A BERNSTEIN TYPE THEOREM FOR MINIMAL GRAPHS OVER CONVEX CONES

NICK EDELEN AND ZHEHUI WANG

ABSTRACT. Given any $n \geq 2$, we show that if $\Omega \subseteq \mathbb{R}^n$ is an open, convex cone (e.g. a half-space), and $u : \Omega \to \mathbb{R}$ is a solution to the minimal surface equation which agrees with a linear function on $\partial \Omega$, then $u$ must itself be linear.

1. Introduction

The classical Bernstein theorem asserts that any entire minimal graph over $\mathbb{R}^n$ with $2 \leq n \leq 7$ is a hyperplane. This was originally proven when $n = 2$ by Bernstein [4], $n = 3$ by De Giorgi [7], $n = 4$ by Almgren [1], and $n = 5, 6, 7$ by Simons [16]. For $n \geq 8$ there were counter examples constructed by Bombieri, De Giorgi and Giusti [6].

Here we prove the following version of Bernstein’s theorem for minimal graphs with Dirichlet boundary conditions in a convex cone. The most important example is when $\Omega$ is a half-space.

Theorem 1.1. Let $\Omega \subseteq \mathbb{R}^n$ be an open, convex, dilation-invariant subdomain of $\mathbb{R}^n$, with $n \geq 2$. Let $l : \mathbb{R}^n \to \mathbb{R}$ be a linear function. Suppose $u \in C^0(\Omega) \cap C^2(\Omega)$ solves

$$
\sum_{i=1}^n D_i \left( \frac{D_i u}{\sqrt{1 + |Du|^2}} \right) = 0 \text{ in } \Omega, \quad u = l \text{ on } \partial \Omega.
$$

Then $u$ is linear. If $\Omega$ is not a half-space, then $u = l$.

We emphasize that unlike the entire case, we require no dimensional restriction. This is due to the fact that the structure of minimizing cones with boundary is much more rigid than those without boundary: Hardt-Simon [10] showed any minimizing hypercone with linear boundary must be planar. Even when $n \leq 7$ and $\Omega$ is a half-space, for general linear $l$ one cannot reflect to reduce to the standard Bernstein problem, as one may not obtain a graph after reflection. (Of course if $u$ has 0 Dirichlet or Neumann data then this reflection argument would work.)
Many others have studied the behavior of minimal graphs over unbounded domains in \( \mathbb{R}^n \). In exterior domains \( \mathbb{R}^n \setminus \Omega \) (\( \Omega \) bounded and \( 2 \leq n \leq 7 \)), \cite{5}, \cite{14} proved that the gradient of a minimal graph \( u \) is bounded and has a limit as \( |x| \to \infty \). When \( n \geq 8 \), \( Du \) may not be bounded, but \cite{15} showed precise cylindrical asymptotics; \cite{20}, \cite{18} proved related results for domains in \( \mathbb{R}^2 \).

When \( \Omega \subset \mathbb{R}^2 \) is contained in a wedge of opening angle \( \angle < \pi \), then \cite{19} showed that any minimal graph over \( \Omega \) with zero Dirichlet data must be 0. In a similar vein, when \( \Omega \subset \mathbb{R}^2 \) is a wedge with opening angle \( \angle \neq \pi, 2\pi \), then \cite{8} showed any minimal graph with zero Neumann data away from the cone point must be constant (see also \cite{12}). In \cite{11} the second named author and his collaborators obtained Liouville type theorems for minimal graphs over half-spaces (for any \( n \)) with linear Dirichlet boundary value or constant Neumann boundary value.

The key to proving Theorem 1.1 is to classify tangent cones of \( \text{graph}(u) \) as linear, either half-planes with \( \Omega \) is a half-space, or \( \Omega \) itself otherwise. When \( \Omega \) is a half-space this follows from \cite{10}, but in our situation the proof becomes easier because our tangent cones are contained \( \overline{\Omega} \times \mathbb{R} \), which means we can use a barrier argument. By considering the tangent cones of \( \text{graph}(u) \) both at 0 and at \( \infty \), we deduce from monotonicity the density is constant, and hence \( \text{graph}(u) \) coincides with its tangent plane. A little extra technical work is required to ensure everything works with our boundary condition.

2. Proof of Theorem 1.1

We first outline our notation. Unless otherwise stated we allow \( n \geq 1 \). We shall denote \( x' \in \mathbb{R}^n \), and \( x = (x_1, \ldots , x_{n+1}) = (x', x_{n+1}) \in \mathbb{R}^n \times \mathbb{R} = \mathbb{R}^{n+1} \). Given a subspace \( V \), write \( \pi_V \) for the linear orthogonal projection onto \( V \). Write \( e_i \) for the standard coordinate vectors of \( \mathbb{R}^{n+1} \).

We will treat \( \mathbb{R}^k \) (\( k \leq n + 1 \)) as a subspace of \( \mathbb{R}^{n+1} \) by identifying \( \mathbb{R}^k \equiv \mathbb{R}^k \times \{0^{n+1-k}\} \subset \mathbb{R}^{n+1} \). Given a non-zero vector \( v \in \mathbb{R}^{n+1} \), and an interval \( I \subset \mathbb{R} \), we write \( Iv = \{ \lambda v : \lambda \in I \} \) for the line segment in the direction \( v \).

Given a function \( u : \Omega \to \mathbb{R} \), for \( \Omega \subset \mathbb{R}^n \), write \( \text{graph}(u) = \{(x', u(x')) : x' \in \Omega \} \). Given a subset \( A \subset \mathbb{R}^k \), we denote \( \overline{A} \) for the closure of \( A \), and \( \text{int} A \) for the interior in \( \mathbb{R}^k \). If there is ambiguity when taking \( \text{int} A \) we will always make explicit which space we consider \( A \) to live in. Write \( d(x, A) = \inf_{y \in A} |x - y| \) for the Euclidean distance from \( x \) to \( A \), and let \( B_r(A) = \{ x : d(x, A) < r \} \) be the open \( r \)-tubular neighborhood about \( A \). If \( B \subset \mathbb{R}^{n+1} \), write \( d(A, B) = \inf_{x \in B} d(x, A) \). Let \( \eta_{x,r}(y) = (y - x)/r \) be the translation/dilation map.
BERNSTEIN TYPE THEOREM

Recall that $T$ is an integer-multiplicity rectifiable $k$-current in an open set $U$ if there is a countably $k$-rectifiable set $M_T \subset U$, a $\mathcal{H}^k|_M$-measurable simple unit $k$-vector $\xi_T$ orienting $T_x M_T$ for $\mathcal{H}^k$-a.e. $x$, and a $\mathcal{H}^k|_M$-measurable positive integer-valued function $\theta_T$, so that

$$T(\omega) = \int_{M_T} <\omega, \xi_T> \theta_T d\mathcal{H}^k$$

for every smooth, compactly-supported $k$-form in $U$. We write $||T|| \equiv \mathcal{H}^k|_M$ for the mass measure of a current. We write $\theta_T(x, r) = ||T||(B_r(x)) / \omega_k r^k$ for the density ratio of $T$ in $B_r(x)$, here $\omega_k$ being the volume of the unit $k$-ball. When it exists, we denote by $\theta_T(x) = \lim_{r \to 0} \theta_T(x, r)$. Given a proper Lipschitz map $f : \mathbb{R}^{n+1} \to \mathbb{R}^{n+1}$, we write $f \sharp T$ for the pushforward.

We denote by $I_k(U)$ the set of integral $k$-currents in $U$: that is, integer-multiplicity rectifiable $k$-currents $T$ in $U$ with the property that both $||T||$ and $||\partial T||$ are Radon measures in $U$. We say $T \in I_k(U)$ is mass-minimizing in an open set $U' \subset U$ if, for every $W \subset \subset U'$ and every $S \in I_k(U')$ satisfying $\partial S = 0$, spt$S \subset W$, we have

$$||T||(W) \leq ||T + S||(W).$$

If $L$ is a Lipschitz submanifold with a fixed (for the duration of this paper) $\mathcal{H}^k|L$-measurable choice of orientation, then we will write $[L]$ for the multiplicity-one rectifiable $k$-current induced by integration. If $E$ is a subdomain of $\mathbb{R}^{n+1}$, we will always orient $E$ with the constant, positive orientation of $\mathbb{R}^{n+1}$. $E$ is called a set of locally-finite perimeter in $U$ if $[E] \in I_{n+1}(U)$.

We will use the following easy facts about convex domains.

**Lemma 2.1.** If $\Omega'$ is an open convex subdomain of $\mathbb{R}^n$, then:

a) $\partial\Omega'$ is locally-Lipschitz, and hence $\Omega'$ is a set of locally-finite perimeter;

b) the nearest point projection $p_{\Omega'} : \mathbb{R}^n \to \overline{\Omega'}$ is 1-Lipschitz;

c) for any ball $B_r(x)$, we have $\mathcal{H}^{n-1}(B_r(x) \cap \partial \Omega') \leq \mathcal{H}^{n-1}(\partial B_r(x))$.

Point c) follows from points a) and b) by showing that $p_{\Omega'} : \partial B_r(x) \to \overline{B_r(x)} \cap \partial \Omega'$ is onto. We leave the rest of the proof to the reader.

We now work towards proving Theorem 1.1. Fix $\Omega \neq \mathbb{R}^n$ to be an open, convex cone in $\mathbb{R}^n$. Fix $l : \mathbb{R}^n \to \mathbb{R}$ a linear function, and
$u \in C^0(\overline{\Omega}) \cap C^2(\Omega)$ a solution to (1). By standard interior estimates $u \in C^\infty(\Omega)$. Define the sets

$$
G = \text{graph}(l_{|\mathbb{R}^n \setminus \Omega}), \quad L = \text{graph}(l_{|\partial \Omega}),
$$

$$
E = \{(x', x_{n+1}) : x' \in \Omega, x_{n+1} < u(x')\}
$$

$$
\cup \{(x', x_{n+1}) : x' \in \mathbb{R}^n \setminus \Omega, x_{n+1} < l(x')\},
$$

so that $\partial E = G \cup \text{graph}(u)$. Let us orient $[\text{graph}(u_{|\Omega})]$, $[G]$, $[\Omega]$ with the upward unit normal. Since $\Omega$ is convex, so is $\text{graph}(l_{|\Omega})$, and so by Lemma 2.1 we can choose an orientation on $L$ such that $[L] \in \mathcal{I}_{n-1}(\mathbb{R}^{n+1})$ and $\partial [G] = -[L]$. Define $T = [\text{graph}(u_{|\Omega})]$.

The bulk of our proof is distributed across three Lemmas. The first (Lemma 2.2) proves that $\text{graph}(u)$ induces an integral mass-minimizing current $T$ with boundary $[L]$. The second (Lemma 2.3) proves the monotonicity formula for $T$. In principle this is standard, but we give an explicit proof because our currents have boundary, and the boundary is not very regular (in particular, $L$ may not be a “nice” varifold boundary of $G$). The last (Lemma 2.5), which is the key of the argument, characterizes tangent cones we can obtain from $T$ as planar.

When $\Omega$ is a half-plane this follows trivially from work of [10], but in our setting the proof can be simplified.

**Lemma 2.2.** In the notation of above, we have:

b) $T$ is mass-minimizing in $\mathbb{R}^{n+1}$.

c) $||T||((B_r(0)) \leq c(n)r^n$ for all $r > 0$.

**Proof.** After rotating $\text{graph}(l)$ to $\mathbb{R}^n$, there is no loss in proving this Lemma under the assumption $l = 0$. Moreover, after rotating in $\mathbb{R}^n$ we can assume that $e_n = (0^{n-1}, 1) \in \Omega \equiv \text{int} \Omega \subset \mathbb{R}^n$.

We first observe that $T = [\text{graph}(u_{|\Omega})] \in \mathcal{I}_n(\Omega \times \mathbb{R})$ is multiplicity-one, smooth, and mass-minimizing. In other words, given $S \in \mathcal{I}_n(\Omega \times \mathbb{R})$ with $\partial S = 0$ and $\text{spt} S \subset W \subset \subset \Omega \times \mathbb{R}$, we have

$$
||T||(W) \leq ||T + S||(W).
$$

This follows by the usual calibration argument.

Trivially $E$ has locally-finite perimeter in $\mathbb{R}^{n+1} \setminus L$, since $E$ is smooth there. Moreover, since $u$ is continuous, we have

$$
||\partial[E]||(\partial \Omega \times \mathbb{R} \setminus L) = 0.
$$
Fix an \( r > 0 \). Let \( \Omega_\epsilon = \Omega + \epsilon d \). By Lemma \( \ref{lem:convex} \), \( D_\epsilon = (\Omega_\epsilon \times \mathbb{R}) \cap B_r(0) \) is a convex set of locally-finite perimeter, with

\[
||\partial[D_\epsilon]||((\Omega_\epsilon \times \mathbb{R}) \cap B_r(0)) \leq \mathcal{H}^n(\partial B_r(0)) \leq c(n) r^n. 
\]

From \( \ref{eq:partial_derivative}, \ref{eq:convex} \) we deduce that \( ||\partial[E]||((\Omega_\epsilon \times \mathbb{R}) \cap B_r(0)) \leq c(n) r^n \), and hence taking \( \epsilon \to 0 \) gives

\[
||\partial[E]||((\Omega \times \mathbb{R}) \cap B_r(0)) \leq c(n) r^n. 
\]

On the other hand, we have the trivial bound

\[
||\partial[E]||((B_r(0) \setminus (\Omega \times \mathbb{R})) = \mathcal{H}^n(G \cap B_r(0)) \leq c(n) r^n. 
\]

Combining \( \ref{eq:partial_derivative}, \ref{eq:convex}, \ref{eq:trivial_bound} \), we obtain

\[
||\partial[E]||((B_r(0) \setminus L) \leq c(n) r^n. 
\]

Now take \( X \in C^1_c(B_r(0), \mathbb{R}^{n+1}) \), and fix \( 0 < \tau < r \). Let \( d : B_{2r}(0) \to \mathbb{R} \) be a smooth function such that

\[
d(x) \in [\tau/2, \tau] \implies x \in B_{2\tau}(L) \setminus B_{\tau/4}(L), \quad |Dd| \leq 2. 
\]

(For example, \( d \) could be a mollification of \( d(\cdot, L) \).) Let \( \eta(\cdot) : \mathbb{R} \to \mathbb{R} \) be a non-negative, increasing function which is \( \equiv 0 \) on \((-\infty, 1/2), \equiv 1 \) on \([1, \infty) \), and \( |\eta'| \leq 10 \). Set \( \phi = \eta(d/\tau) \).

Since \( L \) is countably \((n - 1)\)-rectifiable with locally-finite \( \mathcal{H}^{n-1} \)-measure, we have (\( \ref{eq:bernstein_type_theorem} \) Section 3.2.29)

\[
\limsup_{\tau \to 0} \tau^{-2} \mathcal{L}^{n+1}(B_r(L) \cap B_r(0)) = \mathcal{H}^{n-1}(L \cap B_r(0)) \leq c(n) r^{n-1}. 
\]

We compute, using \( \ref{eq:bernstein_type_theorem}, \ref{eq:limsup} \), and taking \( \tau > 0 \) sufficiently small:

\[
\left| \int_E \phi \text{div}(X) d\mathcal{L}^{n+1} \right| \leq \left| \int \phi X \cdot \nu_E d||\partial[E]|| + |X|_{C^0} \int_{B_r(0)} |D\phi| d\mathcal{L}^{n+1} \right|
\]

\[
\leq |X|_{C^0} ||\partial[E]||((B_r(0) \setminus L) + 20|X|_{C^0} \tau^{-1} \mathcal{L}^{n+1}(B_r(0) \cap B_{2\tau}(L))
\leq c(n)|X|_{C^0} r^n + c(n)|X|_{C^0} \tau r^{n-1}. 
\]

Here \( \nu_E \) is the outward unit normal of \( \partial[E] \) away from \( L \). Letting \( \tau \to 0 \) gives that

\[
\left| \int_E \text{div}(X) d\mathcal{L}^{n+1} \right| \leq c(n)|X|_{C^0} r^n, 
\]

which implies that \( E \) has locally-finite perimeter, and hence \( \partial[E] \) is integral. As a corollary, since \( \mathcal{H}^n(L) = 0 \) we get

\[
||\partial[E]||(L) = 0. 
\]

Finally, we observe that \( \ref{eq:partial_derivative}, \ref{eq:limsup} \) imply

\[
\partial[E] = \partial[E]|_{(\Omega \times \mathbb{R})} + \partial[E]|_{((\mathbb{R}^{n+1} \setminus \overline{\Omega}) \times \mathbb{R})}. 
\]
which gives the equalities of Item a).

Item a) implies \( T = \partial [E] - [G] \in \mathcal{I}_n(\mathbb{R}^{n+1}) \). We show \( T \) is mass-minimizing in \( \mathbb{R}^{n+1} \). Let \( p_\epsilon : \mathbb{R}^{n+1} \rightarrow \Omega_\epsilon \times \mathbb{R} \) denote the nearest-point projection. By Lemma 2.1, \( p_\epsilon \) is area-decreasing, and by construction \((p_0)_*T = T\).

Take \( R > 0 \) and \( S \in \mathcal{I}_n(\mathbb{R}^{n+1}) \) satisfying \( \partial S = 0 \), \( \text{spt} S \subset B_R(0) \). From (5) we have for every \( \epsilon > 0 \):

\[
||T||(B_R(0)) \leq ||T + (p_\epsilon)_*S||(B_R(0))
\leq ||T + S||(B_R(0) \cap (\Omega_\epsilon \times \mathbb{R}))
+ ||T||(B_R(0) \setminus (\Omega_\epsilon \times \mathbb{R})) + ||S||(B_R(0) \setminus (\Omega_\epsilon \times \mathbb{R})).
\]

Taking \( \epsilon \to 0 \) and using that \( ||T||(\mathbb{R}^{n+1} \setminus (\Omega \times \mathbb{R})) = 0 \) gives

\[
||T||(B_R(0)) \leq ||T + S||(B_R(0) \cap \Omega \times \mathbb{R}) + ||S||(B_R(0) \setminus (\Omega \times \mathbb{R})) = ||T + S||(B_R(0)),
\]

which is the required inequality. This proves Item b).

Lastly, combining (10), (12) gives

(13) \[ ||\partial [E]||(B_r(0)) \leq c(n)r^n \quad \forall r > 0. \]

Item c) now follows from Item a), (13) and the trivial bound \( ||[G]||(B_r(0)) \leq c(n)r^n \).

\[ \square \]

**Lemma 2.3.** Suppose \( T \in \mathcal{I}_n(\mathbb{R}^{n+1}) \) is mass-minimizing in \( \mathbb{R}^{n+1} \), with \( \partial T = [L] \) (for \( L \) as above) and \( n \geq 2 \). Given \( r > s > 0 \), we have

(14) \[ \theta_T(0, r) - \theta_T(0, s) \geq \frac{1}{\omega_n} \frac{|x|^{-2}}{|x|^{n+2}d^{|T||}(x)}, \]

and if \( \theta_T(0, r) \) is constant, then \( T \) is a cone (in the sense that \((\eta_{0, \lambda})_*T = T \) for all \( \lambda > 0 \)).

**Proof.** Let \( m(r) = ||T||(B_r(0)) \). For a.e. \( r > 0 \), the slices

\[
T_r := L, \quad r > 0 \in \mathcal{I}_{n-1}(\mathbb{R}^{n+1}),
\]

\[
[L]_r := [L], \quad r > 0 \in [L \cap B_r(0)] \in \mathcal{I}_{n-2}(\mathbb{R}^{n+1})
\]

exist (see e.g. [13, Section 6.4]), and satisfy

\[
T_r = \partial (T \setminus B_r(0)) - [L] \setminus B_r(0),
\]

\[
\partial T_r = -[L]_r = -\partial ([L] \setminus B_r(0)),
\]

where we have oriented \([L \cap B_r(0)]\) in order for the second equality to hold.
Define the homotopy $H(t, x) = tx$. Since $[L]$ is dilation-invariant, we have that $[L]_\lambda = (\eta_{0, \lambda^{-1}})_\sharp [L]_1 = (\eta_{0, \lambda^{-1}})_\sharp [L \cap B_1(0)]$ for all $\lambda > 0$, and $x \in T_xL$ for $||[L]||$-a.e. $x$, and for every $r > 0$:

$$\frac{x}{|x|} \wedge \xi_{[L]_r} = \xi_{[L]} ||[L]|| - a.e.x.$$  

It follows by the coarea formula that $H_\sharp([0, 1] \times [L]_r) = [L] \cap B_r(0)$, and hence $\partial H_\sharp([0, 1] \times T_r) = T_r + [L] \cap B_r(0)$. If we define

$$S_r = H_\sharp([0, 1] \times T_r) - T \cap B_r(0) \in \mathcal{I}_n(\mathbb{R}^{n+1}),$$

then we have $\partial S_r = 0$, and trivially $spt S_r$ is compact. We deduce that

$$m(r) \leq ||T + S_r||(B_r(0)) \leq \frac{\mathcal{L}}{n} ||T||(|\partial B_r(0))$$

holds for a.e. $r > 0$.

The rest of the proof follows the boundaryless case, but for the reader’s convenience we include it. Since $m(r)$ is increasing, we can write $dm = m'_a dr + d\mu_s$ for $d\mu_s$ a union of countably many (positive) Dirac deltas. Let $E$ be the set of $r$ for which $\mu_s(\{r\}) = 0$. We have

$$r \notin E \iff ||T||(|\partial B_r(0)) > 0 \iff ||T||(|\{x \in \partial B_r(0) : |x^T| = 0\}) > 0.$$  

By the coarea formula and slicing theory we get

$$\int_{B_r(0) \cap \partial B_r(0)} gd||T|| = \int_{[r, \sigma] \cap E} \int \frac{|x|}{|x^T|} gd||T||\langle x \rangle dr + \sum_{r \in [\sigma, \partial B_r(0)]} \int \frac{d||T||\langle x \rangle dr}{|x|^n d||T||}(x)$$

for any $\mathcal{H}^n$-measurable function $g : M_T \to \mathbb{R}$. Using (15) and (16), we deduce that for a.e. $\sigma > \tau$, we have

$$\sigma^{-n}m(\sigma) - \tau^{-n}m(\tau)$$

$$= \int_{[\tau, \sigma]} r^{-n}(dm - (n/r)mdr)$$

$$\geq \int_{[\tau, \sigma] \cap E} \int r^{-n} \left(\frac{|x|}{|x^T|} - 1\right) d||T||\langle x \rangle dr + \int_{[\tau, \sigma] \cap E} r^{-n} d\mu_s$$

$$\geq \int_{[\tau, \sigma] \cap E} \int \frac{|x|^2}{|x^T|^n} \frac{|x|}{|x^T|} d||T||\langle x \rangle dr + \sum_{r \in [\tau, \partial B_r(0)]} r^{-n} d||T||\langle x \rangle dr$$

$$= \int_{B_r(0) \cap \partial B_r(0)} \frac{|x|^2}{|x|^n d||T||}(x).$$

This proves the required inequality (14).

When $\eta_T(0, r)$ is constant, then $x^\perp = 0$ for $||T||$-a.e. $x$, and hence $x \in T_x M_T$ for $||T||$-a.e. $x$. It follows from the homotopy formula that $(\eta_{0, \lambda})_\sharp T = T$ for all $\lambda > 0$. \qed
Before proving Lemma 2.5 we need the following helper Lemma.

**Lemma 2.4.** Let \( \Omega' \) be a closed, convex cone strictly contained in \( \mathbb{R}^n \). Let \( K \) be the linear space of translational symmetry of \( \Omega' \), i.e. so \( v \in K \) iff \( v + \Omega' = \Omega' \). Then we can rotate \( \Omega' \) to arrange that \( \Omega' \subset \mathbb{R}^{n-1} \times [0, \infty) \) and \( \Omega' \cap \mathbb{R}^{n-1} = K \).

**Proof.** Since \( \Omega' \neq \mathbb{R}^n \), we can rotate so \( \Omega' \subset \mathbb{R}^{n-1} \times [0, \infty) \). If \( \Omega' = \mathbb{R}^{n-1} \times [0, \infty) \) there is nothing to show, so we can assume \( \Omega' \subsetneq \mathbb{R}^{n-1} \times [0, \infty) \), and hence \( \dim(K) \leq n-2 \). Moreover, by restricting to \( \Omega' \cap K^\perp \) there is no loss in assuming \( K = \{0\} \).

We induct on \( n = 2, 3, \ldots \). If \( n = 2 \), then \( \Omega' \) is a wedge with opening angle \( < \pi \), and so we can deduce the Lemma by choosing \( e_n \) to bisect this angle. Suppose \( n \geq 3 \). Then \( \Omega'' = \Omega' \cap \mathbb{R}^{n-1} \) is a closed convex cone in \( \mathbb{R}^{n-1} \) with 0-dimensions of translational symmetry. By induction, we can rotate so that \( \Omega'' \subset \mathbb{R}^{n-2} \times [0, \infty) \) and \( \Omega'' \cap \mathbb{R}^{n-2} = \{0\} \). In particular, this implies that
\[
d(\Omega', (\mathbb{R}^{n-2} \times (-\infty, 0]) \cap \partial B_1) > 0,\]
and therefore, since \( \Omega' \) is a cone, we can find a \( \theta > 0 \) so that the plane
\[
\mathbb{R}^{n-2} \times \mathbb{R}(\cos \theta e_{n-1} - \sin \theta e_n)
\]
intersects \( \Omega' \) only at 0. By mathematical induction we deduce Lemma 2.4 holds for all \( n \geq 1 \). \( \square \)

**Lemma 2.5.** In the notation of the above, let \( C = \partial [F] - [G] \in \mathcal{I}_n(\mathbb{R}^{n+1}) \) be a mass-minimizing cone, for some \( F \subset \mathbb{R}^{n+1} \), and suppose \( \text{spt} C \subset \Omega \times \mathbb{R} \). Then
a) \( C = [\text{graph}(l|_\Omega)] \) if \( \Omega \) is not a half-space;
b) \( C = [H] \) for some half-plane \( H \) satisfying \( \partial [H] = [L] \), if \( \Omega \) is a half-space.

In particular, we have \( \theta_C(0) = \theta_{\text{graph}(l|_\Omega)}(0) \).

**Remark 2.6.** Our proof of this Lemma in case a) does not actually require \( C \) to be dilation-invariant. However, we feel reducing our problem in both cases to a classification of cones is cleaner. Additionally, since the monotonicity (14) does not require any convexity on \( L \), this reduction may be useful for a larger class of domains \( \Omega \).

**Proof.** We aim to show \( \text{spt} C \) is contained in a hyperplane. We use the maximum principle, by rotating half-planar barriers around the line \( \text{graph}(l|_{\mathbb{R}^{n-1}}) \) until they touch \( \text{spt} C \). We use induction on \( n \) and the Hopf lemma to handle the case when they only touch only at their boundary.
By Lemma 2.4 we can assume $\Omega \subset \mathbb{R}^{n-1} \times [0, \infty)$, and $\Omega \cap \mathbb{R}^{n-1} = K$ is the space of translational symmetry of $\Omega$. Since $l$ is linear the same holds true for $\text{graph}(l|_\Omega)$ with $\text{graph}(l|_{\mathbb{R}^{n-1} \times [0, \infty)})$, $\text{graph}(l|_K)$ in place of $\mathbb{R}^{n-1} \times [0, \infty)$, $K$. After a rotation in $\mathbb{R}^{n+1}$, we can therefore assume that $l = 0$, except that in place of $\text{spt}C \subset \Omega \times \mathbb{R}$ we have that $\text{spt}C \subset \Omega + Rv$, for some non-zero vector $v \in \mathbb{R}^{n+1} \setminus \mathbb{R}^n$. There is no loss in assuming $v \in K$, and that $$\partial F \cap ((\mathbb{R}^n \setminus \Omega) + Rv) = (\mathbb{R}^n \setminus \Omega) + (-\infty, 0]v$$ (as opposed to the region above $\mathbb{R}^n$).

Given $\theta \in \mathbb{R}$ let $H_\theta$ be the half-plane (recall $v \not\in \mathbb{R}^n$)
$$\mathbb{R}^{n-1} \times \{\lambda(\cos \theta e_n + \sin \theta v) : \lambda \geq 0\}.$$ For $\theta \in [-\pi/2, \pi/2]$, let $F_\theta$ be the closed subset of $\mathbb{R}^{n+1}$ such that $\partial F_\theta = H_\pi \cup H_\theta$ and $F_\theta = F$ in $(\mathbb{R}^n \setminus \Omega) + Rv$. By hypothesis we have $F_{\pi/2} \supset \Omega + Rv \supset \text{spt}C$. Note also that $\partial F_\theta = \text{spt}\partial[F_\theta]$. We break into two cases.

**Case 1:** $\Omega \not= \mathbb{R}^{n-1} \times [0, \infty)$. In this case $H_\theta \not\subset \Omega + Rv$ for any $\theta$. Let $\theta^*$ be the least $\theta \in [0, \pi/2]$ for which $\text{spt}C \subset F_\theta$. We aim to show $\theta^* = 0$, since (by considering both $C$ and its reflection across $\mathbb{R}^n$) this will imply $\text{spt}\partial[F] \subset \mathbb{R}^n$, and hence $[F] = [\mathbb{R}^n \times (-\infty, 0)]$, proving the Lemma in case 1.

Suppose, towards a contradiction, $\theta^* > 0$. Define $U = \{x_n > 0\}$. Choose a sequence $x_i \in \text{spt}C \cap U$ such that

$$d(x_i, H_{\theta^*}) \rightarrow 0. \tag{17}$$

Let $y_i = \pi_K(x_i)$. Then $r_i := |y_i - x_i| \geq d(x_i, \mathbb{R}^{n-1})$, and hence $r_i^{-1}d(x_i, H_{\theta^*}) \rightarrow 0$ also.

Define the translated, dilated currents $C_i = (\eta_{y_i, r_i})_\ast C$. Each $C_i$ is mass-minimizing, supported in $\Omega + Rv$, and satisfies $\partial C_i = [L]$. If we set $\tilde{x}_i = \eta_{y_i, r_i}(x_i)$, then $|\tilde{x}_i| = 1$, $\tilde{x}_i \in \text{spt}C_i \cap K \cup U$, and $d(\tilde{x}_i, H_{\theta^*}) \rightarrow 0$.

As in the proof of Lemma 2.2 by comparing the mass of $C$ to that of $C + \partial[F \cup B_r(y)] - \partial[F]$ we deduce that $||C_i||_1(B_r(0)) \leq c(n)R^n$ for all $R > 0$. By standard compactness for area-minimizing currents, after passing to a subsequence we can find $\text{a } C' \in \mathcal{I}_n(\mathbb{R}^{n+1})$ such that $C_i \rightarrow C'$ as currents, $||C_i|| \rightarrow ||C'||$ as Radon measures. We have that $C'$ is mass-minimizing, supported in $\Omega + Rv$ and has boundary $\partial C' = [L]$ (though $C'$ need not be a cone).
We can assume that
\[ \tilde{x}_i \to \tilde{x} \in \partial B_1 \cap H_{\theta^*} \cap (\overline{\Omega} + \mathbb{R}v) \cap \overline{U} \cap K^\perp. \]

We cannot have \( \tilde{x} \in \partial U \), because \( \partial U \cap H_{\theta^*} \cap (\overline{\Omega} + \mathbb{R}v) = K \), and so \( \tilde{x} \in U \). Since \( \text{spt}C_i \to \text{spt}C' \) in the local Hausdorff distance in \( U \), we deduce that \( \text{spt}C' \cap H_{\theta^*} \cap U \neq \emptyset \). But then by the maximum principle \cite{17} we must have \( H_{\theta^*} \subset \text{spt}C' \), which is a contradiction. Therefore we must have \( \theta^* = 0 \), completing the proof of case 1.

**Case 2:** \( \Omega = \mathbb{R}^{n-1} \times [0, \infty) \). This case is essentially a direct consequence of the cone classification due to \cite{10}. However our situation is simpler than that considered in \cite{10}, and so for the reader’s convenience we provide a shorter variant of Hardt–Simon’s proof.

In this case, \( G = \{ x_{n+1} = 0, x_n \leq 0 \} \), and \( L = \mathbb{R}^{n-1} \). Set \( U = \mathbb{R}^{n+1} \setminus G \). We will prove case 2 by induction on \( n \).

If \( n = 1 \), then \( C = \sum_{i=1}^{N} k_i \lfloor l_i \rfloor \) (for \( N \leq 2\theta C(0) \)) is a sum of rays \( l_i \) contained in \( \overline{\Omega} + \mathbb{R}v \), with multiplicities \( k_i \geq 1 \). Since \( C \) is mass-minimizing, we deduce either \( N = 1 \), or \( \text{spt}C \subset \partial \overline{\Omega} + \mathbb{R}v \equiv H_{\pi/2} \cup H_{-\pi/2} \). If \( N = 2 \), then we would have \( \text{spt} \partial[F] = H_{\pi/2} \cup H_{-\pi/2} \cup H_\pi \), which is impossible. Therefore we must have \( N = 1 \), and since \( C \cap U = \partial[F] \cap U \), we deduce \( C \) is a single ray with multiplicity-one. This proves the case \( n = 1 \).

Suppose \( n \geq 2 \), and that Lemma \cite{23} holds for any \( n' < n \) and any half-space \( \Omega' \subset \mathbb{R}^{n'} \). For every \( y \in L \setminus \{0\} \), every tangent cone \( C' \) of \( C \) at \( y \) can be written as \( C' = C'' \times [\mathbb{R}y] \) where \( C'' \) is a mass-minimizing integral \((n-1)\)-current in \((\mathbb{R}y)^\perp \), such that \( \text{spt}C'' \subset (\overline{\Omega} + \mathbb{R}v) \cap (\mathbb{R}y)^\perp \) and \( C'' = \partial[F''] \setminus \{G''\} \) (for some \( F'', G'' \) satisfying \( \partial F'' \cap \{ x_n < 0 \} = G'' = G \cap (\mathbb{R}y)^\perp \)). By our inductive hypothesis applied to \( C'' \) we get that every such \( C' \) is a multiplicity-one half-plane. We deduce by Allard’s boundary regularity theorem \cite{3} that \( C \) is a smooth, closed, multiplicity-one submanifold with boundary \( L \) in some neighborhood of \( L \cap \partial B_1 \).

\footnote{Since \( C' \cap U = \partial[F'] \cap U \) (for some \( F' \)) is mass-minimizing, and \( H_{\theta^*} \) is smooth, in our situation we can easily reduce to the elliptic maximum principle as follows. Any tangent cone of \( C' \) at \( x \) is multiplicity-one and contained in a half-space, and hence is a multiplicity-one plane. Allard’s regularity theorem \cite{2} implies that \( C' \) is smooth nearby \( x \), lies to one side of \( H_{\theta^*} \), and touches \( H_{\theta^*} \) at \( x \). The maximum principle for second-order elliptic PDEs implies \( \text{spt}C' = H_{\theta^*} \) near \( x \). Hence, \( \text{spt}C' \cap H_{\theta^*} \) is non-empty, relatively open, and relatively closed in \( H_{\theta^*} \).}

\footnote{Alternatively, one can reflect \( C \) about \( L \) to obtain a stationary varifold without boundary, whose tangent plane at every point \( L \setminus \{0\} \) is a multiplicity-one plane, and then use Allard’s interior regularity theorem \cite{2}.}
Let $\theta^*$ be the least $\theta \in [-\pi/2, \pi/2]$ such that $F_{\theta} \supset \text{spt} C$. We claim that $\text{spt} C \cap H_{\theta^*} \cap U \neq \emptyset$. Suppose for the moment our claim holds. Then as in case 1, we can deduce by the maximum principle that $H_{\theta^*} \subset \text{spt} C$, and hence by the constancy theorem (and the fact that $C \cup U = \partial [F] \cup U$) we get $C \cup H_{\theta^*} = \partial [F_{\theta^*}] \cup U$.

Since $\text{spt} C$ is smooth, multiplicity-one near $L \setminus \{0\}$, we must have $\text{spt} C = H_{\theta^*}$ near $L \setminus \{0\}$. Therefore if we set $C' = C - \partial [F_{\theta^*}] \cup U$ we can only have $\text{spt} C' \cap L \subset \{0\}$, and hence $\partial C' = 0$. So the integral varifold induced by $C'$ is a stationary cone in $\mathbb{R}^{n+1}$ supported in the half-space $\{x_n \geq 0\}$. It follow that $C' = k[\{x_n = 0\}]$ for some integer $k$, but then the condition $\text{spt} C' \cap L \subset \{0\}$ implies $k = 0$. This proves that $C = \partial [F_{\theta^*}] \cup U$, and finishes case 2 provided our claim holds.

We prove our claim. Since $\text{spt} C$ is a smooth submanifold with boundary $L$ near $L \setminus \{0\}$, supported in $F_{\theta^*}$, the Hopf lemma implies that in a neighborhood $U_y$ of each point $y \in L \cap \partial B_1$ we must have either $H_{\theta^*} \cap U_y = \text{spt} C \cap U_y$, or

$$\inf_{z \in \text{spt} C \cap U_y} \frac{d(z, H_{\theta^*})}{d(z, L)} > 0. \quad (18)$$

If at any $y$ the former case occurs, we are done. Otherwise, take a sequence $x_i \in \text{spt} C \cap \partial B_1 \cap U$ satisfying (17). After passing to a subsequence, we have $x_i \rightarrow x \in \text{spt} C \cap H_{\theta^*} \cap \partial B_1 \cap U$. If $x \in \partial U$, then necessarily $x \in L \cap \partial B_1$, in which case the $x_i$ would violate (18) for large $i$. Therefore we must have $x \in U$, which finishes our Claim, and the proof of case 2. \hfill \square

**Proof of Theorem 1.1.** Let $r_i$ be any sequence $\rightarrow 0$. Let $T_i = \eta_{r_i,z} T$, and $E_i = \eta_{r_i,z} E$. For each $i$ we have by Lemma 2.2 that $T_i = \partial [E_i] - [G]$, $T_i$ is mass-minimizing in $\mathbb{R}^{n+1}$, and $||T_i|| (B_R(0)) \leq c(n) R^n$ for all $R > 0$. By standard compactness for area-minimizing currents (e.g. [13], Section 7.2]), we can find a $T' \in \mathcal{I}_n(\mathbb{R}^{n+1})$ which is mass-minimizing in $\mathbb{R}^{n+1}$, and $E' \subset \mathbb{R}^{n+1}$ with locally-finite perimeter, so that $[E_i] \rightarrow [E']$, $T_i \rightarrow T'$ as currents, and $||T_i|| \rightarrow ||T'||$ as Radon measures.

By monotonicity (14), we get that $\theta_{T'}(0, r) = \lim_{r \rightarrow \infty} \theta_T(0, r) \leq c(n)$ is constant in $r$, and hence $T'$ is a cone. Since $T' = \partial [E'] - [G]$, and we can WLOG assume $E' = E$ in $\mathbb{R}^{n+1} \setminus (\Omega \times \mathbb{R})$, we have by Lemma 2.5 that $\theta_{T'}(0) = \theta_{\text{graph}(l_{\Omega})}(0) = \lim_{r \rightarrow \infty} \theta_T(0, r)$.

On the other hand, we can repeat this same argument with $\tilde{T_i} = \eta_{r_i^{-1},z} T$, $\tilde{E}_i = \eta_{r_i^{-1},z} E$, to deduce that $\theta_{\text{graph}(l_{\Omega})}(0) = \lim_{r \rightarrow 0} \theta_T(0, r)$ also. By monotonicity, we deduce that $\theta_T(0, r)$ is constant in $r$, and $T$ is a cone, and hence $T = T'$. If $\Omega$ is not a half-space, we get that $u = l$. 

BERNSTEIN TYPE THEOREM 11
If $\Omega$ is a half-space, then $u = l'$ for some linear $l' : \mathbb{R}^n \to \mathbb{R}$ which agrees with $l$ on $\mathbb{R}^{n-1} \times \{0\}$. This completes the proof of Theorem 1.1. □
