We define a $D = 26 + 1$ Monstrous, purely bosonic M-theory, whose massless spectrum, of dimension $196,884$, is acted upon by the Monster group. Upon reduction to $D = 25 + 1$, this gives rise to a plethora of non-supersymmetric, gravito-dilatonic theories, whose spectrum irreducibly splits under the Monster as $196,884 = 1 \oplus 196,883$, where the singlet is identified with the dilaton, and $196,883$ denotes the smallest non-trivial representation of the Monster. This clarifies the definition of the Monster as the automorphism of the Griess algebra, by showing that such an algebra is not merely a sum of unrelated spaces, but rather an algebra of massless states for a Monstrous M-theory, which includes Horowitz and Susskind’s bosonic M-theory as a subsector. Remarkably, a certain subsector of Monstrous M-theory, when coupled to a Rarita-Schwinger massless field in $26 + 1$, exhibits the same number of bosonic and fermionic degrees of freedom.

I. INTRODUCTION

The Monster group $M$ was predicted to exist by Fischer and Griess \[1\]. It is the automorphism group of the Griess algebra, as well as the automorphism group of the Monster vertex algebra $\mathcal{V}$ [2, 3]. Conway and Norton defined Monstrous moonshine as the observation that the Fourier coefficients of the $j$-function decompose into dimensions of representations of the Monster group [2] and this was proven by Borcherds using generalized Kac-Moody algebras [4].

In the language of conformal field theory, Monstrous moonshine is the statement that the states of an orbifold theory, which is $D = 25 + 1$ bosonic string theory on $(\mathbb{R}^{24}/\Lambda_{24})/\mathbb{Z}_2$ (where $\Lambda_{24}$ is the Leech lattice \[1, 31, 32\]), are organized in representations of the Monster group, with partition function equivalent to the $j$-function \[8, 12, 14\]. Witten also found the Monster in three-dimensional pure gravity \[22\], for $AdS_3$, where the dual CFT is expected to be that of Frenkel, Lepowsky and Meurman \[3\].

Eguchi, Ooguri and Tachikawa later noticed the elliptic genus of the K3 surface has a natural decomposition in terms of dimensions of irreducible representations of the largest Mathieu group $M_{24}$, and this was named Umbral moonshine \[11\], which generalizes the moonshine correspondence for other sporadic groups \[13\].

With Witten’s proposal \[21\] that M-theory unifies all the ten-dimensional string theories with $N = 1$ supergravity in $D = 10 + 1$, Horowitz and Susskind argued \[23\] there exists a bosonic M-theory in $D = 26 + 1$ that reduces to the bosonic string upon compactification. As the Monster has a string theoretic interpretation in $D = 25 + 1$ \[14–16\], it is also natural to consider its action on fields from $D = 26 + 1$. Support for this is found from bosonic M-theory’s 2-brane near horizon geometry $AdS_4 \times S^{2\,1}$, discussed by Horowitz and Susskind as an evidence for a 2 + 1 CFT dual with global $SO_{24}$ symmetry \[25\]. Noting that the automorphism group of the Leech lattice, the Conway group $Co_0 \[4, 32\]$, is a maximal finite subgroup of $SO_{24}$, and its $\mathbb{Z}_2$ quotient $Co_1$ is a maximal subgroup of the Monster \[4, 5\], this provides a means to realize Monstrous symmetry as a finite subgroup of $R$-symmetry from $D = 26 + 1$ \[27\].

In the present paper, we introduce a purely bosonic gravity theory coupled to $p$-forms in $26 + 1$ space-time dimensions, which contains the aforementioned bosonic string theory \[23\] as a subsector. We name such a theory Monstrous M-theory, or shortly $M^2$-theory, because its massless spectrum has the same dimension (196, 884) as the Griess algebra and it can thus be acted upon by the Monster group $M$. When reducing to $25 + 1$, a plethora of gravito-dilatonic theories is generated, in which the decomposition $196, 884 = 196, 883 \oplus 1$, which first hinted at Monstrous moonshine \[2\], entails the fact that the dilaton in $25 + 1$ is a singlet of $M$ itself. As such, the irreducibility under $M$ is crucially related to dilatonic gravity in $25 + 1$. Thanks to existence of some maps among iso-dimensional representations of the massless little group $SO_{24}$ in $25 + 1$ (which generalize, in a “weak” sense, the triality of $SO_8$), most of the gravito-dilatonic theories in $25 + 1$, named Monstrous gravity theories, display a fermionic (massless) spectrum, as well, such that the whole spectrum is still acted upon by $M$.

All this gives a more concise description of the Monster’s minimal representation 196, 883, coming from the field content of Monstrous gravity in $D = 25 + 1$; as such, this also elucidates the definition of the Monster as the automorphism group of the Griess algebra (the degree two piece of the monster vertex algebra), which has been considered artificial in that it was thought to involve an algebra of two or more unrelated spaces \[4, 5\].

The plan of the paper is as follows. At the start of Sec. II we briefly recall the triality among the 8-dimensional representations of the Lie algebra $\mathfrak{d}_4$, as well as the duality among all semisimpolar representations and their conjugates (and among all the tensor products thereof) in Lie algebras $\mathfrak{d}_n$. Then, we introduce some “weak” generalizations within the Lie algebra $\mathfrak{d}_{12}$, namely weak $\lambda$-triality in Sec. II A and weak $\psi$-triality in Sec. II B. Furthermore, we also introduce a “weak” generalization of the aforementioned duality in Sec. III C. In all these cases, the “weakness” relies on the reducibility of the bosonic representations involved. Next, in Sec. III we introduce and classify non-supersymmetric, gravito-dilatonic theories, named Monstrous gravities, in $25 + 1$ space-time dimensions, whose massless sector (also including fermions in most cases) has dimension 196, 884, namely the same dimension as the Griess algebra $\mathfrak{g}_2$, and can thus be acted upon by the Monster group $M$. A purely bosonic uplift to $26 + 1$ space-time dimensions is discussed in Sec. IV in which the so-called $M^2$-theory is defined, along with some discussion of its Lagrangian in Sec. IV A. Furthermore, Sec. IV B discusses a subsector of the $M^2$-theory displaying the same number of bosonic and fermionic massless degrees of freedom in $26 + 1$; in this framework, after a discussion of some reductions to $25 + 1$, in Sec. IV B 1 a Lagrangian and local supersymmetry transformations are conjectured for the would-be $N = 1$ supergravity in $26 + 1$ space-time dimensions. Then, in Sec. V a cohomological construction of both the $\mathfrak{e}_8$ root lattice and the Leech lattice $\Lambda_{24}$ (respectively determining optimal sphere packing in 8 and 24 dimensions \[4\]) is discussed, and all this is again related to M-theory (i.e., $N = 1$ supergravity) in $10 + 1$ and to the would-be $N = 1$ supergravity $26 + 1$, respectively. Final comments are contained in the conclusive Sec. VI.
II. TRIALITY OF $\mathfrak{d}_4$ AND ITS GENERALIZATIONS IN $\mathfrak{d}_{12}$

By *triality*, denoted by $T$, in this paper we refer to a property of the Lie algebra $\mathfrak{d}_4$ (see e.g. [10]), namely a map of its three 8-dimensional irreducible representations

\[
\begin{align*}
\wedge^1 & \equiv 8_v := (1,0,0,0) \text{ (vector)}; \\
\mathfrak{d}_4 : \quad & \lambda \equiv 8_s := (0,0,0,1) \text{ (semispinor)}; \\
& \lambda' \equiv 8'_s \equiv 8_c := (0,0,1,0) \text{ (conjugate semispinor)}
\end{align*}
\]

among themselves:

\[
T : \begin{bmatrix} \wedge^1 \\ \lambda' \end{bmatrix} \leftrightarrow \begin{bmatrix} \lambda \end{bmatrix}.
\] (2.2)

This property can be traced back to the three-fold structural symmetry of the Dynkin diagram of $\mathfrak{d}_4$, and to the existence of an outer automorphism of $\mathfrak{d}_4$ which interchanges $8_v$, $8_s$ and $8_c$; in fact, the outer automorphism group of $\mathfrak{d}_4$ (or, more precisely, of the corresponding spin group $Spin_{8}$, the double cover of the Lie group $SO_8$) is isomorphic to the symmetric group $S_3$ that permutes such three representations.

Thence, triality affects all tensor products stemming from $8_v$, $8_s$ and $8_c$. In particular, for later convenience, we stress that it maps also the three 56-dimensional irreducible representations of $\mathfrak{d}_4$:

\[
\begin{align*}
\wedge^3 & \equiv 56_v := (0,0,1,1) \text{ (3-form)}; \\
\mathfrak{d}_4 : \quad & \psi \equiv 56_s := (1,0,0,1) \text{ (vector-semispinor)}; \\
& \psi' \equiv 56'_s \equiv 56_c := (1,0,1,0) \text{ (conjugate vector-semispinor)}
\end{align*}
\]

among themselves

\[
T : \begin{bmatrix} \wedge^3 \\ \psi' \end{bmatrix} \leftrightarrow \begin{bmatrix} \psi \end{bmatrix}.
\] (2.4)

We recall here that, in order to correspond to an irreducible representation, the spinor-vector $\psi_\mu^\alpha$ must be gamma-traceless:

\[
\Gamma^\mu_{\alpha\beta} \psi^\beta = 0,
\] (2.5)

where $\mu$ and $\alpha$ are the vector resp. spinor indices, and $\Gamma^\mu_{\alpha\beta} \equiv (\Gamma^\mu)^{\alpha\beta}$ denote the gamma matrices of $\mathfrak{d}_4$. $\psi$ is a Rarita-Schwinger (RS) field of spin/helicity $\frac{3}{2}$, and, in the context of supersymmetric theories, it is named *gravitino* (being the spartner of the graviton $g_{\mu\nu}$). As $[2.2]$ denotes the action of triality $T$ on (semi)spinors, $[2.4]$ expresses the triality $T$ acting on RS fields.

Triality plays an important role in type II string theory, in which $\mathfrak{so}_8$ (compact real form of $\mathfrak{d}_4$) is the algebra of the massless little group (cfr. e.g. [21]).

Within Lie algebras $\mathfrak{d}_n$, one can always have a *duality* between the (semi)spinor representation

\[
\lambda \equiv 2^{n-1} := (0^{n-1},1)
\] (2.6)

and its conjugate representations

\[
\lambda' \equiv (2^{n-1})' := (0^{n-2},1,0)
\] (2.7)

(as well as between tensor products thereof, such as the aforementioned gravitino $\psi$ and conjugate gravitino $\psi'$ representations). In fact, $\lambda$ and $\lambda'$, as well as $\psi$ and $\psi'$, have the same dimension but different Dynkin labels; in all these cases, the “duality” map is nothing but the spinor conjugation between the chiral components of the spinor bundle. On the other hand, there are no known examples of bosonic representations having the same dimension but different Dynkin labels.
A. Weak $\lambda$-triality

However, there may be a “weaker” instance of the aforementioned triality, in which $\lambda$ and $\lambda'$ have the same dimension of a reducible (bosonic) representation, namely of a sum of irreducible (bosonic) representations, of $\mathfrak{d}_n$.

In fact, for $n = 12$ (i.e. in $\mathfrak{d}_{12}$) something remarkable takes place: in $\mathfrak{d}_{12}$, the following three representations have the same dimension $2,048$:

$$\mathfrak{d}_{12} : \begin{cases} \lambda \equiv 2^{11} = 2048 := (0^{11}, 1); \\
\lambda' \equiv (2^{11})' = 2048' := (0^{10}, 1, 0); \\
\land^1 \oplus \land^3 = 24 \oplus 2024 = (1, 0^{11}) \oplus (0^2, 1, 0^9). \end{cases}$$

In other words, in $\mathfrak{d}_{12}$ the reducible bosonic representation given by the sum of the vector (1-form) representation $\land^1$ and of the 3-form representation $\land^3$ has the same dimension of each of the (semi)spinors $\lambda$ and $\lambda'$. Analogously to the aforementioned case of $\mathfrak{d}_4$, one can then define a “triality-like” map, named weak $\lambda$-triality and denoted by $\tilde{T}_\lambda$, between the corresponding representation vector spaces,

$$\tilde{T}_\lambda : \begin{pmatrix} \lambda^1 \oplus \lambda^3 \\ \uparrow \downarrow \\ \lambda' \end{pmatrix} \equiv \begin{pmatrix} \lambda^1 \oplus \lambda^3 \\ \uparrow \downarrow \\ \lambda' \end{pmatrix}.$$ (2.9)

At a glance, one realizes that a crucial difference with (2.2) relies in the reducibility of the bosonic sector of the map, which we will henceforth associate to the “weakness” of $\tilde{T}_\lambda$. However, since no other Dynkin diagram (besides $\mathfrak{d}_4$) has an automorphism group of order greater than 2, one can also conclude that (2.8)-(2.9) cannot be realized as an automorphism of $\mathfrak{d}_{12}$, nor it can be traced back to some structural symmetry of the Dynkin diagram of $\mathfrak{d}_{12}$ itself.

B. Weak $\psi$-triality

As triality $T$ of $\mathfrak{d}_4$ affects all tensor products stemming from $8_n$, $8_s$, and $8_e$, implying in particular (2.4), so the weak $\lambda$-triality $\tilde{T}_\lambda$ of $\mathfrak{d}_{12}$ (2.9) affects all tensor products stemming from $\land^1 \oplus \land^3$, $\lambda$ and $\lambda'$; in particular, in $\mathfrak{d}_{12}$, the following three representations have the same dimension $47,104$:

$$\mathfrak{d}_{12} : \begin{cases} \psi \equiv 47, 104 := (1, 0^{10}, 1); \\
\psi' \equiv 47, 104' := (1, 0^9, 1, 0); \\
2 \cdot (2 \cdot \land^4 \oplus \land^3 \oplus \land^2) = 2 \cdot (2 \cdot 10,626 \oplus 2,024 \oplus 276) \\
= 2 \cdot (2 \cdot (0^3, 1, 0^8) \oplus (0^2, 1, 0^9) \oplus (0, 1, 0^{10})). \end{cases}$$ (2.10)

In other words, in $\mathfrak{d}_{12}$ the reducible bosonic representation given by the sum of the 4-form $\land^4$, 3-form $\land^3$ and 2-form $\land^2$ representations (with multiplicity 4, 2 and 2, respectively) has the same dimension of each of the RS field representations $\psi$ and $\psi'$. Analogously to the aforementioned case of $\mathfrak{d}_4$, one can then define a “triality-like” map, named weak $\psi$-triality and denoted by $\tilde{T}_\psi$, between the corresponding representation vector spaces,

$$\tilde{T}_\psi : \begin{pmatrix} 2 \cdot (2 \cdot \land^4 \oplus \land^3 \oplus \land^2) \\ \uparrow \downarrow \\ \psi \end{pmatrix} \equiv \begin{pmatrix} 2 \cdot (2 \cdot \land^4 \oplus \land^3 \oplus \land^2) \\ \uparrow \downarrow \\ \psi' \end{pmatrix}.$$ (2.11)

Again, (2.8)-(2.9) cannot be realized as an automorphism of $\mathfrak{d}_{12}$, nor it can be traced back to some structural symmetry of the Dynkin diagram of $\mathfrak{d}_{12}$ itself.

C. Weak duality among (sets of) p-forms

Representations with the same dimensions can also be only bosonic. Still, $\mathfrak{d}_{12}$ provides the following example of such a phenomenon: the following two sets of representations have the same dimension 42,504,

$$\mathfrak{d}_{12} : \begin{cases} \land^5 \equiv 42,504 := (0^4, 1, 0^7); \\
4 \cdot \land^4 = 4 \cdot 10,626 = 4 \cdot (0^3, 1, 0^8). \end{cases}$$ (2.12)
In other words, in \( \mathfrak{d}_{12} \) the 5-form representation \( \Lambda^5 \) has the same dimension, namely 42,504, of four copies of the 4-form representation \( \Lambda^4 \). Again, one can then define a “duality-like” map, named (bosonic) weak duality and denoted by \( \mathcal{B} \), between the corresponding representation vector spaces\(^1\),

\[
\mathcal{B} : \Lambda^5 \leftrightarrow 4 \cdot \Lambda^4 .
\] (2.13)

### III. MONSTROUS GRAavity IN \( 25 + 1 \)

In the previous Section we have introduced some maps among fermionic and bosonic representations of \( \mathfrak{d}_{12} \), having the same dimension but different Dynkin labels:

- the weak \( \lambda \)-triality \( \tilde{T}_\lambda \) (2.8)-(2.9), generalizing the triality \( T \) (2.2) of \( \mathfrak{d}_4 \) to \( \mathfrak{d}_{12} \);
- the weak \( \psi \)-triality \( \tilde{T}_\psi \) (2.10)-(2.11), extending the weak triality of \( \mathfrak{d}_{12} \) to its RS sector;
- the bosonic weak duality \( \mathcal{B} \) (2.12)-(2.13) among sets of bosonic (p-form) representations of \( \mathfrak{d}_{12} \).

As triality \( T \) (2.2) of \( \mathfrak{d}_4 \) plays a role in the type II string theories having \( \mathfrak{so}_{24} \) as the algebra of the massless little group, one might ask the intriguing question whether (2.9), (2.11) and (2.13) have some relevance in relation to bosonic string theory \( [23] \), or in more general field theories defined in \( D = s + t = 25 + 1 \) space-time dimensions, in which \( \mathfrak{so}_{24} \) is the algebra of the massless little group. Below, we will show that this is actually the case for a quite large class of non-supersymmetric dilatonic gravity theories in \( 25+1 \), named Monstrous gravities, which we are now going to introduce.

To this aim, we start and display various massless fields in \( D = 25 + 1 \) space-time dimensions. As mentioned, each massless field fits into the following reducible representation \( \mathbf{R} \) of the massless little group \( \mathfrak{so}_{24} \):

<table>
<thead>
<tr>
<th>Field</th>
<th>( \mathbf{R} )</th>
<th>Dynkin labels</th>

</tr>
</tbody>
</table>

We are now going to classify field theories in \( 25 + 1 \) which share the following features:

- **\( \mathbf{a} \)** They all contain gravity (in terms of one 26-bein, then yielding a metric tensor \( g_{\mu \nu} \) and one dilaton scalar field \( \phi \); thus, the Lagrangian density of their gravito-dilatonic sector reads\(^2\)

\[
\mathcal{L} = e^{-2\phi} (R - 4\partial_\mu \phi \partial^\mu \phi) .
\] (3.2)

- **\( \mathbf{b} \)** The relations among all such theories exploit the weak \( \lambda \)-triality \( \tilde{T}_\lambda \) (2.8)-(2.9), the weak \( \psi \)-triality \( \tilde{T}_\psi \) (2.10)-(2.11), as well as the bosonic weak duality \( \mathcal{B} \) (2.12)-(2.13) of \( \mathfrak{so}_{24} \) (real compact form of \( \mathfrak{d}_{12} \)), which is the Lie algebra of the massless little group.

- **\( \mathbf{c} \)** The total number of degrees of freedom of the massless spectrum sums up to

\[
\begin{align*}
299 \cdot (#g) + 47,104 \cdot (#\psi) + 24 \cdot (#\Lambda^1) + 2,048 \cdot (#\lambda) + 1 \cdot (#\phi) \\
+ 42,504 \cdot (#\Lambda^5) + 10,626 \cdot (#\Lambda^4) + 2,024 \cdot (#\Lambda^3) + 276 \cdot (#\Lambda^2)
\end{align*}
= 196,884 .
\] (3.3)

---

1. Of course, all instances of iso-dimensionality among representations given by (2.8)-(2.9), (2.10)-(2.11) and (2.12)-(2.13), hold up to Poincaré/Hodge duality (in the bosonic sector); cfr. (3.7) further below.

2. Throughout our analysis, we rely on the conventions and treatment given in Secs. 22 and 23 of [36].
Consequently, the whole set of massless degrees of freedom of such theories may be acted upon by the so-called Monster group $\mathbb{M}$, the largest sporadic group, because $196,883$ is the dimension of its smallest non-trivial representation $[1]$. For this reason, the gravito-dilatonic theories under consideration will all be named \textit{Monstrous gravities}. Concerning this, we would like to stress that the inclusion of the 300 massless degrees of freedom given by the graviton $g_{\mu\nu}$ (299) and the dilaton $\phi$ (1), rather than by the 2-form $A_{\mu\nu}$ (276) and the vector $A_\mu$ (24), yields the splitting

$$196,884 = 196,883 + 1,$$

which is at the origin of the so-called \textit{Monstrous moonshine} $[2, 6]$. The dilaton $\phi$, which is a singlet of $\mathbb{M}$, coincides with the vacuum state $|\Omega\rangle$ of the chiral Monster conformal theory discussed in $[8, 17, 18]$. Thus, dilatonic gravity in 25 + 1 dimensions seems intimately related to the 196,883-dimensional representation of $\mathbb{M}$. In the context of Witten's three-dimensional gravity $[22]$, this suggests the 196,883 primary operators that create black holes are carrying dilatonic gravity field content. As done in $[22]$, it is enlightening to compare the number 196,883 of primaries with the Bekenstein-Hawking entropy of the corresponding black hole: an exact quantum degeneracy of 196,883 yields an entropy of Witten’s BTZ black hole given by $\ln(196,883) \approx 12.19$, whereas the Bekenstein-Hawking entropy-area formula yields to $4\pi \approx 12.57$. Of course, one should not expect a perfect agreement between such two quantities, because the Bekenstein-Hawking entropy-area formula holds in the semi-classical regime and not in the exact quantum one. As given in (3.3), 196,883 comes from gauge fields (potentials), graviton, etc., albeit without dilaton; in this sense, the quantum entropy $\ln(196,883) \approx 12.19$ has a clear higher-dimensional interpretation, since the BTZ black hole degrees of freedom are expressed in terms of massless degrees of freedom of fields in 25 + 1 space-time dimensions.

### A. Classification

All such theories will be classified by using two sets of numbers:

- $s_1$, a 5-characters string, providing the number of independent “helicity”-h massless fields, with $h = 2, 3, 1, \frac{1}{2}, 0$, respectively denoted by $g$ (graviton), $\psi$ (Rarita-Schwinger field), $\Lambda^1$ (vector, i.e. 1-form, potential), $\lambda$ (spinor field$^3$), and $\phi$ (dilaton):

$$s_1 := (\#g, \#\psi, \#\Lambda^1, \#\lambda, \#\phi) = (1, \#\psi, \#\Lambda^1, \#\lambda, 1);$$

- $s_2$, a 4-character string, providing the number of independent p-form brane potentials, for $p = 5, 4, 3, 2$,

$$s_2 := (\#\wedge^5, \#\wedge^4, \#\wedge^3, \#\wedge^2).$$

Before starting, we should point out that the classification below is unique up to Poincaré/Hodge duality in the p-form potentials’ sector, namely, for $p = 1, \ldots, 5$:

$$\begin{array}{ccc}
\wedge^1 & \leftrightarrow & \wedge^2 \\
\wedge^2 & \leftrightarrow & \wedge^3 \\
\wedge^3 & \leftrightarrow & \wedge^4 \\
\wedge^4 & \leftrightarrow & \wedge^5 \\
\wedge^5 & \leftrightarrow & \wedge^{23} \\
\wedge^3 & \leftrightarrow & \wedge^{22} \\
\wedge^2 & \leftrightarrow & \wedge^{21} \\
\wedge^1 & \leftrightarrow & \wedge^{20}
\end{array}$$

(3.7)

as well as up to chiral/non-chiral arrangements in the fermionic sector,

$$\begin{array}{c|c}
\#\psi & \text{chiral/non-chiral arr.s} \\
2 & (2, 0), (0, 2), (1, 1) \\
4 & (4, 0), (0, 4), (3, 1), (1, 3), (2, 2); \\
\#\lambda & \text{chiral/non-chiral arr.s} \\
1 & (1, 0), (0, 1) \\
2 & (2, 0), (0, 2), (1, 1) \\
3 & (3, 0), (0, 3), (2, 1), (1, 2). \\
\end{array}$$

(3.8)

(3.9)

$^3$ The spinor field gets named \textit{gaugino} (or \textit{dilatino}) in presence of supersymmetry.
Clearly, (3.7) and [3.8]-[3.9] are particularly relevant if supersymmetry in $25 + 1$ were considered; however, we will not be dealing with such an interesting issue here, and we will confine ourselves to make some comments further below (in $26 + 1$).

We will split the Monstrous gravity theories, sharing the features $a - c$ listed above, in five groups, labelled with Latin numbers: 0, 1, 2, 3, 4, specifying the number $\#\psi$ of $h = 3/2$ RS fields. The weak $\psi$-triality $T_{\psi}(2.10)-(2.11)$ of $so_{24}$ maps such five groups among themselves. Then, each of these groups will be split into four subgroups, labelled with Greek letters: $\alpha$, $\beta$, $\gamma$ and $\delta$, respectively characterized by the following numbers $\#\wedge^1$ and $\#\lambda$ of $h = 1$ vectors $\alpha$ resp. $h = 1/2$ spinors:

$$\begin{align*}
(\#\wedge^1, \#\lambda) &= \begin{pmatrix}
(3,0), \ (2,1), \ (1,2), \ (0,3) \\
\alpha, \ \beta, \ \gamma, \ \delta
\end{pmatrix}.
\end{align*}$$

(3.10)

The weak $\lambda$-triality $T_{\lambda}(2.8)-(2.9)$ of $so_{24}$ allows to move among such four subgroups (within the same group). The theories belonging to each of such four subgroups will share the same split of the massless degrees of freedom into bosonic and fermionic ones, respectively specified by the numbers $B$ and $F$. Each of such four subgroups is a set of a varying number of theories, which will be labelled in lowercase Latin letters: $i, ii, iii, \text{ etc.}$. Such theories will be connected by the action of the bosonic weak duality $B(2.12)-(2.13)$ of $so_{24}$, and thus they will differ for the content of 5-form $\wedge^5$ and 4-form $\wedge^4$ (potential) fields.

Modulo all possibilities arising from the combinations of (3.7)–(3.9), the classification of Monstrous gravity theories in $25 + 1$ space-time dimensions is as follows.

\quad (3.26)
\]
4 Group 4 ($\#_g = 4$ theories): 

\[
\begin{align*}
\alpha & (B|F) = (8,468|188,416), \lambda \text{-less} : \begin{bmatrix} s_1 & s_2 & \text{features} \\ (1,4,3,0,1) & (0,0,4,0) & \Lambda^5, \Lambda^4, \Lambda^2\text{-less} \end{bmatrix} \\
\beta & (B|F) = (6,420|190,464) : \begin{bmatrix} s_1 & s_2 & \text{features} \\ (1,4,2,1,1) & (0,0,3,0) & \Lambda^5, \Lambda^4, \Lambda^2\text{-less} \end{bmatrix} \\
\gamma & (B|F) = (4,372|192,512) : \begin{bmatrix} s_1 & s_2 & \text{features} \\ (1,4,1,2,1) & (0,0,2,0) & \Lambda^5, \Lambda^4, \Lambda^2\text{-less} \end{bmatrix} \\
\delta & (B|F) = (2,324|194,560) : \begin{bmatrix} s_1 & s_2 & \text{features} \\ (1,4,0,3,1) & (0,0,1,0) & \Lambda^5, \Lambda^4, \Lambda^2, \Lambda^1\text{-less} \end{bmatrix}
\end{align*}
\]

(3.27) (3.28) (3.29) (3.30)

The above classification contains 60 Monstrous gravity theories, from the purely bosonic, $\Lambda^5$-less, $0.\alpha.i$ theory \((3.11)\) to the theory with the highest $F$, i.e. the $4.\delta$ theory \((3.30)\). As it can be realized at a glance, Monstrous gravity theories are not supersymmetric, as it is evident from the mismatch between $B$ and $F$. Also, it should be noted that all such theories (but the ones of the group 4 \((3.27)-(3.30)\)) contain bosonic string theory, whose (massless, closed string) field content is $\#_g = \#_\phi = \#_\Lambda^2 = 1$ (see e.g. \([23]\)) as a subsector.

IV. MONSTROUS M-THEORY IN 26 + 1

At this point, the natural question arises whether Monstrous gravities classified above can be uplifted to 26 + 1 space-time dimensions, in which the massless little group is $SO_{25}$.

At least in one case, namely for the purely bosonic Monstrous gravity labelled by $0.\alpha.iii$, the answer is positive. The field content of such a theory is specified by the following $s_1$ and $s_2$, as from \((3.11)\):

\[
\begin{align*}
0.\alpha.iii & (B|F) = (196,884|0) : \begin{cases} s_1 = (1,0,3,0,1) \\ s_2 = (2,8,12,8) \end{cases}
\end{align*}
\]

(4.1)

or equivalently:

field $R$ of $so_{24}$ #

$g : 299$ 1
$\psi : 47,104$ 0
$\psi' : 47,104'$ 0
$\Lambda^1 : 24$ 3
$\lambda : 2,048$ 0
$\lambda' : 2,048'$ 0
$\phi : 1$ 1
$\Lambda^5 : 42,504$ 2
$\Lambda^4 : 10,626$ 8
$\Lambda^3 : 2,024$ 12
$\Lambda^2 : 276$ 8

(4.2)

It is then easy to realize that all such bosonic massless ($SO_{24}$-covariant) fields in $25 + 1$ can be uplifted to a smaller set of bosonic massless fields ($SO_{25}$-covariant) fields in $26 + 1$; namely, since

\[
\begin{align*}
so_{25} \quad & so_{24} \quad \text{fields} \\
q & g \rightarrow g, \Lambda^1, \phi \\
\Lambda^5 & \rightarrow \Lambda^5 \\
\Lambda^4 & \rightarrow 42,504, 10,626 \\
\Lambda^3 & \rightarrow 10,626, 2,024 \\
\Lambda^2 & \rightarrow 2,024, 276 \\
300 & \rightarrow 276, 24
\end{align*}
\]

(4.3)
the purely bosonic field content \([4.2]\) of the theory 0.\(\alpha.iii\) in 25 + 1 can be obtained by the \(S^1\) reduction of the following purely bosonic field content in 26 + 1:

\[
\begin{align*}
\text{field} & \quad \mathbf{R} \quad \text{of} \quad \mathfrak{so}_{25} \quad \# \\
g & : \quad 324 \quad 1 \\
\Lambda^1 & : \quad 25 \quad 0 \\
\varphi & : \quad 1 \quad 0 \\
\Lambda^5 & : \quad 53,130 \quad 2 \\
\Lambda^4 & : \quad 12,650 \quad 6 \\
\Lambda^3 & : \quad 2,300 \quad 6 \\
\Lambda^2 & : \quad 300 \quad 2 \\
\end{align*}
\]

So, we have obtained a purely bosonic gravity theory (coupled to p-forms, with \(p = 2,3,4,5\)) in 26 + 1 whose massless spectrum, given by 196,884 degrees of freedom, is acted upon by the Monster group \(\mathbb{M}\), because it corresponds to the sum of its two smallest representations, namely the trivial (singlet) 1 and the non-trivial one \(196,883\). Such a theory will be henceforth named \(\text{Monstrous}\ M\text{-theory}\), or simply \(M^2\text{-theory}\). Note that the disentangling of the 196,884 degrees of freedom into \(196,883 \oplus 1\) occurs only when reducing the theory to 25 + 1, in which case the dilaton \(\phi\) is identified with the singlet of \(\mathbb{M}\).

We would like here to stress that the possibility of an uplift to 26 + 1 is far from being trivial, and when possible, this uniquely fixes the content of the higher dimensional massless spectrum.

### A. Lagrangian(s)

\(A\ priori\), the 196,884-dimensional degrees of freedom of the massless spectrum of \(M^2\)-theory can be realized in various ways at the Lagrangian level. Here, we will attempt at writing down a general Lagrangian for \(M^2\)-theory.

We start and label the massless fields of \(M^2\)-theory, given by \([4.3]\), as follows:

\[
\begin{align*}
\text{field} & \quad \text{label} \quad \# \\
g & : \quad g_{\mu\nu} \quad 1 \\
\Lambda^5 & : \quad C^{(5)A}_{AB} \quad 2 \\
\Lambda^4 & : \quad C^{(4)ij}_{\lambda\mu\nu\rho} \quad 6 \\
\Lambda^3 & : \quad C^{(3)ij}_{\lambda\mu\nu} \quad 6 \\
\Lambda^2 & : \quad C^{(2)ij}_{\lambda\mu} \quad 2 \\
\end{align*}
\]

The uppercase Latin indices take values 1, 2, whereas the lowercase Latin indices run 1, 2, ..., 6. A general definition of the field strengths reads

\[
\begin{align*}
G^{(3)A} & := dC^{(2)A} + A^A_B C^{(3)j} \\
G^{(4)ij} & := dC^{(3)ij} + B^{ij}_{AB} C^{(2)A} \wedge C^{(2)B} + C_{ij} C^{(4)j} \\
G^{(5)ij} & := dC^{(4)ij} + D^{ij}_{AB} C^{(2)A} \wedge C^{(3)j} + E^{ij}_{AB} C^{(5)A}; \\
G^{(6)A} & := dC^{(5)A} + F^{A}_{(BCD)} C^{(2)B} \wedge C^{(2)C} \wedge C^{(2)D} + G^{A}_{ij} C^{(3)ij} \wedge C^{(3)j} + H^{A}_{ij} C^{(4)i} \wedge C^{(2)B},
\end{align*}
\]

where the uppercase bold Latin tensors are constant, and they are possibly given by suitable representation theoretic projectors\(^4\). Then, a general Lagrangian density can be written as

\[
\mathcal{L} = R - \frac{1}{2 \cdot 3!} A_{AB} G^{(3)A} \cdot G^{(3)B} - \frac{1}{2 \cdot 4!} B_{ij} G^{(4)ij} \cdot G^{(4)j} - \frac{1}{2 \cdot 5!} C_{ij} G^{(5)ij} \cdot G^{(5)j} - \frac{1}{2 \cdot 6!} D_{AB} G^{(6)A} \cdot G^{(6)B} + \mathcal{L}_{CS\text{-like}},
\]

\(^4\) All (uppercase and calligraphic) Latin tensors introduced in \([1.7]-[1.9]\) are constant, because there is no scalar field in the (massless) spectrum of the theory.

\(^5\) Here we will not analyze possible characterizations of such tensor as (invariant) projectors. We confine ourselves to remark that, in a very simple choice of covariance (namely, \(A = 1,2\) and \(i = 1,2,...,6\) running over the spin-1/2 and spin-5/2 representations \(2\) and \(6\) of \(\mathfrak{so}_2\)), most of them vanish.
where the calligraphic Latin constant tensors are (symmetric and) positive definite in order for all kinetic terms of p-forms to be consistent. A minimal, Maxwell-like choice is $A_{AB} = D_{AB} = \delta_{AB}$ and $B_{ij} = \delta_{ij}$, such that (4.7) simplifies down to

$$\mathcal{L} = R - \frac{1}{2 \cdot 3!} \sum_{A=1}^{2} G^{(3)A}_{\mu\nu\rho} A^{(3)A}_{\mu\nu\rho} - \frac{1}{2 \cdot 4!} \sum_{i=1}^{6} G^{(4)i}_{\lambda\mu\nu\rho} G^{(4)i}_{\lambda\mu\nu\rho}$$

$$- \frac{1}{2 \cdot 5!} \sum_{i=1}^{6} G^{(5)i}_{\lambda\mu\nu\rho\sigma} G^{(5)i}_{\lambda\mu\nu\rho\sigma} - \frac{1}{2 \cdot 6!} \sum_{A=1}^{2} G^{(6)A}_{\mu\nu\rho\sigma\tau} G^{(6)A}_{\mu\nu\rho\sigma\tau}$$

$$+ \mathcal{L}_{C.S.} \text{-like.}$$  \hspace{1cm} (4.8)

The “topological”, “Chern-Simons-like” Lagrangian occurring in (4.7) and (4.8) is composed by a number of a priori non-vanishing terms, such as for instance:

$$\sqrt{|g|} \mathcal{L}_{C.S.} = \epsilon^{A_1 A_2 A_3 A_4} G^{(6)}_{A_1} G^{(6)}_{A_2} G^{(6)}_{A_3} G^{(6)}_{A_4} C_i$$

$$+ \epsilon^{i j k l m n} G^{(6)}_{i} G^{(6)}_{j} G^{(6)}_{k} G^{(6)}_{l} G^{(6)}_{m} G^{(6)}_{n} C^A + \ldots$$

$$+ \epsilon^{j k l m n p} G^{(6)}_{j} G^{(6)}_{k} G^{(6)}_{l} G^{(6)}_{m} G^{(6)}_{n} G^{(6)}_{p} C^A + \ldots$$

$$+ \epsilon^{i j k l m n p} G^{(6)}_{i} G^{(6)}_{j} G^{(6)}_{k} G^{(6)}_{l} G^{(6)}_{m} G^{(6)}_{n} G^{(6)}_{p} C^A + \ldots$$

$$+ \epsilon^{j k l m n p q} G^{(6)}_{j} G^{(6)}_{k} G^{(6)}_{l} G^{(6)}_{m} G^{(6)}_{n} G^{(6)}_{p} G^{(6)}_{q} C^A + \ldots$$  \hspace{1cm} (4.9)

where the full Lagrangian is shown in Appendix (A). We leave the study of the constant tensors $A$, $\ldots$, $H$, $A$, $\ldots$, $D$, and $E$, $\ldots$, $W$, in (4.6), (4.7), and (4.9), respectively, for further future work.

It is immediate to realize that $M^2$-theory includes Horowitz and Susskind’s bosonic $M$-theory as a truncation; indeed, by setting

$$C^{(2)A} = 0;$$

$$C^{(3)i} = \delta^{i} C;$$

$$C^{(4)i} = 0;$$

$$C^{(5)A} = 0,$$

one obtains ($F = dC$)

$$\mathcal{L} = R - \frac{1}{2 \cdot 4!} F^2,$$  \hspace{1cm} (4.11)

matching the Lagrangian discussed in [23].

Finally, we observe that a Scherk-Schwarz reduction of the Lagrangian (4.7) to $25 + 1$ would provide a quite general Lagrangian for 0.$\alpha.\text{iii}$ gravito-dilatonic theory; we leave this task for further future work.

B. $B = F$ in $26 + 1$

It is remarkable to notice that a certain subsector of $M^2$-theory, when coupled to an $h = 3/2$ field, exhibits an equal number of bosonic and fermionic degrees for freedom (namely, $B = F$), which is a necessary condition for (linearly realized) supersymmetry to hold. Such a subsector of $M^2$-theory is given by

$$\text{field } R \text{ of } \mathfrak{so}_{25} \#$$

$$g : \begin{array}{ccc} 324 & 1 \\ \wedge^1 : & 25 & 0 \\ \varphi : & 1 & 0 \\ \wedge^5 : & 53,130 & 1 \\ \wedge^4 : & 12,650 & 3 \\ \wedge^3 : & 2,300 & 3 \\ \wedge^2 : & 300 & 0 \end{array}$$  \hspace{1cm} (4.12)

Thus, when coupled to a an $h = 3/2$ RS field $\psi$ fitting the $98,304$ irreducible representation (with Dynkin labels $(1,0^{10},1)$), the resulting theory has

$$B = F = 98,304.$$  \hspace{1cm} (4.13)
Trivially, bosonic M-theory \[23\] is a subsector of (the purely bosonic sector of) such a theory in \(26 + 1\).

By recalling \[4.3\] and observing that the RS representation branches from \(26 + 1\) to \(25 + 1\) as
\[
\begin{align*}
98, 304 &= 47, 104 \oplus 47, 104' \oplus 2, 048 \oplus 2, 048', \\
\psi &\psi' \\
\lambda &\lambda'
\end{align*}
\]
the theory with \(B = F = 98, 304\) gives rise to the following massless spectrum, when reduced to \(25 + 1\):

\[
\begin{array}{llll}
\text{field} & \mathbf{R} \text{ of } \mathfrak{so}_{24} & \# \\
g: & 299 & 1 \\
\psi: & 47, 104 & 2 \equiv (\psi \oplus \psi') \\
\wedge^1: & 24 & 1 \\
\lambda: & 2, 048 & 2 \equiv (\lambda \oplus \lambda') \\
\varphi: & 1 & 1 \\
\wedge^5: & 42, 504 & 1 \\
\wedge^4: & 10, 626 & 4 \\
\wedge^3: & 2, 024 & 6 \\
\wedge^2: & 276 & 3
\end{array}
\]

By recalling the treatment of previous Section, one may recognize \[4.15\] as a subsector (in which \[4.13\] holds) of the Monstrous gravity \(2.\gamma.ii\) in \[3.21\], simply obtained by reducing the number of 2-forms from 4 to 3.

Finally, we would like to point out that other examples of subsectors of Monstrous gravity in \(25 + 1\) exist such that \(B = F\); below, we list some of them:

\[
\begin{array}{lll}
0.\gamma.i - iv & (0, 0, 1, 1, 0) & (0, 0, 1, 0) \\
\alpha.i - ii & (0, 2, 0, 0, 0) & (1, 4, 4, 4) \\
\beta.i - ii & (0, 2, 1, 1, 0) & (1, 4, 5, 4) \\
\gamma.i - ii & (1, 2, 0, 1, 1) & (1, 4, 5, 3)
\end{array}
\]

In the first column we report the labels pertaining to the possible parent theories among the 60 Monstrous gravity theories in \(25 + 1\) classified above. Note that, among the \(B = F\) subsectors in \(25 + 1\) reported above, only \([4.15]\) and the second in the last line of \[4.16\] (i.e., the subsector of the \(2.\delta.ii\) Monstrous gravity) contain gravity.

1. \(\mathcal{N} = 1\) Supergravity in \(26 + 1\)?

As pointed out, \(B = F\) is just a necessary but not sufficient condition for supersymmetry to hold. Nevertheless, it is tantalizing to conjecture that the theory in \(26 + 1\) whose massless spectrum is given by \[4.12\] and one Rarita-Schwinger field \(\psi\) is actually an \(\mathcal{N} = 1\) supergravity theory. Inspired by M-theory\(^6\) (i.e., \(\mathcal{N} = 1\) supergravity) in \(10 + 1\), and exploiting a truncation of the purely bosonic Lagrangians discussed in Sec. \[V.A\] (the capped lowercase

---

\(^6\) Throughout our treatment, we refer to the conventions used in Sec. 22 of [36].
Latin indices run \( i = 1, 2, 3 \) throughout, one can also write down a tentative Lagrangian for such a theory:

\[
\mathcal{L} = R - \frac{1}{2} \cdot \frac{1}{4!} \sum_{i=1}^{3} G^{(4)i} \cdot G^{(4)i} - \frac{1}{2 \cdot 5!} \sum_{i=1}^{3} G^{(5)i} \cdot G^{(5)i} - \frac{1}{2 \cdot 6!} G^{(6)} \cdot G^{(6)} + \mathcal{L}_{CS-like}
\]

- \[
- \frac{a}{2} \overrightarrow{\psi} \Gamma^{\mu \nu \rho} \nabla_{\nu} \left( \frac{\omega + \tilde{\omega}}{2} \right) \psi_{\rho}
\]
- \[
+ \sum_{i=1}^{3} b_{i} \overrightarrow{\psi} \Gamma^{\mu \nu \rho} \nabla_{\nu} \left( G^{(4)i} + \tilde{G}^{(4)i} \right)
\]
- \[
+ \sum_{i=1}^{3} c_{i} \overrightarrow{\psi} \Gamma^{\mu \nu \rho} \nabla_{\nu} \left( G^{(5)i} + \tilde{G}^{(5)i} \right)
\]
- \[
+ d_{\mu} \overrightarrow{\psi} \Gamma^{\mu \nu \rho} \nabla_{\nu} \left( G^{(6)} + \tilde{G}^{(6)} \right),
\]

where

\[
\Gamma^{(4)} \cdot G^{(4)i} = \Gamma^{(4)i} \cdot G^{(4)i},
\]

and, upon truncation of (4.6) resp. (4.5),

\[
\begin{align*}
G^{(4)i} & := dC^{(3)i} + C_{ij}^{(4)i}, \\
G^{(5)i} & := dC^{(4)i} + E^{(5)i}, \\
G^{(6)} & := dC^{(5)} + G_{ij}C^{(3)i} \wedge C^{(3)j};
\end{align*}
\]

\[
\sqrt{|g|} \mathcal{L}_{CS-like} = c E_{i} G^{(6)} G^{(6)} G^{(6)} G^{(6)} C^{(3)i}
\]

Moreover,

\[
\tilde{G}^{(4)i} := G^{(4)i} + \epsilon_{i} \overrightarrow{\psi} \Gamma^{(2)} \psi, \\
\tilde{G}^{(5)i} := G^{(5)i} + \epsilon_{i} \overrightarrow{\psi} \Gamma^{(3)} \psi, \\
\tilde{G}^{(6)} := G^{(6)} + g_{ij} \overrightarrow{\psi} \Gamma^{(4)} \psi
\]

are the supercovariant field strengths, and

\[
\nabla_{\mu} (\omega) \psi_{\nu} := \partial_{\mu} \psi_{\nu} + h_{\mu}^{ab} \Gamma_{ab} \psi_{\nu}
\]

is the covariant derivative with

\[
\begin{align*}
\tilde{\omega}_{\mu}^{ab} & := \omega_{\mu}^{ab} + i \overrightarrow{\psi} \Gamma_{ab} \beta, \\
\omega_{\mu}^{ab} & := \omega_{\mu}^{ab} (\epsilon) + K_{ab}^{\mu}, \\
K_{ab}^{\mu} & := i \left[ m \overrightarrow{\psi} \Gamma_{ab} \beta + n \left( \overrightarrow{\psi} \Gamma^{a} \psi^{b} - \overrightarrow{\psi} \Gamma^{a} \psi^{b} + \tilde{\psi} \Gamma^{a} \psi \right) \right].
\end{align*}
\]
The Lagrangian \((4.17)\) should be invariant under the following local supersymmetry transformations with parameter \(\varepsilon\) (a Majorana spinor):

\[
\delta_\varepsilon e^a_\mu = -\frac{i}{2} \varepsilon \Gamma^a \psi_\mu; \tag{4.26}
\]

\[
\delta_\varepsilon \psi_\mu = \mathbf{p} \nabla_\mu (\tilde{\omega}) \varepsilon + \sum_{i=1}^3 \mathbf{q}_i (\Gamma^\alpha_{\beta\gamma\delta} \mu + \mathbf{r}_i \Gamma^\beta_{\gamma\delta} \delta^\alpha_\mu) \varepsilon \tilde{G}^{(4)i}_{\alpha\beta\gamma\delta} + \sum_{i=1}^3 \mathbf{s}_i (\Gamma^\alpha_{\beta\gamma\delta} \mu + \mathbf{t}_i \Gamma^\beta_{\gamma\delta} \delta^\alpha_\mu) \varepsilon \tilde{G}^{(5)i}_{\alpha\beta\gamma\delta} + \mathbf{u} (\Gamma^\alpha_{\beta\gamma\delta} \mu + \mathbf{v}_i \Gamma^\beta_{\gamma\delta} \delta^\alpha_\mu) \varepsilon \tilde{G}^{(6)i}_{\alpha\beta\gamma\delta}\; \tag{4.27}
\]

\[
\delta_\varepsilon C^{(3)i}_{\mu\nu\rho} = \mathbf{w}_i \varepsilon \Gamma_{[\mu\nu]} \psi_{\rho]}; \tag{4.28}
\]

\[
\delta_\varepsilon C^{(4)i}_{\mu\nu\rho\sigma} = \mathbf{x}_i \varepsilon \Gamma_{[\mu\nu}] \psi_{\sigma]}; \tag{4.29}
\]

\[
\delta_\varepsilon C^{(5)i}_{\mu\nu\rho\sigma\tau} = \mathbf{y}_i \varepsilon \Gamma_{[\mu\nu\rho]} \psi_{\sigma\tau]}. \tag{4.30}
\]

To prove (or disprove) the invariance of the Lagrangian \((4.17)\) (with definitions \((4.18)-(4.25)\)) under the local supersymmetry transformations \((4.26)-(4.30)\), and thus fixing the real parameters \(a,...,y\) as well as the tensors \(C, E, G\) and \(E, G\), seems a formidable task, which deserves to be pursued in a separate paper. Under dimensional reduction to 25 + 1, one would then get a would-be type IIA \(N = (1,1)\) supergravity theory; as observed above, this would correspond to a suitable truncation of the Monstrous gravity \(\gamma.\gamma.\\gamma.\\gamma.\) in \((3.21)\); again, we leave this interesting task for further future work.

V. COHOMOLOGICAL CONSTRUCTION OF LATTICES

Let us consider the following (commutative) diagram, starting from the Lie algebra \(e_8\),

\[
\begin{array}{c}
\mathfrak{a}_8 \oplus \wedge^3 \oplus \tilde{\wedge}^3 \\
\downarrow \\
e_8 \\
\downarrow \\
\mathfrak{b}_4 \oplus \mathfrak{g} \oplus \wedge^3 \oplus *\wedge^3 \\
\downarrow \\
\mathfrak{d}_8 \oplus \lambda
\end{array}
\tag{5.1}
\]

where \(\mathfrak{g} := S_2^3\) denotes the \(D = 10 + 1\) graviton representation (which has been related to “super-Ehlers” embeddings in \([37]\)), and \(*\) stands for the Hodge dual \((*\wedge^p := \wedge^{D-p})\). Thus, the number \(#\mathfrak{e}_8\) of roots of the \(e_8\) root lattice reads

\[
#\mathfrak{e}_8 = \dim \mathfrak{e}_8 - 8 = (\dim \mathfrak{b}_4 - 4) + (\dim \mathfrak{g} - 4) + \dim(\wedge^3 \oplus *\wedge^3).
\tag{5.2}
\]

Therefore, the number \(#\mathfrak{e}_8^+\) of positive roots of \(e_8\) is

\[
#\mathfrak{e}_8^+ = \frac{1}{2} \left( (\dim \mathfrak{b}_4 - 4) + (\dim \mathfrak{g} - 4) \right) + \dim \wedge^3_{84} = 120.
\tag{5.3}
\]

Note that it also holds that

\[
\frac{1}{2} \left( (\dim \mathfrak{b}_4 - 4) + (\dim \mathfrak{g} - 4) \right) = \dim \mathfrak{b}_4.
\tag{5.4}
\]

It should be also remarked that \(120 = \binom{10}{3}\), i.e. it matches the number of degrees of freedom of a massless 3-form potential in 11 + 1 space-dimensions; indeed, \(\wedge^3\) in 11 + 1 gives rise to \(\wedge^3 \oplus \wedge^2 = \wedge^3 \oplus \mathfrak{b}_4\) in 10 + 1.

The case of \(e_8\) is peculiar, because the closure (as well as the commutativity) of the diagram \((5.1)\) relies on the existence of the “anomalous” embedding

\[
\mathfrak{d}_8 \supset \mathfrak{b}_4; \quad 16 = 16 \equiv \lambda,
\tag{5.5}
\]

where \(\lambda\) is the spinor representation.
By replacing $b_4$ and $\wedge$ respectively as follows,

$$b_4 \rightarrow b_{12};$$
$$\wedge^3 \rightarrow \Lambda^5 \oplus 3 \cdot \Lambda^4 \oplus 3 \cdot \Lambda^3,$$

one can define the “Leech algebra” $\mathcal{L}_{24}$ in analogy with $\mathfrak{e}_8$ (albeit with $D = 26 + 1$ graviton $g$), through the following diagram:

$$\begin{align*}
\mathcal{L}_{24} & \cong (\Lambda^5 \oplus 3 \cdot \Lambda^4 \oplus 3 \cdot \Lambda^3) \\
& \quad \oplus (\Lambda^6 \oplus 3 \cdot \Lambda^5 \oplus 3 \cdot \Lambda^4) \\
& \quad \oplus (\Lambda^7 \oplus 3 \cdot \Lambda^6 \oplus 3 \cdot \Lambda^5)
\end{align*}$$

$$\begin{align*}
\mathcal{L}_{24} & \cong b_{12} \oplus g \oplus (\Lambda^5 \oplus 3 \cdot \Lambda^4 \oplus 3 \cdot \Lambda^3) \\
& \quad \oplus (\Lambda^6 \oplus 3 \cdot \Lambda^5 \oplus 3 \cdot \Lambda^4) \\
& \quad \oplus (\Lambda^7 \oplus 3 \cdot \Lambda^6 \oplus 3 \cdot \Lambda^5)
\end{align*}$$

The question mark in (5.8) occurs because there is no analogue of the “anomalous embedding” (5.5) for $\mathcal{L}_{24}$. Thus, it holds that

$$\begin{align*}
\# \mathcal{L}_{24} & = \text{dim} \mathcal{L}_{24} - 24 \\
& = (\text{dim} b_{12} - 12) + (\text{dim} g - 12) + \text{dim}(\Lambda^5 \oplus 3 \cdot \Lambda^4 \oplus 3 \cdot \Lambda^3 + \ast (\Lambda^5 \oplus 3 \cdot \Lambda^4 \oplus 3 \cdot \Lambda^3)) \\
& \quad \oplus (3,130+3 \cdot 12,650+3 \cdot 2,300) \\
& = 196,560,
\end{align*}$$

where $\# \mathcal{L}_{24}$ denotes the number of minimal, non-trivial vectors (thus, of norm 4) of the Leech lattice $\Lambda_{24}$. Therefore, the $\mathbb{Z}_2$-modded number of minimal, non-trivial vectors of $\Lambda_{24}$ is

$$\begin{align*}
\# \mathcal{L}_{24}^+ & = \frac{1}{2} \left( (\text{dim} b_{12} - 12) + (\text{dim} g - 12) \right) + \text{dim}(\Lambda^5 \oplus 3 \cdot \Lambda^4 \oplus 3 \cdot \Lambda^3) = 98,280,
\end{align*}$$

which is the number entering the construction of the minimal non-trivial representation of the Monster group $M$ (cfr. [39]). Note that it also holds that

$$\frac{1}{2} \left( (\text{dim} b_{12} - 12) + (\text{dim} g - 12) \right) = \text{dim} b_{12}.$$  

It should be also remarked that $98,280 = \binom{28}{5}$, i.e. it matches the number of degrees of freedom of a massless 5-form potential in $29+1$ space-dimensions; indeed, it can be checked that $\Lambda^5$ in $29+1$ gives rise to $(\Lambda^5 \oplus 3 \cdot \Lambda^4 \oplus 3 \cdot \Lambda^3) \oplus \Lambda^2 = (\Lambda^5 \oplus 3 \cdot \Lambda^4 \oplus 3 \cdot \Lambda^3) \oplus b_{12}$ in $26 + 1$.

(5.3) and (5.10) define a cohomological construction of the 8-dimensional $\mathfrak{e}_8$ root lattice and the 24-dimensional Leech lattice $\Lambda_{24}$, respectively based on the analogy between:

- $M$ theory in $10 + 1$ space-time dimensions, with $SO_9$ massless little group and massless spectrum given by $128$ (gravitino) = 84 (3-form potential) + 44 (graviton); this corresponds to $D0$-branes (supergravitons) in BFSS M(atrix) model, carrying $256 = 128(B) + 128(F)$ Kaluza-Klein states [24];

- the would-be $\mathcal{N} = 1$ supergravity in $26 + 1$ space-time dimensions, with $SO_{25}$ massless little group and massless spectrum given by $98,304$ (would-be gravitino) = $3 \cdot 2,300 + 3 \cdot 12,650 + 53,130$ (set of massless p-forms which is the “[26 + 1]-dimensional analogue” of the 3-form in $10 + 1$) + 324 (graviton); this would correspond to $D0$-branes (would-be “supergravitons”) in the would-be BFSS-like M(atrix) model, carrying $196,608 = 98,304(B) + 98,304(F)$ KK states.

There are many analogies, but the big difference is supersymmetry in $26 + 1$ (and possibly in $25 + 1$), whose nature is at present still conjectural.

The “Leech algebra” $\mathcal{L}_{24}$ encodes $\text{dim} \mathfrak{su}_{25} = 624 = 324 + 300$, and $2 \cdot 97,980 = 2 \cdot (3 \cdot 2,300 + 3 \cdot 12,650 + 53,130) = 195,960$ to get $624 + 195,960 = 196,584$. Removing the $12 + 12 = 24$ Cartans gives $196,560$, the number of minimal Leech vectors. It is thus tempting to conjecture “Monstrous supergravitons” as $D0$ branes, as $\mathcal{L}_{24}$ “sees” 98,304 of the bosonic KK states. On the other hand, the Monster $M$ acts on almost all of these, albeit seeing only $299 + 1$
of the 324 graviton degrees of freedom from 324 + 300, giving 299 + 1 + (300 + 97,980) = 299 + 1 + 98,280 of the Griess algebra. More concisely, the relation between the “Leech algebra” L24 and the Griess algebra is precisely given by the relation between M²-theory and its subsector coupled to a RS field (the would-be gravitino) in 26 + 1, discussed in Sec. [IV,13].

The dimensional reduction 26+1 → 10+1 can proceed along a decomposition proved by Wilson, characterizing the aforementioned number of minimal Leech vectors as

\[ 196,560 = 3 \cdot 240 \cdot (1 + 16 + 256). \] (5.12)

We identify 1 + 16 + 256 = 273 with the (Hermitian part of) Vinberg’s T-algebra \[ \mathfrak{so}_{16} \] (5.13) with spin factor lightcone coordinates \( \mathbf{1}_\alpha \) and \( \mathbf{1}_\beta \) removed, giving 128 + 128 + 16 + 1 = 273 dimensions. The spin factor \( \mathbf{1}_\alpha \oplus \mathbf{1}_\beta \oplus \mathbf{16} \) of \( T_3^{8,2} \) enjoys an enhancement from \( \mathfrak{so}_{16} \to \mathfrak{so}_{17,1} \) Lorentz symmetry, and \( \det(T_3^{8,2}) = \mathfrak{so}_{17,1} \) \[ \text{[28]}. \]

Breaking the \( \mathfrak{so}_{25} \) Lie algebra of massless little group in 26 + 1 with respect to \( \mathfrak{so}_{17,1} \), as well as its \( 4096 \) spinor (both encoded in the so-called “Magic Star algebra” \( f_4^{17} \) \[ \text{[27]} \]), one obtains the decomposition

\[ f_4^{17} := \mathfrak{so}_{25} \oplus 4096 = \mathfrak{so}_{17} \oplus \mathfrak{so}_8 \oplus (17, 8) \oplus (256, 8) \oplus (256, 8_c). \] (5.14)

As \( \mathfrak{so}_8 \) acts on \( S^7 \), one can take the 240 roots as forming a discrete 7-sphere, and the 273 is constructed as 17+256 = 273 by picking one of the 256 spinors. This gives a discrete form of the maximal Hopf fibration \( S^7 \to S^{15} \to S^8 \), and the three maps yield three charts of the form 196,560 = 3 \cdot 240 \cdot 273 (cfr. \[ \text{[51,12]} \]) in a discrete Cayley plane \[ \text{[25,26,31]} \]. Through the super Ehlers embedding \[ \mathfrak{so}_8(8) = \mathfrak{so}_9(\mathbb{R}) \oplus \mathbf{84} \oplus \mathbf{84}' = \mathfrak{so}_9 \oplus \mathbf{44} \oplus \mathbf{84} \oplus \mathbf{84} \], we can identify each discrete \( S^7 \) fiber of 240 \( E_8 \) roots with the M2 and M5 brane gauge fields of \( D = 10 + 1 \) M-theory, as well as with little group \( \mathfrak{so}_9 \) and graviton (44) degrees of freedom, albeit with all 4 + 4 Cartans removed. This is understood with \( \mathfrak{so}_9 \subset \mathfrak{so}_{25} \) acting isometrically on the \( S^8 \) base. From this perspective, the reduction from \( D = 26 + 1 \) to \( D = 10 + 1 \) occurs first along three charts, and gauge and gravity data are encoded in discrete \( S^7 \) chart fibers therein. This picture is further supported by noting the Conway group \( Co_0 \) is a maximal finite subgroup of \( SO_{24} \), and that \( Co_0 \) can be generated by unitary \( 3 \times 3 \) octonion matrices \[ \mathfrak{so}_3 \] of \( F_4 \) type. In general, the stabilizer subgroup of \( 3 \times 3 \) unitary matrices over the octonions lies in \( SO_9 \subset F_4 \) through Peirce decomposition; since there are three independent primitive idempotents in the exceptional Jordan algebra \( J_3^{17} \), there are three such embedded copies of \( SO_9 \), providing three charts for the reduction to \( D = 10 + 1 \). As it is well known, a remarkable class of M-theory compactifications is provided by \( G_2 \) manifolds \[ \text{[34]} \] to \( D = 3 + 1 \), where the internal manifold with \( G_2 \) holonomy is characterized by its invariant 3-form (which comes from an octonionic structure). In the 26 + 1 framework under consideration, a compactification down to \( 3 + 1 \) dimensions can involve a 23-sphere \( S^{23} \), which in turn can be fibrated with an \( \mathbb{CP}^2 \) base and \( S^7 \) fibers. Since \( S^7 \) is the quintessential \( G_2 \) manifold \[ \text{[32]} \], this provides a natural \( 26 + 1 \to 10 + 1 \to 3 + 1 \) pattern of reduction along a \( G_2 \) manifold from the Monstrous M-theory introduced above.

VI. CONCLUSION

We have shown that in 26 + 1 space-time dimensions there exists a purely bosonic theory (named Monstrous M-theory, or simply M²-theory), whose massless spectrum, of dimension 196,884, may be acted upon by the Monster group \( M \). A subsector of such a theory yields Horowitz and Susskind’s bosonic M-theory \[ \text{[23]} \].

When reducing to 25 + 1 space-time dimensions, a certain purely bosonic gravito-dilatonic theory (namely, the 0.a.iii theory, whose massless spectrum is given by \[ \text{[11,12]} \]), arises. Remarkably, this theory contains a subsector given by the massless excitations of the closed and open bosonic string in 25 + 1, namely a graviton, an antisymmetric rank-2 field, a dilaton, and a vector potential, respectively. By generalizing the triality of \( SO_8 \) (massless little group of string theory in 9 + 1) to \( SO_{24} \) (massless little group of bosonic string theory in 25 + 1), such a theory can be shown to be actually part of a web of (at least) some 60 gravito-dilatonic theories, named Monstrous gravity theories. The

---

7 In \[ \text{[5,13]} \] the Greek subscripts discriminate among \( \mathfrak{so}_{16} \)-singlets.
8 \( \mathfrak{so}_{17,1} \) would be the Lorentz symmetry of the 18-dimensional string suggested by Lorentzian Kac-Moody algebras \[ \text{[38]} \].
relation between $SO_8$ and $SO_{24}$ can be interpreted in terms of the Conway group\(^9\) $CO_0$, which is a maximal finite subgroup of $SO_{24}$ itself; as shown by Wilson\(^{32}\), $CO_0$ is generated by unitary $3 \times 3$ octonion matrices, namely by $F_4$ matrices. Interestingly, $SO_8$ can be maximally embedded into $F_4$ in three possible ways, each one providing the manifestly triality-symmetric breaking $f_4 \to so_8 = so_8 \oplus 8_r \oplus 8_l \oplus 8_l$; in this sense, no triality is needed for $so_{24}$, but rather just the threefold nature of the (symmetric) embedding of $SO_8$ in $F_4$. In turn, the “anomalous” embedding $F_4(-20) \subset SO_{25,1}$\(^{29}\) allows one to reduce from $27D$ to lower dimensions in a non-trivial way, namely along the chain $27 \to 26 \to 11 \to 4$ dimensions. In turn, this, as remarked in \(^{25}\), confirms and strengthens Ramond and Sati’s argument that $D = 10 + 1$ M-theory has hidden Cayley plane fibers\(^{31}\).

It is worth recalling that the Moonshine decomposition $196,884 = 196,883 \oplus 1$ always holds in Monstrous gravities, due to the very existence of the dilatonic scalar field in their spectra. In particular, the dilaton $\phi$ is a singlet of $M$, and as such it coincides with the vacuum state $|\Omega\rangle$ of the chiral Monster conformal theory discussed in \(^{8}17,18\). On the other hand, Witten in \(^{22}\) identifies the $\mathbf{1}$ as the stress energy tensor while the other $196,883$ are primary fields transforming in the smallest non-trivial rep of the Monster, according to FLM theory\(^{5}\).

Remarkably, a certain subsector of $M^2$-theory, when coupled to one massless Rarita-Schwinger field in $26 + 1$, gives rise to a theory which has the same number of bosonic and fermionic massless degrees of freedom, namely $B = F = 98,304$, for a total of $196,608$ degrees of freedom.

It is then very tempting to ask whether this gravity theory can actually be supersymmetric in $26 + 1$, giving rise to the would-be $\mathcal{N} = 1$ supergravity in $26 + 1$ space-time dimensions. In this perspective, we have conjectured a quite straightforwardly “$M$-theory-inspired” Lagrangian density as well as the corresponding local supersymmetry transformations in $26 + 1$. The invariance of such a Lagrangian under those supersymmetry transformations is still conjectural, and to prove (or disprove) it seems quite a formidable, though absolutely worthy task, and we leave it for further future work.

At any rate, the reduction of the bosonic sector of such a would-be $\mathcal{N} = 1$ supergravity from $26 + 1$ to $25 + 1$ yields a suitable subsector of the Monstrous gravity $2:7:ii$, simply obtained by reducing the number of 2-forms from $4$ to $3$. It thus becomes evident that there is a certain mismatch, essentially amounting to the $276$ degrees of freedom of a massless 2-form in $25 + 1$, between the total degrees of freedom of the would-be $\mathcal{N} = 1$ supergravity in $26 + 1$ ($98,304 + 98,304 = 196,608$) and the $196,884$ degrees of freedom of (purely bosonic) $M^2$-theory: $196,884 - 196,608 = 276$. Thus, “monstrousity” and “supersymmetry” in $26 + 1$ (as well as, predictably, in $25 + 1$) seem to be slightly mismatching, yet tightly related, concepts.

All this suggests that the Monster group $\mathbb{M}$ has its origin in a gravity theory in $26 + 1$ dimensions, as its definition as the automorphism of the Griess algebra\(^{11,5,7}\) is clarified by showing that such an algebra is not merely a sum of unrelated spaces, but rather the whole massless spectrum of Monstrous gravities in $25 + 1$, which in at least one case (namely, the $0.a.iii$ theory, whose massless spectrum is given by $\{1,1\} \oplus \{1,2\}$) uplifts to Monstrous $M$-theory (i.e., $M^2$-theory) in $26 + 1$. The spectrum of $M^2$-theory dimensionally reduced to $25 + 1$ contains a subsector given by the massless excitations of the closed and open bosonic string in $25 + 1$, namely a graviton, an antisymmetric rank-$2$ field, a dilaton, and a vector potential, respectively; then, since the Monster VOA originates from $D = 25 + 1$ bosonic string through FLM theory\(^{3}\), this shows how the Monster group $\mathbb{M}$ acts on fields originating from $D = 25 + 1$. Unlike the FLM construction, the Leech lattice need not be assumed, but can be derived from $D = 26 + 1$ field content. The $\mathbb{Z}_2$ orbifold is then the elimination of the dual magnetic brane gauge fields, and half the degrees of freedom of the $SO_{25}$ little group and graviton, giving the desired $98,280$.

On the other hand, the discussion of the analogies between the $\mathbb{E}_8$ root lattice and the Leech lattice $\Lambda_{24}$ seems to suggest that $M$-theory in $10 + 1$ and the would-be $\mathcal{N} = 1$ supergravity in $26 + 1$ are tightly related to the lattices $\mathbb{E}_8$ resp. $\Lambda_{24}$, which determine the optimal lattice packings in $D = 8$ resp. $D = 24$.

All in all, it would be interesting to explore the implications of the characterization of the Monster group as acting on the whole massless spectrum of $M^2$-theory in $26 + 1$. Developments for future work may concern further study and formalization of the maps discussed in Sec.\(^{11}\) as pointed out above, no other Dynkin diagram (besides $\mathbb{D}_4$) has an automorphism group of order greater than $2$, thus such maps cannot be realized as an automorphism of $\mathbb{D}_4$, nor they can be traced back to some structural symmetry of the Dynkin diagram of $\mathbb{D}_4$ itself. Moreover, the study of the Lagrangian structure of $M^2$-theory, as well as of its Scherk-Schwarz reduction to $25 + 1$, should be the object of further investigations. Last but not least, we leave the interesting issue of the study of the massive spectrum of (massive variants of) Monstrous gravities and $M^2$-theory for further future work.

We would like to conclude with a sentence by John H. Conway, to whom this paper is dedicated, on the Mon-

---

\(^9\) The Conway group $CO_0$ is the full automorphism of the Leech lattice $\Lambda_{24}$; however, it is not a simple group, nor is it contained in the Monster. In fact, its quotient by its center $\mathbb{Z}_2$, namely the Conway simple group $CO_1 \simeq CO_0/\mathbb{Z}_2$ is contained in $\mathbb{M}$. This means the Monster’s maximal finite subgroup $CO_1$ has the $\mathbb{Z}_2$ action built in, which acts on only half the minimal Leech vectors $196,560/2 = 98,280$. 

ster group \[40\]: “There’s never been any kind of explanation of why it’s there, and it’s obviously not there just by coincidence. It’s got too many intriguing properties for it all to be just an accident.”

Acknowledgements

We would like to acknowledge an informal yet inspiring discussion with Eric Weinstein during the Advances in Quantum Gravity conference, hosted by Laura Deming at Topos House, San Francisco, CA, on July 2016. Since that occasion, we started thinking about the idea of a weak triality for \(\mathfrak{d}_{12}\).
Appendix A: Chern-Simons Lagrangian terms for Monstrous M-theory

The full Lagrangian from Eq. (A.3) is given by

\[
\sqrt{|g|} \mathcal{L}_{CS} = \varepsilon_{2A}^{ABCD} G_{A}^{(6)}(G_{B}^{(6)} G_{C}^{(4)} G_{D}^{(4)} G_{E}^{(4)} G_{F}^{(4)} G_{G}^{(4)} G_{H}^{(4)} G_{I}^{(4)} G_{J}^{(4)} G_{K}^{(4)} G_{L}^{(4)} G_{M}^{(4)} G_{N}^{(4)} G_{O}^{(4)} G_{P}^{(4)} G_{Q}^{(4)} G_{R}^{(4)} G_{S}^{(4)} G_{T}^{(4)} G_{U}^{(4)} G_{V}^{(4)} G_{W}^{(4)} G_{X}^{(4)} G_{Y}^{(4)} G_{Z}^{(4)} \varepsilon_{2B}^{CD} G_{A}^{(6)} G_{B}^{(6)} G_{C}^{(4)} G_{D}^{(4)} G_{E}^{(4)} G_{F}^{(4)} G_{G}^{(4)} G_{H}^{(4)} G_{I}^{(4)} G_{J}^{(4)} G_{K}^{(4)} G_{L}^{(4)} G_{M}^{(4)} G_{N}^{(4)} G_{O}^{(4)} G_{P}^{(4)} G_{Q}^{(4)} G_{R}^{(4)} G_{S}^{(4)} G_{T}^{(4)} G_{U}^{(4)} G_{V}^{(4)} G_{W}^{(4)} G_{X}^{(4)} G_{Y}^{(4)} G_{Z}^{(4)}
\]

(A1)
