}
$$

for all $s \in [0, s_0] \cap S_x$ and $r \in [0, r_0]$. This proves (3.16).
Next, recall that $H(x_0, p_0^i) = 0$ because $p_0^i \in D^u(x_0)$ ($i = 1, 2$). So, by the strict convexity of $H(x_0, \cdot)$, we deduce that there exists $v > 0$ such that

\[
\langle H_p(x_0, p_0^2), p_0^2 - p_0^1 \rangle \geq H(x_0, p_0^2) - H(x_0, p_0^1) + v|p_0^2 - p_0^1|^2 = v|p_0^2 - p_0^1|^2 > 0
\]

\[
\langle H_p(x_0, p_0^1), p_0^2 - p_0^1 \rangle \leq H(x_0, p_0^1) - H(x_0, p_0^1) - v|p_0^2 - p_0^1|^2 = -v|p_0^2 - p_0^1|^2 < 0
\]

Hence, the upper-semicontinuity of the set-valued map $s \mapsto H_p(x(s), D^u(x(s)))$ ensures the existence of numbers $\delta_{1} \in (0, 1)$ and $s_1 \in (0, s_0]$ such that

\[
\|H_p(x(s), p_0^i), \theta_2(s)\| \geq \delta_{1}, \quad \|H_p(x(s), p_0^i), \theta_2(s)\| \leq -\delta_{1} \quad \forall s \in [0, s_1] \cap S.
\]

Therefore, combining (3.17) and (3.19), we conclude that, after possibly replacing $r_0$ by a smaller number $r_1 > 0$,

\[
\langle \xi(s, -r) - x(s), \theta_2(s)\rangle = -\langle H_p(x(s), p_0^1), \theta_2(s)\rangle + o(r) \geq r\delta_{1} + o(r) \geq \frac{\delta_{1}}{2}
\]

for all $s \in [0, s_1] \cap S_{\delta}$ and $r \in [0, r_1]$. By (3.18) and the above inequality we have that $\xi(s, -r) \in C_{\delta}^{\pm}(x(s), \theta_2(s))$ with $\delta_{\delta} = \delta_{0}\delta_{1}/2$.

The analogous statement for $\xi(s, -r)$ in (3.16) can be proved by a similar argument. \hfill \Box

We are now ready to state our main result, which ensures that singular curves coincide up to a bi-Lipschitz reparameterization, at least when $x$ is not a critical point.

**Theorem 3.6.** Let $u$ be a semiconcave solution of $(HJ_{loc})$ and let $x_0 \in \text{Sing}(u)$ be such that $0 \notin H_p(x_0, D^u(x_0))$. Let $x_j \in \text{Lip}^u_0(0, T; \Omega)$ ($j = 1, 2$) be such that $x_j(0) = x_0$ and

\[
x_j^+(0) = H_p(x_0, p_0) \text{ where } p_0 = \text{arg min}\{H(x_0, p) : p \in D^u(x_0)\}.
\]

Then, there exists $\sigma \in (0, T]$ such that there exists a unique bi-Lipschitz homeomorphism

\[
\phi : [0, \sigma] \rightarrow [0, \phi(\sigma))] \subset [0, T_{1}]
\]

satisfying $x_j(s) = x_2(\phi(s))$ for all $s \in [0, \sigma]$.

We begin the proof with the following lemma.

**Lemma 3.7.** Under all assumptions of Theorem 3.6, there exists $\sigma \in (0, T]$ such that for all $s \in [0, \sigma]$ there exists a unique $t_s \in [0, T]$ satisfying $x_2(t_s) = x_1(s)$.

**Proof.** First, reduce $T > 0$ in order to ensure that $x_1$ and $x_2$ are both injective on $[0, T]$ and satisfy $x_j(s) \neq 0$ for a.e. $s \in [0, T]$ ($j = 1, 2$).

Then, observe that Lemma 3.5, applied to $x = x_1$, ensures the existence of $r_1 > 0$, $s_1 \in (0, T]$, and $\delta \in (0, 1)$ such that for a.e. $s \in [0, s_1]$ one can find backward calibrated curves $\xi_{s}^{\pm}$ on $(-\infty, 0]$ satisfying (3.14), (3.15), and (3.16) for all $r \in [0, r_1]$.

Next, choose

\[
\rho = \frac{1 + \sqrt{1 - \delta^2}}{2} \in (\sqrt{1 - \delta^2}, 1)
\]

in Lemma 3.3 and let $s_\rho$, $r_\rho$, and $\sigma_\rho(\cdot)$ be such that

(i) $x_0 \in C_{\rho}^{-}(x_1(s), \theta_1(s))$ for a.e. $s \in [0, s_\rho]$,

(ii) $x_2(t) \in C_{\rho}^{+}(x_1(s), \theta_1(s))$ for all $t \in [0, r_\rho]$ and a.e. $s \in [0, \sigma_\rho(t)]$,

(iii) $|x_2(t) - x_1(s)| \leq \frac{1 + \delta}{2\rho}|x_1^+(0)|$ for all $t \in [0, r_\rho]$ and all $s \in [0, \sigma_\rho(t)]$. 

Intersect at least one of the two calibrated curves. Then, recalling that \( |\varvec{v}| \) is smooth at all points \( \varvec{v} \neq 0 \). However, this can happen only at \( \varvec{v}(0) = \varvec{v}_1(0) = \varvec{v}_2(0) \), because \( u \) is smooth at all points \( \varvec{v}(0) = \varvec{v}_2(0) \).

By possibly reducing \( \rho \), without loss of generality we can suppose that

\[
1 + \rho_{\rho} |\varvec{v}_1(0)| < \delta r_1.
\]

Then, recalling that

\[
\theta_1(s) = \frac{x_1(s)}{|x_1(s)|} \quad \text{and} \quad \theta_2(s) = \frac{p_2^1 - p_1^1}{|p_2^1 - p_1^1|} \quad (s \in [0, T] \text{ a.e.})
\]

are orthogonal unit vectors, we claim that, for a.e. \( s_{1} \leq s \leq s_{1} \wedge \tau_{\rho} \),

\[
C_{\rho}(x_1(s), \theta_1(s)) \cap C_{\rho}(x_1(s), \theta_2(s)) = \{x_1(s)\}.
\]

Indeed, for any \( x \in C_{\rho}(x_1(s), \theta_1(s)) \cap C_{\rho}(x_1(s), \theta_2(s)) \) we have that

\[
|x - x_1(s)|^2 = \langle x - x_1(s), \theta_1(s) \rangle^2 + \langle x - x_1(s), \theta_2(s) \rangle^2
\geq (\rho^2 + \delta^2)|x - x_1(s)|^2.
\]

This yields \( x = x_1(s) \) because \( \rho^2 + \delta^2 > 1 \).

Now, define \( \sigma = \min \{ s_{1}, s_{\rho}, \sigma_{\rho}(\tau_{\rho}) \} \) and fix \( s \in [0, \sigma] \) in the set of full measure on which (i) is satisfied together with (ii) and (iii), that is,

\[
x_2(\tau_{\rho}) \in C_{\rho}(x_1(s), \theta_1(s)) \quad \text{and} \quad |x_2(\tau_{\rho}) - x_1(s)| < \delta r_1
\]

where (3.20) has also been taken into account. By possibly reducing \( \sigma \), we also have that \(|x_2(t) - x_1(s)| < \delta r_1|\) for all \( t \in [0, \tau_{\rho}] \). So, the arc \( x_2 \), restricted to \([0, \tau_{\rho}] \), connects the point \( x_2(\tau_{\rho}) \) of the cone \( C_{\rho}(x_1(s), \theta_1(s)) \) with \( x_0 \in C_{\rho}(x_1(s), \theta_1(s)) \), remaining in the open ball of radius \( \delta r_1 \) centered at \( x_1(s) \). Thus, in view of (3.15) and (3.16), \( x_2 \) must intersect at least one of the two calibrated curves \( \varvec{v}_2^1 \) and \( \varvec{v}_2^2 \). However, this can happen only at \( \varvec{v}_1^1(0) = \varvec{v}_1(0) = \varvec{v}_2^2(0) \), because \( u \) is smooth at all points \( \varvec{v}_2^2(-r) \) with \( 0 < r < \infty \),
whereas $x_2$ is a singular arc. Finally, such an intersection occurs at a unique time $t_s$ owing to Lemma 3.2.

To complete the proof we observe that $x_2(t_s) = x_1(s)$ for all $s \in [0, \sigma]$, not just on a set of full measure. This fact can be easily justified by an approximation argument. □

We are now in a position to prove our main result.

Proof of Theorem 3.6. Let $\sigma \in (0, T]$ be given by Lemma 3.7. Then for each $s \in [0, \sigma]$ there exists a unique $\phi(s) := t_s \in [0, T_1]$ with $x_2(\phi(s)) = x_1(s)$.

Recalling that, thanks to Lemma 3.2, both $x_1(\cdot)$ and $x_2(\cdot)$ can be assumed to be injective on $[0, \sigma]$ and $[0, \phi(\sigma)]$, respectively, we proceed to show that $\phi$ is also an injection. Observe that, for any $0 \leq s_0, s_1 \leq \sigma$, 

$$x_2(\phi(s_1)) - x_2(\phi(s_0)) = \int_{\phi(s_0)}^{\phi(s_1)} \dot{x}_2(t) \, dt = \int_{\phi(s_0)}^{\phi(s_1)} (\dot{x}_2(t) - \dot{x}_2^+(0)) \, dt + (\phi(s_1) - \phi(s_0)) \dot{x}_2^+(0).$$

Therefore, 

$$|x_2(\phi(s_1)) - x_2(\phi(s_0)) - (\phi(s_1) - \phi(s_0)) \dot{x}_2^+(0)| \leq \omega_{\dot{x}_2}(\phi(s_1) \cup \phi(s_0))|\phi(s_1) - \phi(s_0)|,$$

where $\omega_{\dot{x}_2}$ is given by (3.2). Thus, returning to $x_1 = x_2 \circ \phi$ we derive

$$|x_1(s_1) - x_1(s_0)| \leq |\phi(s_1) - \phi(s_0)| \left( |\dot{x}_2^+(0)| - \omega_{\dot{x}_2}(\phi(s_1) \cup \phi(s_0)) \right),$$

$$|x_1(s_1) - x_1(s_0)| \leq |\phi(s_1) - \phi(s_0)| \left( |\dot{x}_2^+(0)| + \omega_{\dot{x}_2}(\phi(s_1) \cup \phi(s_0)) \right).$$

Notice that (3.21) leads to

$$|\phi(s_1) - \phi(s_0)| \geq \frac{|x_1(s_1) - x_1(s_0)|}{|\dot{x}_2^+(0)| + \omega_{\dot{x}_2}(\phi(s_1) \cup \phi(s_0))}$$

and this implies that $\phi$ is injective as so is $x_1$.

Next, we prove that $\phi$ is continuous on $[0, \sigma]$, or the graph of $\phi$ is closed. Let $s_j \to \bar{s}$ be any sequence such that $\phi(s_j) \to \bar{t}$ as $j \to \infty$. Then

$$x_1(s_j) \to x_1(\bar{s}) \quad \text{and} \quad x_2(\phi(s_j)) = x_1(s_j) \to x_2(\bar{t}) \quad \text{as} \quad j \to \infty.$$

So, $x_2(\phi(\bar{s})) = x_1(\bar{s}) = x_2(\bar{t})$. Since $x_2(\cdot)$ is injective, it follows that $\bar{t} = \phi(\bar{s})$.

Being continuous, $\phi$ is a homeomorphism. It remains to prove that $\phi$ is bi-Lipschitz. The continuity of $\phi$ at 0 ensures that, after possibly reducing $\sigma$,

$$\omega_{\dot{x}_1}(s), \omega_{\dot{x}_2}(t) \leq \frac{|\dot{x}_2^+(0)|}{2} = \frac{|\dot{x}_2^+(0)|}{2}$$

for all $s_0, s_1 \in [0, \sigma]$. Thus, by (3.21) we have that

$$|\phi(s_1) - \phi(s_0)| \leq \frac{|x_1(s_1) - x_1(s_0)|}{|\dot{x}_2^+(0)| - \omega_{\dot{x}_2}(\phi(s_1) \cup \phi(s_0))} \leq \frac{2 \text{Lip}(x_1)}{|\dot{x}_2^+(0)|} \cdot |s_1 - s_0|$$

for all $s \in [0, \sigma]$ and $t \in [0, \phi(\sigma)]$. So, $\phi$ is Lipschitz on $[0, \sigma]$. The fact that $\phi^{-1}$ is also Lipschitz follows by a similar argument. Indeed, writing (3.22) for $t_i = \phi(s_i)$ and
appealing to Lemma 3.2 and (3.23) once again we obtain
\[
|t_1 - t_0| \geq \frac{|x_2(t_1) - x_2(t_0)|}{|\dot{x}_2^+(0)| + \omega_{x_2}(t_1 \lor t_0)} = \frac{|x_1(s_1) - x_1(s_0)|}{|\dot{x}_1^+(0)| + \omega_{x_1}(t_1 \lor t_0)}
\]
\[
\geq \frac{|\dot{x}_1^+(0)| - \omega_{x_1}(s_1 \lor s_0)}{|\dot{x}_2^+(0)| + \omega_{x_2}(t_1 \lor t_0)} \cdot |s_1 - s_0| \geq \frac{1}{3} |s_1 - s_0|
\]

The proof is completed noting that \( \phi \) is unique due to the injectivity of \( x_1 \) and \( x_2 \). \( \square \)

**Corollary 3.8.** Let \( x \) be a strict singular characteristic as in (1.3) and let \( y \) be any singular characteristic as in Proposition 2.12. If \( x_0 \) is not a critical point with respect to \( (H, u) \), then there exists \( \sigma > 0 \) and a bi-Lipschitz homeomorphism \( \phi : [0, \sigma] \rightarrow [0, \phi(\sigma)] \) such that \( y(\phi(s)) = x(s) \) for all \( s \in [0, \sigma] \).

For strict singular characteristics, uniqueness holds without reparameterization as we show next.

**Theorem 3.9.** Let \( u \) be a semiconcave solution of \( (H_{ij}) \) and let \( x_0 \in \text{Sing}(u) \) be such that \( 0 \in H_p(x_0, D^+(u(x_0))) \). Let \( x_j : [0, T] \rightarrow \Omega (j = 1, 2) \) be strict singular characteristics with initial point \( x_0 \). Then there exists \( \tau \in (0, T) \) such that \( x_1(t) = x_2(t) \) for all \( t \in [0, \tau] \).

**Proof.** By Theorem 3.6 there exists a bi-Lipschitz homeomorphism \( \phi : [0, \tau_1] \rightarrow [0, \tau_2] \), with \( 0 \leq \tau_j \leq T \) \((j = 1, 2)\), such that
\[
(3.24) \quad x_1(t) = x_2(\phi(t)) \quad \forall t \in [0, \tau_1].
\]

Moreover, since \( x_1 \) and \( x_2 \) are strict characteristics we have that
\[
\begin{cases}
\dot{x}_j^+(t) = H_p(x_j(t), p_j(t)) \\
H(x_j(t), p_j(t)) = \min_{p \in D^+(u(x_j(t)))} H(x_j(t), p)
\end{cases} \quad \forall t \in [0, \tau_1] \quad (j = 1, 2)
\]

Therefore,
\[
H_p(x_1(t), p_1(t)) = \phi'(t)H_p(x_2(\phi(t)), p_2(\phi(t))) \quad (t \in [0, \tau_1])
\]

where, in addition to (3.24), we have that
\[
p_2(\phi(t)) = \arg \min_{p \in D^+(u(x_2(\phi(t))))} H(x_2(\phi(t)), p) = \arg \min_{p \in D^+(u(x_1(t)))} H(x_1(t), p) = p_1(t).
\]

So, \( H_p(x_1(t), p_1(t)) = \phi'(t)H_p(x_2(t), p_1(t)) \) for all \( t \in [0, \tau_1] \). Since \( 0 \notin H_p(x_0, D^+(u(x_0))) \), we conclude that \( \phi'(t) = 1 \), or \( \phi(t) = t \), on some interval \( 0 \leq t \leq \tau \). \( \square \)

Theorem 3.6 and Theorem 3.9 establish a connection between the absence of critical points and uniqueness of strict singular characteristics. In this direction, we also have the following global result.

**Corollary 3.10.** Let \( u \) be a semiconcave solution of \( (H_{ij}) \) and let \( x_0 \in \text{Sing}(u) \). Let \( x_j : [0, T] \rightarrow \Omega (j = 1, 2) \) be strict singular characteristics with initial point \( x_0 \) such that \( 0 \notin H_p(x_j(t), D^+(u(x_j(t)))) \) for all \( t \in [0, T] \). Then \( x_1(t) = x_2(t) \) for all \( t \in [0, T] \).

**Proof.** On account of Theorem 3.9 we have that
\[
\mathcal{T} := \{ t \in (0, T) \mid x_1(t) = x_2(t), \forall t \in [0, \tau] \}
\]
is a nonempty set. Let \( \tau_0 = \sup \mathcal{T} = \max \mathcal{T} \). We claim that \( \tau_0 = T \). For if \( \tau_0 < T \), applying Theorem 3.9 with initial point \( x_1(\tau_0) \) we conclude that \( x_1(t) = x_2(t) \) on some interval \( \tau_0 \leq t < \tau_0 + \delta \), contradicting the definition of \( \tau_0 \). \( \square \)
Another well-known example where we have uniqueness of the generalized characteristic is the mechanical Hamiltonian

\[ H(x, p) = \frac{1}{2} |p|^2 + V(x), \quad (x, p) \in \Omega \times \mathbb{R}^n, \]

with \( V \) a smooth function on \( \Omega \). More precisely, if \( x \in \text{Sing}(u) \), then there exists a unique Lipschitz arc \( y \) determined by \( \dot{y}(t) = p(t) \), where \( y(0) = x \) and \( p(t) = \arg\min_{p \in D^+u(y(t))} |p| \).

In this case, uniqueness follows from semiconcavity by an application of Gronwall’s lemma (see, e.g., [10]) ensuring that, in addition, any generalized characteristic is strict. We now give another justification of such a property from the point of view of this section.

**Corollary 3.11.** If \( H \) is a mechanical Hamiltonian as in (3.25), then the reparameterization \( \phi \) in Theorem 3.6 is the identity.

**Proof.** We observe that, for almost all \( t \geq 0 \),

\[ \dot{y}(t) = \lambda(t)p_0(t) + (1 - \lambda(t))p_1(t) \]

where \( \lambda(t) \in [0, 1] \) and we can assume \( D^+u(y(t)) \) is a segment, say \( [p_1(t), p_0(t)] \), or \( \{p_0(t), p_1(t)\} \in D^+u(y(t)) \). Notice that \( \{p_0(t), p_1(t)\} \) is also the set of extremal points of the convex set \( D^+u(y(t)) \).

Since \( x(t) = y(\phi(t)) \), differentiating we obtain that

\[ \dot{x}(t) = p(t) = \phi'(t)\dot{y}(\phi(t)) = \phi'(t)\lambda(\phi(t))p_0(\phi(t)) + (1 - \lambda(\phi(t)))p_1(\phi(t)) \]

with \( D^+u(y(\phi(t))) = [p_0(\phi(t)), p_1(\phi(t))] \), or \( \{p_0(\phi(t)), p_1(\phi(t))\} \in D^+u(y(\phi(t))) \).

Therefore, there exists a unique \( \lambda_i \in [0, t] \) such that

\[ p(t) = \lambda_i p_0(\phi(t)) + (1 - \lambda_i) p_1(\phi(t)) \]

It follows that

\[ \phi'(t) = \phi'(t)\lambda(\phi(t)) + (1 - \lambda(\phi(t))) = \lambda_i + (1 - \lambda_i) = 1. \]

Thus, \( \phi(t) \equiv t \) and this completes the proof.

**APPENDIX A. EXISTENCE OF STRICT SINGULAR CHARACTERISTICS**

In this Appendix, we prove the following result which ensures the existence of strict singular characteristics mentioned in the Introduction.

We recall that

\[ x^+(t) := \lim_{h \to 0} \frac{x(t + h) - x(t)}{h} \quad (t \in [0, T]) \]

denotes the right derivative of \( x : [0, T] \to \Omega \), whenever such a derivative exists.

**Theorem A.1.** Let \( u \) be a semiconcave solution of \( (HJ)_{\text{loc}} \). If \( x_0 \in \text{Sing}(u) \) satisfies

\[ \{ x^+(t) = H_p(x(t), p(t)) \quad \forall t \in [0, T), \]

\[ x(0) = x_0. \]

and

\[ H(x(t), p(t)) = \min_{p \in D^+u(x(t))} H(x(t), p) \quad \forall t \in [0, T). \]

(A.3)
Remark A.2. The existence of strict singular characteristics for time dependent Hamilton-Jacobi equations was proved by Khanin and Sobolevski under the additional assumption that the solution \( u \) can be locally represented as the minimum of a compact family of smooth functions. Theorem A.1 adapts [13, Theorem 2] to stationary equations removing such an extra assumption.

Proof. The proof, which uses ideas from [13], requires several intermediate steps.

Let \( R_0 > 0 \) be such that the closed ball \( B(x_0, 2R_0) \) is contained in \( \Omega \). Take any sequence of smooth functions \( u_m : B(x_0, 2R_0) \to \mathbb{R} \) such that

\[
\begin{align*}
(a) & \quad u_m \xrightarrow{m \to \infty} u \text{ uniformly on } B(x_0, R_0) \\
(b) & \quad \max\{\|Du\|_{\infty}, \|Du_m\|_{\infty}\} \leq C_1 \\
(c) & \quad D^2u_m \leq C_2 I
\end{align*}
\]

for some constants \( C_1, C_2 > 0 \). A sequence with the above properties can be constructed in several ways, for instance by using mollifiers like in [18, 11]. In view of the above uniform bounds, there exists \( T_0 > 0 \) such that for any \( m \geq 1 \) the Cauchy problem

\[
\begin{align*}
\dot{x}(t) &= H_p(x(t), Du_m(x(t))), \quad t \in [0, T_0] \\
x(0) &= x_0
\end{align*}
\]

has a unique solution \( x_m : [0, T_0] \to B(x_0, R_0) \). Moreover, by possibly taking a subsequence, we can assume that \( x_m \) converges uniformly on \( [0, T_0] \) to some Lipschitz arc \( x : [0, T_0] \to B(x_0, R_0) \). We will show that, after possibly replacing \( T_0 \) by a smaller \( T > 0 \), such a limiting curve \( x \) has the required properties.

Lemma A.3. For every \( \bar{t} \in [0, T_0) \) and \( \epsilon > 0 \) there exists and integer \( m_\epsilon \geq 1 \) and a real number \( \tau_\epsilon \in (0, T_0 - \bar{t}) \) such that

\[
\frac{x_m(t) - x_m(\bar{t})}{t - \bar{t}} \in \text{co} \ H_p(x(\bar{t}), Du^+(x(\bar{t}))) + \epsilon B \quad \forall m \geq m_\epsilon, \quad \forall t \in [\bar{t}, \bar{t} + \tau_\epsilon],
\]

where \( B \) denotes the closed unit ball of \( \mathbb{R}^2 \), centered at the origin.

Proof. We begin by showing that for every \( \bar{t} \in [0, T_0) \) and \( \epsilon > 0 \) there exist \( m_\epsilon \geq 1 \) and \( \tau_\epsilon \in (0, T_0 - \bar{t}) \) satisfying

\[
\dot{x}_m(t) \in H_p(x(\bar{t}), Du^+(x(\bar{t}))) + \epsilon B, \quad t \in [\bar{t}, \bar{t} + \tau_\epsilon] \quad \text{a.e.}
\]

for all \( m \geq m_\epsilon \). We argue by contradiction: set \( \Phi(\bar{t}) = H_p(x(\bar{t}), Du^+(x(\bar{t}))) \) and suppose there exist \( \bar{t} \in [0, T_0), \epsilon > 0 \), and sequences \( m_k \to \infty \) and \( t_k \downarrow \bar{t} \) such that

\[
\begin{align*}
(i) & \quad x_{m_k}(t_k) \not\in \Phi(\bar{t}) + \epsilon B, \quad \forall k \geq 1 \\
(ii) & \quad Du_{m_k}(x_{m_k}(t_k)) \to \bar{p} \quad (k \to \infty)
\end{align*}
\]

where we have used bound \( (b) \) above to justify \( (ii) \). We claim that \( \bar{p} \in D^+u(x(\bar{t})) \). Indeed, in view of \( (c) \) above we have that, for all \( k \geq 1 \),

\[
\begin{align*}
u_{m_k}(x_{m_k}(t_k) + y) - u_{m_k}(x_{m_k}(t_k)) - \langle Du_{m_k}(x_{m_k}(t_k)), y \rangle & \leq C_2 |y|^2, \quad \forall |y| \leq R_0.
\end{align*}
\]

Hence, in the limit as \( k \to \infty \), we get

\[
u(x(\bar{t}) + y) - u(x(\bar{t})) - \langle \bar{p}, y \rangle \leq C_2 |y|^2, \quad \forall |y| \leq R_0,
\]

which in turn proves our claim. Thus, we conclude that

\[
\begin{align*}
x_{m_k}(t_k) &= H_p(x_{m_k}(t_k), Du_{m_k}(x_{m_k}(t_k))) \xrightarrow{k \to \infty} H_p(x(\bar{t}), \bar{p}) \in \Phi(\bar{t})
\end{align*}
\]
in contrast with (i). So, (A.6) is proved.

Finally, (A.5) can be derived from (A.6) by integration. □

By appealing to the upper semi-continuity of $D^+u$ and assumption (A.1) we conclude that there exists $T \in (0, T_0]$ such that

$$0 \notin \text{co } H_p(x(t), Du^+(x(t))) \quad \forall t \in [0, T].$$

Now, fix any $\bar{t} \in [0, T)$ and let $\bar{v} \in \mathbb{R}^2$ be any vector such that

$$\lim_{j \to \infty} \frac{x(\bar{t} + \tau_j) - x(\bar{t})}{\tau_j} = \bar{v}$$

for some sequence $\tau_j \to 0$ ($j \to \infty$). Observe that $\bar{v} \in \text{co } H_p(x(\bar{t}), Du^+(x(\bar{t})))$ in view of Lemma A.3. So, $\bar{v} \neq 0$ owing to (A.7). Set $\check{x} = x(\bar{t})$ and define

$$\bar{p} \in \mathbb{R}^2 \quad \text{by } \bar{v} = H_p(\check{x}, \bar{p}) \quad \text{(or } \bar{p} = L_v(\check{x}, \bar{v})\text{)}$$

$$F_\check{x}(\check{x}) = \{ p^* \in D^+u(\check{x}) : \langle p^*, \bar{v} \rangle = \min_{p \in D^+u(\check{x})} \langle p, H_p(\check{x}, \bar{p}) \rangle \}.$$ Notice that $F_{\check{x}}(\check{x})$ is the exposed face of the convex set $D^+u(\check{x})$ in the direction $\bar{v}$ (see, for instance, [10]). The following lemma identifies $\bar{p}$ (hence $\bar{v}$) uniquely.

**Lemma A.4.** Suppose $\bar{p} \in F_{\check{x}}(\check{x})$. Then $\bar{p}$ is the unique element in $D^+u(\check{x})$ such that

$$H(\check{x}, \bar{p}) = \min_{p \in D^+u(\check{x})} H(\check{x}, p).$$

**Proof.** Since $\bar{p} \in F_{\check{x}}(\check{x})$, we have that

$$\langle \bar{p}, \bar{v} \rangle = \langle \bar{p}, H_p(\check{x}, \bar{p}) \rangle = \min_{p \in D^+u(\check{x})} \langle p, H_p(\check{x}, \bar{p}) \rangle.$$ Therefore, by convexity we conclude that

$$0 \leq \langle H_p(\check{x}, \bar{p}), p - \bar{p} \rangle \leq H(\check{x}, p) - H(\check{x}, \bar{p}) \quad \forall p \in D^+u(\check{x}).$$

Since $H$ is strictly convex in $p$, $\bar{p}$ is the unique element in $D^+u(\check{x})$ satisfying (A.9). □

Notice that the above lemma yields the existence of the right-derivative $\hat{x}^+(\check{x})$ as soon as one shows that $\bar{p} \in F_{\check{x}}(\check{x})$ for any $\bar{v}$ satisfying (A.8).

Next, to show that $\bar{p} \in F_{\check{x}}(\check{x})$, we proceed by contradiction assuming that

$$\bar{p} \notin F_{\check{x}}(\check{x}).$$

Let us define functions $\alpha, \beta : D^+u(\check{x}) \to \mathbb{R}$ by

$$\alpha(p) = \langle p, \bar{v} \rangle - \frac{du}{d\bar{v}}(\check{x}), \quad \beta(x, p) = \langle p - \bar{p}, H_p(x, p) - H_p(x, \bar{p}) \rangle \quad \forall p \in D^+u(\check{x})$$

where we have set $\frac{du}{d\bar{v}}(\check{x}) = \lim_{\lambda \to 0^+} \frac{u(\check{x} + \lambda \bar{v}) - u(\check{x})}{\lambda}$. Recalling that, since $u$ is semiconcave,

$$\frac{du}{d\bar{v}}(\check{x}) = \min_{p \in D^+u(\check{x})} \langle p, \bar{v} \rangle$$

(see, for instance, [10]). The following simple lemma is crucial for the proof.

**Lemma A.5.** If $\bar{p} \notin F_{\check{x}}(\check{x})$, then

$$\mu := \min_{p \in D^+u(\check{x})} \{ \alpha(p) + \beta(\check{x}, p) \} > 0.$$ **Proof.** Observe first that $\beta(x, p) \geq 0$ by convexity and $\alpha(p) \geq 0$ for all $p \in D^+u(\check{x})$ by (A.11). Since we suppose $\bar{p} \notin F_{\check{x}}(\check{x})$, just two cases are possible.
(1) If $\tilde{p} \notin D^+u(\tilde{x})$, then $p \neq \tilde{p}$ for all $p \in D^+u(\tilde{x})$. So $\beta(\tilde{x}, p) > 0$ by strict convexity.

(2) If $\tilde{p} \in D^+u(\tilde{x}) \setminus F_\ell(\tilde{x})$, then $\alpha(p) > 0$.

In conclusion,
$$M(p) := \alpha(p) + \beta(\tilde{x}, p) > 0, \quad \forall p \in D^+u(\tilde{x}).$$

Since $M$ is continuous and $D^+u(\tilde{x})$ is compact, the conclusion follows. \hfill \Box

For any $\varepsilon > 0$ set
$$F^\varepsilon_\ell(\tilde{x}) = F_\ell(\tilde{x}) + \varepsilon B \quad \text{and} \quad V_\ell = D^+u(\tilde{x}) + \varepsilon B.$$ 

Now, let us fix $\varepsilon = \varepsilon(\tilde{v}, \mu) > 0$ such that
$$\min_{p \in V_\ell} \{ \alpha(p) + \beta(\tilde{x}, p) \} \geq \frac{2}{3} \mu.$$

Let $0 < R \leq R_0$ be such that
$$D^+u(x) \subset V_{\ell/2}, \quad \forall x \in B(\tilde{x}, R).$$

Consider the line segment
$$\gamma(t) := \tilde{x} + (t - \tilde{t})\tilde{v} \quad (t \in [\tilde{t}, T])$$

and fix $q \in (0, 1)$. After possible reducing $T$, we can assume that
$$|\gamma(t) - \tilde{x}| \leq qR \quad \text{and} \quad |x(t) - \tilde{x}| \leq qR \quad \forall t \in [\tilde{t}, T].$$

Consequently, there exists $\tilde{m} \in \mathbb{N}$ such that for all $m \geq \tilde{m}$ we have
(i) $D\mu_m(x) \in V_\ell$ for all $x \in B(\tilde{x}, R)$;
(ii) $x_m(t) \in B(\tilde{x}, R)$ for all $t \in [\tilde{t}, T]$.

Moreover, by cutting $T$ down to size, we can have the following property satisfied:
(iii) for any $t \in [\tilde{t}, T]$ there exists $m(t) \geq \tilde{m}$ such that

$$d_{F_\ell(\tilde{x})}(D\mu_m(\gamma(t))) < \varepsilon, \quad \forall m \geq m(t).$$

We observe that (iii) is a consequence of Proposition 3.3.15 in [10] since $\tilde{v} \neq 0$.

For $0 < \delta$ to be chosen later on, we define
$$K_\delta = \bigcup_{\tilde{t} \in T} B(\gamma(t), \delta(t - \tilde{t}))$$

$$= \{ x \in \mathbb{R}^n \cap \text{ there exists } t \in [\tilde{t}, T] \text{ such that } |x - \gamma(t)| \leq \delta(t - \tilde{t}) \}.$$ 

**Lemma A.6.** Let $\varepsilon > 0$ and $m(\cdot)$ be fixed so that (A.12) and (A.13) hold true. If $\tilde{p} \notin F_{\ell}(\tilde{x})$, then there exists $\delta > 0$ such that for all $j$ sufficiently large, $x_m(t) \notin K_\delta$ for all $t \in (\tilde{t} + 3\tau_j, T)$ and $m$ sufficiently large.

**Proof.** Throughout this proof $j \in \mathbb{N}$ is supposed to be so large that $\tau_j < (T - \tilde{t})/3$. Moreover, in order to simplify the notation, abbreviate $\tau$ for $\tau_j$ and we assume $\hat{t} = 0$.

For all $t \in (3\tau, T)$ we have that
$$\frac{d}{dt} \left( u_m(x_m(t)) - \langle \tilde{p}, x_m(t) \rangle \right)$$

$$= \langle Du_m(x_m(t)) - \tilde{p}, x_m(t) \rangle = \langle H_p(x_m(t), Du_m(x_m(t))), Du_m(x_m(t)) - \tilde{p} \rangle.$$ 

Therefore, by integrating on $(\tau, t)$,

$$u_m(x_m(t)) - \langle \tilde{p}, x_m(t) \rangle - u_m(x_m(\tau)) + \langle \tilde{p}, x_m(\tau) \rangle$$

$$= \int_\tau^t \left( H_p(x_m(s), Du_m(x_m(s))), Du_m(x_m(s)) - \tilde{p} \right) ds.$$ 

(A.14)
Similarly,
\[
\frac{d}{dt}(u_m(\gamma(t))) - \langle \tilde{p}, \gamma(t) \rangle = \langle Du_m(\gamma(t)) - \tilde{p}, \tilde{v} \rangle.
\]
So, (iii) and Lebesgue's theorem ensure that
\[
\begin{align*}
& u_m(\gamma(t)) - \langle \tilde{p}, \gamma(t) \rangle - u_m(\gamma(\tau)) + \langle \tilde{p}, \gamma(\tau) \rangle \\
& = \int_{\tau}^{t} \langle Du_m(\gamma(s)) - \tilde{p}, \tilde{v} \rangle \, ds \leq \left( \frac{\partial u}{\partial \tilde{v}}(\tilde{x}) - \langle \tilde{p}, \tilde{v} \rangle + \epsilon |\tilde{v}| \right) (t - \tau).
\end{align*}
\]
Therefore, by (A.14) and (A.15) we obtain
\[
\begin{align*}
& u_m(x_m(t)) - \langle \tilde{p}, x_m(t) \rangle - u_m(x_m(\tau)) + \langle \tilde{p}, x_m(\tau) \rangle \\
& - \left( u_m(\gamma(t)) - \langle \tilde{p}, \gamma(t) \rangle - u_m(\gamma(\tau)) + \langle \tilde{p}, \gamma(\tau) \rangle \right) \\
& \geq \int_{\tau}^{t} \left\{ \left( \alpha(Du_m(x_m(s))) + \beta(x_m(s), Du_m(x_m(s))) - \epsilon |\tilde{v}| \right) \right\} \, ds
\end{align*}
\]
which can be rewritten as
\[
\begin{align*}
& u_m(x_m(t)) - \langle \tilde{p}, x_m(t) \rangle - u_m(x_m(\tau)) + \langle \tilde{p}, x_m(\tau) \rangle \\
& - \left( u_m(\gamma(t)) - \langle \tilde{p}, \gamma(t) \rangle - u_m(\gamma(\tau)) + \langle \tilde{p}, \gamma(\tau) \rangle \right) \\
& \geq \int_{\tau}^{t} \left\{ \left( \alpha(Du_m(x_m(s))) + \beta(x_m(s), Du_m(x_m(s))) - \epsilon |\tilde{v}| \right) \right\} \, ds
\end{align*}
\]
Now, observe the following:
\[
|u_m(\gamma(t)) - \langle \tilde{p}, \gamma(t) \rangle - u_m(\gamma(\tau)) + \langle \tilde{p}, \gamma(\tau) \rangle| \leq (C_1 + |\tilde{p}|)|\gamma(\tau) - x_m(\tau)|
\]\nwhere we recall that $C_1 \geq \|Du_m\|_{\infty}$.
Next, fix $\tau = \tau_j$ with $j$ large enough so that
\[
|\gamma(\tau) - \tilde{\gamma}(\tau)| \leq \frac{\delta \tau}{2} \quad \text{and} \quad m \gg 1 \quad \text{so that} \quad |\tilde{\gamma}(\tau) - \gamma_m(\tau)| \leq \frac{\delta \tau}{2}.
\]
Then
\[
|u_m(\gamma(\tau)) - \langle \tilde{p}, \gamma(\tau) \rangle - u_m(\gamma_m(\tau)) + \langle \tilde{p}, \gamma_m(\tau) \rangle| \leq (C_1 + |\tilde{p}|)\delta \tau.
\]
\[\text{(A.17)}\]
Since $D_{u_m}(x_m(s)) \in V_e$ for all $s \in [0, \tau]$, by (A.12) we have that

\[
\int_\tau^t \left\{ \alpha(D_{u_m}(x_m(s))) + \beta(x_m(s), D_{u_m}(x_m(s))) \right\} \, ds \geq \frac{2}{3} \mu(t - \tau).
\]

We also have that, after cutting down on $T > 0$,

\[
\langle H_p(x_m(s), \bar{p}) - H_p(\bar{x}, \bar{p}), D_{u_m}(x_m(s)) - \bar{p} \rangle
\]

\[
\geq -(C_1 + |\bar{p}|) \cdot C_2|x_m(s) - \bar{x}|
\]

\[
\geq -\epsilon C_2(C_1 + |\bar{p}|)
\]

So, by (A.16), (A.17), (A.18) and (A.19) we conclude that

\[
u_m(x_m(t)) - \langle \bar{p}, x_m(t) \rangle - u_m(\gamma(t)) + \langle \bar{p}, \gamma(t) \rangle
\]

\[
\geq \left( \frac{2}{3} \mu - \epsilon (|\bar{v}| + C_2(C_1 + |\bar{p}|)) \right) (t - \tau) - \delta \tau(C_1 + |\bar{p}|).
\]

On the other hand,

\[
|u_m(x_m(t)) - \langle \bar{p}, x_m(t) \rangle - u_m(\gamma(t)) + \langle \bar{p}, \gamma(t) \rangle| \leq (C_1 + |\bar{p}|)|x_m(t) - \gamma(t)|.
\]

Therefore,

\[
|x_m(t) - \gamma(t)| \geq \frac{2\mu/3 - \epsilon (|\bar{v}| + C_2(C_1 + |\bar{p}|))}{C_1 + |\bar{p}|} (t - \tau) - \delta \tau.
\]

We now take $0 \leq \epsilon (|\bar{v}| + C_2(C_1 + |\bar{p}|)) < \frac{\mu}{3}$ to obtain

\[
|x_m(t) - \gamma(t)| \geq \frac{\mu(t - \tau)}{3(C_1 + |\bar{p}|)} - \delta \tau
\]

and look for $t < T$ such that

\[
\frac{\mu(t - \tau)}{3(C_1 + |\bar{p}|)} - \delta \tau \geq 2\delta t.
\]

So, taking $0 < \delta \leq \frac{\mu}{12(C_1 + |\bar{p}|)}$, we have that (A.21) is satisfied for all

\[
t \geq \frac{2(\delta + \mu)}{\mu} \tau = 2(1 + \frac{\delta}{\mu}) \tau.
\]

Finally, $\frac{\tau}{\mu} \leq \frac{1}{12(C_1 + \bar{p})}$ with $C_1 \geq 1$ gives that (A.21) holds for all $t \in [3\tau, T]$. □

To complete the proof it suffices to note that Lemma A.5 and Lemma A.6 ensure that assuming (A.10) leads to a contradiction. Indeed,

\[
|x_m(t) - \gamma(t)| \geq 2\delta t, \quad \forall t \in [3\tau, T], \forall j \gg 1
\]

implies that $x(t) \not\in K_\delta$ for all $t \in [3\tau, T]$. On the other hand, $x(\tau_i) \in K_\delta$ for $i \gg 1$ and, for any fixed $i$, $\tau_i \in [3\tau, T]$ for $j$ sufficiently large. □
