A BERRY-ESSEEN BOUND WITH (ALMOST) SHARP DEPENDENCE CONDITIONS

MORITZ JIRAK

Abstract. Suppose that the (normalised) partial sum of a stationary sequence converges to a standard normal random variable. Given sufficiently moments, when do we have a rate of convergence of \( n^{-1/2} \) in the uniform metric, in other words, when do we have the optimal Berry-Esseen bound? We study this question in a quite general framework and find the (almost) sharp dependence conditions. The result applies to many different processes and dynamical systems. As specific, prominent examples, we study functions of the doubling map \( 2x \mod 1 \) and the left random walk on the general linear group.

1. Introduction

Suppose that a stationary sequence \( (X_k)_{k \in \mathbb{Z}} \) satisfies the CLT with variance \( s^2 > 0 \), that is,

\[
\frac{1}{\sqrt{n}} S_n \xrightarrow{w} \mathcal{N}(0, s^2), \quad S_n \triangleq \sum_{k=1}^{n} X_k.
\]

(1.1)

The question of the rate of convergence in (1.1) has been extensively studied in the literature under numerous different setups with respect to some metric for probability measures and underlying structure of the sequence \( (X_k)_{k \in \mathbb{Z}} \). Perhaps one of the more important metrics is the uniform (Kolmogorov) metric, given as

\[
\Delta_n \triangleq \sup_{x \in \mathbb{R}} \left| \mathbb{P}(S_n \leq x\sqrt{ns^2}) - \Phi(x) \right|.
\]

(1.2)

Subject to various notions of weak-dependence and additional regularity conditions, the optimal rate of convergence \( n^{-1/2} \) (or related) has been reached in [5], [40], [36], [19], [21], [27], [30], to name a few, but this list is far from being complete. In view of such results, the following question naturally arises.

Question 1.1. What are the sharp (weak) dependence conditions, such that the optimal rate \( n^{-1/2} \) is reached, that is,

\[
\Delta_n \leq C n^{-1/2}
\]

(1.3)

for some constant \( C > 0 \)?
In this note, we (essentially) solve this question in a general framework, improving upon many results in the literature. We achieve this by refining the approach of [27]. However, the solution shows that the question of sharp dependence conditions is, in general, much more complicated, leading to a multitude of open problems.

2. Main results

Throughout this paper, we will use the following notation. For a random variable $X$ and $p \geq 1$, we denote with $\|X\|_p = (\mathbb{E}|X|^p)^{1/p}$ the $L^p$ norm. We use $\lesssim, \gtrsim, (\sim)$ to denote (two-sided) inequalities involving an absolute multiplicative constant. For $a, b \in \mathbb{R}$, we put $a \wedge b = \min\{a, b\}$, $a \vee b = \max\{a, b\}$.

Consider a sequence real-valued, measurable random variables $X_1, \ldots, X_n$. It is well known (cf. [41]), that this sequence can be represented as

$$X_k = g_k(\epsilon_k, \epsilon_{k-1}, \ldots), \quad 1 \leq k \leq n,$$

for some measurable functions $g_k$, where $(\epsilon_k)_{k \in \mathbb{Z}}$ is a sequence of independent and identically distributed random variables. At this stage, it is also worth mentioning that any real valued K-automorphism can be represented as in (2.1), a consequence of Vershik’s famous theorem on lacunary isomorphism, see for instance [16],[42]. This motivates the following setup: Denote the corresponding $\sigma$-algebra with $\mathcal{E}_k = \sigma(\epsilon_j, j \leq k)$. Given a real-valued stationary sequence $(X_k)_{k \in \mathbb{Z}}$, we always assume that $X_k$ is adapted to $\mathcal{E}_k$ for each $k \in \mathbb{Z}$. Hence, we implicitly assume that $X_k$ can be written as in (2.1). For convenience, we write $X_k = g_k(\theta_k)$ with $\theta_k = (\epsilon_k, \epsilon_{k-1}, \ldots)$.

A nice feature of representation (2.1) is that it allows to give simple, yet very efficient and general dependence conditions. Following [43], let $(\epsilon'_k)_{k \in \mathbb{Z}}$ be an independent copy of $(\epsilon_k)_{k \in \mathbb{Z}}$ on the same probability space, and define the ‘filters’ $\theta^{{(l,\prime)}}_k, \theta^{(l,\ast)}_k$ as

$$\theta^{{(l,\prime)}}_k = (\epsilon_k, \epsilon_{k-1}, \ldots, \epsilon_{k-l}, \epsilon_{k-l-1}, \ldots),$$

and

$$\theta^{(l,\ast)}_k = (\epsilon_k, \epsilon_{k-1}, \ldots, \epsilon'_l, \epsilon'_{k-l-1}, \epsilon'_{k-l-2}, \ldots).$$

We put $\theta'_k = \theta^{(l,\prime)}_k = (\epsilon_k, \epsilon_{k-1}, \ldots, \epsilon'_0, \epsilon_{-1}, \ldots)$ and $X^{{(l,\prime)}}_k = g_k(\theta^{{(l,\prime)}}_k)$, in particular, we set $X'_k = X^{(l,\ast)}_k$. Similarly, we write

$$\theta^*_k = \theta^{(l,\ast)}_k = (\epsilon_k, \epsilon_{k-1}, \ldots, \epsilon'_0, \epsilon'_{-1}, \epsilon'_{-2}, \ldots),$$

$X^{{(l,\ast)}}_k = g_k(\theta^{(l,\ast)}_k)$, and $X^*_k = X^{(l,\ast)}_k$. As dependence measures, we may then consider

$$(2.4) \quad \vartheta^*_l(p) = \sup_{k \in \mathbb{Z}} \|X_k - X^{{(l,\ast)}}_k\|_p, \quad \vartheta^*_l(p) = \sup_{k \in \mathbb{Z}} \|X_k - X^{{(l,\ast)}}_k\|_p.$$

\textsuperscript{1}In fact, $g_k$ maps from $\mathbb{R}^k$ to $\mathbb{R}$. 

Observe that if the function $g_k$ satisfies $g_k = g$, that is, it does not depend on $k$, the above simplifies to

\begin{equation}
\vartheta^*_l(p) = \|X_l - X'_l\|_p, \quad \vartheta'_l(p) = \|X_l - X'_l\|_p.
\end{equation}

In this case, the process $(X_k)_{k \in \mathbb{Z}}$ is referred to as (time homogenous) Bernoulli-shift process.

Dependence conditions of type (2.4), (2.5) are very general, easy to verify in many prominent cases, and have a long history going back at least to [3], [25], see Section 3 for a brief account and references for examples.

For any $p \neq 0$, let

\begin{equation}
B(p) = \frac{1}{2} + \frac{p \land 3}{2p} - \frac{1}{p},
\end{equation}

and note that $\lim_{p \to \infty} B(p) = 1/2$. We will derive all of our results under the following assumptions.

**Assumption 2.1.** Let $(X_k)_{k \in \mathbb{Z}}$ be stationary such that for $p > 2$, $a > 0$ and $b > B(p)$

(A1) $\|X_k\|_p < \infty$, $\mathbb{E}X_k = 0$,
(A2) $\sum_{k=1}^{\infty} k^a \vartheta^*_k(p)$ and $\sum_{k=1}^{\infty} k^b \vartheta'_k(p) < \infty$,
(A3) $s^2 \geq s_-^2 > 0$, where $s^2 = \sum_{k \in \mathbb{Z}} \mathbb{E}X_0X_k$ and $s_-$ is an absolute constant.

Existence of $s^2 < \infty$ follows from Lemma 4.6. It is possible to simplify Assumption (A2) by demanding a (slightly) stronger condition, which is done in Proposition 2.2 below.

**Proposition 2.2.** For $p > 2$ and $b > B(p)$, assume

$$
\sum_{k=1}^{\infty} k^b \sup_{l \geq k} \vartheta'_l(p) < \infty.
$$

Then there exists an $a > 0$, such that (A2) is valid.

Recall

$$
\Delta_n = \sup_{x \in \mathbb{R}} |\mathbb{P}(S_n \leq x \sqrt{ns^2}) - \Phi(x)|,
$$

where $s^2 = \sum_{k \in \mathbb{Z}} \mathbb{E}X_0X_k$. The following theorem is our main result.

**Theorem 2.3.** Grant Assumption 2.1. Then there exists $C > 0$, such that

$$
\Delta_n \leq Cn^{(p \land 3)/2 - 1}.
$$

Constant $C$ only depends on quantities appearing in Assumption 4.1.

Theorem 2.3 provides very general convergence rates under mild conditions. As is demonstrated below in Theorem 2.4, the conditions are essentially sharp. A brief survey of examples satisfying the assumptions is given in Section 3. As particular cases, we discuss functions of the dynamical system $Tx = 2x \mod 1$ more detailed in Example 3.1, and the left random
walk on $GL_d(\mathbb{R})$ in Example 3.3. Both problems have been studied in the literature for decades, and it appears that Theorem 2.3 yields the currently best known results.

Let us now turn to the issue of optimality, supplied by the following result.

**Theorem 2.4.** For any $p \geq 3$ and $b < 1/2$, there exists a stationary Bernoulli-shift process $(X_k)_{k \in \mathbb{Z}}$ satisfying (A1), (A3) and

$$
\sum_{k=1}^{\infty} k^b \sup_{l \geq k} \|X_l - X_l'\|_p < \infty,
$$

such that for some $\delta > 0$

$$
\liminf_{n \to \infty} n^{1/2 - \delta} \Delta_n = \infty.
$$

Let us briefly review the indications of Theorems 2.3 and 2.4. First, we see that $b = 1/2$ is the critical boundary case. If $\sum_{k=1}^{\infty} k^b \sup_{l \geq k} \vartheta_l(p) < \infty$, $b > 1/2$, then for large enough $p$ (recall $B(p) \to 1/2$), Theorem 2.3 in conjunction with Proposition 2.2 provides the optimal bound. If $b < 1/2$, Theorem 2.4 implies that the optimal bound $n^{-1/2}$ is not possible in general. We conclude that the conditions of Theorem 2.3 are (essentially) sharp, given sufficient moments.

So far, so good, but the actual proof of Theorem 2.4 raises more questions. The constructed counter example is a linear process

$$
(2.8) \quad X_k = \sum_{j \in \mathbb{N}} \alpha_j \epsilon_{k-j}, \quad E\epsilon_0 = 0, \quad E\epsilon_0^2 = 1, \quad E|\epsilon_0|^3 < \infty,
$$

one may (but this is not necessary) even take the innovations $(\epsilon_k)_{k \in \mathbb{Z}}$ to be Gaussian. The actual source of the lower bound is the slow rate of convergence of the variance $n^{-1}E S_n^2 \to s^2$. In this particular counter example, the optimal rate of convergence can be recovered by changing the normalisation from $\sqrt{n}$ to $\sqrt{E S_n^2}$, which might be somewhat surprising on first sight. It is, however, completely unclear whether this is true more generally or only the case for special (linear) processes. In particular, as has been shown for instance by [20], in case of a normalisation with $\sqrt{E S_n^2}$, the rate of convergence may even be faster than $n^{-1/2}$ for special linear processes. This leads to the following question, most likely very difficult to resolve.

**Question 2.1.** What are sharp (weak/other) dependence conditions, such that the optimal rate $n^{-1/2}$ with normalisation $\sqrt{E S_n^2}$ is reached, that is,

$$
(2.9) \quad \sup_{x \in \mathbb{R}} |\mathbb{P}(S_n \leq x \sqrt{E S_n^2}) - \Phi(x)| \leq C n^{-1/2}
$$

for some constant $C > 0$?

As mentioned above, the work of [20] shows that already the linear case is not trivial.
3. Examples

The literature contains a myriad of examples covered by our setup. Rather than reproducing all these examples, let us mention the following (small fraction of) references \cite{2, 27, 22, 43}, where among others, the following processes are treated: Functions of linear processes, functions of volatility models like Garch, augmented Garch and so on, functions of iterated random models, functions of infinite markov chains, functions of Volterra processes, functions of threshold models, ... . Particularly \cite{43} contains numerous examples.

The setup also contains many dynamical systems: Due to the recent advancements in the theory of dynamical systems, the results also apply to Hölder continuous observables on many (non)-uniformly expanding maps with exponential tails (cf. \cite{31}), sub exponential tails (cf. \cite{11}), and also slowly mixing systems (cf. \cite{10}). Among others, this includes Gibbs-Markov maps, Axiom A diffeomorphisms, dispersing billiards, classes of logistic and Hénon maps or the Gauss fraction. In addition, the doubling map $2x \mod 1$, and cocycles like the left random walk on the general linear group \cite{27, 12}, are also within our framework. Since the latter have been studied for decades, we present a more detailed discussion. To the best of my knowledge, the conditions given below in Corollaries 3.2 and 3.4 improve upon the currently weakest available in the literature. In light of Theorem 2.4, it is tempting to make the conjecture that the conditions are close to being sharp for the doubling map $2x \mod 1$.

**Example 3.1** (Sums of the form $\sum f(t^{2k})$). For the discussion of this example, we largely follow \cite{27}. Consider the measure preserving transformation $T x = 2x \mod 1$ on the probability space $([0,1], \mathcal{B}, \lambda)$, with Borel $\sigma$-algebra $\mathcal{B}$ and Lebesgue measure $\lambda$. Let $U \overset{d}{=} \text{Uniform}[0,1]$. Then $TU = \sum_{j=0}^{\infty} 2^{-j-1} \zeta_j$, where $\zeta_j$ are Bernoulli random variables. The flow $T^kU$ can then be written as $T^kU = \sum_{j=0}^{\infty} 2^{-j-1} \zeta_{k-j}$, see \cite{24}. Note that this implies that $T^kU$ can also be represented as an AR(1) process and in particular, that $T^kU$ is a stationary Bernoulli-shift process. The study about the behaviour of $S_n = \sum_{k=1}^{n} f(T^kU)$ for appropriate functions $f$ has a very long history and dates back to Kac \cite{29}. Since then, numerous contributions have been made, see for instance \cite{2, 4, 6, 15, 14, 23, 24, 32, 34, 35, 37, 39} to name a few. Here, we consider the following class of functions. Recall $B(p)$ in \eqref{2.6}, and let $f$ be a function defined on the unit interval $[0,1]$ such that

\begin{align}
\int_{0}^{1} f(t) dt &= 0, \quad \int_{0}^{1} |f(t)|^{p} dt < \infty, \quad \text{and} \\
\int_{0}^{1} t^{-1} |\log(t)|^{b} w_p(f,t) dt < \infty, \quad b > B(p),
\end{align}

(3.1)
where $w_p(f, t)$ denotes a $L^p([0, 1], \lambda)$ modulus of continuity of $f$, that is, $w_p \geq 0$ is increasing with
\[
\lim_{t \to 0} w_p(f, t) = w_p(f, 0) = 0, \quad \int_0^1 |f(x + t) - f(x)|^p dx \leq w_p^p(t).
\]
Let $X_k = f(T^k U)$. By straightforward computations, we get
\[
\|X_k - X_k^*\|_p \lor \|X_k - X_k'\|_p \lesssim w_p(f, 2^{-k}),
\]
and hence (A2) holds if $\sum_{k \in \mathbb{N}} k^b w_p(f, 2^{-k}) < \infty$. This, however, is equivalent with $\int_0^1 t^{-1} |\log(t)|^b w_p(f, t)dt < \infty$, and we obtain the following result.

**Corollary 3.2.** If $s^2 > 0$ and (3.1) holds for $p > 2$, then Theorem 2.3 applies.

If $p = \infty$, then [14] mention that due to a result of [26], the decay condition
\[
(3.2) \quad \int_0^1 t^{-1} |\log(t)| w_p(f, t)dt < \infty
\]
implies the optimal convergence rate $n^{-1/2}$. However, for $p \to \infty$, we have $B(p) \to 1/2$, hence condition (3.1) is strictly weaker even in the special case $p = \infty$.

**Example 3.3** (Left random walk on $GL_d(\mathbb{R})$). For the discussion of this example, we largely follow [28], where under slightly stronger conditions, the exact transition between a Berry-Esseen bound and Edgeworth expansion in this context is derived. Here, we are only interested in Berry-Esseen bounds, but subject to weaker conditions.

Cocycles, in particular the random walk on $GL_d(\mathbb{R})$, have been heavily investigated in the literature, see e.g. [7] and [1], [9], [12] for some more recent results. We will particularly exploit ideas of [9], [12]. As is pointed out in [13], the argument below also applies to more general cocycles, and consequently also our results.

Let $(\varepsilon_k)_{k \in \mathbb{N}}$ be independent random matrices taking values in $G = GL_d(\mathbb{R})$, with common distribution $\mu$. Let $A_0 = \text{Id}$, and for every $n \in \mathbb{N}$, $A_n = \prod_{i=1}^n \varepsilon_i$. Denote with $\|\cdot\|$ the Euclidean norm on $\mathbb{R}^d$. We adopt the usual convention that $\mu$ has a moment of order $q$, if
\[
(3.3) \quad \int_G (\log N(g))^q \mu(dg) < \infty, \quad N(g) = \max \{\|g\|, \|g^{-1}\|\}.
\]

Let $\mathcal{X} = P_{d-1}(\mathbb{R}^d)$ be the projective space of $\mathbb{R}^d \setminus \{0\}$, and write $\pi$ for the projection from $\mathbb{R}^d \setminus \{0\}$ to $\mathcal{X}$. We assume that $\mu$ is strongly irreducible and proximal, see [9] for details. The left random walk of law $\mu$ started at $\pi \in \mathcal{X}$ is the Markov chain given by $Y_0T = \pi$, $Y_kT = \varepsilon_k Y_{k-1}T$ for $k \in \mathbb{N}$. Following
the usual setup, we consider the associated random variables \((X_k)_{k \in \mathbb{N}}\), given by

\[
X_k = h(\varepsilon_k, Y_{k-1}), \quad h(g, \tau) = \log \|g\| / \|\tau\|,
\]
for \(g \in G\) and \(z \in \mathbb{R}^d \setminus \{0\}\). It follows that, for any \(x \in S^{d-1}\), we have

\[
S_n = \sum_{k=1}^{n} (X_k - \mathbb{E}X_k) = \log \|A_n x\| - \mathbb{E} \log \|A_n x\|.
\]

Following [12], Proposition 3 in [9] implies that, if \(q > 5p/2 + 1/2\), then

\[
\sum_{k=1}^{\infty} k^b \sup_{\tau, \bar{\tau} \in \mathcal{X}} \|X_k - \bar{X}_k\| < \infty.
\]

In particular, it holds that

\[
\lim_{n \to \infty} n^{-1} \mathbb{E} S_n^2 = s^2,
\]
where the latter does not depend on \(\tau \in \mathcal{X}\). We are now in the situation of a quenched setup, that is, instead of \(X_k\), we have

\[
X_k = f_k(\varepsilon_k, \varepsilon_{k-1}, \ldots, \varepsilon_0, x),
\]
where \(x\) is some initial value. Strictly speaking, this quenched setup is not included in our initial setting a priori. However, it is an easy task (but a bit tedious) to check that the results remain equally valid, the crucial points being the validity of (3.5) and (3.6)\(^2\). Due to Proposition 2.2, we obtain the following result.

**Corollary 3.4.** If \(s^2 > 0\) and \(q > 8\) in (3.3), then

\[
\Delta_n \leq C n^{-1/2}.
\]

It appears likely that in this special setup, the moment condition \(q > 8\) can be further relaxed by a modification of the proof, using ideas employed in [12]. This, however, is (way) beyond the scope of this note.

## 4. Proof of the main results

For the proof of the main results, we refine arguments given in [27]. For the reader’s convenience, we largely give the whole proof, explicitly indicating which parts are treated as in [27]. This is done for the main proof, but also for almost all the technical lemmas and results. Conceptually, the proof relies on \(m\)-dependent approximations and delicate conditioning arguments. This means we will first show Theorem 2.3 for certain \(m\)-dependent sequences (Section 4.1, Theorem 4.2), and then show how to derive Theorem 2.3 from this result (Section 4.4).

\(^2\)In fact, \(s\) may even depend on an initial value \(x\), as long as the variance is bounded away from zero.
To simplify the notation in the proofs, we restrict ourselves to the case of (time homogenous) Bernoulli-shift sequences, that is, where
\[ X_k = g(\epsilon_k, \epsilon_{k-1}, \ldots) , \]
and the function \( g \) does not depend on \( k \). This requires substantially less notation (indices) throughout the proofs, in particular (2.5) holds. The more general non-homogenous (but still stationary) case follows from straightforward (notational) adaptations. This is because the key ingredient we require for the proof is the Bernoulli-shift structure (2.1) in connection with the summability condition Assumption 2.1 (ii). Whether \( g \) depends on \( k \) or not is of no relevance in this context.

4.1. M-dependencies. We require some additional notation and definitions. Let \( f_m : S^m \to \mathbb{R} \) be measurable functions, and put \( X_k = f_m(\epsilon_k, \ldots, \epsilon_{k-m+1}) \) for \( m \in \mathbb{N}, k \in \mathbb{Z} \), where \( m = m_n \to \infty \) as \( n \) increases. We work under the following conditions.

**Assumption 4.1.** For \( p > 2 \) and \( a > 0 \), we have uniformly in \( m \)

- (B1) \( \|X_k\|_p < \infty, \mathbb{E}X_k = 0 \),
- (B2) \( \sum_{k=1}^{\infty} k^a \|X_k - X_k^*\|_p < \infty \),
- (B3) \( s^2_m \geq s^2 > 0 \), where \( s^2_m = \sum_{k \in \mathbb{Z}} \mathbb{E}X_k = \sum_{k=-m}^{m} \mathbb{E}X_k \).

Denote with \( s^2_{nm} = n^{-1}\|S_n\|^2_2 \) the sample variance. We are now ready to give the main result of this section.

**Theorem 4.2.** Grant Assumption 4.1, and let \( p > 2 \). Assume in addition that \( m = m_n \to \infty \). Then
\[
\sup_{x \in \mathbb{R}} |\mathbb{P}(S_n/\sqrt{n} \leq x) - \Phi(x/s_{nm})| \lesssim n^{-(p/3)/2+1} .
\]

As mentioned earlier, in broad brushes, the proof of Theorem 4.2 follows arguments given in [27]. We deviate, however, at key steps, by employing (somewhat) different technical lemmas, or lemmas where the proofs have been substantially refined.

These and other new results allow us to improve upon key estimates, respectively weaken the underlying conditions. For the reader’s convenience, we largely provide the whole proof, indicating which parts are treated as in [27]. To this end, let us now recall some notation from [27]. Introduce the \( \sigma \)-algebra
\[
\mathbb{F}_m = \sigma(\epsilon_{-m+1}, \ldots, \epsilon_0, \epsilon_1, \ldots, \epsilon_m, \epsilon_{m+1}, \ldots, \epsilon_{2m}, \epsilon_{2m+1}, \ldots),
\]
where we recall that \( (\epsilon_k)_{k \in \mathbb{Z}} \) and \( (\epsilon_k')_{k \in \mathbb{Z}} \) are mutually independent, identically distributed random sequences. For a \( \sigma \)-algebra \( \mathcal{H} \), we write \( \mathbb{P}_\mathcal{H}(\cdot) \) for

\[ 3 \text{This is also true for the non stationary, quenched setup.} \]
the conditional law and \( \mathbb{E}_H \) for the conditional expectation. Put
\[
S^{(1)}_m = \sum_{k=1}^{n} (X_k - \mathbb{E}_{F_m} X_k) \quad \text{and} \quad S^{(2)}_m = \sum_{k=1}^{n} \mathbb{E}_{F_m} X_k,
\]
yielding the decomposition
\[
S_n = \sum_{k=1}^{n} X_k = S^{(1)}_m + S^{(2)}_m.
\]
To avoid any notational problems, we put \( X_k = 0 \) for \( k \not\in \{1, \ldots, n\} \). Let \( n = 2(N-1)m + m' \), where \( N, m \) are chosen such that \( Cm \leq m' \leq m \) and \( C > 0 \) is an absolute constant, independent of \( m, n \). For \( 1 \leq j \leq N \), we construct the block random variables
\[
(4.2)
U_j = \sum_{k=(2j-1)m+1}^{(2j-1)m+m} (X_k - \mathbb{E}_{F_m} X_k) \quad \text{and} \quad R_j = \sum_{k=(2j-1)m+1}^{2jm} (X_k - \mathbb{E}_{F_m} X_k),
\]
and put \( Y_j^{(1)} = U_j + R_j \), hence \( S^{(1)}_m = \sum_{j=1}^{N} Y_j^{(1)} \). Note that by construction of the blocks, \( Y_j^{(1)}, j = 1, \ldots, N \) are independent random variables under the conditional probability measure \( \mathbb{P}_{F_m} (\cdot) \), and are identically distributed at least for \( j = 1, \ldots, N-1 \) under \( \mathbb{P} \). We also put \( Y_1^{(2)} = \sum_{k=1}^{m} \mathbb{E}_{F_m} X_k \) and \( Y_j^{(2)} = \sum_{k=(j-1)m+1}^{(j+1)m} \mathbb{E}_{F_m} X_k \) for \( j = 2, \ldots, N \). Note that \( Y_j^{(2)}, j = 1, \ldots, N \) is a sequence of independent random variables. The following partial and conditional variances are relevant for the proofs:
\[
\sigma_{j|m}^2 = \frac{1}{2m} \mathbb{E}_{F_m} \left( Y_j^{(1)} \right)^2 \quad \text{and} \quad \sigma_j^2 = \mathbb{E} \sigma_{j|m}^2,
\]
\[
\sigma_m^2 = \frac{1}{n} \mathbb{E}_{F_m} \left( S^{(1)}_m \right)^2 = \frac{1}{N + m'/2m} \sum_{j=1}^{N} \sigma_{j|m}^2,
\]
\[
\overline{\sigma}_m^2 = \mathbb{E} \sigma_m^2 = \frac{1}{N + m'/2m} \sum_{j=1}^{N} \sigma_j^2,
\]
\[
\hat{\sigma}_m^2 = \frac{1}{2m} \sum_{k=1}^{m} \sum_{l=1}^{m} \mathbb{E} X_k X_l.
\]
As we shall see below, these quantities are all closely connected. Note that \( \sigma_i^2 = \sigma_j^2 \) for \( 1 \leq i, j \leq N - 1 \), but \( \sigma_1^2 \neq \sigma_N^2 \) in general. Moreover, we have the (formal) equation
\[
(4.3) \quad 2m \hat{\sigma}_m^2 = ms_m^2 - \sum_{k \in \mathbb{Z}} m \wedge |k| \mathbb{E} X_0 X_k.
\]
The above relation is important, since Lemma 4.6 yields that under Assumption 4.1 we have \( 2\hat{\sigma}_m^2 = s_m^2 + o(1) \). Moreover, Lemma 4.7 implies
\[ \sigma_j^2 = \hat{\sigma}_m^2 + o(1) \text{ for } 1 \leq j \leq N - 1. \]

We conclude that

\[ (4.4) \quad \sigma_j^2 = \frac{s_m^2}{2} + o(1) > 0, \text{ for sufficiently large } m. \]

The same is true for \( \sigma_j^2 \), since \( m' \geq Cm \). All in all, we conclude that we are not facing any degeneracy problems for the partial variances \( \sigma_j^2 \), \( 1 \leq j \leq N \) subject to Assumption 4.1. For the second part \( S_m^{(2)} \), we introduce

\[ \varsigma_m = n^{-1}\|S_m^{(2)}\|^2. \]

One readily derives via conditioning arguments

\[ (4.5) \quad s_{nm}^2 = n^{-1}\|S_n\|^2 = n^{-1}\|S_m^{(1)}\|^2 + n^{-1}\|S_m^{(2)}\|^2 = \sigma_m^2 + \varsigma_m^2. \]

We require some additional notation. Let \((\epsilon_k')_{k \in \mathbb{Z}}\) be independent copies of \((\epsilon_k)_{k \in \mathbb{Z}}\) and \((\epsilon_k'')_{k \in \mathbb{Z}}\). For \( l \leq k \), we then define \( X_k^{(l,')} \), \( X_k^{(l,**)} \) in analogy to \( X_k^{(l)} \), \( X_k^{(l,**)} \) replacing every \( \epsilon_k \) with \( \epsilon_k'' \) at all corresponding places. For \( k \geq 0 \), we also introduce the \( \sigma \)-algebras

\[ E'_k = \sigma(\epsilon_j, j \leq k \text{ and } j \neq 0, \epsilon_0') \text{ and } \quad E^*_k = \sigma(\epsilon_j, 1 \leq j \leq k \text{ and } \epsilon_i', i \leq 0). \]

Similarly, we define \( E''_k \) and \( E^{**}_k \). Throughout the proofs, we make the following conventions.

(i): We do not distinguish between \( N \) and \( N + m'/2m \), since the difference \( m'/2m \) is of no relevance for the proofs. We use \( N \) for both expressions.

(ii): The abbreviations \( I, II, III, \ldots \), for expressions (possible with some additional indices) vary from proof to proof.

(iii): If there is no confusion, we put \( Y_j = (2m)^{-1/2}Y_j^{(1)} \) for \( j = 1, \ldots, N \) to lighten the notation, particularly in part \( A \).

(iv): \( C > 0 \) denotes an absolute constant, which may vary from line to line.

For the proofs, we first establish key preliminary results as lemmas in Section 4.2 below. We then provide the proof of Theorem 4.2 in Section 4.3. Theorem 2.3 is based on Theorem 4.2, the proof is given in Section 4.4. Finally, the results for the lower bound are given in Section 4.5.

4.2. Main Lemmas. We will frequently use the following Lemma in connection with Lemma 4.5, which is essentially a restatement of Theorem 1 in [44], adapted to our setting.

**Lemma 4.3.** Put \( p' = \min\{p, 2\} \). If \( \sum_{k=1}^{\infty} \|X_k - X_k'\|_p < \infty \), then

\[ \|X_1 + \ldots + X_n\|_p \lesssim n^{1/p'}. \]

The next result controls the remainder \( R_j \).

**Lemma 4.4.** Grant Assumption 4.1. Then \( \|R_j\|_p < \infty \) for \( j = 1, \ldots, N \), where \( R_j \) is defined in (4.2).
Lemma 4.4. Without loss of generality, we assume that $j = 1$ since $m \sim m'$. Since $X_k - \mathbb{E}_m X_k \overset{d}{=} \mathbb{E}_m [X_k^{(k-m^*)} - X_k]$ for $m + 1 \leq k \leq 2m$, we have

$$\left\| \sum_{k=m+1}^{2m} X_k - \mathbb{E}_m X_k \right\|_p = \left\| \sum_{k=m+1}^{2m} \mathbb{E}_m [X_k^{(k-m^*)} - X_k] \right\|_p \leq \sum_{k=m+1}^{2m} \left\| X_k^{(k-m^*)} - X_k \right\|_p \leq \sum_{k=1}^{\infty} \left\| X_k^* - X_k \right\|_p < \infty.$$ 

\[ \square \]

The following lemma establishes a simple connection between $\left\| X_k - X_k^* \right\|_p$ and $\left\| X_k - X_k^* \right\|_p$, which we will frequently use without mentioning it explicitly any further.

Lemma 4.5. Grant Assumption 4.1. Then $\sum_{k=1}^{\infty} k^a \left\| X_k - X_k^* \right\|_p < \infty$.

Proof of Lemma 4.5. Observe that we have the inequality

$$\left\| X_k - X_k^* \right\|_p \leq \left\| X_k - X_k^* \right\|_p + \left\| X_k^* - X_k \right\|_p = \left\| X_k - X_k^* \right\|_p + \left\| X_{k+1} - X_{k+1}^* \right\|_p,$$

hence the claim readily follows. \[ \square \]

Lemma 4.6. Assume $\sum_{k=1}^{\infty} k^c \left\| X_k - X_k^* \right\|_p < \infty$ for $c > 0$ and $\mathbb{E} X_k = 0$. Then $\left| \sum_{k=1}^{\infty} \mathbb{E} X_0 X_k \right| < \infty$ and

$$n^{-1} \left\| \sum_{k=1}^{n} X_k \right\|_2^2 = \sum_{k \in \mathbb{Z}} \mathbb{E} X_0 X_k + O(n^{-c}).$$

In particular, $\sigma_m^2 = s_m^2/2 + O(m^{-c})$ and $\sigma_l^2 = s_l^2/2 + O(1)$ as $l \to m$.

Proof of Lemma 4.6. For a random variable $X$, define the projections $\mathcal{P}_t(X) = \mathbb{E}_{\mathcal{E}_t} X - \mathbb{E}_{\mathcal{E}_{t-1}} X$. Note that

$$\mathcal{P}_0(X_k) = \mathbb{E}_{\mathcal{E}_0} [X_k - X_k^*].$$

We then have the well-known decomposition $X_k = \sum_{i=0}^{k} \mathcal{P}_i(X_k)$. Existence of the sum on the right-hand-side follows for instance from the triangle inequality and (4.6). Alternatively, one may also employ martingale arguments. From the orthogonality of the projections, we get

$$\mathbb{E} X_0 X_k = \sum_{i=-\infty}^{0} \mathbb{E} \mathcal{P}_i(X_0) \mathcal{P}_i(X_k).$$

Hence an application of Cauchy-Schwarz and Tonelli’s Theorem yield

$$\sum_{k \in \mathbb{Z}} \left| \mathbb{E} X_0 X_k \right| \lesssim \left( \sum_{i=-\infty}^{0} \left\| \mathcal{P}_i(X_0) \right\|_2 \right)^2 \lesssim \left( \sum_{i=0}^{\infty} \left\| X_i - X_i^* \right\|_2 \right)^2 < \infty.$$
In the same manner, we derive that
\[ \sum_{k=1}^{\infty} k \wedge n |\mathbb{E}X_0 X_k| \lesssim \sum_{k=1}^{\infty} k \wedge n \sum_{i=-\infty}^{0} \|P_i(X_0)\|_2 \|P_i(X_k)\|_2 \]
\[ \lesssim \sum_{k=1}^{\infty} k \wedge n \|X_k - X'_k\|_2. \]
Hence we obtain from \( \sum_{k=1}^{\infty} k^c \|X_k - X'_k\|_p < \infty \) that
\[ n^{-1} \sum_{k=1}^{\infty} k \wedge n |\mathbb{E}X_0 X_k| \lesssim n^{-1} \sum_{k=1}^{n} \|X_k - X'_k\|_2 + \sum_{k>n}^{\infty} \|X_k - X'_k\|_2 \]
\[ \lesssim n^{-1} + n^{-\epsilon} < n^{-\epsilon}, \]
and analogue arguments also lead to
\[ \sum_{k>n}^{\infty} |\mathbb{E}X_0 X_k| \lesssim n^{-\epsilon}. \]

Next, observe that
\[ \left\| \sum_{k=1}^{n} X_k \right\|_2^2 = \sum_{|k| \leq n} \mathbb{E}X_0 X_k - \sum_{|k| > n} |k| \mathbb{E}X_0 X_k. \]
Using the above, we conclude
\[ n^{-1} \left\| \sum_{k=1}^{n} X_k \right\|_2^2 = \sum_{k \in \mathbb{Z}} \mathbb{E}X_0 X_k + \mathcal{O}(n^{-\epsilon}). \]
Hence \( \hat{\sigma}_m^2 = s_m^2/2 + \mathcal{O}(m^{-\epsilon}) \), and \( \hat{\sigma}_l^2 = s_m^2/2 + \mathcal{O}(1) \) as \( l \to m \) readily follows. \( \square \)

The following Lemma is a key result. At some instances, we will employ the same reasoning as in [27], at others, we will argue very differently.

**Lemma 4.7.** Grant Assumption 4.1. Then there exists a \( \delta > 0 \) such that
(i) \( \|\sigma_j^{2|m} - \sigma_j^{2}\|_{p/2} \lesssim \|\sigma_j^{2|m} - \hat{\sigma}_m^{2}\|_{p/2} + m^{-1/2-\delta} \lesssim m^{-1/2-\delta} \)
for \( 1 \leq j \leq N \),
(ii) \( \sigma_j^{2} = \hat{\sigma}_m^{2} + \mathcal{O}(m^{-1/2-\delta}) \) for \( 1 \leq j \leq N \),
(iii) \( \|\sigma_j^{2|m} - \sigma_m^{2}\|_{p/2} \lesssim n^{-1/2-\delta} N^{2/p-1/2+\delta} \).

**Proof of Lemma 4.7.** We first show (i). Without loss of generality, we may assume \( j = 1 \), since \( m \asymp m' \). To lighten the notation, we use \( R_1 = R_1^{(1)} \).
We first establish \( \|\sigma_j^{2|m} - \sigma_m^{2}\|_{p/2} \lesssim m^{-1/2-\delta}, \delta > 0 \). Observe
\[ 2m(\sigma_j^{2|m} - \sigma_m^{2}) = \mathbb{E}_{F_m} \left[ \left( \sum_{k=1}^{m} (X_k^{(**)} + (X_k - X_k^{(**)})) - \mathbb{E}_{F_m} X_k \right) + R_1 \right]^2 - 2m\sigma_m^{2}. \]
Computing the square in the first expression, we obtain a sum of squared terms and of cross terms. We first consider the cross terms, which are

\[
2 \sum_{k=1}^{m} \sum_{l=1}^{m} \mathbb{E}_{F_m} \left[ \mathbb{E}_{F_m} \left[ X_k^{(**)}(X_l - X_l^{(**)}) \right] + \mathbb{E}_{F_m} \left[ X_k^{(**)} \right] \mathbb{E}_{F_m} [X_l] + \mathbb{E}_{F_m} [X_k](X_l - X_l^{(**)}) \right]
\]

\[+ 2 \sum_{k=1}^{m} \mathbb{E}_{F_m} \left[ R_l X_k^{(**)} + R_l (X_k - X_k^{(**)}) + R_l \mathbb{E}_{F_m} [X_k] \right] \]

\[\overset{\text{def}}{=} I_m + II_m + III_m + IV_m + V_m + VI_m.\]

Below, we establish bounds for each of these separate terms.

**Case I\(_m\):** We have

\[I_m/2 = \sum_{l=1}^{m} \sum_{k=1}^{m} \mathbb{E}_{F_m} \left[ X_k^{(**)}(X_l - X_l^{(**)}) \right] + \sum_{l=1}^{m} \sum_{k=1}^{m-1} \mathbb{E}_{F_m} \left[ X_k^{(**)}(X_l - X_l^{(**)}) \right]
\]

\[= \sum_{l=1}^{m} \sum_{k=1}^{m} \mathbb{E}_{F_m} \left[ (X_l - X_l^{(**)}) \mathbb{E} \left[ X_k^{(**)} | \sigma (F_m, E_l, E_l^{(**)}) \right] \right]
\]

\[+ \sum_{l=1}^{m} \sum_{k=1}^{m-1} \mathbb{E}_{F_m} \left[ X_k^{(**)}(X_l - X_l^{(**)}) \right].\]

Observe that we have the distributional identity

\[\mathbb{E} \left[ X_k^{(**)} | \sigma (F_m, E_l, E_l^{(**)}) \right] \overset{\text{d}}{=} \mathbb{E} [X_k | E_l] = \mathbb{E} [X_k - X_k^{(k-l,s)} | E_l].\]

Hence by Cauchy-Schwarz (with respect to \(\mathbb{E}_{F_m}\)) and Jensen’s inequality yield

\[\|I_m\|_{p/2} \lesssim \sum_{l=1}^{m} \sum_{k=1}^{m} \|X_l - X_l^{(**)}\|_p \|X_k - X_k^{(k-l,s)}\|_p + \sum_{l=1}^{m} \sum_{k=1}^{m-1} \|X_k^{(**)}\|_p \|X_l - X_l^{(**)}\|_p\]

which, using Lemma 4.3, is further bounded by

\[\lesssim \left( \sum_{l=1}^{m} \|X_l - X_l^*\|_p \right)^2 + \sum_{l=1}^{m} \sqrt{l} \|X_l - X_l^*\|_p.\]

Due to (B2), we thus obtain

\[(4.11) \quad \|I_m\|_{p/2} \lesssim m^{1/2-a}.\]

**Case II\(_m\):** Since \(\mathbb{E}_{F_m} X_k^{(**)} = \mathbb{E} X_k = 0\), we get II\(_m\) = 0.

**Case III\(_m\):** First, Jensen’s inequality implies

\[(4.12) \quad \|\mathbb{E}_{F_m} X_l\|_p = \|\mathbb{E}_{F_m} [X_l - X_l^{**}]\|_p \leq \|X_l - X_l^{**}\|_p.\]
Cauchy-Schwarz (with respect to $\mathbb{E}_{F_m}$), Jensen’s inequality and (B2) now yield

$$
\|III_m\|_{p/2} \lesssim \left( \sum_{l=1}^{m} \|X_l - X^*_l\|_p \right)^2 < \infty.
$$

**Case IV$_m$**: Let $\tau > 0$ and put $\tau_m = m^{\tau}$. Then by the triangle inequality

$$
\left\| \sum_{k=1}^{m} \mathbb{E}_{F_m} [R_1 X_k^{(*)}] \right\|_{p/2} \leq \left\| \sum_{k=m-\tau_m+1}^{m} \mathbb{E}_{F_m} [R_1 X_k^{(*)}] \right\|_{p/2} + \left\| \sum_{k=1}^{m-\tau_m} \mathbb{E}_{F_m} [X_k^{(*)} R_1] \right\|_{p/2}.
$$

The triangle and Jensen’s inequality, Cauchy-Schwarz and $\|R_1\|_p < \infty$ by Lemma 4.4, then yield

$$
\left\| \sum_{k=m-\tau_m+1}^{m} \mathbb{E}_{F_m} [R_1 X_k^{(*)}] \right\|_{p/2} \lesssim \sum_{k=m-\tau_m+1}^{m} \|X_k\|_p \|R_1\|_p \lesssim \tau_m.
$$

The second term in (4.14) is more complicated. Recall $R_1 = \sum_{k=m+1}^{2m} (X_k - \mathbb{E}_{F_m} X_k)$. Observe that $X_k^{(*)}$ and $X_l^{(l-m+\tau_m,*)}$ are independent for $1 \leq k \leq m - \tau_m$ and $m + 1 \leq l \leq 2m$. Hence

$$
\sum_{k=1}^{m-\tau_m} \mathbb{E}_{F_m} [R_1 X_k^{(*)}] = \sum_{k=1}^{m-\tau_m} \sum_{l=m+1}^{2m} \mathbb{E}_{F_m} [X_k^{(*)} X_l] = \sum_{k=1}^{m-\tau_m} \sum_{l=m+1}^{2m} \mathbb{E}_{F_m} [X_k^{(*)} (X_l - X_l^{(l-m+\tau_m,*)} + X_l^{(l-m+\tau_m,*)})] = \sum_{l=m+1}^{2m} \mathbb{E}_{F_m} \left[ \sum_{k=1}^{m-\tau_m} X_k^{(*)} (X_l - X_l^{(l-m+\tau_m,*)}) \right],
$$

where we used $\mathbb{E}_{F_m} [X_k^{(*)} X_l^{(l-m+\tau_m,*)}] = 0$. Then Cauchy-Schwarz, the triangle and Jensen’s inequality together with Lemma 4.3 and (B2) yield

$$
\left\| \sum_{k=1}^{m-\tau_m} \mathbb{E}_{F_m} [R_1 X_k^{(*)}] \right\|_{p/2} \lesssim \left\| \sum_{k=1}^{m-\tau_m} X_k \right\|_p \sum_{l=\tau_m}^{m} \|X_l - X^*_l\|_p \lesssim \sqrt{m\tau^{-a}} \sum_{l=\tau_m}^{m} l^a \|X_l - X^*_l\|_p \lesssim \sqrt{m\tau^{-a}}.
$$

Piecing both bounds (4.15) and (4.16) together and selecting $\tau > 0$ sufficiently small, it follows that

$$
\|IV_m\|_{p/2} \lesssim \tau_m + \sqrt{m\tau^{-a}} \lesssim m^{1/2-ar}, \quad a > 0.
$$
Case $V_m$: Cauchy-Schwarz, Jensen’s inequality, Lemma 4.4 and (B2) yield
\[
\|V_m\|_{p/2} \lesssim \sum_{k=1}^{m} \|X_k - X_k^{(**)}\|_p \|R_1\|_p < \infty.
\]

Case $VI_m$: Proceeding as above and using (4.12), it follows that $\|VI_m\|_{p/2} < \infty$.

It thus remains to deal with the squared terms, which are
\[
\sum_{k=1}^{m} \sum_{l=1}^{m} \mathbb{E}_{F_m}[X_k^{(**)} X_l^{(**)}] + (X_k - X_k^{(**)})(X_l - X_l^{(**)}) + \mathbb{E}_{F_m}[X_k \mathbb{E}_{F_m}[X_l]] + \mathbb{E}_{F_m}[R_1^2]
\]
\[
= 2m \tilde{\sigma}_m^2 + VII_m + VIII_m + IX_m.
\]

However, using the results from the previous computations and Lemma 4.4, one readily deduces that
\[
(4.18) \quad \|VII_m\|_{p/2}, \|VIII_m\|_{p/2}, \|IX_m\|_{p/2} < \infty.
\]

Piecing everything together, we have established that for sufficiently small $\tau > 0$
\[
\|\sigma_{jm}^2 - \tilde{\sigma}_m^2\|_{p/2} \lesssim m^{-1/2-\tau a} + m^{-1} \lesssim m^{-1/2-\tau a}.
\]

Hence we get that for $\delta = \tau a > 0$
\[
(4.19) \quad \|\sigma_{jm}^2 - \tilde{\sigma}_m^2\|_{p/2} \lesssim m^{-1/2-\delta}.
\]

Moreover, from the above arguments, one also obtains the same bound for $\|\sigma_{jm}^2 - \tilde{\sigma}_m^2\|_{p/2}$, or directly $|\sigma_j^2 - \tilde{\sigma}_m^2| \lesssim m^{-1/2-\delta}$. In either case, (i) and (ii) follow. We now treat (iii). Since $(Y_{j(1)}^{(1)})_{1 \leq j \leq N}$ are independent under $\mathbb{P}_{F_m}$, we have
\[
(4.20) \quad \sigma_m^2 = N^{-1} \sum_{j=1}^{N} \sigma_{jm}^2.
\]

Let $\mathcal{I} = \{1, 3, 5, \ldots\}$ and $\mathcal{J} = \{2, 4, 6, \ldots\}$ such that $\mathcal{I} \cup \mathcal{J} = \{1, 2, \ldots, N\}$. Then
\[
\left\| \sum_{j=1}^{N} \sigma_{jm}^2 - \sigma_j^2 \right\|_{p/2} \leq \left\| \sum_{j \in \mathcal{I}} \sigma_{jm}^2 - \sigma_j^2 \right\|_{p/2} + \left\| \sum_{j \in \mathcal{J}} \sigma_{jm}^2 - \sigma_j^2 \right\|_{p/2}.
\]

Note that $(\sigma_{jm}^2)_{j \in \mathcal{I}}$ is a sequence of independent random variables, and the same is true for $(\sigma_{jm}^2)_{j \in \mathcal{J}}$. Then by Lemma 4.3, we have
\[
\left\| \sum_{j=1}^{N} \sigma_{jm}^2 - \sigma_j^2 \right\|_{p/2} \leq N^{2/p} \left\| \sigma_{jm}^2 - \sigma_j^2 \right\|_{p/2}, \quad \text{for } p \in (2, 3],
\]

\[
\text{for } p \in (2, 3],
\]
which by (i) is of magnitude $O(N^{2/p}m^{-1/2-\delta})$. Hence we conclude from (4.20) the bound
\[ \|\sigma_{jm}^2 - \tau_{jm}^2\|_{p/2} \lesssim n^{-1/2-\delta} N^{2/p-1/2+\delta}. \]
This completes the proof.

For our next result, we require the following preliminary result (Lemma 6.3 in [8]).

**Lemma 4.8.** Let $(U_k)_{1 \leq k \leq n}$ be independent, non-negative variables with $\|U_k\|_q < \infty$, where $1 \leq q \leq 2$. Then for any $0 < u < \sum_{k=1}^{n} EU_k$, we have
\[ P\left( \sum_{k=1}^{n} U_k \leq \sum_{k=1}^{n} EU_k - u \right) \leq \exp\left( -\frac{q-1}{4} \frac{u^{q/(q-1)}}{\left(\sum_{k=1}^{n} EU_k[q]\right)^{1/(q-1)}} \right). \]

We are now ready to establish the following lemma.

**Lemma 4.9.** Grant Assumption 4.1. Then there exists constant $C > 0$, only depending on $p$, such that
\[ P\left( \frac{1}{N} \sum_{j=1}^{N} \sigma_{jm}^2 \leq s_m^2/8 \right) \lesssim \exp\left( -CN \right). \]

**Proof of Lemma 4.9.** Let $\mathcal{I} = \{1, 3, 5, \ldots\}$ and $\mathcal{J} = \{2, 4, 6, \ldots\}$ such that $\mathcal{I} \cup \mathcal{J} = \{1, 2, \ldots, N\}$. Then
\[ P\left( \frac{1}{N} \sum_{j \in \mathcal{I}} \sigma_{jm}^2 \leq s_m^2/8 \right) \leq P\left( \frac{1}{N} \sum_{j \in \mathcal{I}} \sigma_{jm}^2 \leq s_m^2/8 \right). \]

Note that $\{\sigma_{jm}^2\}_{j \in \mathcal{I}}$ is a sequence of independent random variables. Moreover, Lemma 4.6, Lemma 4.7 and the triangle inequality yield that
\[ \sum_{j \in \mathcal{I}} \sigma_{jm}^2 \lesssim \sum_{j \in \mathcal{I}} (s_m^2/2 + O(1))^p/2 \lesssim |\mathcal{I}| \lesssim N, \]
where $|\mathcal{I}|$ denotes the cardinality of $\mathcal{I}$. Similarly, we also have
\[ \sum_{j \in \mathcal{I}} E\sigma_{jm}^2 \geq \sum_{j \in \mathcal{I}} (s_m^2/2 - O(1)) \geq Ns_m^2/4 - O(N). \]
Hence, selecting $u = \sum_{j \in \mathcal{I}} E\sigma_{jm}^2 - Ns_m^2/8$, it follows from the above that $u \gtrsim N$. Setting $q = p/2 > 1$, an application of Lemma 4.8 then yields
\[ P\left( \frac{1}{N} \sum_{j \in \mathcal{I}} \sigma_{jm}^2 \leq s_m^2/8 \right) \lesssim \exp\left( -CN^{2/p-1} \right) \lesssim \exp\left( -CN \right), \]
where $C > 0$ is an absolute constant.
4.3. Proof of Theorem 4.2. We are now ready for the proof of Theorem 4.2, which uses the following decomposition. Let $Z_1, Z_2$ be independent, standard Gaussian random variables. Then

$$
\sup_{x \in \mathbb{R}} |P\left(\frac{S_n}{\sqrt{n}} \leq x\right) - \Phi\left(x/s_{nm}\right)|
= \sup_{x \in \mathbb{R}} |P\left(\frac{S^{(1)}_{|m|}}{\sqrt{n}} \leq x - \frac{S^{(2)}_{|m|}}{\sqrt{n}}\right) - P\left(Z_1\sigma_{|m|} \leq x - Z_2\sigma_{|m|}\right)|
\leq A + B + C,
$$

where $A, B, C$ are defined as

$$
A = \sup_{x \in \mathbb{R}} \left|E\left[\mathbb{P}_{\mathcal{F}_m}\left(\frac{S^{(1)}_{|m|}}{\sqrt{n}} \leq x - \frac{S^{(2)}_{|m|}}{\sqrt{n}}\right) - \mathbb{P}_{\mathcal{F}_m}\left(Z_1\sigma_{|m|} \leq x - \frac{S^{(2)}_{|m|}}{\sqrt{n}}\right)\right]\right|
$$

$$
B = \sup_{x \in \mathbb{R}} \left|E\left[\mathbb{P}_{\mathcal{F}_m}\left(Z_1\sigma_{|m|} \leq x - \frac{S^{(2)}_{|m|}}{\sqrt{n}}\right) - \mathbb{P}_{\mathcal{F}_m}\left(Z_1\sigma_{|m|} \leq x - \frac{S^{(2)}_{|m|}}{\sqrt{n}}\right)\right]\right|
$$

$$
C = \sup_{x \in \mathbb{R}} \left|P\left(\frac{S^{(2)}_{|m|}}{\sqrt{n}} \leq x - Z_1\sigma_{|m|}\right) - P\left(Z_2\sigma_{|m|} \leq x - Z_1\sigma_{|m|}\right)\right|.
$$

We shall see that for all three parts $A, B, C \lesssim n^{-(p/3)/2+1}$, which then clearly implies Theorem 4.2.

4.3.1. Part A. The proof of part $A$ is divided into four major steps.

Proof of $A$. For $L > 0$, put $\mathcal{B}_L = \{L^{-1} \sum_{j=1}^{L} \sigma_{j|m}^2 \geq s_{m}/8\}$, and denote with $\mathcal{B}_L^c$ its complement. Since $S^{(2)}_{|m|} \in \mathcal{F}_m$, we obtain

$$
A = \sup_{x \in \mathbb{R}} \left|E\left[\mathbb{P}_{\mathcal{F}_m}\left(\frac{S^{(1)}_{|m|}}{\sqrt{n}} \leq x - \frac{S^{(2)}_{|m|}}{\sqrt{n}}\right) - \mathbb{P}_{\mathcal{F}_m}\left(Z_1\sigma_{|m|} \leq x - \frac{S^{(2)}_{|m|}}{\sqrt{n}}\right)\right]\right|
\leq E\left[\sup_{y \in \mathbb{R}} \left|\mathbb{P}_{\mathcal{F}_m}\left(\frac{S^{(1)}_{|m|}}{\sqrt{n}} \leq y\right) - \mathbb{P}_{\mathcal{F}_m}\left(Z_1\sigma_{|m|} \leq y\right)\right| \mathbf{1}(\mathcal{B}_N)\right] + 2\mathbb{P}(\mathcal{B}_N).
$$

An application of Lemma 4.9 (improves and replaces Corollary 4.8 in [27]) yields $\mathbb{P}(\mathcal{B}_N^c) \lesssim e^{-CN}$ for some absolute constant $C > 0$. Since $N = n^{1-m}$, $0 < m < 1$, by assumption, it thus suffices to treat

$$
\Delta_{|m|} \overset{\text{def}}{=} \sup_{y \in \mathbb{R}} \left|\mathbb{P}_{\mathcal{F}_m}\left(\frac{S^{(1)}_{|m|}}{\sqrt{n}} \leq y\right) - \mathbb{P}_{\mathcal{F}_m}\left(Z_1\sigma_{|m|} \leq y\right)\right| \mathbf{1}(\mathcal{B}_N).
$$

Step 1: Berry-Esseen inequality. We use exactly (verbatim) the same argument as in [27]. Since we also establish some necessary additional notation in doing so, we provide details. Let $\varphi_j(x) = \mathbb{E}_{\mathcal{F}_m} e^{ixY_j}$, and put $T = n^{b/2-1}c_T$, where $c_T > 0$ will be specified later. Denote with $\Delta_{|m|}^T$ the smoothed version of $\Delta_{|m|}$ (cf. [17]) as in the classical approach. Since $\sigma_{|m|}^2 \geq s_{m}/8 > 0$ on the set $\mathcal{B}_N$ by construction, the smoothing inequality (cf. [17, Lemma 1, XVI.3]) is applicable, and it thus suffices to treat $\Delta_{|m|}^T$. Due to the independence of
is given in full detail, we omit the details of showing the proofs are different in substantial parts. Secondly, one needs to employ the analogous version of Lemma 4.10 in [27] for establishing the bound \((4.26)\) below. Note that the statements of the Lemmas are quite similar, yet the proofs are different in substantial parts. Secondly, one needs to employ the different argument used in the proof of Lemma 4.7 to establish an analogous version of Lemma 4.10 in [27] subject to Assumption 4.1. Since the proof of Lemma 4.7 is given in full detail, we omit the details of showing the analogous version of Lemma 4.10 in [27]. Once this has been done, we can proceed as in [27] to derive

\[
\| \Delta^T \|_1 \leq \int_{-T}^{T} \left\| \prod_{j=1}^{N} \varphi_j(\xi/\sqrt{N}) - \prod_{j=1}^{N} e^{-\sigma_j^2 \xi^2 / 2N} \right\| /|\xi| d\xi.
\]

Set \(t = \xi/\sqrt{N}\). Standard computations and the fact that \(|e^{ix}| = 1\) then imply

\[
\left\| \prod_{j=1}^{N} \varphi_j(t) - \prod_{j=1}^{N} e^{-\sigma_j^2 t^2 / 2} \right\|_1 \\
\leq \sum_{i=1}^{N} \left\| \prod_{j=1}^{i-2} e^{-\sigma_j^2 t^2 / 2} \right\| \left\| \varphi_i(t) - e^{-\sigma_i^2 t^2 / 2} \right\|_1 \left\| \prod_{j=i+2}^{N} \varphi_j(t) \right\|_1 \\
\leq N \left\| \varphi_1(t) - e^{-\sigma_1^2 t^2 / 2} \right\|_1 \left\| \prod_{j=N/2}^{N-1} \varphi_j(t) \right\|_1 + N \left\| \prod_{j=1}^{N/2-3} e^{-\sigma_j^2 t^2 / 2} \right\| \left\| \varphi_1(t) - e^{-\sigma_1^2 t^2 / 2} \right\|_1 \\
+ \left\| \prod_{j=1}^{N/2-3} e^{-\sigma_j^2 t^2 / 2} \right\| \left\| \varphi_N(t) - e^{-\sigma_N^2 t^2 / 2} \right\|_1 \overset{\text{def}}{=} I_N(\xi) + II_N(\xi) + III_N(\xi).
\]

We proceed by obtaining upper bounds for \(I_N(\xi), II_N(\xi)\) and \(III_N(\xi)\).

**Step 2:** In this step things are crucially different from [27]. First, we use Lemma 4.7 instead of Lemma 4.7 in [27] for establishing the bound \((4.25)\) below. Note that the statements of the Lemmas are quite similar, yet the proofs are different in substantial parts. Secondly, one needs to employ the different argument used in the proof of Lemma 4.7 to establish an analogous version of Lemma 4.10 in [27] subject to Assumption 4.1. Since the proof of Lemma 4.7 is given in full detail, we omit the details of showing the analogous version of Lemma 4.10 in [27]. Once this has been done, we can proceed as in [27] to derive

\[
\| \varphi_i(t) - e^{-\sigma_i^2 t^2 / 2} \|_1 \leq C|t|^p m^{-1/2(\sigma_i^3) + 1}, \quad i \in \{1, N\}.
\]

**Step 3:** The third step is devoted to bounding \(\left\| \prod_{j=N/2}^{N-1} \varphi_j(t) \right\|_1\). This can be done by following [27], leading to the upper bound

\[
\left\| \prod_{j=N/2}^{N-1} \varphi_j(t) \right\|_1 \leq e^{-c_{\varphi,1} x^2 N/16} + e^{-\sqrt{N/32} \log 8/7}, \quad \text{for } x^2 < c_{\varphi,2}.
\]

Here \(x = t\sqrt{(m-1)/2m}\) for \(c_{\varphi,3} \leq l \leq m\). It is important to emphasize that \(c_{\varphi,1}, c_{\varphi,2}\) and \(c_{\varphi,3}\) do not depend on \(l, m\) and are strictly positive and finite. No adaptations are necessary here.

**Step 4:** Bounding and integrating \(I_N(\xi), II_N(\xi), III_N(\xi)\):

Here, we largely follow again [27]. However, we do need to employ our different results. For this reason, and since it is the final step and combines
all previous results, we provide details. We first treat \( I_N(\xi) \). Recall that 
\[
t = \xi / \sqrt{N},
\]

hence
\[
|t|^p \lambda^m - (p \lambda^3)/2 + 1 \lesssim |\xi|^p \lambda^3 n^{- (p \lambda^3)/2 + 1} N^{-1}.
\]

By (4.25) and (4.26), it then follows for \( \xi^2 (m - l) < 2c_{\varphi,2}n \), that
\[
I_N(\xi) \lesssim |\xi|^p \lambda^3 n^{- (p \lambda^3)/2 + 1} \left( e^{-c_{\varphi,1} \xi^2 (m - l)/16m} + e^{-\sqrt{N/32} \log 8}/7 \right).
\]

To make use of this bound, we need to appropriately select \( l = l(\xi) \). Recall \( N \asymp n^{1-m} \), \( 0 < m < 1 \) by assumption. Let \( 0 < \lambda < 1 - m \), and put
\[
l'(\xi) = \left( 1(\xi^2 < n^\lambda) + \left( m - \frac{n}{\xi^2} \right) 1(\xi^2 \geq n^\lambda) \right) \vee c_{\varphi,3}
\]

and \( c_2^3 < 2c_{\varphi,2} \). Then, with \( l = l(\xi) = \lfloor l'(\xi) \rfloor \), we obtain from the above
\[
\int_T^{-T} \frac{I_N(\xi)}{\xi} d\xi \lesssim n^{-(p \lambda^3)/2 + 1}.
\]

In order to treat \( II_N(\xi) \), let \( N' = N/2 - 3 \) and recall that
\[
\mathcal{B}_{N'} = \{ N' - 1 \sum_{j=1}^{N'} \sigma_j^2 m \geq s_m^2/8 \}.
\]

Denote with \( \mathcal{B}_{N'}^c \) its complement. Then by Lemma 4.9 and (4.25), it follows that
\[
II_N(\xi) \lesssim |\xi|^p \lambda^3 n^{- (p \lambda^3)/2 + 1} \left( e^{-s_m^2 \xi^2/16} + e^{-CN} \right), \quad C > 0.
\]

From (4.29) above, we thus obtain
\[
\int_T^{-T} \frac{II_N(\xi)}{\xi} d\xi \lesssim n^{-(p \lambda^3)/2 + 1} \int_{|\xi| \leq T} |\xi|^p \lambda^3 \left( e^{-s_m^2 \xi^2/16} + e^{-CN} \right) d\xi
\]

since \( N = n^{1-m}, 0 < m < 1 \) by assumption. Similarly, one obtains the same bound for \( III_N(\xi) \). This completes the proof of part A. \( \square \)

4.3.2. Part B.

Proof of B. Using Lemma 4.9, we can repeat the argument of [27]. Let
\[
\Delta^{(2)}(x) \overset{\text{def}}{=} \mathbb{E} \left[ P_{\mathcal{F}_m} \left( Z_1 \sigma_m \leq x - S_{m}^{(2)} / \sqrt{n} \right) - P_{\mathcal{F}_m} \left( Z_1 \sigma_m \leq x - S_{m}^{(2)} / \sqrt{n} \right) \right].
\]
Recall
\[ \mathcal{B}_N = \{ N^{-1} \sum_{j=1}^{N} \sigma_j^2 m \geq s_m^2/8 \} \]
and \( \mathbb{P}(\mathcal{B}_N^c) \lesssim e^{-CN} \lesssim n^{-(p\wedge 3)/2+1} \) by Lemma 4.9. Using properties of the Gaussian distribution, it follows that
\[
\mathcal{B} \leq \sup_{x \in \mathbb{R}} \left| \mathbb{E} \Delta^{(2)}(x) 1(\mathcal{B}_N) \right| + \sup_{x \in \mathbb{R}} \left| \mathbb{E} \Delta^{(2)}(x) 1(\mathcal{B}_N^c) \right|
\]
\[
\lesssim \mathbb{E} \left[ \left| 1/\sigma_m - 1/\sigma_m \right| 1(\mathcal{B}_N) \right] + n^{-(p\wedge 3)/2+1}.
\]
By \((a - b)(a + b) = a^2 - b^2\), Hölder’s inequality and Lemma 4.7, it follows that
\[
\mathbb{E} \left[ \left| 1/\sigma_m - 1/\sigma_m \right| 1(\mathcal{B}_N) \right] \lesssim \| \sigma_m^2 - \sigma_m^2 \|_{p/2} \lesssim n^{-(p\wedge 3)/2+1}.
\]
Hence \( \mathcal{B} \lesssim n^{-(p\wedge 3)/2+1} \).

4.3.3. Part C.

Proof of \( C \). We can repeat the argument of [27]. Due to the independence of \( Z_1, Z_2 \), we may rewrite \( C \) as
\[
C = \sup_{x \in \mathbb{R}} \left| \Phi \left( \frac{x - S_m^{(2)}/\sqrt{n}}{\sigma_m} \right) - \Phi \left( \frac{x - Z_2 \sigma_m}{\sigma_m} \right) \right|
\]
where \( \Phi(\cdot) \) denotes the cdf of a standard normal distribution. This induces a ‘natural’ smoothing. The claim now follows by repeating the same arguments as in part A. Note however, that the present situation is much easier to handle, due to the already smoothed version (no Berry-Essen inequality is necessary, but can be used), and since \( Y_k^{(2)}, k = 1, \ldots, N \) is a sequence of independent random variables.

4.4. Proofs of Theorem 2.3 and Proposition 2.2. The proof of Theorem 2.3 mainly consists of constructing a good \( m \)-dependent approximation, and then verify the conditions of Theorem 4.2. As in [27], the general idea is to use Lemma 4.10 below. However, due to weaker assumptions, we will proceed differently compared to [27] to control the various bounds and quantities,

Set \( m = Cn^m \) for some \( C > 0 \) and \( 0 < m < 1 \). Moreover, put
\[ E_{kj} = \sigma(\epsilon_k, \ldots, \epsilon_{k-j+1}), \quad X_{kj} = \mathbb{E}[X_k | E_{kj}], \quad S_{nj} = \sum_{k=1}^{n} X_{kj}, \]
with the convention that \( S_n = S_{n\infty} \). The sequence \( (X_{km})_{k \in \mathbb{Z}} \) constitutes our \( m \)-dependent approximation. Further, let \( s_n^2 = n^{-1} \| S_n \|_2^2 \) and recall \( s_{nm}^2 = n^{-1} \| S_{nm} \|_2^2 = \sigma_m^2 + \sigma_m^2 \). We require the following auxiliary result (Lemma 5.1 in [23]).
Lemma 4.10. For every $\delta > 0$, every $m, n \geq 1$ and every $x \in \mathbb{R}$, the following estimate holds:

$$
|\mathbb{P}(S_n/\sqrt{n} \leq xs_n) - \Phi(x)| \leq A_0(x, \delta) + A_1(m, n, \delta)
+ \max\{A_2(m, n, x, \delta) + A_3(m, n, \delta), A_4(m, n, x, \delta) + A_5(m, n, x, \delta)\},
$$

where

$$A_0(x, \delta) = |\Phi(x) - \Phi(x + \delta)|;$$

$$A_1(m, n, \delta) = \mathbb{P}(|S_n - S_{nm}| \geq \delta s_n \sqrt{n});$$

$$A_2(m, n, x, \delta) = |\mathbb{P}(S_{nm} \leq (x + \delta)s_n \sqrt{n}) - \Phi((x + \delta)s_n / s_{nm})|;$$

$$A_3(m, n, x, \delta) = |\Phi((x + \delta)s_n / s_{nm}) - \Phi(x + \delta)|;$$

$$A_4(m, n, x, \delta) = A_2(m, n, x, -\delta) \quad \text{and} \quad A_5(m, n, x, \delta) = A_3(m, n, x, -\delta).$$

Proof of Theorem 2.3. As a preparatory result, note that by Lemma 4.6

$$(4.31) \quad n s_n^2 = n s^2 + \sum_{k \in \mathbb{Z}} (n \wedge |k|) \mathbb{E}[X_0 X_k] + \mathcal{O}(n^{1-b}).$$

By properties of the Gaussian distribution, we then obtain

$$(4.32) \quad \sup_{x \in \mathbb{R}} |\Phi(x/\sqrt{s^2}) - \Phi(x/\sqrt{s_n})| \lesssim n^{-b}.$$  

We first deal with $A_1(m, n, \delta)$. Proceeding exactly as in the proof of Theorem 1 in [33] (see equation 2.15), it follows that

$$
\|S_n - S_{nm}\|_p \leq \sqrt{n} \sum_{k=m}^{\infty} \|X_k - X_k^\prime\|_p \leq \sqrt{nm^{-b}} \sum_{k=m}^{\infty} k^b \|X_k - X_k^\prime\|_p
$$

$$(4.33) \quad \lesssim \sqrt{nm^{-b}}.$$  

We thus conclude from the Markov inequality and (4.31) that

$$
\mathbb{P}(|S_n - S_{nm}| \geq \delta s_n \sqrt{n}) \lesssim (\delta s_n \sqrt{n})^{-p} (\sqrt{nm^{-b}})^p \lesssim (\delta m^b)^{-p},
$$

hence

$$(4.34) \quad A_1(m, n, \delta) \lesssim (\delta m^b)^{-p}.$$  

Next, we deal with $A_2(m, n, x, \delta)$. The aim is to apply Theorem 4.2 to obtain the result. In order to do so, we need to verify Assumption 4.1 for $X_{km}$.

**B1:** Note first that $\mathbb{E}[X_{km}] = \mathbb{E}[X_k] = 0$. Moreover, Jenseins inequality gives

$$
\|X_{km}\|_p = \|\mathbb{E}[X_k | E_{km}]\|_p \leq \|X_k\|_p < \infty.
$$

**B2:** Note that we may assume $k \leq m$, since otherwise $X_{km}^\prime - X_{km} = 0$. Put

$$
E_{km} = \sigma(\epsilon_j, 1 \leq j \leq k, \epsilon'_j, k - m + 1 \leq j \leq 0).$$
Since $E[X_k | \mathcal{E}_{km}] = E[X_k | \mathcal{E}_{km}]^*$, it follows that

$$X_{km}^* - X_{km} = E[X_k^* | \mathcal{E}_{km}] - E[X_k | \mathcal{E}_{km}]$$

(4.35)

$$= E[X_k^* - X_k | \mathcal{E}_{km}] + E[X_k | \mathcal{E}_{km}] - E[X_k | \mathcal{E}_{km}]$$

(4.36)

Hence by Jensen's inequality $\|X_{km}^* - X_{km}\|_p \leq 2\|X_k - X_k^*\|_p$, which gives the claim by (A2). Note that in exactly the same manner, one also obtains $\|X_{km}' - X_{km}\|_p \leq 2\|X_k' - X_k^*\|_p$, which is relevant for our next argument.

(B3): Observe first that due to Lemma 4.6 we have $\sum_{k=1}^{\infty} E[X_{0m} X_{km}] < \infty$, uniformly in $m$. Since $\|X_k - X_{km}\|_p \to 0$, Cauchy-Schwarz yields

$$E[X_{0m} X_{km}] - E[X_0 X_k] \to 0$$

for any fixed $k \in \mathbb{N}$ and large enough $m$. We thus conclude from Lemma 4.6 and arguments from its proof

$$\sum_{k \in \mathbb{Z}} |E[X_0 X_k] - E[X_{0m} X_{km}]| = o(1) + \sum_{|k| > m} |E[X_0 X_k]| = o(1).$$

Hence (B3) follows from (A3). Since $m \asymp n^m$ with $0 < m < 1$, we may thus apply Theorem 4.2 which yields

$$\sup_{x \in \mathbb{R}} A_2(m, n, x, \delta) \lesssim n^{-p/2+1}.$$  

(4.37)

Next, we deal with $A_3(m, n, x, \delta)$. Properties of the Gaussian distribution function give

$$\sup_{x \in \mathbb{R}} A_3(m, n, x, \delta) \lesssim \delta + |s_n^2 - s_{nm}^2|.$$  

However, by the Cauchy-Schwarz inequality, (4.33) and Lemma 4.3, it follows that

$$|s_n^2 - s_{nm}^2| \leq n^{-1} \|S_n - S_{nm}\|_2 \|S_n + S_{nm}\|_2 \lesssim n^{1/2 - bm - 1/2} \lesssim n^{-bm},$$

and we thus conclude that

$$\sup_{x \in \mathbb{R}} A_3(m, n, x, \delta) \lesssim \delta + n^{-bm}.$$  

(4.39)

Finally, setting $\delta = n^{-1/2}$, standard arguments involving the Gaussian distribution function yield that

$$\sup_{x \in \mathbb{R}} A_0(x, \delta) \lesssim \delta = n^{-1/2}.$$  

(4.40)

Piecing together (4.34), (4.37), (4.39) and (4.40), Lemma 4.10 and (4.32) yield

$$\sup_{x \in \mathbb{R}} \left| \mathbb{P}(S_n / \sqrt{n} \leq x) - \Phi(x / s) \right| \lesssim n^{-p/2+1} + n^{-(bm-1/2)p}.$$  

(4.41)

Selecting $m$ sufficiently close to one, this completes the proof since $(b - 1/2)p > p/2 + 3/2 - 1$ by assumption.  

$\Box$
Proof of Proposition 2.2. For any $k \geq 1$, we have
\[ k^b (2k - k) \vartheta'_{2k}(p) \leq \sum_{l=1}^{2k} l^b \sup_{j \geq l} \vartheta'_j(p) \]
by monotonicity. Hence we obtain
\[ \limsup_{k \to \infty} k^{1+b} \vartheta'_k(p) = 0. \]
From Theorem 1 in [43], we have the (adjusted) inequality
\[ \sup_{k \in \mathbb{Z}} \|X_k - X_k^{(s,l)}\|_p^2 \lesssim \sum_{j \geq l} \sup_{k \in \mathbb{Z}} \|X_k - X_k^{(j)}\|_p^2, \]
hence, since $b > 1/2 + (p \wedge 3)/2p - 1/p > 1/2$, we deduce from the above that for sufficiently small $a > 0$
\[ \sum_{k=1}^{\infty} k^a \vartheta'_k(p) \lesssim \sum_{k=1}^{\infty} k^{a-b - 1/2} < \infty. \]

4.5. Proof of Theorem 2.4. Throughout this section, denote with $G_k = \sum_{j=0}^{\infty} \alpha_j \xi_{k-j}$, where $(\xi_i)_{i \in \mathbb{Z}}$ is a sequence of standard i.i.d. Gaussian random variables. The proof of Theorem 2.4 is an (almost) immediate consequence of the following result.

Proposition 4.11. Suppose that $\sum_{j \in \mathbb{N}} |\alpha_j| < \infty$, $\sum_{j \in \mathbb{N}} \alpha_j \neq 0$, and $\|\epsilon_j\|_3 < \infty$. Then
\[ \sup_{x \in \mathbb{R}} \left| \mathbb{P}\left( S_n / \sqrt{ns^2} \leq x \right) - \Phi(x) \right| \lesssim n^{-1/2} + n^{-1} \sum_{j \in \mathbb{N}} j \wedge n |\alpha_j|. \]
Moreover, the above bound is sharp, that is, there exists a linear process with the above properties where the bound is reached (up to a multiplicative constant).

Proof of Theorem 2.4. Let $1+b < a < 3/2$. Then setting $\alpha_j = j^{-a}$, we have
\[ \sum_{j \in \mathbb{N}} j \wedge n |\alpha_j| \asymp n^{-a+2} \]
and
\[ \sum_{k=1}^{\infty} k^b \|X_k - X_k'\|_p < \infty. \]
Since $a < 3/2$, the claim follows from Proposition 4.11 (with $\delta = 3/2-a$).

It remains to establish Proposition 4.11. To this end, we require the following Lemma.
Lemma 4.12. Grant the assumptions of Proposition 4.11 and assume in addition \(E \epsilon_k^2 = 1\). Then

\[
\Delta' = \sup_{x \in \mathbb{R}} \left| P \left( n^{-1/2} \sum_{k=1}^{n} X_k \leq x \right) - P \left( n^{-1/2} \sum_{k=1}^{n} G_k \leq x \right) \right| \lesssim n^{-1/2}.
\]

Proof of Lemma 4.12. Let \(A = \sum_{j \in \mathbb{N}} \alpha_j\). With the convention that \(\alpha_j = 0\) for \(j < 0\), we have the decomposition

\[
\sum_{k=1}^{n} X_k = \sum_{i=1}^{n} \sum_{j=1-i}^{n-i} \alpha_j \epsilon_i + \sum_{i=0}^{\infty} \sum_{j=1+i}^{n+i} \alpha_j \epsilon_{-i} = \sum_{i=1}^{n} A_{n,i} \epsilon_i + \sum_{i=-\infty}^{0} A_{n,-i} \epsilon_i.
\]

Since \(|A_{n,i}| \leq \sum_{j \in \mathbb{N}} |\alpha_j| < \infty\), we have \(E|A_{n,i} \epsilon_i|^3 < \infty\) uniformly in \(n, i\), and

\[
E \sum_{i=-\infty}^{0} |A_{n,-i} \epsilon_i|^3 \lesssim \sum_{j \in \mathbb{N}} n|\alpha_j| \lesssim n.
\]

In addition, straightforward computations imply

\[
\left\| \sum_{i=1}^{n} A_{n,i} \epsilon_i \right\|_2^2 = (n - o(n)) A^2.
\]

By the above and the existing Berry-Esseen literature (cf. [38]), we thus obtain

\[
\Delta' \lesssim \frac{1}{(nA^2)^{3/2}} \left( \sum_{i=1}^{n} E|A_{n,i} \epsilon_i|^3 + n \right) \lesssim n^{-1/2}.
\]

Proof of Proposition 4.11. Let \(s = |\sum_{j \in \mathbb{N}} \alpha_j|\). Due to Lemma 4.12, it suffices to establish

\[
(4.42) \quad \sup_{x \in \mathbb{R}} \left| P \left( n^{-1/2} \sum_{k=1}^{n} G_k \leq x \right) - \Phi \left( \frac{x}{s} \right) \right| \lesssim n^{-1} \sum_{j \in \mathbb{N}} j \wedge n|\alpha_j|
\]

for the upper bound. The (first) claim then follows from the triangle inequality. Let \(s_n^2 = n^{-1} \|S_n\|_2^2\). From the proof of Lemma 4.6, we have

\[
|s^2 - s_n^2| \asymp n^{-1} \sum_{j \in \mathbb{N}} j \wedge n|\alpha_j|.
\]

(4.42) now follows by employing a Taylor expansion for \(\Phi(\cdot)\). If \(n^{-1/2} \sum_{j \in \mathbb{N}} j \wedge n|\alpha_j| \to \infty\), another Taylor expansion also shows that the bound in Proposition 4.11 is sharp. If \(n^{-1/2} \sum_{j \in \mathbb{N}} j \wedge n|\alpha_j| = \mathcal{O}(1)\), one may resort to the standard i.i.d. binomial example, exhibiting the rate \(n^{-1/2}\). \(\square\)
