Abstract. We prove that the energy of any eigenvector of a sum of several independent large Wigner matrices is equally distributed among these matrices with very high precision. This shows a particularly strong microcanonical form of the equipartition principle for quantum systems whose components are modelled by Wigner matrices.

Date: August 17, 2020
Keywords: Equipartition of energy, Wigner matrices, cumulant expansion
AMS Subject Classification (2020): 60B20, 82B10

1. Introduction

Equipartition of energy is a general principle in classical statistical physics stating that in an ergodic system at equilibrium the total energy is shared equally among the elementary degrees of freedom. In quantum systems equipartition breaks down at very low temperatures. Even at higher temperatures there is no general quantum counterpart of this principle apart from the standard quantum virial theorem that only relates the total kinetic energy to a certain derivative of the potential. Nevertheless, in some special cases this principle could be verified; see [3] and references therein for an extensive physics literature on the popular model of a single quantum particle in contact with a quantum heat bath consisting of infinitely many harmonic oscillators.

In the current paper we show that for Wigner random matrices, i.e. for a mean-field quantum system with random quantum transition rates, a particularly strong microcanonical form of the quantum equipartition holds: it is valid separately for every eigenvector.

More precisely, suppose that the total Hamiltonian of a quantum system is represented by a sum of independent $N \times N$ Wigner matrices $H = H_1 + H_2 + \ldots + H_k$, where each $H_i$ represents the Hamiltonian of a subsystem. Let $w = (w(1), \ldots, w(N))^\top \in \mathbb{C}^N$ be an $\ell^2$-normalized eigenvector of $H$ with eigenvalue $\lambda$, i.e. $Hw = \lambda w$. The eigenvalue $\lambda$ is the total energy of $w$:

$$\lambda = E(w) := (w, Hw) = \sum_{i=1}^k (w, H_i w).$$

The energy of the $i$-th subsystem $H_i$ in the state given by $w$ is $E_i(w) := (w, H_i w)$. Our main result asserts that

$$E_i(w) \approx \frac{E(w)}{k}, \quad \forall i = 1, 2, \ldots k,$$

(1.1)

with very high precision and with very high probability. In other words, the total energy is equally distributed among the $k$ subsystems.

Fine properties of eigenvectors of large Wigner matrices have been extensively studied in the recent years. They are delocalized i.e. $\max_i |w(i)| \leq N^{-1/2+\epsilon}$ for any fixed $\epsilon > 0$ with very high probability as $N$ tends to infinity. Delocalization follows directly from the optimal local law, see e.g. [7], and [2] for an optimal rate. Moreover, the eigenvectors are asymptotically normal, in the sense that for any fixed deterministic vector $q \in \mathbb{C}^N$ the moments of $\sqrt{N}|(q, w)|$ coincide with those of the modulus of a standard Gaussian [4, 10, 14]. A multi-variate extension involving the joint moments of several eigenvectors also holds [4]. Furthermore, the quantum unique ergodicity is also valid, stating that

$$\sum_{i \in J} |w(i)|^2 \approx \frac{|J|}{N},$$

(1.2)

for any deterministic subset $J \subset \{1, 2, \ldots, N\}$; see [1, 4, 13]. The key difficulty in these latter results was to prove them microcanonically, i.e. for each eigenvector; this required the sophisticated equilibration mechanism of the Dyson Brownian motion. In contrast, the local law (see Theorem 4.1 later) directly implies the analogous results for a spectral projection on mesoscopic scale, e.g.

$$\frac{1}{2N^\epsilon} \sum_{|\alpha - \alpha_0| \leq N^\epsilon} \sum_{i \in J} |w_{\alpha}(i)|^2 \approx \frac{|J|}{N},$$

(1.3)

instead of (1.2), involving an average over many eigenvectors $w_{\alpha}$ with eigenvalues $\lambda_\alpha$ near $\lambda_{\alpha_0}$ with a fixed $\alpha_0$. Here the eigenvalues $\lambda_\alpha$ are indexed in an increasing order, $\lambda_1 \leq \lambda_2 \leq \ldots \leq \lambda_N$.

In all these previous results the eigenvector was tested against a specific deterministic observable; while in the equipartition relation (1.1) we consider the quadratic form of $w$ with a random $H$, that is far from being independent of $w$. Given the complicated dependence between $w$ and $H$, it is somewhat surprising that the proof of (1.1) is simpler than that of (1.2). In fact, despite this dependence, we can still directly handle $(w, H_i w)$ for an individual eigenvector, i.e. we do not need to establish first a spectrally local-averaged version of (1.1) in the form

$$\frac{1}{2N^\epsilon} \sum_{|\alpha - \alpha_0| \leq N^\epsilon} (w_\alpha, H_i w_\alpha) \approx \frac{\lambda_{\alpha_0}}{k},$$

and then prove that $(w_\alpha, H_i w_\alpha)$ does not change much if the eigenvalue $\lambda_\alpha$ remains close to a fixed energy.

The main reason for the simple proof is algebraic. Consider $k = 2$ for simplicity. It turns out that the quadratic forms of $\mathcal{H} := H_1 - H_2$ are especially small due to a strong algebraic cancellation in the cumulant expansion. Once the smallness of $(w, \mathcal{H} w) = (w, H_1 w) - (w, H_2 w)$ is established, (1.1) follows from $\lambda = (w, H_1 w) + (w, H_2 w)$.

To demonstrate the central role of $\mathcal{H}$, in the next section we first give the proof of (1.1) for $k = 2$ in the Gaussian case, where the mechanism is especially elementary. Then we introduce the general model and properly state our result in Section 3. After collecting some preliminaries from earlier papers in Section 4, we will prove our main theorem starting in Section 5 for the complex Hermitian case under the additional condition $\mathbb{E} h_{i,j}^2 = 0$ on the entries of each
2. A simple proof of (1.1) for the Gaussian case and $k = 2$

Assume we are given two independent GUE random matrices $H_1$ and $H_2$ of size $N \times N$, i.e. their entries are two sets of independent complex centered Gaussian random variables of variance $\frac{1}{2N}$ subject to the symmetry constraint $H_1 = H_1^*$ and $H_2 = H_2^*$. Then clearly the sum
\[
H := H_1 + H_2
\]
also belongs to the standard Gaussian unitary ensemble (GUE). Denote by $(\lambda_\alpha)_\alpha$ the eigenvalues in ascending order of $H$ and let $(w_\alpha)_\alpha$ be an associated normalized eigenbasis, i.e. we have $(w_\alpha, H w_\beta) = \delta_{\alpha\beta} \lambda_\alpha$, for any choice of indices $\alpha, \beta$.

Consider now the random variables
\[
(w_\alpha, H_1 w_\beta) - \frac{\delta_{\alpha\beta}}{2} \lambda_\alpha.
\]
We claim that, for any $N$, these random variables are Gaussian.

**Lemma 2.1.** For any choice of index $\alpha$ the random variable
\[
(w_\alpha, H_1 w_\alpha) - \frac{1}{2} \lambda_\alpha
\]
is a centered real Gaussian random variable with variance $\frac{1}{4N}$, for any $N$. Moreover, for any choice of indices $\alpha$ and $\beta$, with $\alpha \neq \beta$, the random variable
\[
(w_\alpha, H_1 w_\beta)
\]
is a centered complex Gaussian random variable of variance $\frac{1}{4N}$, for any $N$.

**Proof.** Introduce the auxiliary matrix
\[
H := H_1 - H_2,
\]
whose entries are also independent centered Gaussian random variables, up to the symmetry constraint, with variance $\mathbb{E}[|H_{ij}|^2] = \frac{1}{4}$. A simple calculation then shows that $\mathbb{E}[H_{ij} H_{ab}] = 0$, for all $i, j, a, b \in [1, N]$, hence the matrices $H$ and $H$ are independent. In particular, $H$ is independent from $w_\alpha$ and $w_\beta$, for any choice of $\alpha, \beta$.

Observe now that we can write the random variables in (2.2) and (2.3) as
\[
(w_\alpha, H_1 w_\beta) - \frac{1}{2} \lambda_\alpha \delta_{\alpha\beta} = (w_\alpha, H_1 w_\beta) - \frac{1}{2} (w_\alpha, H_1 w_\beta) - \frac{1}{2} (w_\alpha, H_2 w_\beta) = \frac{1}{2} (w_\alpha, H w_\beta).
\]
Hence by the independence of $H$ and $H$ we conclude that $\frac{1}{2} w_\alpha^* H w_\beta$ is a Gaussian random variable. Since $\mathbb{E}[H_{ij}] = 0$, it follows that $\mathbb{E}[w_\alpha^* H w_\beta] = 0$. Further we have
\[
\mathbb{E} |w_\alpha^* H w_\beta|^2 = \sum_{ijab} \mathbb{E} w_\alpha(i) H_{ij} w_\beta(j) w_\alpha(a) H_{ab} w_\beta(b) = \sum_{ijab} \frac{1}{N} \delta_{ia} \delta_{jb} |w_\alpha(a)|^2 |w_\beta(j)|^2 = \frac{1}{N},
\]
where we used independence and that the eigenvectors are $\ell^2$-normalized. The notation $\sum_{ijab}$ means that we sum over all indices from 1 to $N$. This shows (2.2) and (2.3). \qed
Notation: The symbol $O(\cdot)$ stands for the standard big-O notation. We use $c$ and $C$ to denote positive finite constants that do not depend on the matrix size $N$. Their values may change from line to line. We use double brackets to denote index sets, i.e. for $n_1, n_2 \in \mathbb{R}$, \([n_1, n_2] := [n_1, n_2] \cap \mathbb{Z}.

For vectors $v, w \in \mathbb{C}^N$, we write $v^* w = (v, w)$ for their scalar product. For an $N$ by $N$ matrix $A$, we denote by $\|A\|$ its operator norm and by $\|A\|_\infty := \max_{i,j} |A_{ij}|$. We use $\langle A \rangle := \frac{1}{N} \sum_{i} A_{ii}$ to denote the normalized trace of an $N \times N$ matrix $A = (A_{ij})_{N,N}$.

3. Definitions and results

In this section we introduce the model and our main result on equipartition.

**Assumption 3.1.** Fix an integer $k \geq 2$. Let $H_{\tau} := (h_{\tau,ij}), \tau = 1, 2, \ldots k$, be $k$ independent complex Hermitian Wigner matrices of size $N \times N$, i.e., we assume that their entries are independent centred random variables, up to the symmetry constraints $h_{\tau,ij} = \overline{h_{\tau,ji}}$, satisfying

$$E|h_{\tau,ij}|^2 = \frac{1}{N}, \quad 1 \leq i, j \leq N, \quad \tau = 1, \ldots k,$$

and the families of random variables $\{h_{\tau,ij}\}$ have finite moments to all order, i.e., for each $m \geq 3$ there is a positive constant $C_m$ such that

$$E|\sqrt{N}h_{\tau,ij}|^m \leq C_m, \quad m \geq 3, \quad \tau = 1, 2, \ldots k.$$  \hspace{1cm} (3.1)

For the main part of the paper we assume that $H_{\tau}$ are complex Hermitian matrices. This assumption is only for simplicity of the presentation; our result holds and the proof also applies with minor changes to the real symmetric setup as well; see Remark 3.5.

Choose now $k$ possibly $N$-dependent numbers $\sigma_\tau \geq 0$ such that

$$\sum_{\tau=1}^{k} \sigma_\tau^2 = 1,$$

and consider the random matrix

$$H := \sum_{\tau=1}^{k} \sigma_{\tau} H_{\tau}. \hspace{1cm} (3.4)$$

To present our results, we use the following definition of high-probability estimates.

**Definition 3.2.** Let $\mathcal{X} = \mathcal{X}^{(N)}$ and $\mathcal{Y} = \mathcal{Y}^{(N)}$ be two sequences of nonnegative random variables. We say that $\mathcal{Y}$ stochastically dominates $\mathcal{X}$ if, for all (small) $\epsilon > 0$ and (large) $D > 0$,

$$\mathbb{P}(\mathcal{X}^{(N)} > N^\epsilon \mathcal{Y}^{(N)}) \leq N^{-D},$$

for sufficiently large $N \geq N_0(\epsilon, D)$, and we write $\mathcal{X} \prec \mathcal{Y}$ or $\mathcal{X} = O_\prec(\mathcal{Y})$. When $\mathcal{X}^{(N)}$ and $\mathcal{Y}^{(N)}$ depend on a parameter $v \in \mathcal{V}$ (typically an index label or a spectral parameter), then $\mathcal{X}(v) \prec \mathcal{Y}(v)$, uniformly in $v \in \mathcal{V}$, means that the threshold $N_0(\epsilon, D)$ can be chosen independently of $v$.

We often use the notation $\prec$ also for deterministic quantities, then $\mathcal{X}^{(N)} \leq N^\epsilon \mathcal{Y}^{(N)}$ holds with probability one. Stochastic domination has the following properties.

**Lemma 3.3.** (Proposition 6.5 in [5])

1. $X \prec Y$ and $Y \prec Z$ imply $X \prec Z$;
2. If $X_1 \prec Y_1$ and $X_2 \prec Y_2$, then $X_1 + X_2 \prec Y_1 + Y_2$ and $X_1 X_2 \prec Y_1 Y_2$;
(3) If $X \prec Y$, $\mathbb{E} Y \geq N^{-c_1}$ and $|X| \leq N^{c_2}$ almost surely with fixed constants $c_1$ and $c_2$, then we have $\mathbb{E} X \prec \mathbb{E} Y$.

Let $(\lambda_\alpha)_\alpha$ be the eigenvalues of the matrix $H$ in ascending order and let $(w_\alpha)_\alpha$ be a basis of associated normalized eigenvectors. In this paper we are interested in estimating

$$w_\alpha^* H_i w_\beta - \sigma_i \lambda_\alpha \delta_{\alpha \beta}, \quad i = 1, \ldots, k,$$

for any choice of $\alpha, \beta \in [1, N]$.

**Theorem 3.4.** Let $H$ be given by (3.4), and assume $H_i, i = 1, \ldots, k$, satisfy Assumption 3.1 and that $\sigma_i, i = 1, \ldots, k$, satisfy (3.3). Then

$$\left| w_\alpha^* H_i w_\beta - \sigma_i \lambda_\alpha \delta_{\alpha \beta} \right| \prec \frac{1}{\sqrt{N}},$$

for all $\alpha, \beta \in [1, N]$ and $i \in [1, k]$.

**Remark 3.5.** We formulated Theorem 3.4 for complex Hermitian Wigner matrices, but with some modifications our method and results carry over the real symmetric case; see Theorem 8.2 below. The details are given in Section 8.

We further remark that one may also consider a mixed symmetry setup where some $H_i$'s are complex Hermitian Wigner matrices while the remaining $H_i$ are real symmetric Wigner matrices. The arguments in Section 8 can be extended to such a setting and (3.7) indeed holds under this setup as well.

### 4. Preliminaries

In this section we collect some essential tools used in the proof of Theorem 3.4. We start with the Green function of the random matrix $H$ and the corresponding local laws.

#### 4.1. Local law for the Green function and rigidity of eigenvalues.

For any probability measure $\mu$ on $\mathbb{R}$, its Stieltjes transform is defined as

$$m_\mu(z) := \int_{\mathbb{R}} \frac{1}{x - z} d\mu(x), \quad z \in \mathbb{C} \setminus \mathbb{R}. \tag{4.1}$$

We denote the Stieltjes transform of the standard semicircular law by $m_{sc}(z)$.

Let $G$ denote the Green function or resolvent of $H$, i.e.

$$G(z) := \frac{1}{H - z}, \quad z \in \mathbb{C} \setminus \mathbb{R}. \tag{4.2}$$

We refer to $z = E + i\eta$ in (4.1) and (4.2) as spectral parameter. We denote by $m(z)$ the normalized trace of $G(z)$, i.e.,

$$m(z) = \frac{1}{N} \text{Tr} G(z) = \langle G(z) \rangle, \quad z \in \mathbb{C} \setminus \mathbb{R}, \tag{4.3}$$

and note that by the spectral calculus $m(z)$ is the Stieltjes transform of the empirical eigenvalue distribution of $H$. Finally, we recall the deterministic estimate $\|G(z)\|_\infty \leq \|G(z)\| \leq |\eta|^{-1}$ with $\eta = \text{Im} z$.

We are interested for energies $E$ in a neighborhood of the support of the semicircular law, i.e. $|E| < 2 + \varrho$, for some fixed $\varrho > 0$. Further, fix a small $\epsilon > 0$, and introduce the spectral domain

$$\mathcal{E} := \{z = E + i\eta \in \mathbb{C} : E \in [-2 - \varrho, 2 + \varrho], N^{-1+\epsilon} \leq |\eta| \leq 1\}. \tag{4.4}$$
For \( z, z' \in \mathcal{E} \), let \( \Psi(z, z') \) denote the deterministic control parameter
\[
\Psi(z, z') := \frac{1}{\sqrt{N \eta_0}}, \quad \eta_0 = \min\{\|\text{Im} z\|, \|\text{Im} z'\|\},
\]
and we use the convention \( \Psi(z, z) \equiv \Psi(z) \).

Let \( \gamma_\alpha \) be the \( \alpha \)-th \( N \)-quantile of the semicircle law, i.e. \( \gamma_\alpha \) is determined by
\[
\int_{-2}^{\gamma_\alpha} \frac{1}{2\pi} \sqrt{4 - x^2} dx = \frac{\alpha - 1/2}{N}.
\]
The quantile \( \gamma_\alpha \) is often also referred to as the classical location of the eigenvalue \( \lambda_\alpha \).

One ingredient for our work is the following strong local law for the Green function and the eigenvalue rigidity estimate.

**Theorem 4.1** (Theorem 2.1 in [6], Theorem 2.3 in [7]). Let \( H \) be as in (3.4) satisfying Assumption 3.1. Then we have the uniform estimates
\[
|G_{ij}(z) - \delta_{ij} m_{sc}(z)| \prec \left( \frac{\text{Im} m_{sc}(z)}{N\eta} \right)^{1/2} + \frac{1}{N\eta} \prec \Psi(z), \quad |m(z) - m_{sc}(z)| \prec \Psi(z)^2, \tag{4.7}
\]
for all \( z = E + i\eta \in \mathcal{E} \).

Moreover we have the eigenvalue rigidity estimate
\[
|\lambda_\alpha - \gamma_\alpha| \prec \frac{1}{N^{2/3} \min\{\alpha, N - \alpha + 1\}^{1/3}}, \tag{4.8}
\]
for all \( \alpha \in [1, N] \).

**4.2. Cumulant expansion.** A second main tool in the proof of Theorem 3.4 are cumulant expansions which were for example used in [11, 12] to study linear eigenvalue statistics of random matrices. For our purposes the following version from [8, 9] is very suitable.

**Lemma 4.2** (Lemma 2.4 in [9], Lemma 7.1 in [8]). Let \( h \) be a complex-valued random variable with finite moments. Let \( \kappa^{(p,q)} \) be the \( (p, q) \) cumulant of \( h \), which is defined as
\[
\kappa^{(p,q)} := (-1)^{p+q} \left( \frac{\partial^{p+q}}{\partial s^p \partial t^q} \log \mathbb{E} e^{ish + it\theta} \right) \bigg|_{s,t=0}.
\]

Let \( f \in C^\infty(\mathbb{C}^2; \mathbb{C}) \), then for any fixed \( l \in \mathbb{N} \), we have
\[
\mathbb{E} h f(h, \overline{h}) = \sum_{p+q=0}^{l} \frac{1}{p!q!} \kappa^{(p+1,q)} f^{(p,q)}(h, \overline{h}) + \Omega_{l+1}, \tag{4.10}
\]
where
\[
f^{(p,q)}(w_1, w_2) := \partial_{w_1}^p \partial_{w_2}^q f(w_1, w_2), \quad w_1, w_2 \in \mathbb{C},
\]
and the error term \( \Omega_{l+1} \) satisfies
\[
|\Omega_{l+1}| \leq C_l \mathbb{E} [ |h|^{l+2} ] \max_{p+q=l+1} \sup_{|w| \leq M} |f^{(p,q)}(w, \overline{w})| \nonumber \]
\[
+ C_l \mathbb{E} [ |h|^{2l+4} ] \mathbb{E} \left[ \max_{p+q=l+1} \sup_{|w| \leq M} |f^{(p,q)}(w, \overline{w})|^2 \right]^{1/2}, \tag{4.11}
\]
where \( M > 0 \) is an arbitrary cutoff.
We remark Lemma 4.2 is a combination of Lemma 2.4 in [9] and Lemma 7.1 [8]; the combinatoric part comes from [8] and the error estimate is taken from [9].

From (4.9), the first few complex cumulants are given by

\[ \kappa^{(1,0)} = \mathbb{E}h, \quad \kappa^{(1,1)} = \mathbb{E}|h|^2 - \|\mathbb{E}h\|^2, \quad \kappa^{(2,0)} = \mathbb{E}h^2 - (\mathbb{E}h)^2, \]

etc., with \( \kappa^{(q,p)} = \overline{\kappa^{(p,q)}} \).

5. PROOF OF THEOREM 3.4

The proof of Theorem 3.4 is based on an essentially optimal estimate on a distinguished observable we introduce in this section; see (5.2) below. We are going to prove Theorem 3.4 for the case \( k = 2 \), the case of general \( k \) then follows easily by grouping all but one summands in (3.4) together and viewing it as a single Wigner matrix.

Generalizing (2.4), we introduce the auxiliary matrix

\[ \mathcal{H} := \sigma_2 H_1 - \sigma_1 H_2, \]

(5.1)

whose entries are independent centered random variables, up to the symmetry constraint, with variance \( \mathbb{E}|\mathcal{H}_{ij}|^2 = \frac{1}{N}(\sigma_1^2 + \sigma_2^2) = \frac{1}{N}; \) see (3.3). In order to prove Theorem 3.4, we derive a high moment estimate for observables of the form

\[ \frac{1}{N} \text{Tr} \mathcal{H} \text{Im} G(z_1) \mathcal{H} \text{Im} G(z_2) = \langle \mathcal{H} \text{Im} G(z_1) \mathcal{H} \text{Im} G(z_2) \rangle, \quad z_1, z_2 \in \mathcal{E}, \]

(5.2)

where \( G \) denotes the Green function of \( H \); see (4.2) and the set \( \mathcal{E} \) was defined in (4.4). The main technical result of this paper is the following proposition.

Proposition 5.1. Under the assumptions of Theorem 3.4, we have the estimate

\[ \langle \mathcal{H} \text{Im} G(z_1) \mathcal{H} \text{Im} G(z_2) \rangle < 1, \]

(5.3)

uniformly in \( z_1, z_2 \in \mathcal{E} \).

Remark 5.2. Using the deterministic bound \( \|G(z)\| \leq \frac{1}{|z|} \) and the bounds \( \|H_1\|, \|H_2\| < 1 \), which follow from (4.8), we get the a priori bound

\[ \langle \mathcal{H} \text{Im} G(z_1) \mathcal{H} \text{Im} G(z_2) \rangle < \frac{1}{|\text{Im} z_1| |\text{Im} z_2|} < N^2, \]

(5.4)

on the spectral domain \( \mathcal{E} \). Thus (5.3) is an improvement of two orders in \( N \) and gives the correct size, up to factors of \( N^\varepsilon \).

The proof of Proposition 5.1 is postponed to Section 7 and we next show how it implies Theorem 3.4.

Proof of Theorem 3.4. In order to link (5.3) to (3.7) we observe that by spectral decomposition we have

\[ \frac{1}{N} \text{Tr} \mathcal{H} \text{Im} G(z_1) \mathcal{H} \text{Im} G(z_2) = \frac{1}{N} \sum_{\alpha,\beta=1}^N |w^*_\alpha \mathcal{H} w_{\beta}|^2 \frac{\eta_1}{(\lambda_\alpha - E_1)^2 + \eta_1^2} \frac{\eta_2}{(\lambda_\beta - E_2)^2 + \eta_2^2}, \]

(5.5)

where \( z_1 = E_1 + i\eta_1, z_2 = E_2 + i\eta_2, \eta_1 \neq 0, \eta_2 \neq 0. \)

Fix now indices \( \alpha, \beta \) and choose \( E_1 = \lambda_\alpha \) and \( E_2 = \lambda_\beta \), as well as \( \eta_1 = \eta_2 = N^{-1+\varepsilon} \) such that \( z_1, z_2 \in \mathcal{E} \) with very high probability by (4.8). Then we obtain from the uniform bound in (5.3) combined with the representation (5.5) the estimate

\[ |w^*_\alpha \mathcal{H} w_{\beta}|^2 < N \eta_1 \eta_2 < N^{-1}, \]

(5.6)
for all \( \alpha, \beta \in [1, N] \).

Next, similarly to (2.5), we conclude by noticing that
\[
\begin{align*}
\sigma_2 w^*_\alpha H_1 w_\beta - \sigma_1 \delta_{\alpha\beta} = \sigma_2 w^*_\alpha H_1 w_\beta - \sigma_1 \delta_{\alpha\beta} = \\
&= \sigma_2 w^*_\alpha H w_\beta = O \left( \frac{1}{\sqrt{N}} \right),
\end{align*}
\]
where we used (5.6). This concludes the proof of Theorem 3.4. \( \square \)

6. Computation of the expectation

In this section we compute the expectation of the observable \( \langle H \text{Im} G(z_1) \text{Im} G(z_2) \rangle \). Since this random variable is, for \( z_1, z_2 \in \mathbb{C}^+ \), positive, the expectation already indicates its correct size. Also the estimation of the expectation unveils the cancellation mechanism Theorem 3.4 eventually results from.

Lemma 6.1. Let \( z_1, z_2 \in \mathcal{E} \). Then,
\[
\mathbb{E} \langle H \text{Im} G(z_1) \text{Im} G(z_2) \rangle = \text{Im} m_{sc}(z_1) \text{Im} m_{sc}(z_2) + O \left( \frac{1}{\sqrt{N}} \right) + O \left( \Psi^2(z_1, z_2) \right),
\]
where \( \Psi(z_1, z_2) \) is defined in (4.5).

Proof. We start by noticing that it suffices to estimate
\[
\mathcal{X}(z, z') := \langle HG(z)HG(z') \rangle.
\]
for \( z = z_1, z_2 \) and \( z' = z_2, z_2 \). Further introduce the short hand notation
\[
G \equiv G(z), \quad G' \equiv G(z').
\]
Moreover, note that we can write
\[
\mathcal{X}(z, z') = \frac{1}{N} \sum_{ijab} \mathcal{H}_{ij} \text{Tr}(\Delta_{ij} G \Delta_{ab} G') \mathcal{H}_{ab},
\]
where the matrix \( \Delta_{ij} \) is defined to have entries \( (\Delta_{ij})_{nm} = \delta_{in} \delta_{jm} \), or using rank one operators
\[
\Delta_{ij} := |e_i \rangle \langle e_j |,
\]
where \( (e_i)_i \) is the canonical basis in \( \mathbb{C}^N \). Recall that \( \sum_{ijab} \) indicates a sum over all indices from 1 to \( N \).

Our task is to compute
\[
\mathbb{E} \mathcal{X}(z, z') = \frac{1}{N} \sum_{ijab} \mathbb{E} \left[ \mathcal{H}_{ij} \text{Tr}(\Delta_{ij} G \Delta_{ab} G') \mathcal{H}_{ab} \right].
\]
For this we use the cumulant expansions of Lemma 4.2. To get started, we need more notation. Let \( \kappa_{i,j}^{(p,q)} \) denote the cumulants of the matrix entries \( h_{i,j}, i = 1, 2 \). We will for simplicity assume for the moment that \( \mathbb{E} h_{i,j}^2 = 0 \), this condition can easily be relaxed; see Section 9. Together with Assumption 3.1 this implies
\[
\kappa_{i,j}^{(1,0)} = \kappa_{i,j}^{(0,1)} = 0, \quad \kappa_{i,j}^{(1,1)} = \frac{1}{N}, \quad \kappa_{i,j}^{(2,0)} = \kappa_{i,j}^{(0,2)} = 0.
\]
Further, from (3.2) in Assumption 3.1 we have the estimates

\[ |\kappa_{i,j}^{(p,q)}| \leq \frac{C_{p+q}}{N^{d+2}}, \quad p + q \geq 3. \]  

(6.8)

Next, introduce the derivation operator

\[ D_{ji} := (\sigma_2 \partial_{1,ji} - \sigma_1 \partial_{2,ji}), \]  

(6.9)

where \( \partial_{k,ji} \equiv \frac{\partial}{\partial s_{k,ji}}, k = 1, 2. \)

We now have the computational rules,

\[ D_{ji} \mathcal{H}_{ab} = \delta_{ja} \delta_{ib}, \]  

(6.10)

where we used (3.3), and

\[ D_{ji} G(z) = -\sigma_2 \sigma_1 G(z) \Delta^{ji} G(z) + \sigma_1 \sigma_2 G(z) \Delta^{ji} G(z) = 0, \]  

(6.11)

where we used the basic differential rule

\[ \partial_{i,ji} G(z) = -G(z) \sigma_i \Delta^{ji} G(z), \quad l = 1, 2. \]  

(6.12)

We will also require a higher order analogue of \( D \): For \( p, q \in \mathbb{N} \) define

\[ D_{ji}^{(p,q)} := \frac{1}{p!q!} \frac{1}{N^{l+2}} \left( \sigma_2^{\kappa_{i,ji}} (p,q+1) \partial_{i,ji}^{p} \partial_{1,ij}^{q} - \sigma_1^{\kappa_{2,ji}} (p,q+1) \partial_{2,ji}^{p} \partial_{2,ij}^{q} \right), \]  

(6.13)

with this notation we have \( D_{ji} = D_{ji}^{(1,0)} \) and record that

\[ D_{ji}^{(1,0)} G = 0, \quad D_{ji}^{(0,1)} = 0, \]  

(6.14)

where the first relation follows from (6.11), while the second follows from \( \kappa^{(0,2)} = 0 \); see (6.7). With the notation in (6.13) we next recall Lemma 4.2 to obtain the following cumulant expansion lemma.

**Lemma 6.2.** Fix indices \( i, j \) and integers \( d, d' \). Let \( F \) be a monomial in the Green function entries \( (G_{nm}(z))_{nm} \), \( (G_{nm}(z'))_{nm} \), and matrix entries \( (\mathcal{H}_{nm})_{nm} \) of total degree \( d \) in the Green function entries and total degree \( d' \) in \( \mathcal{H}_{nm} \) where \( d' \leq d \). Then for any fixed \( l \in \mathbb{N} \),

\[ \mathbb{E}_{ij} \mathcal{H}_{ij} F = \sum_{p+q=1}^{l} \frac{1}{p!q!} \mathbb{E}_{ij} D_{ji}^{(p,q)} F + \Omega_{l+1}(F), \]  

(6.15)

where \( \mathbb{E}_{ij} \) denotes the expectation with respect to the random variables \( h_{1,ij} \) and \( h_{2,ij} \). The error term satisfies the bound

\[ |\Omega_{l+1}(F)| \prec N^{-(l+2)/2}, \]  

(6.16)

where the explicit constants depend on \( d \) and \( d' \), but are uniform in the matrix indices.

The proof of Lemma 6.2 is postponed to Appendix A. Lemma 6.2 has the following direct corollary whose proof is postponed to Appendix A, too.

**Corollary 6.3.** Fix indices \( i, j \). Let \( F \) be a monomial in the Green function entries \( (G_{nm}(z))_{nm} \), \( (G_{nm}(z'))_{nm} \), and matrix entries \( (\mathcal{H}_{nm})_{nm} \) of total degree \( d \) in Green function entries and total degree \( d' \) in \( \mathcal{H}_{nm} \) where \( d' \leq d \). Then for any fixed \( l \in \mathbb{N} \),

\[ \mathbb{E} \mathcal{H}_{ij} F = \sum_{p+q=1}^{l} \frac{1}{p!q!} \mathbb{E} D_{ji}^{(p,q)} F + \mathbb{E} \Omega_{l+1}(F), \]  

(6.17)
where the error term satisfies the bound
\[
|\mathbb{E} \Omega_{l+1}(F)| < N^{-(l+2)/2},
\]
where the explicit constants depend on \(d\) and \(d'\), but are uniform in the matrix indices.

With Corollary 6.3 and the computational rules (6.10) and (6.14) at hand, we begin to compute the expectation of \(\mathcal{X}(z, z')\):
\[
\mathbb{E}\mathcal{X}(z, z') = \frac{1}{N} \sum_{ijab} \mathbb{E} \mathcal{H}_{ij} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab}
\]
\[
= \frac{1}{N} \sum_{p+q=1}^{l} \frac{1}{N^{2p+1}} \sum_{ijab} \mathbb{E} D_{ji}^{(p,q)} \left[ \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \right] + O_{\prec}(N^{-(l+4)/2})
\]
\[
= \frac{1}{N^2} \sum_{ijab} \mathbb{E} D_{ji}^{(1,0)} \left[ \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \right] + O_{\prec}(N^{-(l+4)/2})
\]
\[
+ \frac{1}{N} \sum_{p+q=2}^{l} \frac{1}{N^{2p+2}} \sum_{ijab} \mathbb{E} D_{ji}^{(p,q)} \left[ \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \right] + O_{\prec}(N^{-(l+4)/2}),
\]
where we used Corollary 6.3 together with (6.8) and power counting to estimate the error term from cutting the cumulant expansion at order \(l\) to be \(N^{-1} N^4 O_{\prec}(N^{-(l+2)/2}) = O_{\prec}(N^{-(l+4)/2})\).

We first focus on the first term on the right side of (6.19). Using (6.10) and (6.11), we get
\[
\frac{1}{N^2} \sum_{ijab} \mathbb{E} D_{ji}^{(1,0)} \left[ \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \right] = \frac{1}{N^2} \sum_{ijab} \mathbb{E} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \delta_{ja} \delta_{ib}
\]
\[
+ \frac{1}{N^2} \sum_{ijab} \mathbb{E} \text{Tr}(\Delta^{ij} (D_{ji} G) \Delta^{ab} G') \mathcal{H}_{ab}
\]
\[
+ \frac{1}{N^2} \sum_{ijab} \mathbb{E} \text{Tr}(\Delta^{ij} G \Delta^{ab} (D_{ji} G')) \mathcal{H}_{ab}
\]
\[
= \frac{1}{N^2} \sum_{ij} \mathbb{E} G_{jj} G_{ii} = \mathbb{E} m(z) m(z'),
\]

Note that the only non-zero term is when \(D_{ji}\) acts on \(\mathcal{H}_{ab}\). By the local law in (4.7), and the deterministic estimate \(|m(z)| \leq \frac{1}{|q|} \leq N\) together with item (3) of Lemma 3.3, the first term on the right side of (6.19) is thus given by
\[
\frac{1}{N^2} \sum_{ijab} \mathbb{E} D_{ji}^{(1,0)} \left[ \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \right] = m_{sc}(z) m_{sc}(z') + O_{\prec}(\Psi(z, z')^2).
\]

Consider next the second term on the right of (6.19). We are going to use yet another cumulant expansion with respect to \(\mathcal{H}_{ab}\) to exploit further cancellation based on (6.14). For this purpose we first note that if \(\{a, b\} \neq \{i, j\}\) as sets, then
\[
D_{ji}^{(p,q)} \left( \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \right) = \mathcal{H}_{ab} D_{ji}^{(p,q)} \left( \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \right),
\]
because then \(\partial_{i,j} \mathcal{H}_{ab} = \partial_{a,b} \mathcal{H}_{ab} = 0\). If \(\{a, b\} = \{i, j\}\), then by power counting using \(|\mathcal{H}_{ab}| \prec 1\) and the boundedness of the Green function entries, we can estimate
\[
\left| \frac{1}{N} \sum_{p+q=2}^{l} \frac{1}{N^{2p+2}} \sum_{ijab} \mathbb{E} D_{ji}^{(p,q)} \left[ \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \right] \right| \prec \frac{1}{N} \frac{1}{N^{3/2}} N^2 \prec \frac{1}{\sqrt{N}},
\]
where we tacitly used item (3) of Lemma 3.3, together with Hölder’s inequality and the deterministic estimate \( \|G(z)\| \leq |\eta|^{-1} \leq N \) and the moment bounds in (3.2). Hence, we have for the second term on the right side of (6.19) that

\[
\frac{1}{N} \sum_{p+q=2} \frac{1}{N^{p+q+1}} \sum_{i,j,a,b} \mathbb{E} D_{ji}^{(p,q)} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \leq \frac{1}{N} \sum_{p+q=2} \frac{1}{N^{p+q+1}} \sum_{\{i,j\} \neq \{a,b\}} \mathbb{E} H_{ab} D_{ji}^{(p,q)} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') + O_{\prec} \left( \frac{1}{\sqrt{N}} \right). \tag{6.23}
\]

Next, using a cumulant expansion to order \( l \) with respect to \( \mathcal{H}_{ab} \), we get

\[
\frac{1}{N} \sum_{p+q=2} \frac{1}{N^{p+q+1}} \sum_{\{i,j\} \neq \{a,b\}} \mathbb{E} D_{ji}^{(p_1,q_1)} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \leq \frac{1}{N} \sum_{p+q=2} \frac{1}{N^{p+q+1}} \sum_{\{i,j\} \neq \{a,b\}} \mathbb{E} D_{ba}^{(p_2,q_2)} D_{ji}^{(p_1,q_1)} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') + O_{\prec} (N^{(-l+1)/2}).
\]

By (6.14), we see that the terms with \( p_2 + q_2 = 1 \) yield a zero contribution, so we have

\[
\frac{1}{N} \sum_{p+q=2} \frac{1}{N^{p+q+1}} \sum_{\{i,j\} \neq \{a,b\}} \mathbb{E} D_{ji}^{(p,q)} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \mathcal{H}_{ab} \leq \frac{1}{N} \sum_{p+q=2} \frac{1}{N^{p+q+1}} \sum_{\{i,j\} \neq \{a,b\}} \mathbb{E} D_{ba}^{(p_2,q_2)} D_{ji}^{(p_1,q_1)} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') + O_{\prec} (N^{(-l+1)/2})
\]

\[
+ \frac{1}{N} \sum_{p+q=2} \frac{1}{N^{p+q+1}} \sum_{\{i,j\} \neq \{a,b\}} \mathbb{E} D_{ba}^{(p_2,q_2)} D_{ji}^{(p_1,q_1)} \text{Tr}(\Delta^{ij} G \Delta^{ab} G')
\]

\[
+ O_{\prec} (N^{(-l+1)/2}). \tag{6.24}
\]

Using the local law for the Green function entries in (4.7) and Lemma 3.3, we can easily bound the second term on the right side by

\[
\left| \frac{1}{N} \sum_{p+q=2} \frac{1}{N^{p+q+1}} \sum_{\{i,j\} \neq \{a,b\}} \mathbb{E} D_{ba}^{(p_2,q_2)} D_{ji}^{(p_1,q_1)} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') \right| \prec \frac{1}{\sqrt{N}}. \tag{6.25}
\]

For the first term on the right side of (6.24), we observe that \( D_{ba}^{(1,1)} D_{ji}^{(1,1)} \) contains four partial derivatives. When those act on the Green function entries \( \text{Tr}(\Delta^{ij} G \Delta^{ab} G') = G_{ja} G_{bi} \), they create by (6.12) monomials of degree six in the Green function entries. Assuming that \( a, b, i, j \) are all distinct, the four partial derivatives will create diagonal as well as off-diagonal Green function entries when acting on \( G_{ja} G_{bi} \) since, e.g. \( \partial_{1,ba} G_{ja} = -\sigma_1 G_{jba} G_{aa} \). Note that the total number of off-diagonal entries does not decrease, hence each resulting monomial contains at least two off-diagonal entries. In power counting we count diagonal entries as \( O_{\prec} (1) \) while the off-diagonal are counted as \( O_{\prec} (\Psi) \). If there are coincidences among the indices, we gain a factor \( 1/N \) in the summation for each coincidence, hence those are negligible when compared with \( \Psi^2 \). We hence have the estimate
\[
\left| \frac{1}{N} \sum_{\{i,j\} \neq \{a,b\}} \mathbb{E} D_{ba}^{(1,1)} D_{ji}^{(1,1)} \text{Tr}(\Delta_{ij} G \Delta_{ab} G') \right| \ll (\Psi(z, z'))^2. \quad (6.26)
\]

In sum, choosing \( l \geq 5 \), we get from (6.26), (6.25), (6.23), and (6.21) that
\[
\mathbb{E} X(z, z') = \frac{1}{N} \mathbb{E} \text{Tr} H G(z) H G(z') = m_{sc}(z) m_{sc}(z') + O_{\prec}((\Psi(z, z'))^2) + O_{\prec}(\frac{1}{\sqrt{N}}). \quad (6.27)
\]

Using linear combinations, Lemma 6.1 follows directly from (6.27). \( \square \)

7. PROOF OF PROPOSITION 5.1

In the previous section we identified the expectation of \( \langle H G H G' \rangle \) in Lemma 6.1. In the current section, we will control the higher moments of \( \langle H G H G' \rangle \) to obtain a high probability bound required to prove Proposition 5.1.

**Proposition 7.1.** Under the assumptions of Theorem 3.4, we have
\[
X(z, z') = m(z) m(z') + O_{\prec}(1), \quad (7.1)
\]
uniformly in \( z, z' \in \mathcal{E} \).

**Proof.** We rewrite \( X \) as
\[
X(z, z') = \frac{1}{N} \sum_{ijab} H_{ij} \text{Tr}(\Delta_{ij} G \Delta_{ab} G') H_{ab} =: \frac{1}{N} \sum_{ijab} H_{ij} X_{ijab} H_{ab}, \quad (7.2)
\]
where we introduced
\[
X_{ijab} \equiv \text{Tr}(\Delta_{ij} G \Delta_{ab} G') = G_{ja} G_{bi}. \quad (7.3)
\]
As in Section 6, we assume for the moment that \( \mathbb{E} h_{n, ij}^2 = 0 \), \( \epsilon = 1, 2 \), \( i, j \in [1, N] \). This implies that \( k_{n, ij}^{(0,2)} = k_{n, ij}^{(2,0)} = 0 \) as well as \( D_{ji}^{(0,1)} \equiv 0 \). We are going to explain in Section 9 how this additional assumption can easily be dropped.

Next, we observe from (6.10) and (6.14) that
\[
\frac{1}{N^2} \sum_{ijab} D_{ji}^{(1,0)} X_{ijab} H_{ab} = \frac{1}{N^2} \sum_{ij} G_{ij} G_{jj}' = m(z) m(z') := \varpi(z, z'), \quad (7.4)
\]
where we introduce the shorthand \( \varpi \). For \( n, m \in \mathbb{N} \), define
\[
P(n, m) := (X - \varpi)^n (X - \varpi)^m. \quad (7.5)
\]

Fix a (large) \( D \in \mathbb{N} \), \( z, z' \in \mathcal{E} \), and consider
\[
\mathbb{E} P(D, D) = \sum_{ijab} \mathbb{E} \left[ \prod_{n=1}^{D} \left( \frac{1}{N} H_{in, jn} X_{in, jn, an, bn} H_{an, bn} - \frac{1}{N^2} \delta_{j_{n, an}} \delta_{i_{n, bn}} G_{i_{n, in}} G_{j_{n, jn}} \right) \right] \times \prod_{n=D+1}^{2D} \left( \frac{1}{N} H_{in, in} X_{in, jn, an, bn} H_{an, bn} - \frac{1}{N^2} \delta_{j_{n, an}} \delta_{i_{n, bn}} G_{i_{n, in}} G_{j_{n, jn}} \right), \quad (7.6)
\]
where \( i = (i_1, i_2, \ldots, i_{2D}) \in [1, N]^{2D} \), and similarly \( j, a, b \in [1, N]^{2D} \) are \( 8D \) free summation indices corresponding to \( 4D \) factors of \( H \)'s. In the expression above, we call, for each \( n \), \( H_{in, jn} \) and \( H_{an, bn} \) ‘twins’.
We now successively use the cumulant expansions from Corollary 6.3 to expand the summands in (7.6) in all the factors of \( \mathcal{H}'s \). We start by expanding in the variable \( \mathcal{H}_{l_1 j_1} \) to obtain
\[
\mathbb{E}\left[ (X(z, z') - \kappa(z, z')) P(D - 1, D) \right] = \frac{1}{N} \sum_{p_1 + q_1 = 1, i_1 j_1 a_1 b_1} \sum_{l} \frac{1}{N^{p_1 + q_1 + 1}} \mathbb{E} \left[ D^{(p_1, q_1)} (X_{i_1 j_1 a_1 b_1} \mathcal{H}_{a_1 b_1} P(D - 1, D)) \right] 
- \mathbb{E} \left[ \kappa P(D - 1, D) \right] + \mathbb{E} \left[ O_\prec (N^{-\frac{l+4}{2}}) P(D - 1, D) \right].
\] (7.7)

First, using that \( |X| \leq \eta_0^{-2} \leq N^2 \) and \( |\kappa| \leq \eta_0^{-2} \leq N^2 \), with \( \eta_0 = \min\{|\text{Im} z|, |\text{Im} z'|\} \), the third term on the right of (7.7) is bounded as \( O_\prec (N^{-\frac{l+4}{2}}) \), hence for \( l \geq 10D \), that error term is bounded as \( O_\prec (\left( \frac{1}{\sqrt{N}} \right)^{2D}) \). Here, we also tacitly used, as we will do repeatedly below, item (3) of Lemma 3.3 to justify the estimate. Second, in the first term on the right, for \( p + q = 1 \), we consider the derivation \( D^{(1,0)}_{j_1 j_1} \) (recall from (6.7) that \( D^{(0,1)}_{j_1 j_1} = 0 \)). When \( D^{(1,0)}_{j_1 j_1} \) acts on a Green function in \( X_{i_1 j_1 a_1 b_1} \) we get a zero contribution thanks to (6.14). If \( D^{(1,0)}_{j_1 j_1} \) acts on its twin \( \mathcal{H}_{a_1 b_1} \), we generate by (7.4) the term \( \mathbb{E}[\kappa P(D - 1, D)] \) which will precisely cancel with the second term on the right side of (7.7).

Thus, choosing \( l \geq 10D \), we have
\[
\mathbb{E} P(D, D) = \frac{1}{N^2} \sum_{i_1 j_1 a_1 b_1} \mathbb{E} \left[ X_{i_1 j_1 a_1 b_1} \mathcal{H}_{a_1 b_1} D^{(1,0)}_{j_1 j_1} P(D - 1, D) \right] 
+ \frac{1}{N} \sum_{p_1 + q_1 = 1, i_1 j_1 a_1 b_1} \sum_{l} \frac{1}{N^{p_1 + q_1 + 1}} \mathbb{E} \left[ D^{(p_1, q_1)} (X_{i_1 j_1 a_1 b_1} \mathcal{H}_{a_1 b_1} P(D - 1, D)) \right] 
+ O_\prec \left( \left( \frac{1}{\sqrt{N}} \right)^{2D} \right).
\] (7.8)

Consider now the first term on the right side of (7.8). When \( D^{(1,0)}_{j_1 j_1} \) acts on \( P(D - 1, D) \) it either acts on a Green function entry \( G_{i_2 j_2} \) or \( G_{a_2 b_2} \), or it acts on \( \mathcal{H}_{i_2 j_2} \) or \( \mathcal{H}_{a_2 b_2} \); \( i, j \in [2, \ldots, 2D] \). In the former case we get by (6.14) a zero contribution, in the latter case by (6.10) the number of free summation indices in \( P(D - 1, D) \) gets reduced from \( 4(2D - 1) \) to \( 4(2D - 1) - 2 \). Bearing this in mind, we expand the first term on the right side of (7.8) using \( \mathcal{H}_{a_1 b_1} \) to obtain, with \( l \geq 10D \),
\[
\frac{1}{N^2} \sum_{i_1 j_1 a_1 b_1} \mathbb{E} \left[ X_{i_1 j_1 a_1 b_1} \mathcal{H}_{a_1 b_1} D^{(1,0)}_{j_1 j_1} P(D - 1, D) \right] 
= \frac{1}{N^2} \sum_{i_1 j_1 a_1 b_1} \sum_{p_2 q_2 = 1} \frac{1}{N^{p_2 + q_2 + 1}} \mathbb{E} \left[ D^{(p_2, q_2)} (X_{i_1 j_1 a_1 b_1} D^{(1,0)}_{j_1 j_1} P(D - 1, D)) \right] + O_\prec \left( \left( \frac{1}{\sqrt{N}} \right)^{2D} \right),
\]

(7.9)
where we used (6.14). For the first term on the right side, the number of free summation indices in \( D_{b_1a_1}^{(1,0)} D_{j_1i_1}^{(1,0)} P(D - 1, D) \) is \( 4(2D - 1) - 4 \) by (6.10) and (6.14). Or put differently, there are \( 2(2D - 1) - 2 \) factors of \( H \)'s left that we can use in cumulant expansions.

For the second term on the right side of (7.9), we either get a zero contribution when \( D_{j_1i_1}^{(1,0)} \) acts on a Green function entry of \( P(D - 1, D) \), or the number of free summation indices gets reduced by two if \( D_{j_1i_1}^{(1,0)} \) acts on a factor of \( H \). For the higher derivative terms in \( D_{b_1a_1}^{(p_2,q_2)} \), with \( p_2 + q_2 \geq 2 \), acting on \( X^{i_1j_1a_1b_1} D_{j_1i_1}^{(1,0)} P(D - 1, D) \), either the number of Green function entries is increased by one for each derivative hitting a Green function entry, or the number of free summation indices is reduced by two for each derivative hitting a factor \( H \). We have now expanded the first term on the right of (7.8) in \( H_{i_1j_1} \) and \( H_{a_1b_1} \). Before we go on and expand the remaining \( H \)'s in \( P(D - 1, D) \), we return to second term on the right of (7.8).

Consider the second term on the right side of (7.8). Since \( p_1 + q_1 \geq 2 \), we do not have further cancellations from (6.14) in \( D_{j_1i_1}^{(p_1,q_1)} X^{i_1j_1a_1b_1} H_{a_1b_1} P(D - 1, D) \). If one of the derivatives in \( D_{j_1i_1}^{(p_1,q_1)} \) acts on \( H_{a_1b_1} \), the number of free summation indices is reduced by two, if none of the derivatives act on \( H_{a_1b_1} \), we use a cumulant expansion in \( H_{a_1b_1} \) stopped at order \( l \geq 10D \). The leading term containing \( D_{b_1a_1}^{(1,0)} \) will then either give a zero contribution if it acts on any Green function entry by (6.14) or it will reduce the number of free summation indices by two. For the terms containing \( D_{b_1a_1}^{(p_2,q_2)} \), \( p_2 + q_2 \geq 2 \), we have no cancellation due to (6.14) but the number of free summation indices gets reduced by two for each derivative acting on a factor \( H \).

To sum up, after performing all the derivatives by Leibniz rule, the terms on the right side of (7.8) can be classified by the number of collapses, \( M \), of two free summation indices when \( H_{i_1j_1} \) or \( H_{a_1b_1} \) act on some other \( H \)'s (except their own twin), and the number of cumulant expansions \( L \) in total; the number of cumulant expansions, \( L_1 \), starting from order one, i.e. with \( p_n + q_n \geq 1 \); and the number of cumulant expansions, \( L_2 \), starting from order two, i.e. with \( p_n + q_n \geq 2 \). For the moment either \( L = 1 \) or \( 2 \), with \( L_1 + L_2 = L \). Because of the bounds \( |G_{ij}(z)| < 1 \), \( \|G(z)\| \leq |\eta|^{-1} \leq N \) and Lemma 3.3(3), we may ignore the number of Green function entries in the power counting and do not keep track of them.

We have now fully expanded (7.8) in terms of \( H_{i_1j_1} \) and \( H_{a_1b_1} \). We will continue expanding in the remaining \( H \)'s while keeping track of the numbers \( M \), \( L_1 \) and \( L_2 \) introduced above.

Pick now one of the resulting terms from above, if that term contains \( H_{i_2j_2} \) and its twin \( H_{a_2b_2} \) we expand first in \( H_{i_2j_2} \). When \( D_{b_2a_2}^{(0,1)} \) acts on \( H_{a_2b_2} \) we get the cancellation with \( \kappa \) from (7.4), so that we are left with a cumulant expansion with \( p_2 + q_2 \geq 2 \) only. In case the twin \( H_{a_2b_2} \) is missing, we note that the number of free summation indices has already been reduced by two. If we pick a term that does not contain \( H_{i_2j_2} \), we go on and expand in the next \( H \), \( H_{a_2b_2} \) or if missing the next available \( H \). In this way we successively expand all factors \( H \)'s, except those appearing in the error term of a cumulant expansion cut at order \( l \geq 10D \).

A resulting fully expanded term containing no more \( H \)'s is then classified by the total number of collapses of free summation indices, \( M \), resulting from (6.10). The number of free summation indices in such a term is \( 8D - 2M \) whereas the number of total cumulant expansion, \( L \), in that term is \( 4D - M \). As above, let \( L_1 \) be the number of cumulant expansions with \( p_n + q_n = 1 \) and let \( L_2 \) be the number of cumulant expansions with \( p_n + q_n \geq 2 \). Note that \( L_2 = 4D - M - L_1 \).

Hence a fully expanded term with given \( M \), \( L_1 \) and \( L_2 \) gives a contribution to (7.6) bounded by

\[
\frac{1}{N^{2D}} N^{8D-2M} \left[ \sum_{p_n+q_n=1} \left( \frac{1}{\sqrt{N}} \right)^{p_n+q_n+1} \right]^{L_1} \left[ \sum_{p_n+q_n=2} \left( \frac{1}{\sqrt{N}} \right)^{p_n+q_n+1} \right]^{L_2}
\]
\[ N^{6-2M}N^{-L_1}N^{-L_2} = \left( \frac{1}{\sqrt{N}} \right)^{-M+L_1} , \quad (7.10) \]
where we used that \(|G_{ij}| < 1\), as well as \(\|G(z)\| \leq \frac{1}{|m|} \leq N\) with probability one and that there are no more \(H\)'s in a fully expanded term so that by Lemma 3.3 we get the first line. To obtain the second line we used that \(D\) and \(l \geq 10D\) are fixed numbers, and for the third line we used that \(L_2 = 4D - M - L_1\). Summarizing, so far we have expanded (7.6) in all the factors \(H\) and showed that each resulting fully expanded term with given \(M, L_1\) and \(L_2\) is bounded by (7.10).

We next claim that \(L_1 \leq M\) for any fully expanded term. Indeed if for some pair of indices \(i_n j_n\) or \(a_n b_n\) there is no collapse, meaning that the derivatives in \(\mathcal{D}_{j_n a_n}^{p_n, q_n}\) (or \(\mathcal{D}_{b_n a_n}^{p_n, q_n}\)) exclusively acted on Green function entries, then we have due to (6.14) that \(p_n + q_n \geq 2\) in order to get a non-zero contribution.

Thus we reach the maximum for \(M = L_1\) in (7.10), and the term is stochastically dominated by one, i.e. each fully expanded term is stochastically bounded by one. The number of generated terms in the expansion is bounded by \((CD)^{7D}\) if we choose \(l\) to be proportional to \(D\).

It follows that
\[
\mathbb{E} P(D, D) = \mathbb{E} |\mathcal{X}(z, z') - \mathcal{X}(z, z')|^2 D < 1 , \quad (7.11)
\]
for any \(D\), hence by Markov’s inequality we have
\[
|\mathcal{X}(z, z') - \mathcal{X}(z, z')| < 1 , \quad (7.12)
\]
which was to be proven for fixed \(z, z' \in \mathcal{E}\).

It remains to extend this bound to a uniform bound for all \(z, z' \in \mathcal{E}\). Let \(\mathcal{L} \subset \mathcal{E} \times \mathcal{E}\) be a lattice such that \(|\mathcal{L}| = O(N^{10})\) and for any \((z, z') \in \mathcal{E} \times \mathcal{E}\) there is a \((z_0, z'_0) \in \mathcal{L}\) such that \(|(z, z') - (z_0, z'_0)| = O(N^{-10})\). Since \((HG(z)HG(z'))\) is Lipschitz continuous in \((z, z')\) with constant bounded by \(\eta_0^{-4} \leq N^4\), \(\eta_0 = \min(|\text{Im} z|, |\text{Im} z'|)\), as follows from (6.12), the uniform estimate follows from a union bound over \(\mathcal{L}\) and (7.12). This concludes the proof of Proposition 7.1, modulo the assumption that \(\mathbb{E} h_{i,j}^2 = 0\). This condition can easily be removed as we will show in Section 9.

\[\square\]

Remark 7.2. We can strengthen the estimate (7.1) to
\[
\mathcal{X}(z, z') = m(z)m(z') + O_{\prec}(\Psi^2(z, z')) + O_{\prec}\left( \frac{1}{\sqrt{N}} \right) = m_{sc}(z)m_{sc}(z') + O_{\prec}(\Psi^2(z, z')) + O_{\prec}\left( \frac{1}{\sqrt{N}} \right) .
\]

To establish this, one needs to count the number of off-diagonal Green function entries generated along the expansion procedure and then use \(|G_{ij}| \prec \Psi + \delta_{ij}\).

8. REAL SYMMETRIC CASE

In this section, we outline how our results for the complex Hermitian setup carry over to the real symmetric one. We start with the analogue to Assumption 3.1.

Assumption 8.1. Fix an integer \(k \geq 2\). We assume that \(H := (h_{i,j})\) are \(k\) independent real symmetric Wigner matrices of size \(N \times N\), i.e., we assume that their entries are independent.
centred random variables, up to the symmetry constraints \( h_{i,ij} = h_{i,ji} \), satisfying

\[
\mathbb{E} h_{i,ij}^2 = \frac{1 + \delta_{ij}}{N}, \quad 1 \leq i, j \leq N, \quad \iota = 1, \ldots, k, \tag{8.1}
\]

and the families of random variables \( \{h_{i,ij}\} \) have finite moments to all order, i.e., they satisfy (3.2).

We then have the following result for the real symmetric case.

**Theorem 8.2.** Let \( H \) be given by (3.4) and assume that \( H_\iota, \iota = 1, \ldots, k, \) satisfy Assumption 8.1 and that \( \sigma_\iota, \iota = 1, \ldots, k, \) satisfy (3.3). Then

\[
\left| w^*_\alpha H_{ij} w_\beta - \sigma_\iota \lambda_\alpha \delta_{\alpha\beta} \right| \prec \frac{1}{\sqrt{N}}, \tag{8.2}
\]

for all \( \alpha, \beta \in \llbracket 1, N \rrbracket \) and \( \iota \in \llbracket 1, k \rrbracket \).

**Proof.** In the following we sketch the proof of Theorem 8.2 for \( k = 2 \). First, we define the cumulants, \( \kappa_{(p)}_{i,ij} = \kappa_{(p)}_{i,ji} \) for the real random variables \( h_{i,ij} \) as

\[
\kappa_{(p)}_{i,ij} := (-i)^p \frac{\partial^p}{\partial s^p} \log \mathbb{E} e^{ish_{i,ij}} \bigg|_{s=0}, \tag{8.3}
\]

and note that they satisfy the estimate (6.8).

Second, we introduce the real symmetric analogue to \( D_{(p,q)}^{ji} \) by setting

\[
D_{(p)}^{ji} := \frac{1}{p! N^{p+1}} \left( \sigma_2 \kappa_{(p+1)}^{1,ji} \frac{\partial^p}{\partial s^p} - \sigma_1 \kappa_{(p+1)}^{2,ji} \frac{\partial^p}{\partial s^p} \right), \quad p \in \mathbb{N}. \tag{8.4}
\]

With these definitions we obtain the following cumulant expansion formula for the real symmetric case: Let \( F \) be a monomial in the Green function entries and entries of \( H \) as in Corollary 6.3, then we have for any \( l \in \mathbb{N}, \)

\[
\mathbb{E} H_{ij} F = \sum_{p=1}^{l} \frac{1}{N^{p+1/2}} \mathbb{E} D_{(p)}^{ji} F + \mathbb{E} \Omega_{l+1}(F), \tag{8.5}
\]

where the error term satisfies the bound

\[
|\mathbb{E} \Omega_{l+1}(F)| \prec N^{-(l+1)/2}. \tag{8.6}
\]

Third, we recall that the basic differentiation rule for the real symmetric setup;

\[
\partial_{\iota,ji} G(z) = -G(z) \sigma_\iota \Delta^{ji} G(z) - G(z) \sigma_\iota \Delta^{ij} G(z), \quad \iota = 1, 2. \tag{8.7}
\]

It is then easy to check that we have the computational rules

\[
D_{(1)}^{ji} G(z) = 0, \tag{8.8}
\]

as well as

\[
D_{(1)}^{ji} H_{ab} = \delta_{ja} \delta_{ib} + \delta_{ia} \delta_{jb}, \tag{8.9}
\]

where \( H_{ab} = \sigma_2 H_1 - \sigma_1 H_2 \) and where we used (3.3) and (8.1).

Armed with these definitions and rules, we turn to the computation of \( \mathbb{E} \langle H G(z) H G(z') \rangle \). We follow the computation in Section 6 up to (6.20) that now becomes

\[
\frac{1}{N^2} \sum_{i,j,a,b} \mathbb{E} D_{(1)}^{ji} \left[ \text{Tr}(\Delta^{ij} G \Delta^{ab} G') H_{ab} \right] = \frac{1}{N^2} \sum_{i,j,a,b} \mathbb{E} \text{Tr}(\Delta^{ij} G \Delta^{ab} G') D_{(1)}^{ji} H_{ab}.
\]
where we used the local law for the Green function in (4.7) to get the last line; where we used the fact that Theorem 4.1 holds for real symmetric Wigner matrices as well. The only change was the additional error term $O_{\prec}((\Psi(z,z'))^2)$ in (8.10). Following the computation in Section 6 further, we conclude that Lemma 6.1 holds in the real symmetric setup, too.

We move on to bound the higher moments of $\langle HGH' \rangle$ following the arguments in Section 7. Due to the modified rule (8.9) in the real setup, we redefine $\kappa(z, z')$ from (7.4) as

$$\kappa(z, z') := m(z)m(z') + \frac{1}{N^2} \sum_{ij} G_{ij}(z)G_{ji}(z'),$$

so that

$$\frac{1}{N^2} \sum_{ijab} D_{ji}^{(1)} X_{ijab}H_{ab} = \kappa(z, z'),$$

holds with the adapted notation where $X_{ijab}$ given in (7.3). This modification of $\kappa$ ensures that $X(z, z') - \kappa(z, z')$ is a self-normalizing quantity, i.e., in the computation of $\mathbb{E}P(D, D)$, with $P$ from (7.5), when some $\mathcal{H}_{a_n, b_n}$ acts on its twin $\mathcal{H}_{a_n, b_n}$ we get a zero contribution to $\mathbb{E}P(D, D)$ as in the complex Hermitian computation.

Yet, if some $\mathcal{H}_{a_n, b_n}$ acts on another $\mathcal{H}$ which is not its own twin, then we get an additional contribution from the second term on the right side of (8.9) which is absent in the complex case. However, when this happens the number of free summation indices is reduced by two and we continue to expand the resulting term in the same way as in the complex case. Thus the modified rule (8.9) produces more terms in the expansion of $\mathbb{E}P(D, D)$, but after all terms are fully expanded in the $\mathcal{H}$’s, the size of the terms are estimated by the same power counting as in the complex Hermitian case. In this way one obtains that

$$\langle H \mathbb{E}m(z)H \mathbb{E}m(z') \rangle = \mathbb{E}m(z)\mathbb{E}m(z') + O_{\prec}(1),$$

uniformly in $z, z' \in \mathcal{E}$, similar to Proposition 7.1. The proof of Theorem 8.2 is then concluded in the same way as in Section 5. □

9. Complex case revisited

In this last section, we return to the complex Hermitian case. In the proof of Proposition 5.1 in Section 7, we assumed for simplicity that $\mathbb{E}h^2_{t,ij} = \kappa_{t,ij}^{(0,2)} = 0$. In this section, we explain how this assumption can be removed. Even if $\kappa_{t,ij}^{(0,2)} \neq 0$ and hence $D_{ji}^{(0,1)} \neq 0$, we have

$$D_{ji}^{(0,1)}G(z) = D_{ji}^{(0,1)}G(z) = 0,$$

similar to (6.14). Further, (6.10) is modified as

$$D_{ji}^{(0,1)}H_{ab} = \delta_{ib}\delta_{ja}, \quad D_{ji}^{(1,0)}H_{ab} = \sigma^2_{1} \kappa_{1,ji}^{(0,2)} \delta_{ia}\delta_{jb} + \sigma^2_{1} \kappa_{2,ji}^{(0,2)} \delta_{ia}\delta_{bj}.$$  

Since the cumulant expansions of Corollary 4.2 remain valid, it is straightforward to check that Proposition 7.1 holds true also when $\kappa_{t,ij}^{(0,2)}$ do not necessarily vanish, after modifying the
definition of $\kappa$ similarly to the real symmetric case in order to obtain self-normalizing quantities in the moment bounds of $\mathcal{X} - \kappa$. More precisely, redefining

$$\kappa(z, z') := m(z)m(z') + \frac{1}{N} \sum_{ij} (\sigma^2_{k_{1,ij}} G_{ij}(z) G_{ji}(z') + \sigma^2_{k_{2,ij}} G_{ij}(z) G_{ji}(z')),$$

we find that

$$\frac{1}{N^2} \sum_{ijab} (D_{ji}^{(0,1)} + D_{ji}^{(1,0)}) X_{ijab}^* \mathcal{H}_{ab} = \kappa(z, z'),$$

with $X_{ijab}^*$ given in (7.3). We leave the further details aside. Finally, the proof of Theorem 3.4 from Proposition 7.1 remains unaffected by this modification.

**APPENDIX A. PROOF OF LEMMA 6.2**

**Proof of Lemma 6.2.** Fix the indices $i$ and $j$. We write $F \equiv F(h_{1,ij}, h_{1,ji}, h_{2,ij}, h_{2,ji})$ to emphasize the explicit dependences. From Lemma 4.2 and the definition of $D_{ji}^{(p,q)}$ in (6.13) we directly obtain (6.15) where $\Omega_{l+1}(F)$ is the sum of two error terms $\Omega_{1,l+1}$ and $\Omega_{1,l+2}$, the first coming from cumulant expansion with respect to $h_{1,ij}$, the second from expanding with respect to $h_{2,ij}$ in $\mathcal{H}_{ij}$. To bound the error term $\Omega_{1,l+1}$, we choose $M = N^{−1/4}$ in (4.11). Then together with the moment bounds in (3.2), for any (large) $D > 0$, we have

$$|\Omega_{1,l+1}| \leq \frac{C_l}{N^2} \max_{p+q=l+1} \sup_{w \in \mathbb{C}, |w| \leq N^{-1/4}} \left| \frac{\partial_p \partial_q F(w, \overline{\mathcal{H}}_{2,ij}, h_{2,ji})}{\partial w} \right|$$

$$+ \frac{C_{l,D}}{N^{D/2}} \left( \mathbb{E}_{ij} \left[ \max_{p+q=l+1} \sup_{|w| \leq |h_{1,ij}|} \left| \frac{\partial_p \partial_q F(w, \overline{\mathcal{H}}_{2,ij}, h_{2,ji})}{\partial w} \right|^2 \right] \right)^{1/2}, \quad (A.1)$$

for $N$ sufficiently large, where we used Hölder’s inequality and the moment assumption (3.2) to conclude that, for any $l$ and $D$,

$$\mathbb{E}_{ij} |h_{1,ij}|^{l+2} \leq \frac{C_l}{N^2}, \quad \mathbb{E}_{ij} \left[ |h_{1,ij}|^{l+1+1} |h_{1,ij}| > N^{-1/4} \right] \leq \frac{C_{l,D}}{N^{D/2}}, \quad (A.2)$$

for $N$ sufficiently large.

Consider next the Green function entry $G_{ab} \equiv G_{ab}(z)$ for some fixed $z \in \mathcal{E}$ and some choice of indices $a, b$. We write $G_{ab} = G_{ab}(h_{1,ij}, h_{1,ji})$ in the following. Recall from the local law in (4.7) that $|G_{ab}(h_{1,ij}, h_{1,ji})| \prec \delta_{ab} + \Psi(z)$. Hence using a Neumann expansion of the resolvent we get

$$G_{ab}(w, \overline{w}) = G_{ab}(h_{1,ij}, h_{1,ji}) - \text{Tr} \left[ \Delta^{ab} G(h_{1,ij}, h_{1,ji}) \sigma_1 \left( (w - h_{1,ij}) \Delta^{ij} + (\overline{w} - h_{1,ji}) \Delta^{ji} \right) G(w, \overline{w}) \right].$$

Thus denoting

$$\hat{\Lambda}_o := \sup_{w \in \mathbb{C}, |w| \leq N^{-1/4}} \max_{a,b} |G_{ab}(w, \overline{w})|,$$

we get from (A.3) and $|h_{1,ij}| \prec \frac{1}{\sqrt{N}}$ that

$$\hat{\Lambda}_o \prec 1 + \frac{1}{N^{1/4}} \hat{\Lambda}_o,$$

hence $\hat{\Lambda}_o \prec 1$. Next observe that $\partial_i \partial_j F$ is a polynomial in the Green function entries and the matrix entries of $\mathcal{H}$ of degree at most $d + d' + l + 2$. Since $F$ was a monomial, the number of monomial summands in $\partial_i \partial_j F$ depends on $p, q$ and $d + d' + l + 2$ but is independent of $N$. Using the bounds $|\mathcal{H}_{ab}| \prec 1$ and $\hat{\Lambda}_o \prec 1$, we conclude that $\sup_{w \in \mathbb{C}, |w| \leq N^{-1/4}} |\partial_i \partial_j F(w, \overline{w})| \prec 1$. 

for all \( p, q \) with \( p + q \leq l + 1 \). It follows that the first term on the right side of (A.1) is of order \( O(\frac{N}{l+1}) \).

To control the second term on the right side of (A.1) we use once more that \( \partial_p \partial_q F \) is finite linear combination of monomials in the Green function entries and the matrix entries of \( H \). The maximal number of Green function entries occurring is \( d + l + 2 \), estimating each factor by \( \|G\|_\infty \leq \frac{1}{\eta_0} \leq \frac{1}{N} \), we get a contribution of order \( N^{d+l+2} \) from the Green function entries. From the factors of \( H_{ab} \) we use that \( |H_{ab}| \ll 1 \) and the moment bounds in (3.2) to conclude that

\[
\left( \mathbb{E}_{ij} \left[ \max_{p+q=l+1} \sup_{|w| \leq |h_{1,ij}|} |\partial_i \partial_j F(w, \overline{w}, h_{2,ij}, h_{2,ji})|^2 \right] \right)^{1/2} \ll N^{d+l+2}.
\]

Hence choosing \( D \) sufficiently large the second term on the right side in (A.1) is bounded by \( O(\frac{N}{l+1}) \). In sum, we have that \( |\Omega_{1,l+1}(F)| \ll N^{-(l+2)}/2 \). In the same way one derive the corresponding bound on \( \Omega_{2,l+1}(F) \).

**Proof of Corollary 6.3.** Corollary 6.3 follows from Lemma 6.2, together with an application of item (3) of Lemma 3.3 using the the estimates \( |G_{ij}(z)| \ll 1, \|G(z)\| \leq |\eta|^{-1} \leq N \), and the moment assumptions in Assumption 3.1 combined with Hölder’s inequality.
