ON THE FINITE REPRESENTATION OF GROUP EQUIVARIANT OPERATORS VIA PERMUTANT MEASURES

STEFANO BOTTEGHI, MARTINA BRASINI, PATRIZIO FROSINI, AND NICOLA QUERCIOLI

ABSTRACT. The study of $G$-equivariant operators is of great interest to explain and understand the architecture of neural networks. In this paper we show that each linear $G$-equivariant operator can be produced by a suitable permutant measure, provided that the group $G$ transitively acts on a finite signal domain $X$. This result makes available a new method to build linear $G$-equivariant operators in the finite setting.

Keywords: GEO, GENEO, permutant, permutant measure.

INTRODUCTION

The development of new mathematical approaches and results for deep learning is an important goal in the present time. In particular, new methods and theories are requested in order to understand and control the behavior of neural networks. In this line of research, the scientific community is devoting more and more attention to the use of equivariant operators, since they appear to be of great importance for the progress of machine learning [2, 7, 20]. We recall that an operator is called equivariant with respect to a group if the action of the group commutes with the operator. This property is of use when we want to mimic the behavior of observers and agents that are known to respect some symmetries. In fact, the use of equivariant operators allows us to inject pre-existing knowledge into the system, thus increasing our control on the construction of neural networks [4]. Furthermore, invariant and non-expansive operators can be used to reduce data variability [18, 19], and in the last years equivariant transformations have been studied for learning symmetries [21, 11].

Recently, the topological-geometrical study of group equivariant non-expansive operators (GENEOs) has been proposed in [5] as a mathematical approach to machine learning. The main idea is that the analysis of the topological and geometrical properties of the spaces of GENEOs could make available new theoretical results for building neural networks in a more transparent and interpretable way. In this setting, GENEOs could be seen as multi-level components that can be joined and connected in order to form neural networks by applying the operations of chaining, convex combination and direct product. In this framework, it is important to develop a good topological and geometrical theory of the spaces of GENEOs, in order to make available new methods for approximating external agents in such spaces (and managing relations and conflicts that can arise in intelligent structures [12]) through what could be called “geometrical agent engineering”. An approach based on GENEOs could contribute to explain and understand the architecture of neural networks. Another important reason to study the space of GENEOs is the existence of a link between these operators and Topological Data Analysis, with
particular reference to persistent homology \cite{14, 5}. A central role in this link is taken by the so-called natural pseudo-distance \cite{8, 9, 10, 15}. We already know that every linear \( G \)-equivariant operator (GEO) can be represented as a \( G \)-convolution, provided that the group \( G \) is compact and its action is transitive \cite{17}. Unfortunately, the computation of the integral representing such a convolution is usually not trivial since in many applications the group \( G \) is far from being small. In order to solve this problem, a new technique to build GEOs with respect to a group \( G \) has been recently proposed, based on the concept of permutant \cite{13, 16, 6}. In plain words, a permutant is a collection of automorphisms of the domain of the signals we are interested in, under the assumption that such a collection is stable for the conjugation action of the group \( G \). A permutant is not required to be a group. When a permutant \( H \) for \( G \) is available, by choosing a suitable measure \( \mu \) on \( H \) we can define a GEO \( F \) for \( G \) by setting \( F(\varphi) := \int_{h \in H} \varphi h^{-1} \, d\mu \) for every admissible signal \( \varphi \), under suitable technical assumptions. The main benefit of this procedure is that the permutant \( H \) can be much smaller than the group \( G \), so that the computation of the GEO defined by \( H \) and \( \mu \) can be much simpler than the computation of GEOs represented as \( G \)-convolutions.

In this paper we extend the definitions of permutant and GEO associated with a permutant by introducing the definitions of permutant measure and GEO associated with a permutant measure. In our mathematical setting we can study the relationship between linear GEOs and GEOs associated with permutant measures. In particular, we can prove that these two concepts coincide, provided that the group \( G \) transitively acts on a finite signal domain \( X \). This theorem is based on some well known facts in representation theory and makes available a new method to build all linear GEOs with respect to a transitively acting group in the finite setting. We also prove an analogous statement for GENEOs.

The outline of the paper is as follows. In Section 1 we recall the main definitions in our mathematical setting, and introduce the concept of permutant measure together with some of its properties. In Section 2 we prove our main result about GEOs (Theorem 2), which is adapted to GENEOs in Section 3 (Theorem 3). In Section 4 we conclude the paper with a brief discussion.

1. Mathematical setting

Let \( \mathbb{R}^X \cong \mathbb{R}^n \) be the vector space of all functions from a finite set \( X = \{x_1, \ldots, x_n\} \) to \( \mathbb{R} \). We would like to recall that \( \mathbb{R}^X \) has the canonical basis \( \{1_{x_i}\}_{j} \), where \( 1_x : X \to \mathbb{R} \) is the function taking the value 1 at \( x \) and the value 0 at every point \( y \) with \( y \neq x \). We also consider the group \( \text{Aut}(X) \) of all permutations on \( X \) and a subgroup \( G \) of \( \text{Aut}(X) \). \( \text{Aut}(X) \) and \( G \) naturally act on \( \mathbb{R}^X \) by composition on the right. We endow \( \mathbb{R}^X \) with the \( L^\infty \)-norm: \( \|\varphi\|_\infty := \max\{|\varphi(x_i)| : 1 \leq i \leq n\} \).

**Remark 1.1.** If we endow \( X \) with the discrete topology, \( \mathbb{R}^X \) coincides with \( C^0(X, \mathbb{R}) \).

In this paper we will use the multiplicative notation to denote the composition of functions, and the cycle notation to represent permutations.

1.1. **Group equivariant operators.** We give the following definition.

**Definition 1.1.** A Group Equivariant Operator (GEO) for \( (\mathbb{R}^X, G) \) (with respect to the identity \( \text{id}_G : g \mapsto g \)) is a function

\[
F : \mathbb{R}^X \longrightarrow \mathbb{R}^X
\]

such that \( F(\varphi g) = F(\varphi)g \), for all \( \varphi \in \mathbb{R}^X \) and \( g \in G \).
An important subset of the set of GEOs is given by the set of Group Equivariant Non-Expansive Operators (GENEOs), i.e., GEOs $F$ such that $\|F(\varphi_1) - F(\varphi_2)\|_\infty \leq \|\varphi_1 - \varphi_2\|_\infty$, for all $\varphi_1, \varphi_2 \in \mathbb{R}^X$. In a more general framework, GEOs and GENEOs can be defined from $(\mathbb{R}^X, G)$ to $(\mathbb{R}^Y, H)$ with respect to a group homomorphism $T: G \to H$, where equivariance means that $F(\varphi g) = F(\varphi)T(g)$, for all $\varphi \in \mathbb{R}^X$ and $g \in G$. For further information, we refer the reader to [5]. Obviously, the set of GEOs from $(\mathbb{R}^X, G)$ to $(\mathbb{R}^X, G)$ is not empty because it contains at least the identity operator $\text{id}_{\mathbb{R}^X}: \varphi \mapsto \varphi$.

1.2. Permutants and permutant measures.

**Definition 1.2.** A finite signed measure $\mu$ on $\text{Aut}(X)$ is called a permutant measure with respect to $G$ if each subset $H$ of $\text{Aut}(X)$ is measurable and $\mu$ is invariant under the conjugation action of $G$ (i.e., $\mu(H) = \mu(gHg^{-1})$ for every $g \in G$). Equivalently, we can say that a signed measure $\mu$ on $\text{Aut}(X)$ is a permutant measure with respect to $G$ if each singleton $\{h\} \subseteq \text{Aut}(X)$ is measurable and $\mu(\{h\}) = \mu(\{ghg^{-1}\})$ for every $g \in G$.

With a slight abuse of notation, we will denote by $\mu(h)$ the signed measure of the singleton $\{h\}$ for each $h \in \text{Aut}(X)$.

**Example 1.1.** Let us consider a positive integer number $n$ and the finite set $X := \{(\cos \frac{2\pi k}{n}, \sin \frac{2\pi k}{n}) \in \mathbb{R}^2 : k \in \mathbb{N}, 0 \leq k \leq n - 1\}$. Let $G$ be the group of all rotations of $X$ of an angle $\alpha$ around the point $(0,0)$, with $\alpha$ multiple of $\frac{2\pi}{n}$. After fixing an integer number $m$, let us consider the map $h \in \text{Aut}(X)$ that takes each point $(\cos \frac{2\pi k}{n}, \sin \frac{2\pi k}{n})$ to the point $(\cos \frac{2\pi (k+m)}{n}, \sin \frac{2\pi (k+m)}{n})$. Moreover, we define the function $\mu_1: \mathcal{P}(\text{Aut}(X)) \to \mathbb{R}$ that takes each subset $C$ of $\text{Aut}(X)$ to 1 if $\tilde{h} \in C$ and to 0 if $\tilde{h} \notin C$, where $\mathcal{P}(\text{Aut}(X))$ is the power set of $\text{Aut}(X)$. Since the orbit of $\tilde{h}$ under the conjugation action of $G$ is the singleton $\{\tilde{h}\}$, the function $\mu_1$ is a permutant measure. We also observe that while the cardinality of $G$ is $n$, the cardinality of the support $\text{supp}(\mu_1) := \{h \in \text{Aut}(X) : \mu_1(h) \neq 0\}$ of the signed measure $\mu_1$ is 1.

**Example 1.2.** Let us consider the set $X$ of the vertices of a cube in $\mathbb{R}^3$, and the group $G$ of the orientation-preserving isometries of $\mathbb{R}^3$ that take $X$ to $X$. Let $\pi_1, \pi_2, \pi_3$ be the three planes that contain the center of mass of $X$ and are parallel to a face of the cube. Let $h_i: X \to X$ be the orthogonal symmetry with respect to $\pi_i$, for $i \in \{1, 2, 3\}$. We have that the set $\{h_1, h_2, h_3\}$ is an orbit under the conjugation action of $G$. We can now define a permutant measure $\mu_2$ on the group $\text{Aut}(X)$ by setting $\mu_2(h_1) = \mu_2(h_2) = \mu_2(h_3) = c$, where $c$ is a positive real number, and $\mu_2(h) = 0$ for any $h \in \text{Aut}(X)$ with $h \notin \{h_1, h_2, h_3\}$. We also observe that while the cardinality of $G$ is 24, the cardinality of the support $\text{supp}(\mu_2) := \{h \in \text{Aut}(X) : \mu_2(h) \neq 0\}$ of the signed measure $\mu_2$ is 3.

Permutant measures give a simple method to build GEOs, as shown by the following result.

**Proposition 1.1.** If $\mu$ is a permutant measure with respect to $G$ then the map $F_\mu(\varphi) := \sum_{h \in \text{Aut}(X)} \varphi h^{-1} \mu(h)$ is a linear GEO.
Proposition 1.2. The next corollary immediately follows.

Proof. Since $\text{Aut}(X)$ linearly acts on $\mathbb{R}^X$ by composition on the right, $F_\mu$ is linear. Moreover, for every $\varphi \in \mathbb{R}^X$ and every $g \in G$

\begin{equation}
F_\mu(\varphi g) = \sum_{h \in \text{Aut}(X)} \varphi gh^{-1} \mu(h) = \sum_{h \in \text{Aut}(X)} \varphi gh^{-1} g^{-1} \mu(gh^{-1}) = \sum_{f \in \text{Aut}(X)} \varphi f^{-1} g \mu(f) = F_\mu(\varphi) g,
\end{equation}

since $\mu(h) = \mu(ghg^{-1})$ and the map $h \mapsto f := ghg^{-1}$ is a bijection from $\text{Aut}(X)$ to $\text{Aut}(X)$. \qed

Obviously, $F_\mu(\varphi) = \sum_{h \in \text{Aut}(X)} \varphi h^{-1} \mu(h) = \sum_{h \in \text{supp}(\mu)} \varphi h^{-1} \mu(h)$, where $\text{supp}(\mu) := \{h \in \text{Aut}(X) : \mu(h) \neq 0\}$. In Examples 1.1 and 1.2, $|\text{supp}(\mu_i)| \ll |G|$ for $i = 1, 2$, and hence in those cases summations on $\text{supp}(\mu_i)$ are simpler than summations on the group $G$. The condition $|\text{supp}(\mu)| \ll |G|$ is not rare in examples and is the main reason to build GEOs by means of permutant measures, instead of using the representation of GEOs as $G$-convolutions.

Example 1.3. The GEOs associated with the permutant measures defined in Examples 1.1 and 1.2 are respectively $F_{\mu_1}(\varphi) = \varphi \bar{h}^{-1}$ and $F_{\mu_2}(\varphi) = c_1 \varphi h_1^{-1} + c_2 \varphi h_2^{-1} + c_3 \varphi h_3^{-1}$.

It is interesting to observe that the set $\text{PM}(G)$ of permutant measures with respect to $G$ is a lattice. Indeed, if $\mu_1, \mu_2 \in \text{PM}(G)$, then the measures $\mu', \mu''$ on $\text{Aut}(X)$, respectively defined by setting $\mu'(h) := \min\{\mu_1(h), \mu_2(h)\}$ and $\mu''(h) := \max\{\mu_1(h), \mu_2(h)\}$, still belong to $\text{PM}(G)$. Moreover, if $\mu \in \text{PM}(G)$ then $|\mu| \in \text{PM}(G)$. Furthermore, $\text{PM}(G)$ is closed under linear combination. Therefore, $\text{PM}(G)$ has a natural structure of real vector space. We can compute the dimension of $\text{PM}(G)$ by considering the conjugation action of $G$ on $\text{Aut}(X)$.

**Proposition 1.2.** $\dim \text{PM}(G) = |\text{Aut}(X)/G|$.

Proof. Consider a permutant measure $\mu$ on $\text{Aut}(X)$. We define the function $f_\mu : \text{Aut}(X)/G \to \mathbb{R}$ by setting $f_\mu(\mathcal{O}) = \mu(h)$, where $h \in \mathcal{O}$. Since $\mu$ is invariant under the conjugation action of $G$, $f_\mu$ is well defined. One could easily check that the map $\mu \mapsto f_\mu$ is an isomorphism between $\text{PM}(G)$ and the space $\mathbb{R}^{\text{Aut}(X)/G}$ of all real-valued functions on $\text{Aut}(X)/G$. Since $\{1_{\mathcal{O}}\}_{\mathcal{O} \subseteq \text{Aut}(X)/G}$ is a basis for $\mathbb{R}^{\text{Aut}(X)/G}$, $\dim \mathbb{R}^{\text{Aut}(X)/G} = |\text{Aut}(X)/G|$. Hence, the statement is proved. \qed

Proposition 1.2 and the well-known Burnside’s Lemma imply that $\dim \text{PM}(G) = \frac{1}{|G|} \sum_{g \in G} |\text{Aut}(X)^g|$. We recall that $\text{Aut}(X)^g$ denotes the set of elements fixed by the action of $g$, i.e., $\text{Aut}(X)^g := \{h \in \text{Aut}(X) | ghg^{-1} = h\}$.

Let us now recall the concept of permutant [13, 16, 6], which is related to the one of permutant measure.

**Definition 1.3.** We say that a subset $H \subseteq \text{Aut}(X)$ is a permutant for $G$ if either $H = \emptyset$ or $gHg^{-1} = H$ for every $g \in G$.

Note that a subset $H$ of $\text{Aut}(X)$ is a permutant for $G$ if and only if $H$ is a union of orbits for the conjugation action of $G$ on $\text{Aut}(X)$. It follows that the number of permutants for $G$ is equal to $2^{|\text{Aut}(X)/G|}$. Let us denote by $\text{Perm}(G)$ the set of all permutants for $G$. From Proposition 1.2, the next corollary immediately follows.
Corollary 1.1. \( \dim \PM(G) = \log_2 |\Perm(G)|. \)

The following definition extends the one of versatile group (cf. [6]) and is of use in studying permutants.

**Definition 1.4.** If \( k \) is a positive integer, we say that the group \( G \subseteq \Aut(X) \) is \( k \)-weakly versatile if for every pair \((x, z) \) \( \in X \times X \) with \( x \neq z \) and every subset \( S \) of \( X \) with \( |S| \leq k \), a \( g \in G \) exists such that \( g(x) = x \) and \( g(z) \notin S \).

The previous definition allows us to highlight an interesting property of permutants.

**Lemma 1.1.** If \( G \) is \( k \)-weakly versatile, then every permutant \( H \neq \emptyset, \{ \id_X \} \) has cardinality strictly greater than \( k \).

**Proof.** By contradiction, let us assume that a non-empty permutant \( H = \{ h_1, \ldots, h_r \} \neq \{ \id_X \} \) exists, with \( 1 \leq r \leq k \). Since \( H \neq \{ \id_X \} \), we can assume that \( h_1 \) is not the identity. Let us take a point \( x \in X \) such that \( h_1(x) \neq x \) and set \( z := h_1(x) \), \( S := \{ h_1(x), \ldots, h_r(x) \} \). \( G \) is \( k \)-weakly versatile and hence a \( g \in G \) exists, such that \( g(x) = x \) and \( g(z) \notin S \). Since \( gHg^{-1} = H \), an index \( i \) exists such that \( gh_1 = h_ig \). It follows that \( g(z) = g(h_1(x)) = h_i(g(x)) = h_i(x) \in S \), against the assumption that \( g(z) \notin S \). \( \square \)

We stress that when the group \( G \) becomes larger and larger the lattice \( \PM(G) \) becomes smaller and smaller. This duality implies that the method described by Proposition 1.1 is particularly interesting when \( G \) is large. In some sense, this duality is analogous to the one described in [14, Subsection 3.1].

2. **REPRESENTATION OF LINEAR GEOs VIA PERMUTANT MEASURES**

A natural question arises from Proposition 1.1. Which linear GEOs can be represented as GEOs associated with a permutant measure?

We can prove the following result.

**Theorem 1.** If \( G \) transitivity acts on \( X \), then for every linear group equivariant operator \( F \) for \((\mathbb{R}^X, G)\) a permutant measure \( \mu \) exists such that

\[
F(\varphi) = F_\mu(\varphi) := \sum_{h \in \Aut(X)} \varphi h^{-1} \mu(h)
\]

for every \( \varphi \in \mathbb{R}^X \), and \( \sum_{h \in \Aut(X)} |\mu(h)| = \max_{\varphi \in \mathbb{R}^X \setminus \{0\}} \frac{\|F(\varphi)\|_\infty}{\|\varphi\|_\infty} \).

In order to prove this statement, let us consider the matrix \( B = (b_{ij}) \) associated with \( F \) with respect to the basis \( \{ \mathbb{1}_{x_1}, \ldots, \mathbb{1}_{x_n} \} \).

**Remark 2.1.** We observe that \( \mathbb{1}_x h^{-1} = \mathbb{1}_{h(x)} \) for every \( h \in \Aut(X) \) and every \( x \in X \).

In the following, for every \( g \in G \) we will denote by \( \sigma_g : \{1, \ldots, n\} \to \{1, \ldots, n\} \) the function defined by setting \( \sigma_g(j) = i \) if and only if \( g(x_j) = x_i \). We observe that \( \sigma_g^{-1} = \sigma_g^{-1} \).

We need the following lemmas.

**Lemma 2.1.** An \( n \)-tuple of real numbers \( \alpha = (\alpha_1, \ldots, \alpha_n) \) exists such that each row and each column of \( B \) can be obtained by permuting \( \alpha \).

**Proof.** Let us choose a function \( \mathbb{1}_{x_j} \) and a permutation \( g \in G \). By equivariance we have that

\[
F(\mathbb{1}_{x_j} g) = F(\mathbb{1}_{x_j}) g.
\]
The left-hand side of the equation can be rewritten as:

\[ F(1_x, g) = F(1_{g^{-1}(x)}) = \sum_{i=1}^{n} b_{i\sigma^{-1}_g(j)} 1_{x_i}. \]

On the right-hand side we get

\[ F(1_x, g) = \left( \sum_{i=1}^{n} b_{ij} 1_{x_i} \right) g = \sum_{i=1}^{n} b_{ij} (1_{x_i} g) = \sum_{i=1}^{n} b_{ij} (1_{g^{-1}(x_i)}) = \sum_{s=1}^{n} b_{\sigma_g(s)j} 1_{x_s}, \]

by setting \( x_s = g^{-1}(x_i) \). Therefore, we obtain the following equation:

\[ \sum_{i=1}^{n} b_{i\sigma^{-1}_g(j)} 1_{x_i} = \sum_{s=1}^{n} b_{\sigma_g(s)j} 1_{x_s}. \]

This immediately implies that \( b_{i\sigma^{-1}_g(j)} = b_{\sigma_g(i)j} \), for any \( i \in \{1, \ldots, n\} \). Since this equality holds for any \( j \in \{1, \ldots, n\} \) and any \( g \in G \), we have that \( b_{ij} = b_{\sigma_g(i)\sigma_g(j)} \) for every \( i, j \in \{1, \ldots, n\} \) and every \( g \in G \).

Now we are ready to show that all the rows of \( B \) are permutations of the first row, and all the columns are permutations of the first column. Since \( G \) is transitive, for every \( p, q \in \{1, \ldots, n\} \) there exists \( g_{pq} \in G \) such that \( g_{pq}(x_p) = x_q \). Consider the \( \bar{i} \)-th row of \( B \). We know that \( b_{ij} = b_{\sigma_{\bar{g}_1}(i)\sigma_{\bar{g}_1}(j)} = b_{1\sigma_{\bar{g}_1}(j)} \), for any \( j \in \{1, \ldots, n\} \). Since \( \sigma_{\bar{g}_1} \) is a permutation, the \( \bar{i} \)-th row is a permutation of the first row. By the same arguments, we can assert that every column of \( B \) is a permutation of the first column of \( B \).

Let us now consider a real number \( y \), and denote by \( r(y) \) (respectively \( s(y) \)) the number of times \( y \) occurs in each row (respectively column) of \( B \). Both \( nr(y) \) and \( ns(y) \) represent the number of times \( y \) appears in \( B \). Since \( nr(y) = ns(y) \), each row and column contains the same elements (counted with multiplicity). Hence, the statement of our lemma is proved.

The following result is well known [11].

**Lemma 2.2** (Birkhoff–von Neumann decomposition). Let \( M \) be a \( n \times n \) real matrix with non-negative entries, such that both the sum of the elements of each row and the sum of the elements of each column is equal to \( \bar{c} \). Then for every \( h \in \text{Aut}(X) \) a non-negative real number \( c(h) \) exists such that \( \sum_{h \in \text{Aut}(X)} c(h) = \bar{c} \) and \( M = \sum_{h \in \text{Aut}(X)} c(h) P(h) \), where \( P(h) \) is the permutation matrix associated with \( h \).

We recall that the permutation matrix associated with the permutation \( h : X \rightarrow X \) is the \( n \times n \) real matrix \( (p_{ij}(h)) \) defined by setting \( p_{ij}(h) = 1 \) if \( h(x_j) = x_i \) and \( p_{ij}(h) = 0 \) if \( h(x_j) \neq x_i \). Equivalently, we can define the permutation matrix associated with the permutation \( h : X \rightarrow X \) as the \( n \times n \) real matrix \( P(h) \) such that \( P(h)e_j = \sigma_{h(i)} \) for every column vector \( e_j := e^{t}(0, \ldots, 1, \ldots, 0) \in \mathbb{R}^n \) (where 1 is in the \( j \)-th position).

We observe that \( P(h^{-1}) = P(h)^{-1} \) and \( P(h_1h_2) = P(h_1)P(h_2) \) for every \( h, h_1, h_2 \in \text{Aut}(X) \).

**Remark 2.2.** In general, the representation \( M = \sum_{h \in \text{Aut}(X)} c(h) P(h) \), stated in Lemma 2.2, is not unique. As an example, consider the set \( X = \{1, 2, 3\} \) and the group \( G = \text{Aut}(X) \). Let \( F : \mathbb{R}^X \rightarrow \mathbb{R}^X \) be the linear application that maps \( 1_j \) to \( \sum_{i \in X} 1_i \), for any \( j \in X \). One could easily check that \( F \) is a linear GEO for \((\mathbb{R}^X, G)\). Indeed, we have that \( F(1_j h) = F(1_j) = F(1_j) h \) for any \( j \in X \) and any \( h \in \text{Aut}(X) \). The matrix \( B \) associated
with $F$ with respect to the basis $\{1_j\}_j$ is:

$$B = \begin{pmatrix} 1 & 1 & 1 \\ 1 & 1 & 1 \\ 1 & 1 & 1 \end{pmatrix}.$$ 

One could represent $B$ at least in two different ways:

$$B = \begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix} + \begin{pmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 & 1 \\ 0 & 1 & 0 \\ 1 & 0 & 0 \end{pmatrix}.$$ 

We proceed in our proof of Theorem 1 by taking the linear maps $F^\oplus, F^\ominus : \mathbb{R}^X \to \mathbb{R}^X$ defined by setting $F^\oplus(1_x) := \sum_{i=1}^n \max\{b_{ij}, 0\} 1_x$, and $F^\ominus(1_x) := \sum_{i=1}^n \max\{-b_{ij}, 0\} 1_x$, for every index $j \in \{1, \ldots, n\}$. We can easily check that

1. $F^\oplus, F^\ominus$ are linear GEOs;
2. The matrices associated with $F^\oplus$ and $F^\ominus$ with respect to the basis $\{1_x, \ldots, 1_{xn}\}$ of $\mathbb{R}^X$ are $B^\oplus = (b_{ij}) = (\max\{b_{ij}, 0\})$ and $B^\ominus = (b_{ij}) = (\max\{-b_{ij}, 0\})$, respectively (in particular, $B^\oplus, B^\ominus$ are non-negative matrices);
3. $F = F^\oplus - F^\ominus$ and $B = B^\oplus - B^\ominus$;
4. Lemma 2.1 and the definitions of $B^\oplus, B^\ominus$ imply that two $n$-tuples of real numbers $\alpha^\oplus = (\alpha_1^\oplus, \ldots, \alpha_n^\oplus)$, $\alpha^\ominus = (\alpha_1^\ominus, \ldots, \alpha_n^\ominus)$ exist such that each row and each column of $B^\oplus$ can be obtained by permuting $\alpha^\oplus$, and each row and each column of $B^\ominus$ can be obtained by permuting $\alpha^\ominus$.

Let us now focus on $F^\oplus$.

From Property 4 and Lemma 2.2 this result follows:

**Corollary 2.1.** For every $h \in \text{Aut}(X)$ two non-negative real numbers $c^\oplus(h), c^\ominus(h)$ exist, such that $F^\oplus(\varphi) = \sum_{h \in \text{Aut}(X)} c^\oplus(h) \varphi h^{-1}$ and $F^\ominus(\varphi) = \sum_{h \in \text{Aut}(X)} c^\ominus(h) \varphi h^{-1}$ for every $\varphi \in \mathbb{R}^X$.

**Proof.** Let us start by considering the statement concerning $c^\oplus(h)$ and $F^\oplus(h)$. Without loss of generality, since $F^\oplus$ is linear, it will suffice to prove the existence of a suitable non-negative function $c^\oplus(h)$, such that $F^\oplus(1_x) = \sum_{h \in \text{Aut}(X)} c^\oplus(h) 1_x h^{-1}$, for any $j \in \{1, \ldots, n\}$. The column coordinate vector of the function $F^\oplus(1_x)$ relative to the basis $\{1_{x_1}, \ldots, 1_{xn}\}$ is $B^\ominus e_j$. Property 4 and Lemma 2.2 imply that for every $h \in \text{Aut}(X)$ a non-negative real number $c^\ominus(h)$ exists, such that

$$B^\ominus e_j = \sum_{h \in \text{Aut}(X)} c^\ominus(h) P(h) e_j = \sum_{h \in \text{Aut}(X)} c^\ominus(h) e_{\sigma(h)(j)}.$$ 

Since the column vector $e_{\sigma(h)(j)}$ represents the column coordinate vector of the function $1_{h(x)}$ relative to the basis $\{1_{x_1}, \ldots, 1_{xn}\}$, we can conclude that

$$F^\ominus(1_x) = \sum_{h \in \text{Aut}(X)} c^\ominus(h) 1_{h(x)} = \sum_{h \in \text{Aut}(X)} c^\ominus(h) 1_{x_j} h^{-1}.$$ 

The proof of the statement concerning $c^\ominus$ is analogous.
Remark 2.3. In general, the function $c: \text{Aut}(X) \to \mathbb{R}$ associated with the Birkhoff–von Neumann decomposition does not induce a permutant measure, i.e., the function $\mu_c$ that takes each subset $H$ of $\text{Aut}(X)$ to the value $\mu_c(H) := \sum_{h \in H} c(h)$ is not a permutant measure. For example, let us consider the set $X = \{1, 2, 3, 4\}$ and the group $S_4$ of all permutations of $X$. Let us define a linear GEO $F: \mathbb{R}^X \to \mathbb{R}^X$ for $(\mathbb{R}^X, S_4)$ by setting $F(1_j) = \sum_{i \in X} 1_i$ for every index $j$. After fixing the basis $\{1_j\}_j$, the matrix $B$ associated with $F$ has the following form:

$$B = \begin{pmatrix} 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \\ 1 & 1 & 1 & 1 \end{pmatrix}.$$

As guaranteed by Lemma 2.2, $B$ can be decomposed as follows:

$$B = P(\text{id}_X) + P(\sigma) + P(\sigma^2) + P(\sigma^3),$$

where $\sigma = (1 \ 2 \ 3 \ 4) \in S_4$, in cycle notation. Let $\langle \sigma \rangle$ be the cyclic group generated by $\sigma$. The function $c: \text{Aut}(X) \to \mathbb{R}$ associated with the previous decomposition of $B$ is defined as follows: $c(h) = 1$ if $h \in \langle \sigma \rangle$, otherwise $c(h) = 0$. Let us now consider the permutation $g = (1 \ 2) \in S_4$, in cycle notation. Since $\sigma^2 = (1 \ 3)(2 \ 4)$, we have that:

$$c(g\sigma^2g^{-1}) = c((1 \ 2)(1 \ 3)(2 \ 4)(1 \ 2)) = c((1 \ 4)(2 \ 3)) = 0.$$ 

Since $c(\sigma^2) = 1$, $c$ is not invariant under the conjugation action of $S_4$, and hence $\mu_c$ is not a permutant measure.

Let us now go back to the proof of Theorem 1 and consider the functions $c^\oplus, c^\ominus: \text{Aut}(X) \to \mathbb{R}$ introduced in Corollary 2.1. In order to define the permutant measure $\mu$ on $\text{Aut}(X)$ we will need the next lemma.

Lemma 2.3. If $g \in G$ then $B^\oplus P(g) = P(g)B^\oplus$.

Proof. Let us consider a permutation $g \in G$. The function $R_{g^{-1}}: \mathbb{R}^X \to \mathbb{R}^X$, which maps $\varphi$ to $\varphi g^{-1}$, is a linear application. Furthermore, $R_{g^{-1}}(1_{x_j}) = 1_{x_j}g^{-1} = 1_{y_{g(x_j)}}$ for every index $j$. Hence, the matrix $N$ associated to $R_{g^{-1}}$ with respect to the basis $\{1_{x_1}, \ldots, 1_{x_n}\}$ verifies the equality $Ne_j = e_{\sigma_j(j)}$, so that $N = P(g)$ (we set $e_j := t(0, \ldots, 1, \ldots, 0) \in \mathbb{R}^n$, where 1 is in the $j$-th position). Since $F^\oplus$ is a GEO, the equality $F^\ominus R_{g^{-1}} = R_{g^{-1}}F^\ominus$ holds. This immediately implies that $B^\oplus P(g) = P(g)B^\oplus$. \qed
Lemma 2.3 guarantees that \( P(g)B^\oplus P(g)^{-1} = B^\oplus \) for every \( g \in G \). From this equality and Lemma 2.2 it follows that

\[
B^\oplus = \frac{1}{|G|} B^\oplus + \ldots + \frac{1}{|G|} B^\oplus
\]

(2.1)

\[
= \frac{1}{|G|} \sum_{g \in G} P(g)B^\oplus P(g)^{-1}
\]

\[
= \sum_{h \in \text{Aut}(X)} \frac{c^\oplus(h)}{|G|} P(g)P(h)P(g)^{-1}
\]

\[
= \sum_{h \in \text{Aut}(X), g \in G} \frac{c^\oplus(h)}{|G|} \sum_{g \in G} P(ghg^{-1}).
\]

Therefore, for every index \( j \) we have that

\[
B^\oplus e_j = \sum_{h \in \text{Aut}(X), g \in G} \frac{c^\oplus(h)}{|G|} \sum_{g \in G} P(ghg^{-1})e_j
\]

(2.2)

\[
= \sum_{h \in \text{Aut}(X), g \in G} \frac{c^\oplus(h)}{|G|} \sum_{g \in G} e_{g h g^{-1}(j)}.
\]

This means that

\[
F^\oplus(\mathbf{1}_{x_j}) = \sum_{h \in \text{Aut}(X), g \in G} \frac{c^\oplus(h)}{|G|} \sum_{g \in G} \mathbf{1}_{ghg^{-1}(x_j)}
\]

(2.3)

\[
= \sum_{h \in \text{Aut}(X), g \in G} \frac{c^\oplus(h)}{|G|} \sum_{g \in G} \mathbf{1}_{x_j} gh^{-1} g^{-1}.
\]

Since \( F^\oplus \) is linear, it follows that

\[
F^\oplus(\varphi) = \sum_{h \in \text{Aut}(X), g \in G} \frac{c^\oplus(h)}{|G|} \sum_{g \in G} \varphi gh^{-1} g^{-1}
\]

(2.4)

for every \( \varphi \in \mathbb{R}^X \).

We observe that the permutations \( gh^{-1} g^{-1} \) in the previous summation are not guaranteed to be different from each other, for \( g \) varying in \( G \) and \( h \) varying in \( \text{Aut}(X) \).

For each \( h \in \text{Aut}(X) \), let us consider the orbit \( \mathcal{O}(h) \) of \( h \) under the conjugation action of \( G \) on \( \text{Aut}(X) \), and set

\[
\mu^\oplus(h) := \sum_{f \in \mathcal{O}(h)} \frac{c^\oplus(f)}{|\mathcal{O}(f)|} = \sum_{f \in \mathcal{O}(h)} \frac{c^\oplus(f)}{|\mathcal{O}(h)|}
\]

\[
\mu^\ominus(h) := \sum_{f \in \mathcal{O}(h)} \frac{c^\ominus(f)}{|\mathcal{O}(f)|} = \sum_{f \in \mathcal{O}(h)} \frac{c^\ominus(f)}{|\mathcal{O}(h)|}.
\]

In other words, we define the measures \( \mu^\oplus(h), \mu^\ominus(h) \) of each permutation \( h \) as the averages of the functions \( c^\oplus, c^\ominus \) along the orbit of \( h \) under the conjugation action of \( G \). Let \( G_h \) be the stabilizer subgroup of \( G \) with respect to \( h \), i.e., the subgroup of \( G \)
Proposition 2.1. We need the next statement.

If \( f \) containing the elements that fix \( h \) by conjugation. We recall that by conjugating \( h \) with respect to every element of \( G \) we obtain each element of the orbit \( \mathcal{O}(h) \) exactly \( |G_h| \) times, and the well-known relation \( |G_h||\mathcal{O}(h)| = |G| \) (cf. \[3\]). Let us now set \( \delta(f, h) = 1 \) if \( f \) and \( h \) belong to the same orbit under the conjugation action of \( G \), and \( \delta(f, h) = 0 \) otherwise.

We observe that the following properties hold for \( f, h \in \text{Aut}(X) \):

1. \( G_{h^{-1}} = G_h \);
2. if \( f \in \mathcal{O}(h) \) then \( G_f \) is isomorphic to \( G_h \);
3. \( f^{-1} \in \mathcal{O}(h^{-1}) \iff f \in \mathcal{O}(h) \iff h \in \mathcal{O}(f) \).

Therefore, equality (2.4) implies

\[
F^\oplus(\varphi) = \sum_{h \in \text{Aut}(X)} \frac{c^\oplus(h)}{|G|} |G_h| \sum_{f^{-1} \in \mathcal{O}(h^{-1})} \varphi f^{-1}
\]

\[= \sum_{h \in \text{Aut}(X)} \frac{c^\oplus(h)}{|G|} G_h \sum_{f \in \mathcal{O}(h)} \varphi f^{-1}
\]

\[= \sum_{h \in \text{Aut}(X)} \frac{c^\oplus(h)}{|G|} G_h \sum_{f \in \text{Aut}(X)} \delta(f, h) \varphi f^{-1}
\]

\[= \sum_{f \in \text{Aut}(X)} \left( \sum_{h \in \text{Aut}(X)} \frac{c^\oplus(h)}{|G|} G_h \delta(f, h) \right) \varphi f^{-1}
\]

\[= \sum_{f \in \text{Aut}(X)} \left( \sum_{h \in \text{Aut}(X)} \frac{c^\oplus(h)}{|\mathcal{O}(h)|} \delta(f, h) \right) \varphi f^{-1}
\]

\[= \sum_{f \in \text{Aut}(X)} \varphi f^{-1} \mu^\oplus(f).
\]

The definition of \( \mu^\oplus \) immediately implies that \( \mu^\oplus(H) = \mu^\oplus(gHg^{-1}) \) for every \( g \in G \) and every subset \( H \) of \( \text{Aut}(X) \). In other words, \( \mu^\oplus \) is a non-negative permutant measure with respect to \( G \). Quite analogously, we can prove the equality \( F^\ominus(\varphi) = \sum_{f \in \text{Aut}(X)} \varphi f^{-1} \mu^\ominus(f) \), and that \( \mu^\ominus \) is a non-negative permutant measure with respect to \( G \). As a result, the function \( \mu := \mu^\oplus - \mu^\ominus \) is a permutant measure and the equality \( F(\varphi) = \sum_{f \in \text{Aut}(X)} \varphi f^{-1} \mu(f) \) holds, since \( F = F^\oplus - F^\ominus \).

It remains to prove that \( \sum_{h \in \text{Aut}(X)} |\mu(h)| \leq \max_{\varphi \in \mathbb{R} \setminus \{0\}} \frac{\|F(\varphi)\|_\infty}{\|\varphi\|_\infty} \).

This statement is trivial if \( F \equiv 0 \), since in this case \( \mu \) is the null measure. Hence we can assume that \( F \) is not the null map and \( B \) is not the null matrix. In order to proceed, we need the next statement.

Proposition 2.1. If \( f_1, f_2 \in \text{Aut}(X) \) and an index \( s \in \{1, \ldots, n\} \) exists, such that \( f_1(x_s) = f_2(x_s) \) (i.e., \( \sigma_{f_1}(s) = \sigma_{f_2}(s) \)), then either \( c^\oplus(f_1) = 0 \), or \( c^\ominus(f_2) = 0 \), or both.
Proof. By applying the equality $F^\oplus(\varphi) = \sum_{h \in \Aut(X)} c^\oplus(h) \varphi h^{-1}$ for $\varphi = 1_{x_1}$, we obtain that
\begin{equation}
(2.6) \quad b_{\sigma f_1}^{\oplus}(s) = \left( \sum_{i=1}^{n} b_{i}^{\oplus} 1_{x_i} \right) (x_{\sigma f_1}(s))
= F^\oplus(1_{x_1})(x_{\sigma f_1}(s))
= F^\oplus(1_{x_1})(f_1(x_1))
= \sum_{h \in \Aut(X)} c^\oplus(h) 1_{x_1} h^{-1}(f_1(x_1))
\geq c^\oplus(f_1) 1_{x_1} f_1^{-1}(f_1(x_1))
= c^\oplus(f_1) 1_{x_1}(s)
= c^\oplus(f_1).
\end{equation}

Analogously, the inequality $b_{\sigma f_2}^{\oplus}(s) \geq c^\ominus(f_2)$ holds. Therefore,
\begin{equation}
c^\oplus(f_1) > 0 \implies b_{\sigma f_1}^{\oplus}(s) > 0 \implies b_{\sigma f_1}^{\oplus}(s) = 0 \implies b_{\sigma f_2}^{\oplus}(s) = 0 \implies c^\ominus(f_2) = 0.
\end{equation}

It follows that either $c^\ominus(f_1) = 0$, or $c^\ominus(f_2) = 0$, or both. \hfill \Box

**Corollary 2.2.** For every $f \in \Aut(X)$ either $c^\ominus(f) = 0$, or $c^\ominus(f) = 0$, or both.

**Proof.** Set $f_1 = f_2$ in Proposition 2.1 \hfill \Box

Let us now set $c := c^\oplus - c^\ominus$. Corollary 2.2 implies that $|c(h)| = c^\oplus(h) + c^\ominus(h)$ for every $h \in \Aut(X)$. The definitions of $\mu^\oplus$ and $\mu^\ominus$ immediately imply that $\sum_{f \in \Omega(h)} h^\oplus(f) = \sum_{f \in \Omega(h)} h^\ominus(f)$ and $\sum_{f \in \Omega(h)} h^\ominus(f) = \sum_{f \in \Omega(h)} c^\ominus(f)$ for each $h \in \Aut(X)$. It follows that $\sum_{f \in \Omega(h)} |\mu(f)| \leq \sum_{f \in \Omega(h)} \mu^\ominus(f) + \sum_{f \in \Omega(h)} \mu^\oplus(f) = \sum_{f \in \Omega(h)} c^\ominus(f) + \sum_{f \in \Omega(h)} c^\ominus(f) = \sum_{f \in \Omega(h)} |c(f)|$ for each $h \in \Aut(X)$, and hence
\begin{equation}
\sum_{h \in \Aut(X)} |\mu(h)| \leq \sum_{h \in \Aut(X)} |c(h)|.
\end{equation}

By setting $1_X = \sum_{j=1}^{n} 1_{x_j}$ and recalling the statement of Corollary 2.1, we obtain $F^\ominus(1_X) = \left( \sum_{h \in \Aut(X)} c^\ominus(h) \right) 1_X$ and $F^\oplus(1_X) = \left( \sum_{h \in \Aut(X)} c^\oplus(h) \right) 1_X$. Since any line in $B$ is a permutation of the first row of $B$, we get $F^\oplus(1_X) = \left( \sum_{j=1}^{n} b_{i}^{\oplus} \right) 1_X$ and $F^\ominus(1_X) = \left( \sum_{j=1}^{n} b_{i}^{\ominus} \right) 1_X$. As a consequence, the equalities $\sum_{h \in \Aut(X)} c^\ominus(h) = \sum_{j=1}^{n} b_{i}^{\ominus}$ and $\sum_{h \in \Aut(X)} c^\ominus(h) = \sum_{j=1}^{n} b_{i}^{\ominus}$ hold, and therefore $\sum_{h \in \Aut(X)} |c(h)| = \sum_{h \in \Aut(X)} c^\ominus(h) + \sum_{h \in \Aut(X)} c^\ominus(h) = \sum_{j=1}^{n} b_{i}^{\ominus} + \sum_{j=1}^{n} b_{i}^{\ominus} = \sum_{j=1}^{n} |b_{i}|$.

Let us now consider the function $\bar{\varphi} := \sum_{j=1}^{n} \text{sgn}(b_{i}) 1_{x_j} \in \mathbb{R}^X \setminus \{0\}$. By recalling that any line in $B$ is a permutation of the first row of $B$, we have that $\sum_{j=1}^{n} |b_{i}| = |\sum_{j=1}^{n} b_{i} \text{sgn}(b_{i})| \geq |\sum_{j=1}^{n} b_{i} \text{sgn}(b_{i})|$ for every index $i$. It follows that
\begin{equation}
\|F(\bar{\varphi})\|_\infty = \left\| \sum_{i=1}^{n} \left( \sum_{j=1}^{n} b_{i} \text{sgn}(b_{i}) \right) 1_{x_i} \right\|_\infty = \sum_{j=1}^{n} |b_{i}| = \sum_{h \in \Aut(X)} |c(h)| \geq \sum_{h \in \Aut(X)} |\mu(h)|.
\end{equation}

Since $\|\bar{\varphi}\|_\infty = 1$, $\|F(\bar{\varphi})\|_\infty \geq \sum_{h \in \Aut(X)} |\mu(h)|$.

For every function $\varphi \in \mathbb{R}^X$ we have that $F(\varphi) = F_\mu(\varphi) := \sum_{h \in \Aut(X)} \varphi h^{-1} \mu(h)$. Hence, $\|F(\varphi)\|_\infty \leq \sum_{h \in \Aut(X)} \|\varphi h^{-1}\|_\infty |\mu(h)| = \|\varphi\|_\infty \sum_{h \in \Aut(X)} |\mu(h)|$. Therefore, $\|F(\varphi)\|_\infty \leq \sum_{h \in \Aut(X)} |\mu(h)|$ for every $\varphi \in \mathbb{R}^X \setminus \{0\}$. 

\hfill \Box
In conclusion, \( \sum_{h \in \text{Aut}(X)} |\mu(h)| = \max_{\varphi \in \mathbb{R}^X \setminus \{0\}} \frac{||F(\varphi)||_{\infty}}{||\varphi||_{\infty}}. \)

\[ \square \]

**Example 2.1.** The simplest non-trivial example concerning the statement of Theorem 1 can be described as follows. Let \( X = \{1, 2\} \) and \( G = \text{Aut}(X) = \{\text{id}_X, (1 \ 2)\} \). Let us consider the linear GEO \( F : \mathbb{R}^X \rightarrow \mathbb{R}^X \) defined by setting \( F(1_1) = 1_1 - 1_2 \) and \( F(1_2) = 1_2 - 1_1 \). By defining \( \mu(\text{id}_X) := 1 \) and \( \mu((1 \ 2)) := -1 \), we get that \( \mu \) is a permutant measure with respect to \( G \) and \( F(\varphi) = \sum_{h \in \text{Aut}(X)} \varphi h^{-1} \mu(h) \) for every \( \varphi \in \mathbb{R}^X \).

Furthermore, \( \sum_{h \in \text{Aut}(X)} |\mu(h)| = 2 = \frac{||F(1_1-1_2)||_{\infty}}{||1_1-1_2||_{\infty}} = \max_{\varphi \in \mathbb{R}^X \setminus \{0\}} \frac{||F(\varphi)||_{\infty}}{||\varphi||_{\infty}}. \)

We now observe that the assumption that \( G \) transitively acts on \( X \) cannot be removed from Theorem 1.

**Example 2.2.** Let us consider the set \( X = \{1, 2\} \) and the group \( G = \{\text{id}_X\} \subseteq \text{Aut}(X) = \{\text{id}_X, (1 \ 2)\} \). Take the operator \( F : \mathbb{R}^X \rightarrow \mathbb{R}^X \) defined by setting \( F(1_i) = 1_i \) for any \( i \in X \). Although \( F \) is a linear GEO, there does not exist a permutant measure \( \mu \) on \( \text{Aut}(X) \), such that \( F(\varphi) = F_{\mu}(\varphi) := \sum_{h \in \text{Aut}(X)} \varphi h^{-1} \mu(h) \) for every \( \varphi \in \mathbb{R}^X \).

By contradiction, let us assume that such a permutant measure \( \mu \) exists. Then,

\[ 1_1 = F(1_1) = 1_1 \text{id}_X \mu(\text{id}_X) + 1_1(1 \ 2) \mu(1 \ 2) = 1_1 \mu(\text{id}_X) + 1_2 \mu(1 \ 2). \]

Since \( \{1_1, 1_2\} \) is a basis for \( \mathbb{R}^X \), the equalities \( \mu(\text{id}_X) = 1 \) and \( \mu(1 \ 2) = 0 \) must hold.

It follows that

\[ F(1_2) = 1_2 \text{id}_X \mu(\text{id}_X) + 1_1(1 \ 2) \mu(1 \ 2) = 1_2. \]

This contradicts the assumption that \( F(1_2) = 1_1 \).

**Example 2.3.** Let us set \( X = \{1, 2, 3, 4\} \) and \( G = \text{Aut}(X) \). Let \( F \) be a linear GEO with respect to \( G \). Let \( B = (b_{ij}) \) be the matrix associated with \( F \) with respect to the basis \( \{1_{x_1}, \ldots, 1_{x_n}\} \). In the proof of Lemma 2.1 we have seen that \( b_{ij} = b_{\sigma(i)\sigma(j)} \) for any \( g \in G \). It follows that two values \( \alpha, \beta \in \mathbb{R} \) exist, such that \( b_{ij} = \alpha \) if \( i = j \) and \( b_{ij} = \beta \) if \( i \neq j \). By using the cycle notation, let us set \( \sigma = (1 \ 2 \ 3 \ 4) \in \text{Aut}(X) \) and \( \langle \sigma \rangle = \{\text{id}_X, \sigma, \sigma^2 = (1 \ 3)(2 \ 4), \sigma^3 = (1 \ 4 \ 3 \ 2)\} \), i.e., the cyclic group generated by \( \sigma \). We have that \( B = \alpha P(\text{id}_X) + \beta P(\sigma) + \beta P(\sigma^2) + \beta P(\sigma^3) \). Therefore, by setting \( c(\text{id}_X) := \alpha, c(\sigma) := c(\sigma^2) := c(\sigma^3) := \beta, \) and \( c(h) := 0 \) for every \( h \notin \langle \sigma \rangle \), we get \( F(\varphi) = \sum_{h \in \text{Aut}(X)} \varphi h^{-1} c(h) \).

However, the signed measure \( c \) is not a permutant measure, since the orbits under the conjugation action of \( G \) are the sets

\[ \mathcal{O}(\text{id}_X) = \{\text{id}_X\} \]
\[ \mathcal{O}(\sigma) = \{(1 \ 2 \ 3 \ 4), (1 \ 2 \ 4 \ 3), (1 \ 3 \ 2 \ 4), (1 \ 3 \ 4 \ 2), (1 \ 4 \ 2 \ 3), (1 \ 4 \ 3 \ 2)\} \]
\[ \mathcal{O}(\sigma^2) = \{(1 \ 2)(3 \ 4), \sigma^2 = (1 \ 3)(2 \ 4), (1 \ 4)(2 \ 3)\} \]
\[ \mathcal{O}(1 \ 2) = \{(1 \ 2), (1 \ 3), (1 \ 4), (2 \ 3), (2 \ 4), (3 \ 4)\} \]
\[ \mathcal{O}(1 \ 2 \ 3) = \{(1 \ 2 \ 3), (1 \ 2 \ 4), (1 \ 3 \ 2), (1 \ 3 \ 4), (1 \ 4 \ 2), (1 \ 4 \ 3), (2 \ 3 \ 4), (2 \ 4 \ 3)\} \]

and, according to our definition, \( c \) is not constant on the orbits \( \mathcal{O}(\sigma) \) and \( \mathcal{O}(\sigma^2) \).

Following the proof of Theorem 1, we can get a permutant measure \( \mu \) by computing an average on the orbits. In other words, we can set

\[ \mu(h) := \begin{cases} 
\frac{c(\text{id}_X)}{\mathcal{O}(\text{id}_X)} = \frac{c(h)}{\mathcal{O}(h)} = \frac{\beta}{3}, & \text{if } h = \text{id}_X \\
0, & \text{otherwise}.
\end{cases} \]

By making this choice, the equality \( F(\varphi) = \sum_{h \in \text{Aut}(X)} \varphi h^{-1} \mu(h) \) holds for every \( \varphi \in \mathbb{R}^X \), i.e., \( F \) is the linear GEO associated with the permutant measure \( \mu \).

Proposition 2.1 and Theorem 1 immediately imply the following statement.
Theorem 2. Assume that $G \subseteq \text{Aut}(X)$ transitively acts on the finite set $X$ and $F$ is a map from $\mathbb{R}^X$ to $\mathbb{R}^X$. The map $F$ is a linear group equivariant operator for $(\mathbb{R}^X, G)$ if and only if a permutant measure $\mu$ exists such that $F(\varphi) = \sum_{h \in \text{Aut}(X)} \varphi^{-1} h \mu(h)$ for every $\varphi \in \mathbb{R}^X$.

3. Representation of linear GENEOs via permutant measures

Our main result about the representation of linear GEOs can be extended to GENEOs.

Theorem 3. Assume that $G \subseteq \text{Aut}(X)$ transitively acts on the finite set $X$ and $F$ is a map from $\mathbb{R}^X$ to $\mathbb{R}^X$. The map $F$ is a linear group equivariant non-expansive operator for $(\mathbb{R}^X, G)$ if and only if a permutant measure $\mu$ exists such that $F(\varphi) = \sum_{h \in \text{Aut}(X)} \varphi^{-1} h \mu(h)$ for every $\varphi \in \mathbb{R}^X$, and $\sum_{h \in \text{Aut}(X)} |\mu(h)| \leq 1$.

Proof. If $F$ is a linear group equivariant non-expansive operator for $(\mathbb{R}^X, G)$, then Theorem guarantees that in PM($G$) a permutant measure $\mu$ exists, such that $F(\varphi) = \sum_{h \in \text{Aut}(X)} \varphi^{-1} h \mu(h)$ for every $\varphi \in \mathbb{R}^X$, and $\sum_{h \in \text{Aut}(X)} |\mu(h)| = \max_{\varphi \in \mathbb{R}^X \setminus \{0\}} \frac{\|F(\varphi)\|_{\infty}}{\|\varphi\|_{\infty}}$. Since $F$ is non-expansive, the inequality $\sum_{h \in \text{Aut}(X)} |\mu(h)| \leq 1$ follows. This proves the first implication in our statement.

Let us now assume that a permutant measure $\mu$ exists such that $F(\varphi) = \sum_{h \in \text{Aut}(X)} \varphi^{-1} h \mu(h)$ for every $\varphi \in \mathbb{R}^X$, with $\sum_{h \in \text{Aut}(X)} |\mu(h)| \leq 1$. Then Proposition states that $F$ is a linear group equivariant operator for $(\mathbb{R}^X, G)$. Moreover,

$$\|F(\varphi)\|_{\infty} = \left\| \sum_{h \in \text{Aut}(X)} \varphi^{-1} h \mu(h) \right\|_{\infty} \leq \sum_{h \in \text{Aut}(X)} \left\| \varphi^{-1} h \right\|_{\infty} |\mu(h)| = \sum_{h \in \text{Aut}(X)} \|\varphi\|_{\infty} |\mu(h)| = \|\varphi\|_{\infty} \left( \sum_{h \in \text{Aut}(X)} |\mu(h)| \right) \leq \|\varphi\|_{\infty}. $$

This proves that $F$ is non-expansive, and concludes the proof of the second implication in our statement. \qed

4. Discussion

In our paper we have proved that all linear GEOs and GENEOs can be produced by means of a dual method based on the concept of permutant measure with respect to a group $G$, under the assumption that $G$ transitively acts on a finite set. This method could be particularly useful when we have to deal with a large group $G$, as frequently happens in real applications. Summations on large groups can indeed present computational difficulties, while summations on the supports of permutant measures are often easier. The use of the set of all permutant measures also benefits of its lattice structure. The availability of the approach we have studied in this paper could be relevant for the
application of GEOs and GENEOs as multi-level components in deep learning and make the construction of neural networks more transparent and interpretable, according to the mathematical framework proposed in [5]. The next natural step in this line of research is the extension of our approach to topological groups. We plan to study this possible extension in a forthcoming paper.

5. Acknowledgements

This research has been partially supported by INdAM-GNSAGA. The authors thank Alessandro Achille, Fabio Anselmi and Giovanni Paolini for their helpful advice. The authors of this paper have been listed in alphabetical order.

This paper is dedicated to the memory of Dr. Mohamed Mashally.
