QUANTITATIVE ANALYSIS OF A SUBGRADIENT-TYPE METHOD FOR
EQUILIBRIUM PROBLEMS

Abstract. We use techniques originating from the subdiscipline of mathematical logic called ‘proof mining’ to provide rates of metastability and - under a metric regularity assumption - rates of convergence for a subgradient-type algorithm solving the equilibrium problem in convex optimization over fixed-point sets of firmly nonexpansive mappings. The algorithm is due to H. Iiduka and I. Yamada who in 2009 gave a noneffective proof of its convergence.

Keywords: Equilibrium problems, firmly nonexpansive mappings, subgradient-type method, proof mining

MSC2010 Classification: 47H06, 47J25, 90C33, 03F10

1. Introduction

In [2], the following equilibrium problem over the fixed point set of a firmly nonexpansive mapping is studied: let \( f : \mathbb{R}^N \times \mathbb{R}^N \to \mathbb{R} \) be a function such that:

1. \( f(x, x) = 0 \) for any \( x \in \mathbb{R}^N \);
2. \( f(\cdot, y) \) is continuous for any \( y \);
3. \( f(x, \cdot) \) is convex for any \( x \).

Now we can state the equilibrium problem for \( f \) (a so called equilibrium function) over the fixed point set \( \text{Fix}(T) \) of \( T : \mathbb{R}^N \to \mathbb{R}^N \) is a firmly nonexpansive mapping with a nonempty fixed point set.

Problem 1 (Equilibrium problem of \( f \) over \( \text{Fix}(T) \)). Find a \( u \in \text{EP}(\text{Fix}(T), f) := \{ u \in \text{Fix}(T) \mid f(u, y) \geq 0 \ \forall y \in \text{Fix}(T) \} \).

Iiduka and Yamada proposed a subgradient-type iterative algorithm \( (x_n)_{n \in \mathbb{N}} \) (see also [3] for a related algorithm also discussed in [2]) and showed that it converges to a point in \( \text{EP}(\text{Fix}(T), f) \). However, there is no quantitative information given in the theorem. In this paper we provide explicit quantitative versions of this result as well as of several intermediate convergence results such as

\[ \lim_{n \to \infty} f(y_n, x_n) = 0 \ \text{as well as} \ \lim_{n \to \infty} \|x_n - Tx_n\| = 0. \]

We use implicitly methods (resp. results that had been obtained using such methods) from the subdiscipline of mathematical logic called proof mining which aims at the extraction of effective bounds from prima facie nonconstructive proofs by logical transformations (see [4] for a book treatment and [5] for a recent survey). As common in applications of proof mining, all the later results and proofs are stated without any reference to mathematical logic.

In the context of convergence results and Cauchy statements however, there is in general no guarantee to have a computable rate of convergence and in fact in the case at hand even for \( N = 1 \) and \( f \equiv 0 \) one can construct a simple computable \( T \) such that \( (x_n)_{n \in \mathbb{N}} \) has no computable rate by adapting a counterexample from [9].

Logically speaking, this is because the formulation of the Cauchy-property of a sequence \( (x_n)_{n \in \mathbb{N}} \) (say in a metric space \( (X, d) \), that is

\[ \forall k \in \mathbb{N} \exists N \in \mathbb{N} \forall n \geq N \left( d(x_n, x_m) < \frac{1}{k+1} \right) \]

is of the form \( \forall \exists \forall \) which, in general, is of too high logical complexity (and thus not covered by the general logical metatheorems used in proof mining to extract bounds from noneffective proofs). On the other hand, there is a guarantee on the existence of explicit quantitative information on a (classically equivalent but constructively weakened) reformulation of the convergence or Cauchy statements into what is known in logic as Herbrand

\(^0\)This paper is a condensed version of the Bachelor thesis [10] of the first author written under the supervision of the 2nd author.

Date: August 18, 2020.
normal form. In the context of the above example, this reformulation is given by (here $\{n; n + g(n)\} := \{n, n + 1, n + 2, \ldots, n + g(n)\}$)

$$\forall k \in \mathbb{N} \forall g \in \mathbb{N} \exists n \in \mathbb{N} \forall i, j \in \{n; n + g(n)\} \left( d(x_i, x_j) < \frac{1}{k + 1} \right).$$

This statement is of the general form $\forall \exists$ (considering the leading two universal quantifiers as one and disregarding the last universal quantifier as it is bounded) and for statements of the above form, the logical metatheorems of proof mining guarantee the extractability of highly uniform effective bounds on $\exists \forall n \in \mathbb{N}'$ (see [4]). Such bounds are by now well-known in the literature under the name of rates of metastability (after Tao, see e.g. [12, 11]). It is these rates of metastability which we extract for the convergence results from [2] (see Theorem 3). However, in Section 3 we even give a rate of convergence, modulo an additional metric regularity assumption.

1.1. Analytical preliminaries. Throughout, we consider $\mathbb{R}^N (N \geq 1)$ as the Euclidean space with the usual inner product $\langle \cdot, \cdot \rangle$ and the induced Euclidean norm $\|\cdot\|$. With $B_r(x)$ and $\overline{B}_r(x)$, we denote the open and closed ball with radius $r > 0$ and center $x \in \mathbb{R}^N$ with respect to $\|\cdot\|$, respectively. Throughout, if not stated otherwise, let $T : \mathbb{R}^N \to \mathbb{R}^N$ be a firmly nonexpansive mapping, that is for all $x, y \in \mathbb{R}^N$:

$$\|Tx - Ty\|^2 \leq (x - y, Tx - Ty).$$

In particular, $T$ is also nonexpansive.

1.2. The subgradient method of Iiduka and Yamada. For the equilibrium problem utilizing the subgradient of the equilibrium function $f$:

Algorithm 2 (Subgradient-type method for Problem 1). Choose $\varepsilon_0 \geq 0$, $\lambda_0 > 0$ and $x_0 \in \mathbb{R}^N$ arbitrarily and define $\rho_0 := \|x_0\|$ and set $n = 0$. Then, repeat:

- Given $x_n \in \mathbb{R}^N$ and $\rho_n > 0$, choose $\varepsilon_n \geq 0$ and $\lambda_n > 0$.
- Find a point $y_n \in K_n := \overline{B}_{\rho_{n+1}}(0)$ such that
  $$f(y_n, x_n) \geq 0 \text{ and } \max_{y \in K_n} f(y, x_n) \leq f(y_n, x_n) + \varepsilon_n.$$

- Choose $\xi_n \in \partial f(y_n, \cdot)(x_n)$ arbitrarily, define
  $$x_{n+1} = T(x_n - \lambda_n f(y_n, x_n)\xi_n) \text{ and } \rho_{n+1} = \max\{\rho_n, \|x_{n+1}\|\}$$
  and update $n \to n + 1$.

In [2], the following theorem on the correctness of the algorithm is established:

Theorem 3 (Iiduka and Yamada, [2]). Let $\text{Fix}(T) \neq \emptyset$. Assume that there is an $M > 0$ with $\|\xi_n\| \leq M$ for all $n \in \mathbb{N}$. Then the sequences $(x_n)_{n \in \mathbb{N}}, (y_n)_{n \in \mathbb{N}}$ generated by the algorithm satisfy:

(a) For all $u \in \Omega_n := \{u' \in \text{Fix}(T) \mid f(y_n, u') \leq 0\}$:

$$\|x_{n+1} - u\|^2 \leq \|x_n - u\|^2 + \lambda_n(M^2\lambda_n - 2)(f(y_n, x_n))^2.$$  

In particular, if $\lambda_n \in [0, 2/M^2]$

$$\|x_{n+1} - u\| \leq \|x_n - u\|.$$

(b) If $\Omega := \bigcap_{n=1}^{\infty} \Omega_n \neq \emptyset$ and $\lambda_n \in [a, b] \subseteq (0, 2/M^2)$ for some $a, b > 0$ and all $n \in \mathbb{N}$, then the sequences $(x_n)_{n \in \mathbb{N}}, (y_n)_{n \in \mathbb{N}}$ are bounded and

$$\lim_{n \to \infty} f(y_n, x_n) = 0 \text{ as well as } \lim_{n \to \infty} \|x_n - Tx_n\| = 0.$$

(c) If $\varepsilon_n \geq 0$ for all $n$ with $\lim_{n \to \infty} \varepsilon_n = 0$, in addition to the requirements for (b), then $(x_n)_{n \in \mathbb{N}}$ converges to a point in $\text{EP(\text{Fix}(T), f)}$.

In this paper we establish quantitative versions of the claims in this theorem.
2. A First Quantitative Analysis

A first consequence of Theorem 3 is the following reformulation of (parts of) part (a).

**Lemma 4.** Let \( u \in \Omega \neq \emptyset \) and \( M > 0 \) with \( M \geq \|\xi_n\| \) for all \( n \in \mathbb{N} \). Suppose \( \lambda_n \in [0, 2/M^2] \) for all \( n \in \mathbb{N} \). Then
\[
\|x_{n+1} - u\|^2 \leq \|x_n - u\|^2
\]
for all \( n \in \mathbb{N} \). Especially, \( \|x_n - u\|^2 \) converges.

As the required sequences are monotone, we can obtain a direct rate of metastability for the sequence \( \left( \|x_n - u\|^2 \right)_{n \in \mathbb{N}} \) from the next lemma which follows immediately from [4], Proposition 2.27 and Remark 2.29.

**Lemma 5** (Quantitative version of Lemma 4). Let \( u \in \Omega \neq \emptyset \) with \( c_u \geq \|x_0 - u\|^2 \) and let \( M \geq \|\xi_n\| \) for all \( n \in \mathbb{N} \). Further, let \( \lambda_n \in [0, 2/M^2] \) for all \( n \in \mathbb{N} \). Then for all \( k \in \mathbb{N} \) and all \( g \in \mathbb{N} \):
\[
\exists n \leq \Phi_1(k, g, c_u) \forall i, j \in [n; n + g(n)] \left( \|x_i - u\|^2 - \|x_j - u\|^2 \right) < \frac{1}{k+1}
\]
where
\[
\Phi_1(k, g, c_u) = g((c_u(k+1))) + g(n),
\]
Here \( g^{(n)}(0) \) denotes the \( n \)-th iteration of \( g \) starting from 0.

A lemma used in the proof (in [2]) of Theorem 3 part (b) and (c), is the following which is a direct corollary of part (a).

**Lemma 6** (Iiduka and Yamada, [2], p. 257). Let \( u \in \Omega \neq \emptyset \) and \( M > 0 \) with \( M \geq \|\xi_n\| \) for all \( n \in \mathbb{N} \). Let further \( \lambda_n \in [a, b] \subseteq (0, 2/M^2) \) for all \( n \in \mathbb{N} \). Then
\[
0 \leq -a(M^2b - 2)(f(y_n, x_n))^2 \leq \|x_n - u\|^2 - \|x_{n+1} - u\|^2
\]
for all \( n \in \mathbb{N} \).

Using this lemma, we obtain the following quantitative analysis of the convergence of \( f(y_n, x_n) \) towards 0.

**Proposition 7** (Quantitative version of Theorem 3 part (b), I). Let \( u \in \Omega \neq \emptyset \), \( c_u \geq \|x_0 - u\|^2 \), and let \( M \geq \|\xi_n\| \) for all \( n \in \mathbb{N} \). Further, let \( \lambda_n \in [a, b] \subseteq (0, 2/M^2) \) for all \( n \in \mathbb{N} \). Then for all \( k \in \mathbb{N} \) and all \( g \in \mathbb{N} \):
\[
\exists n \leq \Phi_2(k^2 + 2k, g, c_u) \forall i \in [n; n + g(n)] \left( f(y_i, x_i) \right) < \frac{1}{k+1}
\]
where
\[
\Phi_2(k, g, c_u) = \Phi_1 \left( \left\lfloor \frac{k+1}{\alpha(a, b, M)} \right\rfloor + 1, g + 1, c_u \right)
\]
and \( \alpha(a, b, M) = -a(M^2b - 2) \).

**Proof.** Let \( k \in \mathbb{N} \) and \( g \in \mathbb{N} \) be arbitrary. By Lemma [5]
\[
\exists n \leq \Phi_1 \left( \left\lfloor \frac{k+1}{\alpha(a, b, M)} \right\rfloor + 1, g + 1, c_u \right)
\]
such that for all \( i \in [n; n + g(n)] \) (as then \( i + 1 \in [n; n + g(n) + 1] \):
\[
(f(y_i, x_i))^2 \leq -\frac{1}{a(M^2b - 2)} \left( \|x_i - u\|^2 - \|x_{i+1} - u\|^2 \right)
\]< \frac{1}{a(M^2b - 2)} \left( \left\lfloor \frac{k+1}{\alpha(a, b, M)} \right\rfloor + 1 \right).
\]
\[
\leq -\frac{1}{\alpha(a, b, M)} \frac{\alpha(a, b, M)}{k+1} = \frac{1}{k+1}
\]
where the first inequality follows from Lemma [5]. From this the claim is immediate.

**Lemma 8** (Iiduka and Yamada, [2], p. 257). Let \( u \in \Omega \neq \emptyset \) be arbitrary and \( M > 0 \) with \( M \geq \|\xi_n\| \) for all \( n \in \mathbb{N} \). Let further \( \lambda_n \in [a, b] \subseteq (0, 2/M^2) \) for all \( n \in \mathbb{N} \).
(i) For all $n \in \mathbb{N}$:  
$$\|x_n - x_{n+1}\|^2 \leq \|x_n - u\|^2 - \|x_{n+1} - u\|^2 + 2Mb(y_n, x_n) \|x_n - x_{n+1}\|.$$  
In particular, if $L \geq \text{diam}\{x_n \mid n \in \mathbb{N}\}$:  
$$\|x_n - x_{n+1}\|^2 \leq \|x_n - u\|^2 - \|x_{n+1} - u\|^2 + 2MbL(y_n, x_n).$$

(ii) For all $n \in \mathbb{N}$:  
$$\|x_{n+1} - T x_{n+1}\| \leq \|x_n - x_{n+1}\| + Mbf(y_n, x_n).$$

**Proposition 9** (Quantitative version of Theorem 3 part (b), II). Let $u \in \Omega \neq \emptyset$, $c_u \geq \|x_0 - u\|^2$, $L \geq \text{diam}\{x_n \mid n \in \mathbb{N}\}$ as well as $M \geq \|\xi_n\|$ for all $n \in \mathbb{N}$. Further, let $\lambda_n \in [a, b] \subseteq (0, 2/M^2)$ for all $n \in \mathbb{N}$. Then, for all $k \in \mathbb{N}$ and all $g \in \mathbb{N}^N$:  
$$\exists n \leq \Phi_3(k, g, c_u) \forall i \in [n; n + g(n)] \left(\left\|x_i - T x_i\right\| < \frac{1}{k + 1}\right),$$  
where we have  
$$\Phi_3(k, g, c_u) = \Phi_1\left(\left(\eta(a, b, M, L)\right)^4(k + 1)^2 - 1, g', c_u\right) + 1$$

with $g'(n) = g(n + 1)$ as well as  
$$\eta(a, b, M, L) = \left(\frac{\sqrt{2MbL}}{\eta\alpha(a, b, M)} + \frac{Mb}{\eta\alpha(a, b, M)} + 1\right)$$

and $\alpha(a, b, M) = -a(M^2b - 2)$ with $\Phi_1$ as in Lemma 3.

**Proof.** Let $k \in \mathbb{N}$ and $g \in \mathbb{N}^N$ be arbitrary. As an abbreviation, we write  
$$\Delta_{u, n} = \|x_n - u\|^2 - \|x_{n+1} - u\|^2.$$  
Using Lemma 6 we at first have  
$$f(y_n, x_n) \leq \frac{1}{\sqrt{\alpha(a, b, M)}} \sqrt{\Delta_{u, n}}.$$  
Further, we have (using Lemma 8 and Lemma 4) for any $u \in \Omega$:  
$$\|x_{n+1} - T x_{n+1}\| \leq \|x_n - x_{n+1}\| + Mbf(y_n, x_n) \leq \sqrt{\Delta_{u, n}} + \sqrt{2MbL}\sqrt{f(y_n, x_n)} + Mbf(y_n, x_n)$$

and therefore (using Lemma 6 again):  
$$\|x_{n+1} - T x_{n+1}\| \leq \frac{\sqrt{2MbL}}{\sqrt{\alpha(a, b, M)}} \sqrt{\Delta_{u, n}} + \left(\frac{Mb}{\sqrt{\alpha(a, b, M)}} + 1\right) \sqrt{\Delta_{u, n}}$$

for all $n \in \mathbb{N}$.

By Lemma 5 we have that  
$$\exists m \leq \Phi_3(k, g, c_u) - 1$$

such that (using (*) for all $i \in [m; m + g(m + 1)]$:

$$\|x_{i+1} - T x_{i+1}\| < \frac{\sqrt{2MbL}}{\sqrt{\alpha(a, b, M)}} \frac{1}{\eta(a, b, M, L)(k + 1)} + \left(\frac{Mb}{\sqrt{\alpha(a, b, M)}} + 1\right) \frac{1}{\eta(a, b, M, L)(k + 1)} \leq \frac{1}{k + 1}. \frac{1}{\eta(a, b, M, L)(k + 1)} \leq \frac{1}{k + 1}. \frac{1}{\eta(a, b, M, L)(k + 1)} \leq \frac{1}{k + 1}.$$  

If we define $n = m + 1$, then $n \leq \Phi_3(k, g, c_u)$ and  
$$i \in [n; n + g(n)] \Rightarrow i - 1 \in [m; m + g(m + 1)]$$

and thus by the above we have  
$$\|x_i - T x_i\| < \frac{1}{k + 1}$$

for all $i \in [n; n + g(n)]$.  

\[\square\]
Remark 10. Note that a bound \( L \) on the diameter of \((x_n)_{n \in \mathbb{N}}\) as used in Proposition 9 as an input can actually be obtained in terms of \( c_u \) by setting \( L := 2\sqrt{c_u} \) as we have:
\[
\|x_n - x_m\| \leq \|x_n - u\| + \|x_m - u\| \leq \|x_0 - u\| + \|x_0 - u\| \leq 2\sqrt{c_u}.
\]

To obtain a rate of metastability for the sequence \((x_n)_{n \in \mathbb{N}}\), we apply recent results of Kohlenbach, Leuștean and Nicolae [7] on Fejér-monotone sequences. Other examples of application of these recent results are especially the derivation of a quantitative version of asymptotic regularity of compositions of two mappings (see [7]). We recall the definition of Fejér monotonicity.

Definition 11. Let \((X, d)\) be a metric space, \(F \subseteq X\) nonempty and \((x_n)_{n \in \mathbb{N}}\) be a sequence in \(X\). \((x_n)_{n \in \mathbb{N}}\) is called Fejér-monotone with respect to \(F\), if for all \(n \in \mathbb{N}\) and all \(p \in F\):
\[
d(x_{n+1}, p) \leq d(x_n, p).
\]

The authors actually introduce a generalized form of Fejér monotonicity, but for the purpose of this work, the above is enough. However, we pass to the notion of uniform Fejér monotonicity, as introduced in [6], to formulate the (following) quantitative results.

For this, one considers approximations of the approached set \(F\) in form of a descending sequence of sets
\[
AF_k \supseteq AF_{k+1}
\]
for \(k \in \mathbb{N}\) with
\[
F = \bigcap_{k \in \mathbb{N}} AF_k.
\]

Definition 12. \((x_n)_{n \in \mathbb{N}}\) is called uniformly Fejér monotone with respect to \(F\) and \((AF_k)_{k \in \mathbb{N}}\) if for all \(n, r, m \in \mathbb{N}\):
\[
\exists k \in \mathbb{N} \forall p \in AF_k \forall l \leq m \left( d(x_{n+l}, p) < d(x_n, p) + \frac{1}{r} \right).
\]

Any function \(\chi(n, m, r)\) producing such a \(k \in \mathbb{N}\) is called a modulus of \((x_n)_{n \in \mathbb{N}}\) being uniformly Fejér monotone.

Under the assumption of \((X, d)\) being boundedly compact, the authors obtain (in a slightly generalized setting) an explicit effective rate of metastability for the sequence \((x_n)_{n \in \mathbb{N}}\). This rate only depends on the particular uniform quantitative reformulations of the assumptions of the setting such as a modulus of uniform Fejér monotonicity and some further quantitative information on the space \((X, d)\) and on how the sequence \((x_n)_{n \in \mathbb{N}}\) approaches the set \(F\).

With quantitative information on the space \((X, d)\) we here mean explicitly a modulus of total boundedness (as defined in [6]) or a ‘modulus of bounded compactness’. This will be discussed in the proof of Theorem 17.

With quantitative information on how the sequence \((x_n)_{n \in \mathbb{N}}\) approaches the set \(F\), we mean a bound on \((x_n)_{n \in \mathbb{N}}\) having approximate \(F\)-points. For this, recall the following definition from [6].

Definition 13. \((x_n)_{n \in \mathbb{N}}\) has approximate \(F\)-points if \(\forall k \in \mathbb{N} \exists \Omega \in \mathbb{N} (x_N \in AF_k)\). A bound \(\Phi(k)\) on ‘\(\exists \Omega \in \mathbb{N}\) is called an approximate \(F\)-point bound.

As a feasibility check on whether these results can be applied and whether the setup of [2] fits into the above framework, note that part (a) of Theorem 8 can be seen (modulo some refinement of the approximations \(\Omega_n\)) as hinting the uniform Fejér monotonicity of \((x_n)_{n \in \mathbb{N}}\) (as the sequence from Algorithm 2) with respect to the set \(\Omega\) being taken as \(F\).

We at first focus on whether (quantitative versions of) these properties of uniform Féjer monotonicity and approximate \(F\)-/\(\Omega\)-points can be obtained by suitably modifying the approximations \(\Omega_n\).

For this, we need to weaken the conditions of \(\Omega_n\) to allow \((x_n)_{n \in \mathbb{N}}\) to lie in them further along the approximation. As none of these \(x_n\) is expected to be a fixed point of \(T\) or to satisfy \(f(y_n, x_n) \leq 0\), we weaken these properties to that of approximate fixed point and \(f(y_m, u) \leq \frac{1}{k+1}\), respectively. Part (b) of Theorem 8 gives, as a feasibility check, that in the long run \(f(y_n, x_n)\) is expected to decrease and that the sequence \(x_n\) contains better and better approximate fixed points of \(T\).

Using this motivation, we define
\[
\Omega'_k := \left\{ u \in \mathbb{R}^N \mid \|u - Tu\| \leq \frac{1}{k+1} \text{ and } f(y_j, u) \leq \frac{1}{k+1} \text{ for all } j \leq k \right\}
\]
which plays the role of $AF_k$. By construction, we naturally have that $(\Omega_k)$ is descending and

$$\Omega = \bigcap_{k \in \mathbb{N}} \Omega_k.$$  

Further, we obtain the following lemma giving a quantitative version of $(x_n)_{n \in \mathbb{N}}$ having approximate $\Omega$-points with respect to $(\Omega_k)_{k \in \mathbb{N}}$ (modulo some quantitative reformulations of the parameters of Algorithm 2).

**Lemma 14.** Let $u \in \Omega \neq \emptyset$ with $c_n \geq \|x_n - u\|^2$ and let $M \geq \|\xi_n\|$ for all $n \in \mathbb{N}$. Let $\lambda_n \in [a, b] \subseteq (0, 2/M^2)$ for all $n \in \mathbb{N}$ and let $L \geq \text{diam}(\{x_n \mid n \in \mathbb{N}\})$. Further, let $\varepsilon_n \geq 0$ for all $n \in \mathbb{N}$ and let $\varepsilon_n \to 0$ ($n \to \infty$) where $\tau$ is a nondecreasing rate of convergence for $\varepsilon_n \to 0$ ($n \to \infty$), that is $\tau(k + 1) \geq \tau(k)$ and

$$\forall k \in \mathbb{N} \forall n \geq \tau(k) \left(\varepsilon_n \leq \frac{1}{k + 1}\right).$$

Then

$$\forall k \in \mathbb{N} \exists n \leq \Phi(k, \lambda, \lambda, \lambda, \varepsilon, u) \quad (x_n \in \Omega_k'),$$

where

$$\Phi(k, \lambda, \lambda, \lambda, \varepsilon, u) = \left[c_n \cdot (\sigma(a, b, M, L))^416(k + 1)^4 \cdot (\max\{k, \tau(2k + 1)\} + 1) \right] + 1$$

with

$$\sigma(a, b, M, L) = \left(\frac{\sqrt{2MbL}}{\sqrt{\alpha(a, b, M)}} + \frac{Mb + 1}{\sqrt{\alpha(a, b, M)}} + 1\right)$$

and $\alpha(a, b, M) = -a(M^2b - 2)$.

**Proof.** Let $k \in \mathbb{N}$. We again write

$$\Delta_{u,n} = \|x_n - u\|^2 - \|x_{n+1} - u\|^2$$

and as in the proof of Proposition 9 we obtain

$$\|x_{n+1} - T x_{n+1}\| \leq \frac{\sqrt{2MbL}}{\sqrt{\alpha(a, b, M)}} \sqrt{\Delta_{u,n}} + \left(\frac{Mb}{\sqrt{\alpha(a, b, M)}} + 1\right) \sqrt{\Delta_{u,n}}.$$  

Note, that for $m : n \to m$ we have

$$\Phi_1(k, m, \lambda, \varepsilon, u) = [c_n(k + 1)] \cdot m$$

and so

$$\Phi(k, \lambda, \lambda, \lambda, \varepsilon, u) = \Phi_1(\{\sigma(a, b, M, L))^416(k + 1)^4 \cdot (\max\{k, \tau(2k + 1)\} + 1, c_n + 1$$

Hence by Lemma 14 we have that $\exists m \leq \Phi(k, \lambda, \lambda, \lambda, \varepsilon, u) - 1 \forall i \in [m; m + \max\{k, \tau(2k + 1)\} + 1]$ and

$$\left(\Delta_{u,i} = \|x_i - u\|^2 - \|x_{i+1} - u\|^2 < \frac{1}{\sigma^4(a, b, M, L)16(k + 1)^4}\right).$$

Especially, for $n = \max\{m, k, \tau(2k + 1)\}$, we have $n \in [m; m + \max\{k, \tau(2k + 1)\}]$ and thus $n, n + 1 \in [m; m + \max\{k, \tau(2k + 1)\} + 1]$ as well as also $n + 1 \geq \tau(2k + 1)$. The latter gives $\varepsilon_{n+1} \leq \frac{1}{k + 1}$. Therefore, using ($*1$) and ($*2$):

$$\|x_{n+1} - T x_{n+1}\| + f(y_{n+1}, x_{n+1}) + \varepsilon_{n+1}$$

$$< \left(\frac{\sqrt{2MbL}}{\sqrt{\alpha(a, b, M)}} \sigma(a, b, M, L)2(k + 1) \right) \left(\frac{Mb + 1}{\sqrt{\alpha(a, b, M)}} + 1\right) \frac{1}{(\sigma(a, b, M, L))^4(k + 1)^2} + \frac{1}{2(k + 1)}$$  

$$\leq \left(\frac{\sqrt{2MbL}}{\sqrt{\alpha(a, b, M)}} \sigma(a, b, M, L)2(k + 1) \right) \left(\frac{Mb + 1}{\sqrt{\alpha(a, b, M)}} + 1\right) \frac{1}{2(k + 1)} = \frac{1}{k + 1}$$

as $\sigma(a, b, M, L) \geq 1$.

By the above, we have

$$\|x_{n+1} - T x_{n+1}\| \leq \frac{1}{k + 1}$$

as well as $f(y_{n+1}, x_{n+1}) + \varepsilon_{n+1} \leq \frac{1}{k + 1}$. 

separately as \( f(y_{n+1}, x_{n+1}) \geq 0 \) by definition from Algorithm 2. Also by the definition of Algorithm 2, we have
\[
\max_{y \in K_{n+1}} f(y, x_{n+1}) \leq f(y_{n+1}, x_{n+1}) + \varepsilon_{n+1} \leq \frac{1}{k+1}
\]
By definition of the \( K_j \), as \( K_j \subseteq K_{j+1} \) and \( y_j \in K_j \), we have \( y_0, \ldots, y_{n+1} \in K_{n+1} \). Therefore, we have especially
\[
f(y_j, x_{n+1}) \leq \frac{1}{k+1}
\]
for all \( j \leq n + 1 \) and as \( n + 1 \geq k \) by definition of \( n \), we have \( x_{n+1} \in \Omega_k' \).

The next two lemmas now give the quantitative version of the uniform Féjér monotonicity of \((x_n)_{n \in \mathbb{N}}\) with respect to \( \Omega \) and \((\Omega_k')_{k \in \mathbb{N}}\).

**Lemma 15.** Let \( M \geq \|\xi_n\| \) for all \( n \in \mathbb{N} \) and let \( \lambda_n \in [a, b] \subseteq (0, 2/M^2) \) for all \( n \in \mathbb{N} \). Now, let \( n \in \mathbb{N} \) be fixed. For any \( k \geq n \) and any \( u \in \Omega_k' \):
\[
\|x_{n+1} - u\|^2 \leq \left(\|x_n - u\| + \frac{1}{k+1}\right)^2 + \frac{1}{k+1} f(y_n, x_n) 2b(1 + M).
\]
In particular, we have
\[
\|x_{n+l} - u\| \leq \|x_n - u\| + \frac{l}{k+1} + \frac{\sqrt{2b(1 + M)^2}}{\sqrt{k+1}} \sum_{j=0}^{l-1} \sqrt{f(y_{n+j}, x_{n+j})}
\]
for all \( u \in \Omega_k' \) and for all \( l \in \mathbb{N} \) with \( n + l \leq k + 1 \) (where for \( l = 0 \) the sum is 0).

**Proof.** We give a quantitative analysis of the proof of (3.6) in [2]. At first, note that \( \xi_n \in \partial f(y_n, \cdot)(x_n) \) by the definition of Algorithm 2. Thus, by the definition of the subgradient, we have especially
\[
f(y_n, u) \geq f(y_n, x_n) + \langle u - x_n, \xi_n \rangle
\]
and thus
\[
(x_n - u, \xi_n) \geq f(y_n, x_n) - f(y_n, u)
\]
for all \( u \in \Omega_k' \).

Therefore, we have:
\[
\|x_{n+1} - u\|^2 = \|T(x_n - \lambda_n f(y_n, x_n) \xi_n) - u\|^2 \\
\leq \|T(x_n - \lambda_n f(y_n, x_n) \xi_n) - Tu + Tu - u\|^2 \\
\leq \left( \|T(x_n - \lambda_n f(y_n, x_n) \xi_n) - Tu\| + \|u - Tu\| \right)^2 \\
\leq \left( \|x_n - \lambda_n f(y_n, x_n) \xi_n\| + \|u - Tu\| \right)^2 \\
\leq \|x_n - u\|^2 + 2 \|x_n - \lambda_n f(y_n, x_n) \xi_n\| \|u - Tu\|^2 \\
\leq \|x_n - u\|^2 - 2\lambda_n f(y_n, x_n) (x_n - u, \xi_n) + \lambda_n^2 \|f(y_n, x_n)\|^2 \|\xi_n\|^2 \\
\leq \|x_n - u\|^2 + 2 \|x_n - \lambda_n f(y_n, x_n) \xi_n\| \|u - Tu\|^2 \\
\leq \|x_n - u\|^2 + \lambda_n f(y_n, x_n) (x_n - u, \xi_n) + 2 \|x_n - Tu\| \lambda_n f(y_n, x_n) \|\xi_n\| \\
\leq \|x_n - u\|^2 + \lambda_n (f(y_n, x_n))^2 \|\xi_n\|^2 - 2\lambda_n f(y_n, x_n) (x_n - u, \xi_n) + 2 \|x_n - Tu\| \lambda_n f(y_n, x_n) \|\xi_n\| \\
\leq \|x_n - u\|^2 + \lambda_n (f(y_n, x_n))^2 (\lambda_n M^2 - 2) + 2 \lambda_n f(y_n, x_n) f(y_n, u) + 2bM f(y_n, x_n) \frac{1}{k+1} \\
\leq \|x_n - u\|^2 + \|u - Tu\|^2 + \frac{1}{k+1} f(y_n, x_n) 2b(1 + M) \\
\leq \left(\|x_n - u\| + \frac{1}{k+1}\right)^2 + \frac{1}{k+1} f(y_n, x_n) 2b(1 + M)
\]
From this, it naturally follows that
\[
\|x_{n+1} - u\| \leq \|x_n - u\| + \frac{1}{k+1} + \frac{\sqrt{2b(1+M)}}{k+1}\sqrt{f(y_n, x_n)}.
\]

The claim
\[
\|x_{n+1} - u\| \leq \|x_n - u\| + \frac{l}{k+1} + \frac{\sqrt{2b(1+M)}}{k+1}\sum_{j=0}^{l-1} \sqrt{f(y_{n+j}, x_{n+j})}
\]
follows from this by induction on \(l \geq 1\) with \(n+l \leq k+1\) (the case of \(l = 0\) is trivial). \(\square\)

**Lemma 16.** Let \(M \geq \|\xi_n\|\) for all \(n \in \mathbb{N}\) and let \(\lambda_n \in [a, b] \subseteq (0, 2/M^2)\) for all \(n \in \mathbb{N}\). Further let \(c \geq f(y_n, x_n)\) for all \(n \in \mathbb{N}\). Then \((x_n)_{n \in \mathbb{N}}\) is uniformly Fejér monotone with modulus \(\chi(n, m, r)\), that is for all \(r, n, m \in \mathbb{N}\):
\[
\forall u \in \Omega_k^r \forall l \leq m \left(\|x_{n+l} - u\| \leq \|x_n - u\| + \frac{1}{r+1}\right)
\]
where
\[
k = \chi(n, m, r) = \max \left\{ n + m, \left( (r+1)^2m^2(1 + \sqrt{2be(1+M)})^2 \right) \right\}.
\]

**Proof.** Fix \(r, n, m \in \mathbb{N}\). Let \(k = \chi(n, m, r)\), \(u \in \Omega_k^r\) and \(l \leq m\). By Lemma 15 we have (as \(k+1 \geq n+m \geq n+l\) by definition)
\[
(\star) \quad \|x_{n+l} - u\| \leq \|x_n - u\| + \frac{l}{k+1} + \frac{\sqrt{2b(1+M)}}{k+1}\sum_{j=0}^{l-1} \sqrt{f(y_{n+j}, x_{n+j})}
\]
by using \(f(y_n, x_n) \leq c\), we obtain
\[
\|x_{n+l} - u\| \leq \|x_n - u\| + \frac{l}{k+1} + \frac{\sqrt{2b(1+M)}}{k+1}l\sqrt{c}
\]
\[
\leq \|x_n - u\| + \frac{m}{k+1} + \frac{m\sqrt{2be(1+M)}}{k+1}
\]
from (\(\star\)) as \(l \leq m\). As
\[
k \geq \left( (r+1)^2m^2(1 + \sqrt{2be(1+M)})^2 \right),
\]
we obtain
\[
\|x_{n+l} - u\| \leq \|x_n - u\| + \frac{m}{(r+1)^2m^2(1 + \sqrt{2be(1+M)})^2} + \frac{m}{(r+1)m(1 + \sqrt{2be(1+M)})}
\]
\[
\leq \|x_n - u\| + \frac{1}{r+1} \cdot \frac{1}{m(1 + \sqrt{2be(1+M)})} \cdot m + \frac{m\sqrt{2be(1+M)}}{k+1}
\]
from this. \(\square\)

Applying Theorem 5.1 from [6], we now obtain a rate of metastability for \((x_n)_{n \in \mathbb{N}}\).

**Theorem 17** (Quantitative version of Theorem 3 part (c), 1). Let \(c \geq f(y_n, x_n)\) and \(M \geq \|\xi_n\|\) for all \(n \in \mathbb{N}\). Also, let \(\lambda_n \in [a, b] \subseteq (0, 2/M^2)\) for all \(n \in \mathbb{N}\) as well as \(L \geq \text{diam}\{x_n \mid n \in \mathbb{N}\}\). Further, let \(\varepsilon_n \geq 0\), \(\varepsilon_n \to 0\) \((n \to \infty)\) and \(\tau\) be a nondecreasing rate of convergence for \(\varepsilon_n \to 0\) \((n \to \infty)\). Let \(u \in \Omega \neq \emptyset\) with \(c_u \geq \|x_0 - u\|^2\).

Then, for all \(k \in \mathbb{N}\) and all \(g \in \mathbb{N}^\mathbb{N}\):
\[
\exists n \leq \Sigma(k, g) \forall i, j \in [n; n+g(n)] \left( \|x_i - x_j\| \leq \frac{1}{k+1} \right)
\]
for \(\Sigma(k, g) = \Sigma_0(P(k), k, g, \chi, \Phi)\) with
\[
P(k) = \left( (8k + 8)\sqrt{N}L \right)^N
\]
and
\[
\begin{align*}
\Sigma_0(0, k, g, \chi, \Phi) &= 0, \\
\Sigma_0(n + 1, k, g, \chi, \Phi) &= \Phi(\chi_g^{max}(\Sigma_0(n, k, g, \chi, \Phi), 4k + 3)),
\end{align*}
\]
where we define
\[
\chi(n, m, r) = \max \{n + m, [(r + 1)^2]^{\beta}(b, e, M)\},
\]
\[
\chi_g(n, k) = \chi(n, g(n), k), \quad \chi_g^{max}(n, k) = \max \{\chi_g(i, k) \mid i \leq n\},
\]
and we define \(k\) as we assume \(L\) to be a modulus of total boundedness of \(B_L(0)\) and, considering the definition of (II)-moduli of total boundedness from [6], it is straightforward to see that \(\Phi(k) := [c_u(\sigma(a, b, M, L))^416(k + 1)^4] \cdot \max \{k, r(2k + 1)\} + 1, 1\),
\]
as well as
\[
\begin{align*}
\alpha(a, b, M) &:= -a(M^2b - 2), \\
\beta(b, e, M) &:= \left(1 + \sqrt{2be(1 + M)}\right)^2, \\
\sigma(a, b, M, L) &:= \left(\frac{\sqrt{2M}}{\sqrt{\alpha(a, b, M)}} + \frac{Mb}{\sqrt{\alpha(a, b, M)}} + 1\right).
\end{align*}
\]

Proof. The proof is an application of Theorem 5.1 from [6] with \(X := B_L(x_0)\) and \(F := \Omega \cap X, AF_k := \Omega_k \cap X\) (and \(G := H := Id\)). Here we use that we have
\[
(x_n)_{n \in \mathbb{N}} \subseteq B_L(x_0)
\]
as we assume \(L \geq \text{diam}\{x_n \mid n \in \mathbb{N}\}\) and we have \(\|x_n - x_0\| \leq \text{diam}\{x_n \mid n \in \mathbb{N}\}\) by definition of the diameter. By Example 2.8 of [6], the function \(\gamma(k) = \left(2(k + 1)\sqrt{NL}\right)^N\) is a modulus of total boundedness of \(L = B_L(0)\) and, considering the definition of (II)-moduli of total boundedness from [6], it is straightforward to see that these moduli are ‘translation-invariant’ in the case of normed vector spaces, i.e. any (II)-modulus of total boundedness for a set \(A \subseteq \mathbb{R}^N\) is also a (II)-modulus of total boundedness for \(A + v := \{a + v \mid a \in A\}\) with \(v \in \mathbb{R}^N\). In our situation, we thus have that the particular \(\gamma\) is also a (II)-modulus of total boundedness for \(B_L(x_0) = B_L(0) + x_0\). By Lemma [13] \(\Phi\) is an approximate \(F\)-point bound and by Lemma [13] \(\chi\) is a modulus for \((x_n)_{n \in \mathbb{N}}\) being uniformly Fejér monotone w.r.t. \(F\) (and \(AF_k\)). Applying Theorem 5.1 with \(\gamma, \Phi, \chi\) gives the result.

Remark 18. In the above theorem, we can obtain a bound \(e\) on \(f(y_n, x_n)\) in terms of \(c_u, a, b\) and \(M\) by setting
\[
e := \frac{c_u}{\sqrt{-a(M^2b - 2)}}
\]
as we have (using Lemma [9]):
\[
f(y_n, x_n) \leq \frac{1}{\sqrt{-a(M^2b - 2)}} \sqrt{\|x_n - u\|^2 - \|x_{n+1} - u\|^2} \\
\leq \frac{1}{\sqrt{-a(M^2b - 2)}} \|x_n - u\| \\
\leq \frac{\sqrt{c_w}}{\sqrt{-a(M^2b - 2)}}.
\]

3. Adding further assumptions

In this section, we investigate two sets of assumptions to strengthen Theorem [17].

3.1. Uniform closedness. In [6], the authors introduce the notion of uniform closedness, an additional assumption on the way the sets \(AF_k\) approach the set \(F\) (using the notation of the previous general setting of Definition [13]).

We recall the corresponding definition.

Definition 19. Let \((X, d)\) be a metric space and \(F \subseteq X\) be nonempty. Let \(AF_k \subseteq X\) be closed with \(AF_k \supseteq AF_{k+1}\) and \(F = \cap_{k \in \mathbb{N}} AF_k\). \(F\) is called uniformly closed for \((AF_k)_{k \in \mathbb{N}}\) with moduli \(\delta_F, \omega_F : \mathbb{N} \to \mathbb{N}\) if
\[
\forall k \in \mathbb{N} \forall p, q \in X \left( q \in AF_{\delta_F(k)} \text{ and } d(p, q) \leq \frac{1}{\omega_F(k) + 1} \Rightarrow p \in AF_k \right).
\]
Under the assumption of uniform closedness, the authors obtain Theorem 5.3 in [6] as a strengthening of Theorem 5.1. In the following, we will observe that, under further quantitative assumptions on the equilibrium function \( f \), \( \Omega \) is uniformly closed with the previously defined approximations \((\Omega'_k)_{k \in \mathbb{N}}\) and compute the corresponding moduli of uniform closedness.

**Definition 20.** Let \( g : D \subseteq \mathbb{R}^N \to \mathbb{R} \) be uniformly continuous. A modulus of uniform continuity for \( g \) on \( D \subseteq \mathbb{R}^N \) is a function \( \sigma : \mathbb{N} \to \mathbb{N} \) such that

\[
\forall k \in \mathbb{N} \forall x, x' \in D \left( \|x - x'\| \leq \frac{1}{\sigma(k) + 1} \Rightarrow |g(x) - g(x')| \leq \frac{1}{k + 1} \right).
\]

This notion of modulus of uniform continuity differs from the commonly known modulus of continuity in (numerical) analysis but is commonly used in computable and constructive analysis as well as in proof mining (see e.g. [1][3][13]).

We then obtain the following result giving corresponding moduli of uniform closedness in terms of moduli of uniform continuity.

**Lemma 21.** Let \((y_j)_{j \in \mathbb{N}}\) be a sequence in \( \mathbb{R}^N \) (defining \( \Omega'_k \)) and let \( \sigma_j \) be moduli of uniform continuity for \( f(y_j, \cdot) \) for all \( j \in \mathbb{N} \) on some subset \( D \subseteq \mathbb{R}^N \). Then

\[
\forall k \in \mathbb{N} \forall u, u' \in D \left( u' \in \Omega'_k \right) \text{ and } \|u - u'\| \leq \frac{1}{\omega_k(k + 1)} \Rightarrow u \in \Omega'_k
\]

where

\[
\left\{ \begin{array}{l}
\delta(k) = 2k + 1, \\
\sigma^\text{max}(k) = \max\{\sigma_i(k) \mid i \leq j\}, \\
\omega_k(k) = \max(4k + 3, \sigma^\text{max}(2k + 1)) \end{array} \right.
\]

**Proof.** Let \( k \in \mathbb{N} \) and let \( u, u' \in D \) with \( u' \in \Omega'_{2k+1} \) and

\[
\|u - u'\| \leq \frac{1}{\omega_k(k + 1)}.
\]

\( u' \in \Omega'_{2k+1} \) is by definition equivalent to

\[
\|u' - Tu'\| \leq \frac{1}{2(k + 1)} \text{ and } \forall j \leq 2k + 1 \left( f(y_j, u') \leq \frac{1}{2(k + 1)} \right).
\]

As \( T \) is especially nonexpansive, we have \( \|Tu - Tu'\| \leq \|u - u'\| \). As \( \omega_k(k) \geq 4k + 3 \), we have further

\[
\|u - u'\| \leq \frac{1}{\omega_k(k + 1)} \leq \frac{1}{4(k + 1)}
\]

and thus

\[
\|u - Tu\| \leq \|u - u'\| + \|u' - Tu'\| + \|Tu - Tu'\|
\]

\[
\leq 2\|u - u'\| + \|u' - Tu'\|
\]

\[
\leq 2\frac{1}{4(k + 1)} + \frac{1}{2(k + 1)} = \frac{1}{k + 1}.
\]

As \( \omega_k(k) \geq \sigma^{\text{max}}(2k + 1) \geq \sigma_i(2k + 1) \) for all \( i \leq k \) by assumption, we have

\[
\|u - u'\| \leq \frac{1}{\omega_k(k + 1)} \leq \frac{1}{\sigma_i(2k + 1) + 1}
\]

for all \( i \leq k \) and as \( \sigma_i \) is a modulus of uniform continuity for \( f(y_i, \cdot) \), we have

\[
f(y_i, u) \leq f(y_i, u') + |f(y_i, u) - f(y_i, u')|
\]

\[
\leq \frac{1}{2(k + 1)} + \frac{1}{2(k + 1)} = \frac{1}{k + 1}
\]

for all \( i \leq k \). Thus, by definition we have \( u \in \Omega'_k \). \( \Box \)

Using these moduli, we obtain the following strengthening of Theorem 17 in correspondence to Theorem 5.3 instead of Theorem 5.1 (of [6]).
Theorem 22 (Quantitative version of Theorem 3 part (c), II). In addition to the assumptions of Theorem 17, let $\sigma$ be a modulus of uniform continuity for $f(g_j, \cdot)$ for any $j \in \mathbb{N}$ on $B_L(x_0)$.

Then, for all $k \in \mathbb{N}$ and all $g \in \mathbb{N}^N$:

$$\exists n \leq \tilde{\Sigma}(k, g) \forall i, j \in [n; n + g(n)] \left( \|x_i - x_j\| \leq \frac{1}{k + 1} \quad \text{and} \quad x_i \in \Omega^k \right)$$

for $\tilde{\Sigma}(k, g) = \Sigma_0(P(k_0), k_0, g, \chi_k, \Phi)$ with $P, \chi, \Phi$ and $\Sigma_0$ as in Theorem 17 as well as

$$k_0 := \max \left\{ k, \left[ \frac{\omega_0(k) - 1}{2} \right] \right\}$$

and

$$\chi_k(n, m, r) := \max \{ \delta_0(k), \chi(n, m, r) \},$$

where we define

$$\delta_0(k) = 2k + 1,$$

$$\sigma_{\max}^j(k) = \max \{ \sigma_i(k) \mid i \leq j \},$$

$$\omega_0(k) = \max \{ 4k + 3, \sigma_{\max}^j(2k + 1) \}.$$

Proof. Apply Theorem 5.3 of [1] under the same considerations as in the proof of Theorem 14 using Lemma 21 with $D := B_L(x_0)$. The Lemmas 14 and 16 apply as before. \qed

Remark 23. This theorem is a finitization of Theorem 3 part (c) as it (ineffectively, but elementary) implies back the statement of (c): the metastability trivially implies the Cauchy-statement (and thus convergence) of $(x_n)_{n \in \mathbb{N}}$. Further: For $M \in \mathbb{N}$ and $g$ s.t. $n \mapsto M$, Theorem 22 gives $\exists i \geq M \ (x_i \in \Omega^k)$. Thus, as $\Omega^k$ is closed, we have $x := \lim_{n \to \infty} x_n \in \Omega^k$ and as $k$ was arbitrary, we have $x \in \Omega$ by $\Omega = \bigcap_{k \in \mathbb{N}} \Omega^k$. As in [2], p. 258, it follows elementary that $x \in EP(Fix(T), f)$.

3.2. Regularity conditions. Using the recent quantitative treatment [8] of very general scenarios of regularity conditions in the context of Fejér monotone sequences, we can give an improvement of Theorems 17 and 22 by adding assumptions on (a quantitative version of) a regularity condition for $\Omega$ and obtain (under this assumption) even rates of convergence for the sequence approximating an equilibrium point.

Central for the further results is the following quantitative version of regularity, defined as modulus of regularity in [8]. For this, given a function $F : \mathbb{R}^N \to \mathbb{R}$, we write $zer F$ for the set of zeros of $F$.

Definition 24 ([8]). Let $F : \mathbb{R}^N \to \mathbb{R}$ be a function with $zer F \neq \emptyset$ and fix $z \in zer F$ and $r > 0$. A function $\phi : (0, \infty) \to (0, \infty)$ is a modulus of regularity for $F$ w.r.t. $zer F$ and $B_r(z)$ if for all $\varepsilon > 0$ and all $x \in B_r(z)$:

$$|F(x)| < \phi(\varepsilon) \Rightarrow \text{dist}(x, zer F) < \varepsilon.$$ 

The setting for these regularity conditions in [8] is far more general, e.g. being in the context of abstract metric spaces. We will, however, only need the above version for functions over $\mathbb{R}^N$.

Under the assumption of a modulus of regularity for $F$ together with the Fejér monotonicity of a sequence $(x_n)_{n \in \mathbb{N}}$ w.r.t. $zer F$ and some further assumptions on quantitative information on the way how the sequence $(x_n)_{n \in \mathbb{N}}$ interacts with $F$, the authors obtain effective rates of convergence for the sequence $(x_n)_{n \in \mathbb{N}}$.

By quantitative information on the interaction of $(x_n)_{n \in \mathbb{N}}$ with $F$, we mean precisely that $(x_n)_{n \in \mathbb{N}}$ has approximate $F$ zeros. For this, recall the following (modification of the) definition from [8].

Definition 25. Let $F$ be as above. We say that a sequence $(x_n)_{n \in \mathbb{N}}$ has approximate $F$ zeros if

$$\forall k \in \mathbb{N} \exists n \in \mathbb{N} \left( F(x_n) < \frac{1}{k + 1} \right).$$

A bound on $\forall n \in \mathbb{N}$ is called an approximate zero bound.

Notice the similarity of approximate zeros with approximate $F$-points from Definition 13 (although there $F$ has a different meaning). Guided by this similarity, the fact that the particular sequence $(x_n)_{n \in \mathbb{N}}$ from Algorithm 2 has approximate $\Omega$-points (relative to the representation $(\Omega^k)_{k \in \mathbb{N}}$) and the fact that $(x_n)_{n \in \mathbb{N}}$ is Fejér monotone w.r.t. $\Omega$, we are particularly interested in a function $F$ where (1) $zer F = \Omega$ and (2) $|F(x)| < 1/(k + 1)$ relates to $x \in \Omega^k$. Towards a particular choice, we first define the set-valued function $\gamma : \mathbb{R}^N \to \mathcal{P}(\mathbb{N})$ through

$$\gamma(x) := \{ k \in \mathbb{N} \mid f(y_j, x) > \frac{1}{k + 1} \text{ for some } j \leq k \}$$
and the corresponding function $G : \mathbb{R}^N \to \mathbb{R}$ defined through

$$G(x) = \begin{cases} 0 & \text{if } \gamma(x) = \emptyset, \\ 2 & \text{if } \gamma(x) = \mathbb{N}, \\ \min \gamma(x) & \text{otherwise.} \end{cases}$$

Given a mapping $T : \mathbb{R}^N \to \mathbb{R}^N$, we may further define the function

$$F(x) = \max(\|x - Tx\|, G(x)).$$

This function is now an adequate choice which fulfills the previously desired requirements (1) and (2). For this, note first that $\gamma(x)$ has the following property whose proof is immediate:

**Lemma 26.** For any $x \in \mathbb{R}^N$ and any $k \in \mathbb{N}$: $k \in \gamma(x)$ implies $j \in \gamma(x)$ for all $j \geq k$.

In the following, we verify properties (1) and (2) for $F$:

**Lemma 27.** For all $x \in \mathbb{R}^N$ and all $k \in \mathbb{N}$: $x \in \Omega'_k$ iff $F(x) \leq \frac{1}{k+1}$. In particular, $x \in \Omega$ iff $x \in \ker F$.

**Proof.** Let $x \in \mathbb{R}^N$ and let $k \in \mathbb{N}$ and suppose first that $x \in \Omega'_k$. Then, we have

$$\|x - Tx\| \leq \frac{1}{k+1} \quad \text{and} \quad f(y_j, x) \leq \frac{1}{k+1} \quad \text{for all } j \leq k.$$ 

The latter gives $k \not\in \gamma(x)$ and thus $j \not\in \gamma(x)$ for all $j \leq k$ by the contraposition of Lemma 26. Now, either $\gamma(x) = \emptyset$ or $\gamma(x) \neq \emptyset$. The former gives $G(x) = 0 \leq \frac{1}{k+1}$ by definition, the latter gives $\inf \gamma(x) \geq k + 1$ and thus $G(x) = 1/(\inf \gamma(x)) \leq 1/(k + 1)$. In any way $F(x) \leq 1/(k + 1)$.

Now, suppose $x \not\in \Omega'_k$. Then, $\|x - Tx\| > \frac{1}{k+1}$ or $f(y_j, x) > \frac{1}{k+1}$ for some $j \leq k$. The former gives $F(x) > \frac{1}{k+1}$ immediately. The latter gives $k \in \gamma(x)$. Thus,

$$\inf \gamma(x) \leq k < k + 1$$

and therefore, we have $\gamma(x) = \mathbb{N}$ where $G(x) = 2 > \frac{1}{k+1}$ by definition, or $\inf \gamma(x) \geq 1$ where then

$$G(x) = \frac{1}{\inf \gamma(x)} > \frac{1}{k + 1}.$$ 

In any way $F(x) > 1/(k + 1)$.

Together with the previous results on approximate $\Omega$ points from Lemma 14 we obtain the following result regarding approximate $F$ zeros.

**Lemma 28.** Let $u \in \Omega \not= \emptyset$ with $c_u \geq \|x_0 - u\|^2$ and let $M \geq \|\xi_n\|$ for all $n \in \mathbb{N}$. Let $\lambda_n \in [a, b] \subseteq (0, 2/M^2)$ for all $n \in \mathbb{N}$ as well as $L \geq \text{diam}\{x_n \mid n \in \mathbb{N}\}$. Further, let $\varepsilon_n \geq 0$ for all $n \in \mathbb{N}$ and let $\varepsilon_n \to 0$ ($n \to \infty$) where $\tau$ is a nondecreasing rate of convergence for $\varepsilon_n \to 0$ ($n \to \infty$). Let $\Phi$ be as in Lemma 14. Then for any $k \in \mathbb{N}$

$$\exists n \leq \Phi(k, a, b, M, L, \tau, c_u) \left( F(x_n) \leq \frac{1}{k + 1} \right).$$

**Proof.** By Lemma 14 we have

$$\exists n \leq \Phi(k, a, b, M, L, \tau, c_u) \left( x_n \in \Omega'_k \right).$$

By Lemma 27 this implies $F(x_n) \leq \frac{1}{k+1}$.

As the function $F$ may be perceived to be quite ‘constructed’, it is of interest to see equivalent characterizations for the existence of a modulus of regularity for $F$. The following easy consequence of Lemma 27 gives a result in this vein.

**Lemma 29.** Let $u \in \Omega$ and let $r > 0$. Then:

1. If $\phi : (0, \infty) \to (0, \infty)$ is a modulus of regularity for $F$ w.r.t. $\Omega$ and $B_r(u)$, then
   $$\forall \varepsilon > 0 \forall x \in B_r(u) \left( x \in \Omega'_r \right) \Rightarrow \text{dist}(x, \Omega) < \varepsilon.$$

2. If $\phi : (0, \infty) \to \mathbb{N}$ is such that
   $$\forall \varepsilon > 0 \forall x \in B_r(u) \left( x \in \Omega'_{\phi(\varepsilon)} \right) \Rightarrow \text{dist}(x, \Omega) < \varepsilon,$$
   then $1/(\phi(\varepsilon) + 1)$ is a modulus of regularity for $F$ w.r.t. $\Omega$ and $B_r(u)$.
Using this lemma, we obtain the following rate of convergence for the sequence \((x_n)_{n \in \mathbb{N}}\) generated by Algorithm 2 under the assumption of a modulus of regularity for \(F\).

**Theorem 30.** Let \(u \in \Omega \neq \emptyset\) with \(c_b \geq \|x_0 - u\|^2\) and let \(M \geq \|\xi_n\|\) for all \(n \in \mathbb{N}\). Let \(\lambda_n \in [a,b] \subseteq (0,2/M^2)\) for all \(n \in \mathbb{N}\) as well as \(L \geq \text{diam}\{x_n \mid n \in \mathbb{N}\}\). Further, let \(\varepsilon_n \geq 0\) for all \(n \in \mathbb{N}\) and suppose \(\varepsilon_n \to 0\) \((n \to \infty)\) with a rate of convergence \(\tau\).

If \(\psi : (0,\infty) \to \mathbb{N}\) is such that
\[
\forall \varepsilon > 0 \exists x \in B_{\sqrt{\varepsilon}}(u) \left( x \in \Omega^\prime_{\phi(\varepsilon)} \Rightarrow \text{dist}(x,\Omega) < \varepsilon \right),
\]
then \((x_n)_{n \in \mathbb{N}}\) is convergent with \(x = \lim_{n \to \infty} x_n \in \text{EP}(\text{Fix}(T), f)\) and
\[
\forall k \in \mathbb{N} \forall n \geq \Phi\left( \frac{1}{2(k + 1)} \right) \left( \|x_n - x\| < \frac{1}{k + 1} \right)
\]
where we define
\[
\phi(\varepsilon) = \frac{1}{\psi(\varepsilon) + 1}
\]
and
\[
\Phi(\varepsilon) := \left[ c_a(\sigma(a,b,M,L))^4 \left( \left[ \frac{1}{\varepsilon} \right] + 1 \right)^4 \right] \cdot \max \left( \left[ \frac{1}{\varepsilon} \right], \tau \left( 2 \left[ \frac{1}{\varepsilon} \right] + 1 \right) \right) + 1,
\]
as well as
\[
\alpha(a,b,M) := -a(M^2b - 2), \quad \sigma(a,b,M,L) := \left( \frac{\sqrt{2MbL}}{\sqrt{\alpha(a,b,M)}} + \frac{Mb + 1}{\sqrt{\alpha(a,b,M)}} + 1 \right).
\]

**Proof.** The proof is an application of Theorem 4.1, (i) of [3]. Fejér monotonicity of \((x_n)_{n \in \mathbb{N}}\) w.r.t \(\Omega\) is already contained in (a) of Theorem 3. By Lemma 29 (2), \(\phi\) is a modulus of regularity for \(F\).

Now, let \(\varepsilon > 0\). Then, by Lemma 28 we obtain
\[
\exists n \leq \Phi(\varepsilon) \left( F(x_n) \leq \frac{1}{\left[ 1/\varepsilon \right] + 1} < \varepsilon \right).
\]
As \(\varepsilon\) was arbitrary, Theorem 4.1 of [3] applies as \(\Omega\) is closed and we obtain \(x = \lim_{n \to \infty} x_n \in \Omega\) with the desired rate of convergence. We obtain \(x \in \text{EP}(\text{Fix}(T), f)\) as in [2], p. 258.
