ON TRANSVERSALITY OF BENT HYPERPLANE ARRANGEMENTS AND THE TOPOLOGICAL EXPRESSIVENESS OF RELU NEURAL NETWORKS

J. ELISENDA GRIGSBY AND KATHRYN LINDSEY

Abstract. Let $F : \mathbb{R}^n \to \mathbb{R}$ be a feedforward ReLU neural network. It is well-known that for any choice of parameters, $F$ is continuous and piecewise (affine) linear. We lay some foundations for a systematic investigation of how the architecture of $F$ impacts the geometry and topology of its possible decision regions, $F^{-1}(-\infty,t)$ and $F^{-1}(t,\infty)$, for binary classification tasks. Following the classical progression for smooth functions in differential topology, we first define the notion of a generic, transversal ReLU neural network and show that almost all ReLU networks are generic and transversal. We then define a partially-oriented linear 1–complex in the domain of $F$ and identify properties of this complex that yield an obstruction to the existence of bounded connected components of a decision region. We use this obstruction to prove that a decision region of a generic, transversal ReLU network $F : \mathbb{R}^n \to \mathbb{R}$ with a single hidden layer of dimension $n+1$ can have no more than one bounded connected component.

1. Introduction

Neural networks have rapidly become one of the most widely-used tools in the machine learning toolkit. Unfortunately, despite—or, perhaps, because of—their spectacular success in applications, significant foundational questions remain. Of these, we believe many would benefit greatly from the direct attention of theoretical mathematicians, particularly those in the geometric topology, nonlinear algebra, and dynamics communities. An important goal of this paper and its sequels is to advertise some of these problems to those communities.

Recall that one can view a (trained) feedforward neural network as a particular type of function, $F : \mathbb{R}^n \to \mathbb{R}^m$, between Euclidean spaces. The inputs to the function are data feature vectors and the outputs are typically used to answer $m$–class classification problems by partitioning the input space into decision regions according to which component of the function output is maximized at that point.

The main purpose of the present work is to present a framework for studying the question: How does the architecture of a feedforward neural network constrain the topology of its decision regions? Here, the architecture of a feedforward neural network refers simply to the dimensions of the hidden layers. The neural networks we consider here will be fully-connected ReLU networks without skip connections. The topological expressiveness of an

---

JEG was partially supported by Simons Collaboration grant 635578.
KL was partially supported by NSF grant number DMS-1901247.
architecture is the collection of possible homeomorphism types of decision regions that can appear as the parameters vary (cf. [2, 9]).

First: why should the machine learning community care about topological expressiveness?

Recall that a cornerstone theoretical result in the study of neural networks (for a variety of activation functions, including the widely-used ReLU function that is our focus here) is the Universal Approximation Theorem ([5, 13, 1]), which says that a sufficiently high-dimensional neural network can approximate any continuous function on a compact set to arbitrary accuracy. This is the version of representational power or expressiveness frequently cited by practitioners as a guarantee that feedforward neural networks can yield a solution to any data question one might throw at them.

Yet continuous functions can be quite poorly behaved, and certain classes of poorly behaved continuous functions are undesirable targets for learning. For example, functions with high Lipschitz constants and ones whose partial derivatives are highly variable with respect to the input direction lead to the easy production of adversarial examples and hence to potentially poor generalization to unseen data (cf. [4, 19, 15]). Moreover, for classification problems, it is the partitioning of the feature space into decision regions and not the specific form of the function we learn that is relevant.

It is important to remark at this point that homeomorphism is a very coarse equivalence relation. Two different decision regions can be homeomorphic and still have quite different geometric properties (shape, volume, etc.). However, homeomorphism is a good equivalence relation to consider on a first pass, because the coarsest, most fundamental global features of the data are preserved by homeomorphism (number of connected components, homology groups, etc.), and these coarse features are very likely to be stable under different data representation choices. The flip side of this observation is that if a particular architecture lacks the topological expressiveness to capture obvious topological features inherent in a well-sampled labeled data set, it will not generalize well to unseen data.

In the present work, we will focus on the simplest case of feedforward neural networks, $F : \mathbb{R}^n \to \mathbb{R}$, with 1-dimensional output. Such a network is typically used to answer binary (aka Yes/No) classification problems by choosing a threshold, $t \in \mathbb{R}$, and declaring the sublevel set of $t$ to be the “N” decision region, the superlevel set of $t$ to be the “Y” decision region, and the level set of $t$ to be the decision boundary. That is:

$$N_F(t) := F^{-1}((\infty, t))$$
$$B_F(t) := F^{-1}(\{t\})$$
$$Y_F(t) := F^{-1}((t, \infty)).$$

Classical results in differential topology now tell us that if $F$ were smooth, we could perturb $F$ slightly to be Morse, and the indices and values of its critical points would then provide strong information about the topology of its decision regions. Unfortunately, a ReLU neural network map $F$ is clearly not smooth; it is continuous and piecewise affine linear. Yet $F$ will
typically1(i.e., for almost all choices of parameters) be well-behaved enough that the information we need to understand the topology of the decision regions should be extractable directly from the weights and biases of the neural network. We don’t make it to the finish line in the present work, but we make a good start.

We begin by reviewing some standard results in the theory of affine hyperplane arrangements and convex polyhedra, relying heavily on Grunert’s work [7] on polyhedral complexes (Definition 3.11) and Hanin-Rolnick’s work [11] (see also [16, 17, 10]) generalizing the classical notion of hyperplane arrangements to so-called bent hyperplane arrangements (Definition 6.1). These ideas dovetail nicely and provide the right formalism for understanding the class of ReLU neural network maps. Note that the appearance of polyhedral complexes in the study of ReLU networks is well-known, and made explicit, e.g., in the relationship between ReLU neural networks with rational parameters and tropical rational functions [22]. Our contribution here is to formalize the relationship enough to open a path for applying classical ideas in differential topology to extract information about the topology of decision regions. We summarize our main results below. More precise versions of these theorems, along with their proofs, appear in later sections.

**Theorem 1.** Let \( F : \mathbb{R}^n \to \mathbb{R} \) be a ReLU neural network map. \( F \) is continuous and affine linear on the cells of a canonical realization of the domain, \( \mathbb{R}^n \), as a polyhedral complex, \( \mathcal{C}(F) \).

Moreover, when \( F \) is generic (Definition 2.9) and transversal (Definition 8.2), we explicitly identify cells of this polyhedral complex with natural objects defined by Hanin-Rolnick:

**Theorem 2.** Let \( F : \mathbb{R}^n \to \mathbb{R} \) be a generic, transversal ReLU neural network map. The \( n \)-cells of the canonical polyhedral complex, \( \mathcal{C}(F) \), are the closures of the activation regions (Definition 6.4) of \( F \), and the \((n-1)\)-skeleton of \( \mathcal{C}(F) \) is the bent hyperplane arrangement (Definition 6.1) of \( F \).

We slightly extend classical transversality results (Theorems 7 and 8) to obtain:

**Theorem 3.** Almost all ReLU neural networks are generic and transversal.

We show that every parametrized family of neural networks (Definition 2.4) \( \mathcal{F} : \mathbb{R}^{n_0} \times \mathbb{R}^{D(n_0, \ldots, n_m, 1)} \to \mathbb{R} \) is piecewise smooth in the following sense:

**Theorem 4.** Every parametrized family of ReLU neural networks \( \mathcal{F} \) is smooth on the complement of a codimension 1 algebraic set.

Many of the key observations in Theorems 1–4 were proved in [11]. The theorems above place those results in a broader context. Once we’ve established these foundational results, we turn our attention to addressing some first questions about architecture’s impact on topological expressiveness. We

---

1We’d like to use the word *generically* here, but the term *generic* is unavoidably used in a different context later in the paper (Definition 2.9).
begin by using the framework developed above to recast and reprove the result of Johnson\cite{Johnson2018} that inspired this study. A variant of this result was proved independently by Hanin-Sellke \cite{Hanin-Sellke2019}:

**Theorem 5.** For any integer $n \geq 2$, let $F : \mathbb{R}^n \to \mathbb{R}$ be a ReLU neural network, all of whose hidden layers have dimension $\leq n$. Then for any decision threshold $t \in \mathbb{R}$, each of $Y_F(t)$, $B_F(t)$, and $N_F(t)$ is either empty or unbounded.

**Remark 1.1.** Theorem 5 is not quite true for $n = 1$. For example, it is easy to see that the neural network map $F : \mathbb{R}^1 \to \mathbb{R}^1$ defined by $F(x) = \sigma(x)$ has $B_F(t) = \{t\}$ for all $t > 0$. However, Hanin-Sellke \cite{Hanin-Sellke2019} prove, subject to the assumptions in the statement of Theorem 5 with no restrictions on $n$, that $Y_F(t)$ and $N_F(t)$ are either empty or unbounded.

We also have the following new application:

**Theorem 6.** Let $F : \mathbb{R}^n \to \mathbb{R}^{n+1}$ be a ReLU neural network with input dimension $n$ and a single hidden layer of dimension $n + 1$. Each decision region of $F$ associated to a transversal threshold can have no more than 1 bounded connected component.

A crucial player in the proof of Theorem 6 is the 1–skeleton, $C(F)_1$, of the polyhedral complex, $C(F)$, which is naturally endowed with a partial orientation pointing in the direction in which $F$ increases (Definition 9.15). This partially-oriented graph will figure prominently in the sequel, as it is precisely the information needed to determine geometric and topological information about the decision regions. Note that the partial orientation data can be extracted directly from the weight matrices of the neural network using the chain rule (Lemma 9.17).

This paper is heavy on definitions and notation, since we pulled from a variety of sources to lay necessary foundations for a consistent and general theory. Some sections may therefore be safely skimmed on a first reading and referenced only as needed to understand the proofs of the main results. Sections 2 and 9 largely fall into this category. Similarly, Section 7 establishes important results about parameterized neural network maps, but nothing in this section is referenced elsewhere in the paper.

Sections 3 and 4 establish notation and key terminology. We do the bulk of the technical work in Sections 5, 6, 8, and the new applications can be found in Section 10.

Acknowledgements. The authors would like to thank Jesse Johnson for proposing many of the questions at the heart of this investigation; Boris Hanin for illuminating conversations during the Foundations of Deep Learning program at the Simons Institute for the Theory of Computing in the summer of 2019; Jenna Rajchgot for very helpful discussions about algebraic geometry; Yaim Cooper and Jordan Ellenberg for inspiration and encouragement.

2. Layer maps and hyperplane arrangements

In what follows, let
- ReLU : $\mathbb{R} \to \mathbb{R}$ denote the function ReLU$(x) := \max\{0, x\}$, and
- $\sigma : \mathbb{R}^n \to \mathbb{R}^n$ denote the function that applies ReLU to each coordinate.

Definition 2.1. Let $n_0 \in \mathbb{N}$. A neural network defined on $\mathbb{R}^{n_0}$ with ReLU activation function on all hidden layers and one-dimensional output is a finite sequence of natural numbers $n_1, \ldots, n_m$ together with affine maps $A_i : \mathbb{R}^{n_i} \to \mathbb{R}^{n_{i+1}}$ for $i = 0, \ldots, m$. This determines a function $F : \mathbb{R}^{n_0} \to \mathbb{R}$, which we call the associated neural network map, given by the composition

$$
\mathbb{R}^{n_0} \xrightarrow{F_1 = \sigma \circ A_1} \mathbb{R}^{n_1} \xrightarrow{F_2 = \sigma \circ A_2} \mathbb{R}^{n_2} \xrightarrow{F_3 = \sigma \circ A_3} \cdots \xrightarrow{F_m = \sigma \circ A_m} \mathbb{R}^{n_m} \xrightarrow{G = A_{m+1}} \mathbb{R}^1.
$$

Such a neural network is said to be of architecture $(n_0, \ldots, n_m, 1)$, depth $m + 1$, and width $\max\{n_1, \ldots, n_m, 1\}$. The $k$th layer map of such a neural network is the composition $\sigma \circ A_k$ for $k = 1, \ldots, m$ and is the map $G = A_k$ for $k = m + 1$.

Remark 2.2. Note that in Definition 2.1 the activation function on the final layer map is the Identity function, not $\sigma$. Accordingly, we use the notation $G$ on the output layer map to distinguish it from the hidden layer maps, $F_k$. 
An affine map \( A : \mathbb{R}^n \to \mathbb{R}^m \) is specified by a weight matrix \( W \in M_{m \times n}(\mathbb{R}) \) and a bias vector \( \vec{b} \in \mathbb{R}^m \), as follows. Let \( (W | \vec{b}) \) denote the \( m \times (n + 1) \) matrix whose final column is \( \vec{b} \). For each \( \vec{x} \in \mathbb{R}^n \), let \( \vec{x}' := (\vec{x}, 1) \) be the image of \( \vec{x} \) under the embedding of \( \mathbb{R}^n \) into \( \mathbb{R}^{n+1} \) fixing the final coordinate to 1. Then

\[
(1) \quad A(\vec{x}) = (W | \vec{b}) \vec{x}',
\]

where the product on the right is the matrix product, viewing \( \vec{x}' \) as an \((n + 1) \times 1\) matrix.

**Definition 2.3.** For any network architecture \((n_0, \ldots, n_m, 1)\), the total dimension \( D(n_0, \ldots, n_m, 1) \) of the parameter space of neural networks of architecture \((n_0, \ldots, n_m, 1)\) is the total number of parameters (weights and biases) that define the matrices \( A_1, \ldots, A_{m+1} \).

**Definition 2.4.** Let \((n_0, \ldots, n_m, 1)\) be a network architecture. The parameterized family of ReLU neural networks with architecture \((n_0, \ldots, n_m, 1)\) is the map

\[
\mathcal{F} : \mathbb{R}^{n_0} \times \mathbb{R}^{D(n_0, \ldots, n_m, 1)} \to \mathbb{R}
\]

defined as follows. For each \( \mathbf{s} \in \mathbb{R}^{D(n_0, \ldots, n_m, 1)} \),

\[
\mathcal{F}_\mathbf{s} : \mathbb{R}^{n_0} \times \{\mathbf{s}\} \to \mathbb{R}
\]

is the ReLU neural network map associated to the weights and biases given by \( \mathbf{s} \).

Observe that for each row of \( W \), the corresponding row \((W_i | b_i) \in \mathbb{R}^{n+1} \) of the augmented matrix \((W | b) \in M_{m \times (n+1)}(\mathbb{R})\) determines a set \( S_i \subset \mathbb{R}^n \) that is the solution set to a homogeneous equation:

\[
(2) \quad S_i := \{ \vec{x} \in \mathbb{R}^n \mid (W_i | b_i) \cdot (\vec{x} | 1) = 0 \}.
\]

If we know the weight vector is non-zero (i.e. \( W_i \neq 0 \)) and hence \( S_i \) is a hyperplane, we will denote it by \( H_i \). In this case, \( \mathbb{R}^n \setminus H_i \) has two connected components,

\[
(3) \quad H_i^+ := \{ \vec{x} \in \mathbb{R}^n \mid (W_i | b_i) \cdot (\vec{x} | 1) > 0 \}
\]

\[
(4) \quad H_i^- := \{ \vec{x} \in \mathbb{R}^n \mid (W_i | b_i) \cdot (\vec{x} | 1) < 0 \},
\]

which endows \( H_i \) with a co-orientation, pointing toward \( H_i^+ \).

We define:

**Definition 2.5.** An ordered affine solution set arrangement in \( \mathbb{R}^n \) is a finite ordered set, \( \mathcal{S} = \{ S_1, \ldots, S_m \} \), where each \( S_i \) is the solution set to a homogeneous affine linear equation as described above in equation (2).

**Remark 2.6.** If \( W_i \neq 0 \), \( S_i \) will be a hyperplane. However, in the degenerate case \( W_i = 0 \), \( S_i \) is not a hyperplane. \( S_i \) is empty if \( b_i \neq 0 \) and \( S_i \) is all of \( \mathbb{R}^n \) if \( b_i = 0 \).

**Definition 2.7.** An ordered affine solution set arrangement, \( \mathcal{S} = \{ S_1, \ldots, S_m \} \), is said to be in general position (aka generic) if for all subsets \( \{ S_{i_1}, \ldots, S_{i_p} \} \subseteq \mathcal{S} \), it is the case that \( S_{i_1} \cap \ldots \cap S_{i_p} \) is an affine linear subspace of \( \mathbb{R}^n \) of dimension \( n - p \), where a negative-dimensional intersection is understood to be empty.
Remark 2.8. Note that the solution set of an affine linear equation is an affine linear subspace of $\mathbb{R}^n$ of dimension $n-1$ iff it is nondegenerate. Accordingly, generic implies nondegenerate.

Definition 2.9.

(i) A layer map of a neural network is said to be degenerate if a row, $W_i$, of its associated weight matrix, $W$, is $0$ for some $i$. (Note that the corresponding bias, $b_i$, may be zero or nonzero.) Otherwise the layer map is said to be nondegenerate. A neural network with at least one degenerate layer map is said to be degenerate and is said to be nondegenerate otherwise.

(ii) A layer map of a neural network is said to be generic if the corresponding affine solution set arrangement is generic (Definition 2.7). A neural network whose layer maps are all generic is said to be generic.

Remark 2.10. In Definition 2.1, we define the width of a neural network of architecture $(n_0,\ldots,n_m,1)$ to be $M = \max\{n_0,\ldots,n_m,1\}$. If one of the hidden layers, $\mathbb{R}^{n_i}$, has dimension $n_i \leq M$, we shall find it convenient to replace it with a layer of dimension $M$, imbedding $\mathbb{R}^{n_i}$ into $\mathbb{R}^M$ in the standard way and replacing the affine map $A_i : \mathbb{R}^{n_i-1} \to \mathbb{R}^{n_i}$ with the degenerate map whose final $M-n_i$ components are all 0. With this understood, all neural networks described in the present work will have hidden layers of dimension equal to the width.

Lemma 2.11. Let $A : \mathbb{R}^n \to \mathbb{R}^n$ be an affine linear map given by $A(\vec{x}) := (W|b)\vec{x}'$ as in Equation 2, and let $S = \{S_1,\ldots,S_n\}$ be the associated affine solution set arrangement in $\mathbb{R}^n$ described in Equation 2. Then $A$ is an invertible function if and only if $S$ is generic.

Proof. Since translation by $\vec{b}$ is an invertible operation, the Invertible Matrix Theorem tells us that $A$ is an invertible function iff the $n \times n$ weight matrix $W$ is invertible iff the row space of $W$ has dimension $n$. But this is true iff, for each $k \leq n$, the rank of any $k \times n$ matrix $W'$ obtained by choosing $k$ rows of $W$ has dimension $k$. By the rank-nullity theorem, the above condition is equivalent to the kernel of $W'$ having dimension $n-k$, and this is equivalent to every $k$-fold intersection of affine solution sets in $S$ being an affine linear subspace of dimension $n-k$ (i.e., $S$ is generic), as desired.

Definition 2.12. The co-oriented ordered hyperplane arrangement associated to the $k^{th}$ layer of a neural network map is the (possibly empty) set formed by removing the degenerate solution sets from the affine solution set arrangement associated to that layer map and assigning a co-orientation to the remaining hyperplanes as described in the text before Definition 2.5.

The geometry and combinatorics of hyperplane arrangements is a beautiful and rich subject in its own right. We content ourselves here with recalling the notions that will be important for this paper, referring the interested reader to [18] for more details.

Definition 2.13. An ordered, co-oriented hyperplane arrangement,

$$A = \{H_1,\ldots,H_j\},$$
in $\mathbb{R}^n$ is an ordered set of co-oriented affine hyperplanes in $\mathbb{R}^n$. By forgetting the ordering of the set and the co-orientations of the affine hyperplanes we obtain a classical hyperplane arrangement; that is, a finite set, $\mathcal{A} = \{H_1, \ldots, H_j\}$, of affine hyperplanes in $\mathbb{R}^n$.

**Remark 2.14.** We shall use $\mathcal{A}$ (resp., $H_i$) if the hyperplanes in our arrangement are ordered and co-oriented and $\mathcal{A}$ (resp., $H_i$) if not.

The **rank** of a hyperplane arrangement $\mathcal{A}$ in $\mathbb{R}^n$ is the dimension of the space spanned by the normals to the hyperplanes in $\mathcal{A}$.

**Definition 2.15.** Let $(n_0, \ldots, n_m)$ be a neural network architecture.

(i) The **affine solution set arrangement map** is the map that associates to each parameterization $s \in \mathbb{R}^{D(n_0, \ldots, n_m)}$ the $(m + 1)$–tuple $(S_0, \ldots, S_m)_s$ of affine solution set arrangements associated to $s$, where $S_i$ is the affine solution set arrangement associated to the neural network layer map $F_{i+1} : \mathbb{R}^{n_i} \to \mathbb{R}^{n_{i+1}}$ endowed with the weights and biases specified by $s$.

(ii) The **co-oriented hyperplane arrangement map** is the map that associates to each parameterization $s \in \mathbb{R}^{D(n_0, \ldots, n_m)}$ the $(m + 1)$–tuple $(A_0, \ldots, A_m)_s$ of co-oriented hyperplane arrangements, where $A_i$ is obtained from the affine solution set arrangement $S_i$ defined in part (i) by removing the degenerate solution sets and endowing the remaining hyperplanes with co-orientations as in equation (4).

**Remark 2.16.** Note that in Definition **2.15**, $|A_i| \leq n_{i+1}$, with equality if and only if the corresponding layer map is nondegenerate. Degenerate arrangements are rare, cf. Remark **2.8** and Lemma **2.17**.

Recall that a property $P$ is said to hold for almost every point $x$ in $\mathbb{R}^n$ (with respect to Lebesgue measure) if the set of points $x \in \mathbb{R}$ for which $P(x)$ is false is a (Lebesgue measurable) set of measure 0 (equivalently, a null set). The following well-known lemma (cf. [18]) follows in a straightforward way from standard facts in linear algebra. Alternatively, the reader may obtain the result using Theorem [7].

**Lemma 2.17.** Let $(n_0, \ldots, n_m)$ be a network architecture. For almost every $s \in \mathbb{R}^{D(n_0, \ldots, n_m)}$, each $S_i$ in $(S_0, \ldots, S_m)$ is a generic (co-oriented) hyperplane arrangement.

### 3. Polyhedral complexes

We will need some basic facts about the geometry and combinatorics of convex polytopes, polyhedral sets, and polyhedral complexes. We quickly recall relevant background and terminology, referring the interested reader to [6, 7] for a more thorough treatment.

**Definition 3.1.** [6, Sec. 2.6, 3.1]

(i) A polyhedral set $\mathcal{P}$ in $\mathbb{R}^n$ is an intersection of finitely many closed affine half spaces $H_1^+, \ldots, H_m^+ \subseteq \mathbb{R}^n$. 

(ii) A convex polytope in $\mathbb{R}^n$ is a bounded polyhedral set.

**Remark 3.2.** A polyhedral set is is an intersection of convex sets, hence convex.

**Definition 3.3.** [6, Sec. 2.2]

(i) We call a hyperplane $H$ in $\mathbb{R}^n$ a cutting hyperplane of $P$ and say $H$ cuts $P$ if there exists $x_1, x_2 \in P$ with $x_1 \in P \cap H^+$ and $x_2 \in P \cap H^-$. 

(ii) We call a hyperplane $H$ in $\mathbb{R}^n$ a supporting hyperplane of $P$ and say $H$ supports $P$ if $H$ does not cut $P$ and $H \cap P \neq \emptyset$.

**Definition 3.4.** [6, Sec. 2.6]

(i) A subset $F \subset P$ is said to be a face of $P$ if either $F = \emptyset$, $F = P$, or $F = H \cap P$ for some supporting hyperplane of $P$.

(ii) $\emptyset$ and $P$ are called the improper faces of $P$. All other faces are proper.

(iii) If $F$ is a maximal proper face of $P$ (that is, it is contained in no proper faces of $P$ but itself), we say $F$ is a maximal proper face of $P$. We shall refer to a maximal proper face of $P$ as a facet of $P$.

**Remark 3.5.** Each region of a hyperplane arrangement is the interior of a polyhedral set.

**Lemma 3.6** can be found in [6, Sec. 2.6]:

**Lemma 3.6.** Every polyhedral set $P$ of dimension $n$ has an irredundant realization as an intersection $P = H_1^+ \cap \ldots \cap H_m^+$ satisfying the property that

$$P \neq \left( \bigcap_{i=1}^m H_j^+ \right)_{j \neq i}$$

for each $i = 1, \ldots, m$. Moreover, for an irredundant realization as above, the set of facets of $P$ is precisely the set of proper faces of the form $P \cap H_i$.

**Definition 3.7.** Let $S$ be a subset of $\mathbb{R}^n$. The affine hull of $S$, denoted $\text{aff}(S)$, is the minimal affine linear subspace of $\mathbb{R}^n$ containing $S$. Equivalently $\text{aff}(S)$ is the intersection of all affine linear subspaces of $\mathbb{R}^n$ containing $S$.

**Remark 3.8.** Note that a single point in $\mathbb{R}^n$ may be considered a 0-dimensional affine linear subspace of $\mathbb{R}^n$.

**Definition 3.9.** For $0 \leq k \leq n$, a polyhedral set of dimension $k$ in $\mathbb{R}^n$ is a polyhedral set whose affine hull has dimension $k$.

**Definition 3.10.** Let $P$ be a polyhedral set of dimension $n$.

(i) A $k$–face of $P$ is a face of $P$ that has dimension $k$.

(ii) A facet of $P$ is an $(n-1)$–face of $P$.

(iii) A vertex of $P$ is a 0–face of $P$.

**Definition 3.11.** [7, Definition 1.9] A polyhedral complex $C$ of dimension $d$ is a finite set of polyhedral sets of dimension $k$, for $0 \leq k \leq d$, called the cells of $C$, satisfying the additional properties:

(i) If $P \in C$, then every face of $P$ is in $C$. 

(ii) If \( P, Q \in \mathcal{C} \), then \( P \cap Q \) is a single mutual face of \( P \) and \( Q \).

In the above, we refer to the cells of dimension \( d \) as the top-dimensional cells of \( \mathcal{C} \).

**Definition 3.12.** The domain or underlying set \( |\mathcal{C}| \) of a polyhedral complex \( \mathcal{C} \) is the union of its cells.

**Definition 3.13.** Let \( \mathcal{C} \) be a polyhedral complex of dimension \( d \). The \( k \)-skeleton of \( \mathcal{C} \), denoted \( \mathcal{C}_k \), is the subcomplex of all polyhedral sets of \( \mathcal{C} \) of dimension \( i \), where \( 0 \leq i \leq k \). Note that \( \mathcal{C}_0 \subseteq \mathcal{C}_1 \subseteq \ldots \subseteq \mathcal{C}_{d-1} \subseteq (\mathcal{C}_d = \mathcal{C}) \).

**Remark 3.14.** Note that in the present work, we shall require all of our polyhedral sets to have finitely many faces and all of our polyhedral complexes to contain finitely many polyhedral sets.

**Definition 3.15.** If \( \mathcal{C} \) is a polyhedral complex embedded in \( \mathbb{R}^n \) and \( |\mathcal{C}| = \mathbb{R}^n \), we call \( \mathcal{C} \) a polyhedral decomposition of \( \mathbb{R}^n \).

**Definition 3.16.**

(i) Any hyperplane arrangement \( \mathcal{A} \) in \( \mathbb{R}^n \) induces a polyhedral decomposition, \( \mathcal{C}(\mathcal{A}) \), of \( \mathbb{R}^n \) as follows. Define the \( n \)-dimensional cells of \( \mathcal{C}(\mathcal{A}) \) to be the closures of the regions of \( \mathcal{A} \), and for \( 0 < i < n \), inductively define the \( i \)-dimensional cells of \( \mathcal{C}(\mathcal{A}) \) to be the facets of the \( i + 1 \) dimensional cells.

(ii) Any affine solution set arrangement \( \mathcal{S} = \{S_1, \ldots, S_m\} \) in \( \mathbb{R}^n \) induces a polyhedral decomposition, \( \mathcal{C}(\mathcal{S}) \), formed by first removing the degenerate affine solution sets from \( \mathcal{S} \) to obtain a hyperplane arrangement, \( \mathcal{A} \), and setting \( \mathcal{C}(\mathcal{S}) := \mathcal{C}(\mathcal{A}) \).

Note that the domain of the \( n-1 \) skeleton of \( \mathcal{C}(\mathcal{A}) \) in Definition 3.16 is the union of the hyperplanes comprising \( \mathcal{A} \).

**Definition 3.17.** Let \( M, R \) be polyhedral complexes. A map \( f : |M| \to |R| \) is cellular if for every cell \( K \in M \) there exists a cell \( L \in R \) with \( f(K) \subseteq L \).

**Definition 3.18.** Let \( M \) be polyhedral complexes with \( |M| \) embedded in \( \mathbb{R}^m \). A map \( f : |M| \to \mathbb{R}^r \) is linear on cells of \( M \), if for each cell \( K \in M \), the restriction of \( f \) to \( |K| \) is an affine linear map.

**Definition 3.19.** Let \( M \) and \( M' \) be polyhedral complexes. \( M' \) is said to be a subdivision of \( M \) if \( |M| = |M'| \) and each cell of \( M' \) is contained in a cell of \( M \).

**Definition 3.20.** (\( \square \)) Let \( M \) and \( R \) be polyhedral complexes with a map \( f : |M| \to \mathbb{R}^r \) linear on cells of \( M \), where \( R \) is embedded in \( \mathbb{R}^r \). The level set complex of \( f \) is the set \( M_{\in R} \) defined as \( M_{\in R} := \{ S \cap f^{-1}(Y) \mid S \in M, Y \in R \} \).

The assertion that a level set complex is a polyhedral complex is justified by the following lemma:
Lemma 3.21. ([7] Lemma 2.5) Let $M$ be a polyhedral complex embedded in some $\mathbb{R}^m$ with a map $f : |M| \to \mathbb{R}^r$ linear on cells and let $R$ be a polyhedral complex embedded in $\mathbb{R}^r$. The level set complex $M \in R$ is a polyhedral complex whose underlying set $|M| \in R$ is also embedded in $\mathbb{R}^m$.

Lemma 3.22. If $f : |M| \to \mathbb{R}^r$ is as above and $|R| = \mathbb{R}^r$ as in Definition 3.15, then

(i) $f : M \in R \to R$ is cellular, and
(ii) $M \in R$ is a subdivision of $M$.

Proof. Immediate from the definitions. \qed

In the present work, we will be most interested in the simple case of level set complexes for maps $\mathbb{R}^n \to \mathbb{R}$, where the single 0–cell of the polyhedral complex $R \subseteq \mathbb{R}$ is a threshold $t \in \mathbb{R}$, and the two 1–cells are the unbounded intervals $(-\infty, t]$ and $[t, \infty)$.

Definition 3.23. An interval complex is a polyhedral complex on $\mathbb{R}$ of the form $\{(-\infty, t], \{t\}, [t, \infty)\}$ for some $t \in \mathbb{R}$.

(See Section 1.2.2 in [7].) In this case, Grunert’s Lemma 3.21 above gives realizations of the sub- and super-level sets of the threshold $t \in \mathbb{R}$ as polyhedral complexes.

4. Transversality

In this subsection, we recall notions of transversality and state and prove two easy extensions of classical transversality results.

4.1. Classical transversality results. We now briefly review some classical transversality results, following [8].

We denote the tangent space of a smooth manifold $X$ at a point $x \in X$ by $T_x X$. Recall that for a smooth map $f : X \to Y$ of manifolds with $f(x) = y$, the derivative $df_x$ is a linear map between tangent spaces, $df_x : T_x X \to T_y Y$, and the image $df_x(T_x X)$ is a linear subspace of $T_y Y$. Recall, also, that the sum of two linear subspaces $U$ and $V$ of a linear space $W$ is the set $U + V := \{u + v : u \in U, v \in V\}$.

In Definition 4.1 and Theorems 7 and 8, assume $X$ to be a smooth manifold with or without boundary, $Y$ and $Z$ to be smooth manifolds without boundary, $Z$ a smoothly embedded submanifold of $Y$, and $f : X \to Y$ a smooth map.

Definition 4.1. We say that $f$ is transverse to $Z$ and write $f \pitchfork Z$ if

\[ df_p(T_p X) + T_{f(p)} Z = T_{f(p)} Y \]

for all $p \in f^{-1}(Z)$.

Remark 4.2. Definition 4.1 allows for the possibility that $X$ is a manifold of dimension 0, i.e. consists of (without loss of generality) a single point $p$. In this case $T_p\{p\} = \{0\}$ and so $df_p(T_p\{p\}) = \{0\}$, so condition 5 reduces to the condition that if $f(p) \in Z$, then $Z$ and $Y$ must agree in a neighborhood of $f(p)$.
Remark 4.3. Note that if the image \( f(X) \) does not intersect \( Z \), then condition (5) is vacuously true, so \( f \) is transverse to \( Z \).

**Theorem 7** (Map Transversality Theorem). [8, p. 28] If \( f \) is transverse to \( Z \), then \( f^{-1}(Z) \) is an embedded submanifold of \( X \). Furthermore, the codimension of \( f^{-1}(Z) \) in \( X \) equals the codimension of \( Z \) in \( Y \).

**Remark 4.4.** The Map Transversality Theorem uses the standard convention that the dimension of the empty set can assume any number. In the Map Transversality Theorem, if \( f^{-1}(Z) = \emptyset \), one considers the codimension of \( f^{-1}(Z) \) in \( X \) to be the codimension of \( Z \) in \( Y \).

**Theorem 8** (Parametric Transversality Theorem). [8, p. 68] Let \( S \) be a smooth manifold and let \( F : X \times S \to Y \) be a smooth map. If \( F \) is transverse to \( Z \), then for (Lebesgue) almost every \( s \in S \) the restriction map \( F_s : X \to Y \) given by \( F_s(x) = F(x, s) \) is transverse to \( Z \).

We wish to apply the Parametric Transversality Theorem to the parametrized family of neural networks of a fixed architecture (Definition 2.4), but this family does not satisfy the smoothness requirements, so we develop the necessary non-smooth analogues in §4.2.

### 4.2. Extensions of the classical transversality results to maps on polyhedral complexes that are smooth on cells.

We introduce a polyhedral analogue of Definition 4.1.

**Definition 4.5.** Let \( X \) be a polyhedral complex of dimension \( d \) in \( \mathbb{R}^n \), let \( f : |X| \to \mathbb{R}^r \) be a map which is smooth on all cells of \( X \) and let \( Z \) be a smoothly embedded submanifold (without boundary) of \( \mathbb{R}^r \). We say that \( f \) is transverse on cells to \( Z \) and write \( f \triangleleft c Z \) if:

(i) the restriction of \( f \) to the interior, \( \text{int}(C) \), of every \( k \)–cell \( C \) of \( X \) is transverse to \( Z \) (in the sense of Definition 4.1) when \( 1 \leq k \leq d \), and

(ii) the restriction of \( f \) to every 0–cell (vertex) of \( X \) is transverse to \( Z \).

**Remark 4.6.** We note that a function defined on a 0-cell is considered to be (vacuously) smooth.

Note that condition (i) of Definition 4.5 implies that if \( f \) is transverse to \( Z \) and there exists a vertex \( v \) of \( X \) such that \( f(v) \in Z \), then \( Z \) must have the full dimension \( r \). Thus, if \( \dim(Z) < r \), as is the case in all situations we will consider, \( f \) being transverse to \( Z \) implies no vertex of \( X \) is sent by \( f \) to \( Z \). We will be particularly interested in the case in which the codomain is an interval complex, i.e. \( r = 1 \) and \( Z = \{t\} \) is a threshold in \( \mathbb{R} \).

**Corollary 4.7** (Corollary of Theorem 7). Let \( X \) be a polyhedral complex of dimension \( d \) in \( \mathbb{R}^n \). Let \( f : |X| \to \mathbb{R}^r \) be a map which is smooth on cells of \( X \) and let \( Z \) be a smoothly embedded submanifold of \( \mathbb{R}^r \) for which \( f \triangleleft c Z \). Then we have:

- For every cell \( C \in X \) of dimension \( k \), where \( 1 \leq k \leq d \), \( f^{-1}(Z) \cap \text{int}(C) \) is a (possibly empty) smoothly embedded submanifold of \( \text{int}(C) \). Furthermore, the codimension of \( f^{-1}(Z) \cap \text{int}(C) \) in \( \text{int}(C) \) equals the codimension of \( Z \) in \( \mathbb{R}^r \).
• If \( \dim(Z) < r \), then for every cell \( C \in X \) of dimension 0 (vertex), \( f(C) \notin Z \).

Proof. This follows immediately from Theorem \([7]\) since the interior of any polyhedral set of dimension \( k \in \mathbb{N} \) is a nonempty smooth manifold. \( \square \)

We will need the following version of the Parametric Transversality Theorem for families of maps that are linear on cells of a polyhedral complex.

Proposition 4.8. Let \( X \) be a polyhedral complex in \( \mathbb{R}^n \), \( S \) a smooth manifold without boundary, and \( Z \subseteq \mathbb{R}^r \) a smoothly embedded submanifold without boundary. Suppose that for each cell \( C \in X \), the restricted map \( F|_{C \times S} : C \to \mathbb{R}^r \) is smooth and the further restricted map \( F|_{C' \times S} : C' \times S \to \mathbb{R}^r \), where

\[
C' = \begin{cases}
\text{int}(C) & \text{if } C \text{ is of dimension } \geq 1, \\
C & \text{if } C \text{ is of dimension } 0,
\end{cases}
\]

is transverse to \( Z \). Then for (Lebesgue) almost every \( s \in S \), the map

\[
f_s : |X| \times \{s\} \to \mathbb{R}^r
\]

given by \( f_s(x) = F(x,s) \) is transverse to \( Z \).

Proof. For each cell \( C \in X \), the Parametric Transversality Theorem implies that there exists a null set \( S_C \subset S \) such that \( f_s|_{C' \times \{s\}} \) is transverse to \( Z \) for every \( s \in S \setminus S_C \). Let \( S_X = \bigcup_{C \in X} S_C \); as a finite union of null sets, \( S_X \) is a null set. Then for every \( C \in X \) and \( s \in S \setminus S_X \), we have that

\[
f_s|_{C' \times \{s\}} : C' \times \{s\} \to \mathbb{R}^r
\]

is transverse to \( Z \). Hence \( f_s \) is transverse to \( Z \) for all \( s \in S \setminus S_X \). \( \square \)

5. Maps on polyhedral complexes and transversal thresholds

We now turn to applying the transversality statements developed in the previous section to ReLU neural network maps.

Definition 5.1. Let \( M \) be a polyhedral complex embedded in \( \mathbb{R}^{n_0} \), \( n_0 \in \mathbb{N} \), and let \( F : |M| \to \mathbb{R} \) be a map that is smooth on cells. A threshold \( t \in \mathbb{R} \) is said to be transversal for \( F \) and \( M \) if \( F \) is transverse on cells (Definition \([4.5]\)) to the (0-dimensional) submanifold \( \{t\} \) of \( \mathbb{R} \). In this case, we write \( F \bowtie_{t} \{t\} \).

Remark 5.2. Although Section \([4.2]\) and Definition \([5.1]\) require only that the map \( F \) be smooth on cells, from this point onwards we restrict to the case that \( F \) is affine linear on cells, since this is the setting relevant for understanding neural network maps. In this case, we can recast transversality on cells for affine linear maps \( F \) in terms of \( F \)-nonconstant cellular neighborhoods, as follows.

For the remainder of this section, let \( M \) be a polyhedral complex embedded in \( \mathbb{R}^{n_0} \), \( n_0 \in \mathbb{N} \), and let \( F : |M| \to \mathbb{R} \) be a map that is linear on cells.

Definition 5.3. A point \( x \in M \) is said to have a \( F \)-nonconstant cellular neighborhood in \( M \) if \( F \) is nonconstant on each cell of \( M \) containing \( x \).
Note that each vertex of $M$ is itself a cell on which $F$ is necessarily constant; hence, no vertex of $M$ can be said to have a $F$-nonconstant cellular neighborhood.

**Lemma 5.4.** A threshold $t \in \mathbb{R}$ is transversal for $F$ and $M$ if and only if each point $p \in F^{-1}\{\{t\}\}$ has a $F$-nonconstant cellular neighborhood in $M$.

**Proof.** This is a matter of working through definitions. Assume $F$ is linear on cells. The threshold $t$ is transversal for $F$ and $M$ if and only if for any $k$-cell $C \in X$ with $k \geq 1$ the restriction of $f$ to $\text{int}(C)$ is transverse to $\{t\}$, and the restriction of $f$ to any 0-cell $X$ is transverse to $\{t\}$. This is equivalent to the statement that if $p \in F^{-1}\{\{t\}\}$ and $p$ is in a cell $C \in M$, then

$$df_p(T_p C) + T_f(\{t\}) \cap \mathbb{R} = T_f(\{t\}) \mathbb{R}.$$

Since $T_f(\{t\}) \cap \mathbb{R} = 0$, this equality holds if and only if $df_p(T_p C) = T_f(\{t\}) \mathbb{R}$ for every cell $C$ containing $p$, which is the definition of $p$ having a nonconstant cellular neighborhood. \hfill $\Box$

**Remark 5.5.** For $F : |M| \to \mathbb{R}$ a map which is linear on the cells of a polyhedral complex $M \subseteq \mathbb{R}^n$ as above, [7, Sec. 3.2] defines the notion of a regular point of $F$, by analogy to ideas from classical smooth Morse theory. Informally, a regular point of $F$ is one for which there exists a local coordinate system on which the function $F$ agrees with one of the coordinates. Although we won’t need this more general notion in the present work, we remark that it follows immediately from the definitions that a regular, non-vertex, point of $M$ necessarily has a $F$-nonconstant cellular neighborhood.

**Lemma 5.6.** Let $t \in \mathbb{R}$ be a transversal threshold for $F$ and $M$. Then for every cell $C \in M$, $F^{-1}\{\{t\}\} \cap C$ is either empty or aff($F^{-1}\{\{t\}\} \cap C$) is a hyperplane in aff($C$). Moreover, whenever $F^{-1}\{\{t\}\} \cap C$ is nonempty, the hyperplane aff($F^{-1}\{\{t\}\} \cap C$) cuts $C$ (as in Definition 3.3).

**Proof.** The statement that $F^{-1}\{\{t\}\} \cap C$ is a submanifold of codimension 1 in $C$ is from the Map Transversality Theorem (Theorem [7]); its affine hull is a hyperplane because $F$ is affine linear. Let $H = \text{aff}(F^{-1}\{\{t\}\} \cap C) \neq \emptyset$. If $H$ were a supporting hyperplane of $C$, then $H \cap C$ would be a non-empty lower-dimensional face of $C$, all of whose points map to $t$. Applying Lemma 5.4, this would contradict the assumption that $t$ is a transversal threshold. Hence, $H$ cuts $C$ whenever $F^{-1}\{\{t\}\} \cap C \neq \emptyset$. \hfill $\Box$

**Lemma 5.7.** All but finitely many thresholds $t \in \mathbb{R}$ are transversal for $F$ and $M$.

**Proof.** The polyhedral complex $M$ is, by definition, finite. Hence there are only finitely many cells on which $F$ is constant. But Lemma 5.4 tells us that the images of the constant cells are the only nontransversal thresholds for $F$ and $M$. The result follows. \hfill $\Box$
6. Bent hyperplane arrangements and canonical polyhedral complexes

The following notions were introduced in [11].

**Definition 6.1.** [11, Eqn. (2), Lem. 4] Let
\[
\mathbb{R}^{n_0} \xrightarrow{F_1 = \sigma \circ A_1} \mathbb{R}^{n_1} \xrightarrow{F_2 = \sigma \circ A_2} \cdots \xrightarrow{F_m = \sigma \circ A_m} \mathbb{R}^{n_m} \xrightarrow{G = A_{m+1}} \mathbb{R}^1.
\]
be a ReLU neural network. Let
\[
A^{(k)} = \{H^{(k)}_{1}, \ldots, H^{(k)}_{n_k}\}
\]
denote the hyperplane arrangement in \(\mathbb{R}^{n_{k-1}}\) associated to the layer map \(F_k\) (Definition 2.12).

(i) A bent hyperplane associated to the \(k\)th layer of \(F\), for \(k \in \{2, \ldots, m\}\), is the preimage in \(\mathbb{R}^{n_0}\) of any hyperplane \(H^{(k)}_{i}\) (in \(\mathbb{R}^{n_{k-1}}\)) associated to the \(k\)th layer map:
\[
(F_{k-1} \circ \cdots \circ F_1)^{-1}\left(H^{(k)}_i\right).
\]
A bent hyperplane associated to the first layer of \(F\) is any hyperplane \(H^{(1)}_i\) (in \(\mathbb{R}^{n_0}\)) associated to the first layer map.

(ii) The bent hyperplane arrangement associated to the \(k\)th layer of \(F\), for \(k \in \{2, \ldots, m\}\), is the set
\[
B^{(k)}_F := (F_{k-1} \circ \cdots \circ F_1)^{-1}\left(\bigcup_{j=1}^{n_k} H^{(k)}_j\right).
\]
The bent hyperplane arrangement associated to the first layer of \(F\) is the hyperplane arrangement (in \(\mathbb{R}^{n_0}\)) associated to the first layer of \(F\).

(iii) The bent hyperplane arrangement associated to the entire neural network is the union of the bent hyperplane arrangements associated to the layers:
\[
\mathcal{B}_F := \bigcup_{k=1}^{m} B^{(k)}_F.
\]

**Remark 6.2.** Note that the preimage of the hyperplane (in \(\mathbb{R}^{n_m}\)) associated to the final layer \(G\) of the neural network is not included in the bent hyperplane arrangement. This omission is motivated by the fact there is no factor of \(\sigma\) in \(G\), and so \(G\) does not cause the preimage of this hyperplane in \(\mathbb{R}^{n_0}\) to belong to the locus where the neural network map is non-differentiable.

**Lemma 6.3.** A neural network map is smooth on the complement of its bent hyperplane arrangement.

**Proof.** Clearly, each layer map \(F_k : \mathbb{R}^{n_{k-1}} \to \mathbb{R}^{n_k}\) is smooth on the complement of the domain of its associated hyperplane arrangement \(A^{(k)}\), and the final layer map \(G\) is smooth everywhere since it is affine. The restriction of the neural network map \(F\) to \(\mathbb{R}^{n_0} \setminus \mathcal{B}_F\) can be viewed as the composition of the restriction of the layer maps to complements of the domains their associated hyperplane arrangement; thus, as a composition of smooth maps, the restriction of \(F\) to \(\mathbb{R}^{n_0} \setminus \mathcal{B}_F\) is smooth. \(\square\)
Definition 6.4. [11, Def 1, Lem 2] Let $F : \mathbb{R}^{n_0} \to \mathbb{R}$ be a ReLU neural network map. An activation region of $F$ is a connected component of the complement of the bent hyperplane arrangement associated to $F$, i.e. a connected component of $\mathbb{R}^{n_0} \setminus B_F$.

Remark 6.5. Note that it is possible for the preimage of a hyperplane arrangement associated to a (non-first) layer map to have codimension 0, not 1, in $\mathbb{R}^{n_0}$. In this case, the bent hyperplane arrangement does not everywhere look locally like a hyperplane arrangement.

As a simple example of this phenomenon, consider a two-layer ReLU neural network

$$F : \mathbb{R}^n \xrightarrow{F_1} \mathbb{R}^n \xrightarrow{F_2} \mathbb{R},$$

where $\mathcal{A}^{(1)}$ is the standard coordinate hyperplane arrangement, and $\mathcal{A}^{(2)} = \{ H^{(2)} \}$, where $H^{(2)}$ is any hyperplane through the origin. Then

$$B_F^{(1)} = \{ H_1^{st}, H_2^{st} \},$$

the standard co-oriented coordinate axes, and

$$B_F^{(2)} = \{ (x, y) \in \mathbb{R}^2 \mid x, y \leq 0 \}$$

the closed all-negative orthant. In particular, the bent hyperplane arrangement is codimension 0, not 1, and hence the closure of the activation regions (Definition 6.4) is a proper subset of $\mathbb{R}^n$.

This phenomenon arises when a map fails to be transversal to a threshold, an observation that motivates Definition 8.2 and Theorem 2. Note that it is also a measure zero phenomenon. See Theorem 3.

We now turn our attention to constructing a canonical polyhedral decomposition of the domain of a ReLU neural network using the work of [7]. In the transversal case, we explicitly relate this decomposition to the bent hyperplane arrangements and activation regions in Theorems 1 and 2.

Definition 6.6. A polyhedral subcomplex of a polyhedral complex $C$ is a subset $C' \subseteq C$ such that for every cell $P$ in $C'$, every face of $P$ is also in $C'$. The underlying set for a subcomplex $C'$, denoted $\vert C' \vert$, is the union of the cells in $C'$.

Definition 6.7. Let

$$F : \mathbb{R}^{n_0} \xrightarrow{F_1} \mathbb{R}^{n_1} \xrightarrow{F_2} \cdots \xrightarrow{F_m} \mathbb{R}^{n_m} \xrightarrow{G} \mathbb{R}$$

be a ReLU neural network. For $i \in \{1, \ldots, m\}$, denote by $R^{(i)}$ the polyhedral complex on $\mathbb{R}^{n_{i-1}}$ induced (as in Definition 3.16) by the hyperplane arrangement associated to the $i^{th}$ layer map $F_i$ (Definition 2.12). Inductively define polyhedral complexes $C(F_1), \ldots, C(F_m \circ \ldots \circ F_1)$ on $\mathbb{R}^{n_0}$ as follows:

Set

$$C(F_1) := R^{(1)},$$

and for $i = 2, \ldots, m$, inductively set

$$C(F_i \circ \ldots \circ F_1) := C(F_{i-1} \circ \ldots \circ F_1) \cap R^{(i)}.$$

The canonical polyhedral complex associated to the neural network is the polyhedral complex

$$C_F := C(F_m \circ \ldots \circ F_1).$$
Remark 6.8. Note that level set complexes were only defined for maps that are linear on cells, so for the inductive step (i) of Definition 6.7, to make sense, and in order to assert that each $C(F_i \circ \ldots \circ F_1)$ is a polyhedral complex, we must justify that for each $i$ the map $F_i \circ \ldots \circ F_1 : \mathbb{R}^{n_i} \to \mathbb{R}^{n_i}$ is linear on cells of $C(F_i \circ \ldots \circ F_1)$; this is done in Theorem 1.

Remark 6.9. Note that canonical polyhedral complexes do not depend on the final layer map, $G$, which is purely affine and does not have a factor of $\sigma$. Compare with Remark 6.2.

Theorem 1. Let $F : \mathbb{R}^{n_{0}} \xrightarrow{F_1} \mathbb{R}^{n_1} \xrightarrow{F_2} \cdots \xrightarrow{F_m} \mathbb{R}^{n_m} \xrightarrow{G} \mathbb{R}$ be a ReLU neural network. For each $i = 1, \ldots, m$, $C(F_i \circ \ldots \circ F_1)$ is a polyhedral decomposition of $\mathbb{R}^{n_0}$ such that

(i) $F_i \circ \ldots \circ F_1$ is linear on the cells of $C(F_i \circ \ldots \circ F_1)$,
(ii) $\bigcup_{k=1}^{i} B_F^{(k)}$ is the domain of a polyhedral subcomplex of $C(F_i \circ \ldots \circ F_1)$.

Proof. For each $i = 1, \ldots, m$, denote by $A^{(i)}$ the hyperplane arrangement (of $\leq n_i$ affine hyperplanes in $\mathbb{R}^{n_i-1}$) associated to the layer map $F_i : \mathbb{R}^{n_i-1} \to \mathbb{R}^{n_i}$ (Definition 2.12), and denote by $R^{(i)}$ the induced polyhedral decomposition of $\mathbb{R}^{n_i-1}$ (Definition 3.16). We proceed by induction on $i$.

For $i = 1$, it is immediate that $B_F^{(1)} = A^{(1)}$ forms the $(n_0 - 1)$-skeleton of $R^{(1)}$ and $F_1$ is linear on cells of $C(F_1) = R^{(1)}$.

Now consider $i > 1$ and assume the statement holds for $i - 1$. Lemma 3.21 together with condition (i) of the inductive hypothesis implies $C(F_i \circ \ldots \circ F_1)$ is a polyhedral complex.

By condition (i) of the inductive hypothesis, each cell in $C(F_{i-1} \circ \ldots \circ F_1)$ is the intersection of a cell in $C(F_{i-1} \circ \ldots \circ F_1)$ with the preimage of a cell in $R^{(i)}$. The map $F_{i-1} \circ \ldots \circ F_1$ is linear on each such intersection by assumption. The layer map $F_i : \mathbb{R}^{n_{i-1}} \to \mathbb{R}^{n_i}$ is linear on cells of $R^{(i)}$. Condition (i) follows.

By condition (ii) of the inductive hypothesis, $\bigcup_{k=1}^{i-1} B_F^{(k)}$ is the domain of a polyhedral subcomplex of $C(F_{i-1} \circ \ldots \circ F_1)$. The polyhedral complex $C(F_i \circ \ldots \circ F_1)$ is, by definition, formed by subdividing the polyhedral complex $C(F_{i-1} \circ \ldots \circ F_1)$, so $\bigcup_{k=1}^{i-1} B_F^{(k)}$ is the domain of a polyhedral subcomplex of $C(F_i \circ \ldots \circ F_1)$. Let $R^{(i)}_{(n_{i-1}-1)}$ denote the $(n_{i-1} - 1)$-skeleton of $R^{(i)}$. Noting that the domain of $R^{(i)}_{(n_{i-1}-1)}$ is the union of the hyperplanes in $A^{(i)}$, we have $|C(F_{i-1} \circ \ldots \circ F_1)|_{\in R^{(i)}_{(n_{i-1}-1)}} = B_F^{(i)}$.

Since the union of two subcomplexes of a polyhedral complex is a subcomplex, we see that $\bigcup_{k=1}^{i} B_F^{(k)}$ is a polyhedral subcomplex of $C(F_i \circ \ldots \circ F_1)$, which is condition (ii).

\[\square\]

In Definition 5.1, we say what it means for a threshold $t$ to be transversal for $F$ and $M$, where $M$ is an arbitrary polyhedral complex and $F : [M] \to \mathbb{R}$ is linear on cells of $M$. Equipped with the result (Theorem 1) that a neural
network map $F : \mathbb{R}^{n_0} \to \mathbb{R}$ is linear on cells of its canonical polyhedral complex $C(F)$, it is natural to use $M = C(F)$ to make the following definition.

**Definition 6.10.** A threshold $t \in \mathbb{R}$ is a transversal threshold for a neural network

$$F : \mathbb{R}^{n_0} \xrightarrow{F_1} \mathbb{R}^{n_1} \xrightarrow{F_2} \ldots \xrightarrow{F_m} \mathbb{R}^{n_m} \xrightarrow{G} \mathbb{R}$$

if $t$ is a transversal threshold for $F$ and its canonical polyhedral complex $C(F) = C(F_m \circ \ldots \circ F_1)$.

7. Piecewise smoothness of the parametrized family of neural networks

**Lemma 7.1.** Fix any network architecture $(n_0, \ldots, n_m, 1)$. Then there exists a finite set $E$ of polynomials in the variables $x_1, \ldots, x_{n_0}, s_1, \ldots, s_D$ such that

(i) If $T$ is a term of a polynomial in $E$, then $T$ has the form

$$x s_{1}^{\tau_1} \ldots s_{D}^{\tau_D}$$

for some $x \in \{x_0, \ldots, x_{n_0}, 1\}$ and $(\tau_1, \ldots, \tau_D) \in \{0,1\}^D$, and

(ii) $F$ is smooth on the complement of the set $Z_F$ defined by

$$Z_F := \{(x, s) \in \mathbb{R}^{n_0} \times \mathbb{R}^D : f_i((x, s)) = 0 \text{ for some } f_i \in E\}.$$ 

**Proof.** Fix a network architecture $(n_0, \ldots, n_m, 1)$. For brevity, let $D = D(n_0, \ldots, n_m, 1)$. The idea is to let $E$ be the set of all possible “inputs” of any ReLU in the expression defining $F$. Rather than presenting a formal proof, we give an illustrative example that demonstrates all the key ideas.

We consider the network architecture $(1, 2, 1)$. The parametrized family of neural networks of this architecture is the map $F : \mathbb{R} \times \mathbb{R}^7 \to \mathbb{R}$ given by

$$(x, (a, b, c, d, e, f, g)) \mapsto \text{ReLU}((e \cdot \text{ReLU}(ax + b) + f \cdot \text{ReLU}(cx + d) + g))$$

Each of the three ReLU’s in this expression acts as either the identity or 0, depending on the sign of its argument.

Let $E$ be the set of all possible expressions that are inputs of a ReLU in the expression for $F$, allowing for the possibility that each nested ReLU could be either 0 or the identity. That is,

$$E = \{ax + b, cx + d, e(ax + b) + f(cx + d) + g, e(ax + b) + g, f(cx + d) + g, g\}.$$ 

Let $Z_F \subset \mathbb{R} \times \mathbb{R}^7$ be the set of points $(x, s)$ where at least one function in $E$ evaluates to 0.

For any fixed input $(x, s)$, $F(x, s)$ is given by one of $2^3$ possible (not necessarily distinct) formulas (which correspond to each of the 3 ReLU’s being in one of two possible “states”). Let $H$ be the set of $2^3$ (not necessarily distinct) functions formed by replacing each ReLU with either 0 or the identity. That is, $H$ is the set consisting of the following 8 (not necessarily
distinct) functions:

\[
\begin{align*}
(x, (a, b, c, d, e, f, g)) & \mapsto e \cdot (ax + b) + f \cdot (cx + d) + g \\
(x, (a, b, c, d, e, f, g)) & \mapsto e \cdot (ax + b) + f \cdot 0 \cdot (cx + d) + g \\
(x, (a, b, c, d, e, f, g)) & \mapsto e \cdot 0 \cdot (ax + b) + f \cdot (cx + d) + g \\
(x, (a, b, c, d, e, f, g)) & \mapsto 0(e \cdot (ax + b) + f \cdot (cx + d) + g) \\
(x, (a, b, c, d, e, f, g)) & \mapsto 0(e \cdot (ax + b) + f \cdot 0 \cdot (cx + d) + g) \\
(x, (a, b, c, d, e, f, g)) & \mapsto 0(e \cdot 0 \cdot (ax + b) + f \cdot (cx + d) + g) \\
(x, (a, b, c, d, e, f, g)) & \mapsto 0(e \cdot 0 \cdot (ax + b) + f \cdot 0 \cdot (cx + d) + g)
\end{align*}
\]

Which of these 8 functions represents the value of \( F \) at a given point can only change at points where the argument of a ReLU in the expression for \( F \) – i.e. a polynomial in \( E \) – changes sign. Now, since all the functions in \( E \) are continuous and \( Z_F \) is their set of zeros, for any point \((x, s) \in (\mathbb{R} \times \mathbb{R}^7) \setminus Z_F\) it follows from continuity that there exists a neighborhood \( U \) of \((x, s)\) on which the sign of each function in \( E \) is constant. Consequently, there is a fixed function \( f \in H \) such that \( F \) agrees with \( f \) on \( U \). Since all functions in \( H \) are smooth, this implies that the restriction of \( F \) to \( \mathbb{R} \times \mathbb{R}^7 \setminus Z_F \) is smooth.

\[ \square \]

**Theorem 4.** Fix any network architecture \((n_0, \ldots, n_m, 1)\). Then there exists an algebraic set \( Z_F \subset \mathbb{R}^{n_0} \times \mathbb{R}^{D(n_0, \ldots, n_m, 1)} \) such that

(i) The parametrized family of neural networks of architecture \((n_0, \ldots, n_m, 1)\),

\[ F : \mathbb{R}^{n_0} \times \mathbb{R}^{D(n_0, \ldots, n_m, 1)} \to \mathbb{R}, \]

is smooth on the complement of \( Z_F \).

(ii) \( Z_F \) is the vanishing set of a polynomial, and hence is a closed, nowhere dense subset with Lebesgue measure 0.

(iii) the complement of \( Z_F \) consists of finitely many connected components.

**Proof.** Let \( E \) be the set of polynomials constructed in Lemma 7.1, define the polynomial \( F := \prod_{f_i \in E} f_i \), and observe that the set \( Z_F \subset \mathbb{R}^{n_0} \times D(n_0, \ldots, n_m, 1) \) from Lemma 7.1 is the vanishing set for \( F \). Standard results in real algebraic geometry imply that \( Z_F \), as a codimension one algebraic set, is nowhere dense, has Lebesgue measure 0, and its complement consists of finitely many connected components (see e.g. [3] [20]). \[ \square \]

**Proposition 7.2.** For any network architecture \((n_0, \ldots, n_m, 1)\), let \( Z_F \) be the algebraic set constructed in the proof of Lemma 7.1 for the parametrized family of neural networks

\[ F : \mathbb{R}^{n_0} \times \mathbb{R}^{D(n_0, \ldots, n_m, 1)} \to \mathbb{R}, \]
and for each \( s \in \mathbb{R}^{D(n_0, \ldots, n_m, 1)} \), denote by \( F_s \) the neural network map defined by \( F_s(x) = F(x, s) \). Then

\[
\bigcup_{s \in Z_F} (B_{F_s} \times \{s\}) \subseteq Z_f.
\]

**Proof.** Fix a parameter \( s \in \mathbb{R}^{D(n_0, \ldots, n_m, 1)} \). The bent hyperplane arrangement \( B_{F_s} \) is the union the preimages in \( \mathbb{R}^{n_0} \) of the hyperplanes in the hyperplane arrangements associate to the layer maps of \( F_s \). Each such hyperplane is the vanishing set of the argument of a ReLU in the expression for \( F_s \). Thus the polynomial in the variables \( x_1, \ldots, x_{D(n_0, \ldots, n_m, 1)} \) that defines such a hyperplane is obtained by substituting the values for \( s \) into one of the polynomials in the set \( E \) constructed in the proof of Lemma 7.1, implying \( F(x, s) = 0 \), where \( F \) is the product of the polynomials in \( E \). Hence, any point \( x \) in the preimage in \( \mathbb{R}^{n_0} \) of such a hyperplane satisfies \((x, s) \in Z_F\). \( \Box \)

8. **Transversal neural networks**

In what follows, let \( \pi_j : \mathbb{R}^m \to \mathbb{R} \) denote the projection onto the \( j \)th coordinate.

**Definition 8.1.** Let

\[
\mathbb{R}^{n_0} \xrightarrow{F_1 = \sigma \circ A_1} \mathbb{R}^{n_1} \xrightarrow{F_2 = \sigma \circ A_2} \ldots \xrightarrow{F_m = \sigma \circ A_m} \mathbb{R}^{n_m} \xrightarrow{G = A_{m+1}} \mathbb{R}^1
\]

be a ReLU neural network. For each \( i \in \{1, \ldots, m\} \) and \( j \in \{1, \ldots, n_i\} \), the node map, \( F_{i,j} \), is the map

\[
\pi_j \circ A_i \circ F_{i-1} \circ \ldots \circ F_1 : \mathbb{R}^{n_0} \to \mathbb{R}.
\]

**Definition 8.2.** A ReLU neural network

\[
F : \mathbb{R}^{n_0} \xrightarrow{F_1} \mathbb{R}^{n_1} \xrightarrow{F_2} \ldots \xrightarrow{F_m} \mathbb{R}^{n_m} \xrightarrow{G} \mathbb{R}
\]

is said to be transversal if, for each \( i \in \{1, \ldots, m\} \) and each \( j \in \{1, \ldots, n_i\} \), \( t = 0 \) is a transversal threshold (Definition 5.7) for the node map

\[
F_{i,j} : \mathbb{R}^{n_0} \to \mathbb{R}.
\]

**Remark 8.3.** The descriptors *generic* and *transversal*, when applied to ReLU neural networks, are similar but complementary concepts. We devote a few words to explaining the difference.

A ReLU neural network is *generic* if each solution set arrangement for each layer map is generic. It is not immediate, yet it is true, that if a solution set arrangement is generic then each solution set in the arrangement intersects each *intersection* of solution sets in that layer transversely.

In contrast, if a ReLU neural network is *transversal* then it follows from the definitions that each bent hyperplane intersects the bent hyperplanes from all previous layers transversely.

Put simply, when applied to ReLU neural networks, the term *generic* describes intersections of cells associated to a single layer map, and the term *transversal* describes intersections of cells associated to different layer maps.
Theorem 2. If a ReLU neural network

$$F : \mathbb{R}^{n_0} \xrightarrow{F_1} \mathbb{R}^{n_1} \xrightarrow{F_2} \ldots \xrightarrow{F_m} \mathbb{R}^{n_m} \xrightarrow{G} \mathbb{R}$$

is transversal (in the sense of Definition 8.2), then the bent hyperplane arrangement $\mathcal{B}_F$ is the domain of the $(n_0 - 1)$–skeleton of the canonical polyhedral complex $\mathcal{C}(F_m \circ \ldots \circ F_1)$ and the closures of the activation regions of $F$ are the $n_0$–cells of $\mathcal{C}(F_m \circ \ldots \circ F_1)$.

Proof. We proceed by induction on $m$. The base case $m = 1$ is immediate. Now consider any fixed value of $m > 1$ and assume the result holds for all smaller values of $m$. In particular, for each node map $F_{m,j}$, $j \in \{1, \ldots, n_m\}$, the bent hyperplane arrangement $\mathcal{B}_{F_{m,j}} = \bigcup_{i=1}^{m-1} \mathcal{B}_{F_{m,j}}^{(i)}$ is the domain of the $(n_0 - 1)$–skeleton of $\mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$. But for each $i \in \{1, \ldots, m-1\}$ and $j \in \{1, \ldots, n_m\}$, we have $\mathcal{B}_{F_{m,j}}^{(i)} = \mathcal{B}_F^{(i)}$, so the bent hyperplane arrangement,

$$\mathcal{B}_F' := \bigcup_{i=1}^{m-1} \mathcal{B}_F^{(i)},$$

for the first $m - 1$ layers is the $(n_0 - 1)$–skeleton of the polyhedral complex $\mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$.

To see that $\mathcal{B}_F'$ is contained in the $(n_0 - 1)$–skeleton of $\mathcal{C}(F_m \circ \ldots \circ F_1)$, we begin by noting that $\mathcal{B}_F'$ is contained in the $(n_0 - 1)$–skeleton of $\mathcal{C}(F_m \circ \ldots \circ F_1)$ since $\mathcal{C}(F_m \circ \ldots \circ F_1)$ is a subdivision of $\mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$. Moreover, by definition

$$\mathcal{B}_F = \mathcal{B}_F' \cup \bigcup_{j=1}^{n_m} F_{m,j}^{-1}(\{0\}).$$

It therefore suffices to show that $\bigcup_{j=1}^{n_m} F_{m,j}^{-1}(\{0\})$ is contained in the $(n_0 - 1)$–skeleton of $\mathcal{C}(F_m \circ \ldots \circ F_1)$.

But since 0 is a transversal threshold for each node map $F_{m,j} : \mathbb{R}^{n_0} \rightarrow \mathbb{R}$, this follows from the Map Transversality Theorem. Explicitly, for every cell $C \in \mathcal{C}(F_m \circ \ldots \circ F_1)$, Theorem 7 tells us that $C \cap F_{m,j}^{-1}(\{0\})$ is codimension 1 in $C$. Since $\mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$ has dimension $n_0$, it follows that any new cell in $\mathcal{B}_F \setminus \mathcal{B}_F'$ has dimension $\leq (n_0 - 1)$, as desired.

To see that $\mathcal{C}(F_m \circ \ldots \circ F_1)$ is contained in $\mathcal{B}_F$ we will show that any $k$–cell $C$ in $\mathcal{C}(F_m \circ \ldots \circ F_1)_{n_0-1}$ is also in $\mathcal{B}_F$.

Since $\mathcal{C}(F_m \circ \ldots \circ F_1)$ is, by definition, a subdivision of $\mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$, the cell $C$ is contained in a cell $C'$ of $\mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$. Assume WLOG that $C'$ has minimal dimension among all cells in $\mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$ containing $C$, and let $k'$ be the dimension of $C'$. If $k' \leq n_0 - 1$, then $C \subseteq C' \subseteq \mathcal{C}(F_{m-1} \circ \ldots \circ F_1)_{n_0-1}$, and the inductive hypothesis tells us $C \subseteq \mathcal{B}_F'$, as desired.

So we may assume that $C'$ has dimension $n_0$. Therefore the construction described in the proof of Theorem 1 and the fact that $C$ has dimension $\leq n_0 - 1$ (see also Lemma 5.6) tells us that $C$ is equal to the intersection of $C'$ with $F_{m,j}^{-1}(\{0\})$ for some node $j$ in the $m$th layer map. It follows that $C \subseteq \mathcal{B}_F$.

We conclude that $\mathcal{B}_F = \mathcal{C}(F_m \circ \ldots \circ F_1)_{n-1}$ as desired. \qed
For any given architecture
\[ R^{n_0} \xrightarrow{F_1} R^{n_1} \xrightarrow{F_2} \cdots \xrightarrow{F_m} R^{n_m} \xrightarrow{G} R \]
of feedforward ReLU neural network, almost every (with respect to Lebesgue measure on \( R^{D(n_0,\ldots,n_m,1)} \)) choice of parameters yields a transversal ReLU neural network.

**Proof.** We proceed by induction on \( m \), the number of hidden layers. When \( m = 1 \), each node map \( F_{1,j} : R^{n_0} \to R \) is an affine linear map, so \( F \) is transversal if and only if the node map \( F_{1,j} \) has at least one nonzero value. That is, if and only if the associated weight, bias vector \( (W_j|b_j) \) is nonzero for each \( j \). The set of such parameters clearly forms a null set, as desired.

Now consider a fixed value of \( m \geq 2 \), and assume the result holds for smaller values of \( m \). For any neural network \( F \) of architecture \((n_0, \ldots, n_m, 1)\) and any \( j \in \{1, \ldots, n_m\} \), the node map \( F_{m,j} \) is a neural network of architecture \((n_0, \ldots, n_{m-1}, 1)\). Note that such a neural network \( F \) is transversal if and only if the node map \( F_{m,1} \) is a transversal neural network and for every \( j \in \{1, \ldots, n_m\} \) the node map \( F_{m,j} \) has \( t = 0 \) as a transversal threshold.

For any \( n \in \mathbb{N} \), let \( \lambda_n \) denote Lebesgue measure on \( R^n \). By the inductive assumption, there exists a \( \lambda_{D(n_0,\ldots,n_{m-1},1)} \)-null set \( N_1 \subset R^{D(n_0,\ldots,n_{m-1},1)} \) such that for every parameter in \( R^{D(n_0,\ldots,n_{m-1},1)} \setminus N_1 \), the node map \( F_{m,1} \) is transversal. Let \( N_2 \) denote the set of points in \( R^{D(n_0,\ldots,n_{m-1},1)} \) whose projection to the first \( D(n_0, \ldots, n_{m-1}, 1) \)-coordinates is in \( N_1 \); then \( \lambda_{D(n_0,\ldots,n_{m-1},1)}(N_2) = 0 \). Let \( \delta = D(n_0, \ldots, n_{m-1}, 1) - D(n_0, \ldots, n_{m-1}, 1) \).

We will show that for each parameter \( s \in R^{D(n_0,\ldots,n_{m-1},1)} \setminus N_2 \), there exists a set \( Y_s \subset R^\delta \) such that \( \lambda_s(Y_s) = 0 \) and for every \( x \in R^\delta \setminus Y_s \), the neural network \( F \) associated to the parameter \( (s, x) \in R^{D(n_0,\ldots,n_{m-1},1)} \) satisfies that for every \( j \in \{1, \ldots, n_m\} \) the node map \( F_{m,j} \) has \( t = 0 \) as a transversal threshold.

Assuming such sets \( Y_s \) are defined, set
\[ N_3 := \left\{ (s, x) : s \in R^{D(n_0,\ldots,n_{m-1},1)} \setminus N_2, \ x \in Y_s \right\}. \]
Tonelli’s Theorem will then imply that \( \lambda_{D(n_0,\ldots,n_{m-1},1)}(N_3) = 0 \). Then, for every parameter in \( R^{D(n_0,\ldots,n_{m-1},1)} \setminus (N_2 \cup N_3) \), the associated neural network is transversal.

So fix \( s \in R^{D(n_0,\ldots,n_{m-1},1)} \). Then, for each \( j \in \{1, \ldots, n_m\} \), we represent the parameterized family of the layer-\( m \), node-\( j \) node maps of neural networks of architecture \((n_0, \ldots, n_m, 1)\) whose first \( m-1 \) layers are determined by \( s \) by
\[ (\mathcal{F}_{m,j})_s : R^{n_0} \times R^{n_{m-1}+1} \to R. \]
(The coordinate in \( R^{n_{m-1}+1} \) parameterizes the possible weights and bias for the \( j \)th affine linear map of the \( m \)th layer.) Let \( C(F_{m-1} \circ \ldots \circ F_1) \) denote the canonical polyhedral complex (on \( R^{n_0} \)) associated to the first \( m-1 \) layers of every neural network \( F \) whose first \( m-1 \) layer maps are specified by the parameter \( s \). By construction, for each \( w \in R^{n_{m-1}+1} \), the node map
\[ (\mathcal{F}_{m,j})_s|_w : R^{n_0} \times \{w\} \to R, \]
given by
\[ (\mathcal{F}_{m,j})_s|_w(x) = (\mathcal{F}_{m,j})_s(x, w) \]
is linear on the cells of $\mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$. Therefore, by Parametric Transversality (Proposition \ref{thm:transversality}), to prove that $(F_{m,j})_{s} |_{w}$ is transverse to $\{0\} \subset \mathbb{R}$ for $\lambda_{n_{m-1}+1}$-almost every $w \in \mathbb{R}^{n_{m-1}+1}$, it suffices to show that for every cell $C \in \mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$, the parametrized map

$$(F_{m,j})_{s}|_{C'} \times \mathbb{R}^{n_{m-1}+1} \to \mathbb{R}$$

is transverse to $\{0\}$, where $C'$ is $C$ if $\dim(C) = 0$ and $C' = \text{int}(C)$ otherwise. For any such $C$, to show that $(F_{m,j})_{s}|_{C'} \times \mathbb{R}^{n_{m-1}+1}$ is transverse to $\{0\} \subset \mathbb{R}$, it suffices to show that $(F_{m,j})_{s}|_{C'} \times \mathbb{R}^{n_{m-1}+1}$ is surjective, since the whole space, $\mathbb{R}$, is clearly transverse to any embedded submanifold.

Accordingly, fix a non-empty cell, $C \in \mathcal{C}(F_{m-1} \circ \ldots \circ F_1)$. Then $C'$ is non-empty, so its image in $\mathbb{R}^{n_{m-1}}$ under $F_{m-1} \circ \ldots \circ F_1$ is non-empty. Let $p \in \mathbb{R}^{n_{m-1}}$ be a point in this image. We claim that for every $t \in \mathbb{R}$ there exists some affine linear transformation $\mathbb{R}^{n_{m-1}} \to \mathbb{R}$ sending $p$ to $t$. This is true because every affine linear transformation $A$ sends $p$ to some value, $t_0$, and if $t_0 \neq t$ then the affine linear transformation $A + (t - t_0)$ will send $p$ to $t$. So $(F_{m,j})_{s}|_{C'} \times \mathbb{R}^{n_{m-1}+1}$ is surjective.

Thus, for $\lambda_{n_{m-1}+1}$-almost every $w \in \mathbb{R}^{n_{m-1}+1}$, the node map $(F_{m,j})_{s}|_{w}$ is transverse to $\{0\};$ let $Y_{s,j}$ be the $\lambda_{n_{m-1}+1}$-null set where this fails. Set $Y_s$ to be the set of points $x$ in $\mathbb{R}^\delta$ such that for some $j \in \{1, \ldots, n_m\}$, the projection of $x$ to its $(n_{m-1} + 1)$ coordinates representing the weights and biases representing the $j^{th}$ affine map of $(m-1)^{th}$ layer is in $Y_{s,j}$. By construction, $\lambda_\delta(Y_s) = 0$.

\[\square\]

9. Binary codings of regions of co-oriented hyperplane arrangements and the gradient vector field of a ReLU neural network map

In this section, we collect elementary facts about co-oriented hyperplane arrangements that will be useful in the proofs of Theorems \ref{thm:transversality} and \ref{thm:expressiveness}. We also introduce a partial orientation on $\mathcal{C}(F_1)$, the 1–skeleton of the bent hyperplane arrangement of a generic, transversal ReLU neural network, defined using the gradient of the neural network function $F$. This partially-oriented graph plays an important role in the proof of Theorem \ref{thm:expressiveness}.

Definition 9.1. A region of a (possibly ordered, co-oriented) hyperplane arrangement $\mathcal{A}$ in $\mathbb{R}^n$ is a connected component of $\mathbb{R}^n \setminus \bigcup_{H \in \mathcal{A}} H$. Let $r(\mathcal{A})$ denote the number of regions of $\mathcal{A}$.

Note that each region, $R$, of an ordered, co-oriented hyperplane arrangement $\mathcal{A} = \{H_1, \ldots, H_k\}$ is naturally labeled with a binary $k$–tuple, $\vec{\theta} \in \{0, 1\}^k$, where the $i^{th}$ component of $\vec{\theta}$ associated to $R$ is 1 (resp. 0) if the co-orientation of $H_i$ points towards (resp., away from) $R$. 
There are 7 regions in the complement of 3 co-oriented hyperplanes in $\mathbb{R}^2$. The assignment of binary 3–tuples to regions is not surjective.

**Definition 9.2.** We shall denote the region of $\mathbf{A}$ labeled by the binary $k$–tuple $\vec{\theta}$ by $R_{\vec{\theta}}(\mathbf{A})$ and refer to it as the $\vec{\theta}$ region of $\mathbf{A}$. If the ordered, co-oriented hyperplane arrangement $\mathbf{A}$ is clear from context, we will abbreviate the notation to $R_{\vec{\theta}}$.

The assignment of binary $k$–tuples to regions of an ordered, co-oriented hyperplane arrangement $\mathbf{A}$ is clearly injective, but it need not be surjective, as illustrated in Figure 1. Lemma 9.3 gives a sufficient condition for the assignment to be bijective.

The contents of Lemmas 9.3 and 9.4 are well known and follow immediately from a classical theorem of Zaslavsky [21] (cf. [18, Thm. 2.5]). We include proofs here for completeness.

**Lemma 9.3.** Let $\mathbf{A} := \{H_1, \ldots, H_k\}$ be a generic ordered, co-oriented hyperplane arrangement in $\mathbb{R}^n$, where $k \leq n$. Then $r(\mathbf{A}) = 2^k$, and hence there is a one-to-one correspondence between regions of $\mathbf{A}$ and binary $k$–tuples.

**Proof.** An elementary fact, [18, Lem. 2.1 (a)], used in the proof of Zaslavsky’s theorem is that if $\mathbf{A}$ is a hyperplane arrangement, $H \in \mathbf{A}$ is a hyperplane, $\mathbf{A}' := \mathbf{A} \setminus \{H\}$ is the deleted arrangement, and $\mathbf{A}'' := \{K \cap H \mid K \in \mathbf{A}'\}$ is the restricted arrangement, then $r(\mathbf{A}) = r(\mathbf{A}') + r(\mathbf{A}'')$. If $\mathbf{A}$ is generic, then the result follows from a double induction on $n$ and $k$, since $r(\mathbf{A}') = 2^{k-1}$ and $r(\mathbf{A}'') = 2^{k-1}$. □

**Lemma 9.4.** Let $\mathbf{A} = \{H_1, \ldots, H_k\}$ be a (generic or non-generic) ordered, co-oriented hyperplane arrangement of $k \leq n$ hyperplanes in $\mathbb{R}^n$. $\mathbf{A}$ has no bounded regions.
This result follows from [18] Lem. 2.1 (b), but, since no proof is provided for part (b), we present a different approach (which has the added benefit of reminding the reader of a notion of duality between the domain and the parameter space of an affine linear map). The classical Minkowski-Weyl theorem (cf. [6]) tells us that every convex polytope \( P \subseteq \mathbb{R}^n \) (see Definition 3.1) has two equivalent representations:

(i) as an intersection of half-spaces (\( H \) representation), a minimal sub- set of which give rise to the facets of \( P \), and

(ii) as a convex hull of points (\( V \) representation), a minimal sub- set of which are the vertices of \( P \).

Moreover, these representations are dual in the sense that if \( P \) is a convex polytope in \( \mathbb{R}^n \), we can define a so-called polar dual to \( P \), \( P^* \subseteq (\mathbb{R}^n)^* \), as follows. First translate \( P \) so that the origin is in its interior. Then define

\[
P^* := \{ \bar{y} \in \mathbb{R}^n \mid \bar{x} \cdot \bar{y} \leq 1 \ \forall \bar{x} \in P \}.
\]

\( P^* \) is also a convex polytope of dimension \( n \), and its vertices (resp., facets) are in natural bijective correspondence with the facets (resp., vertices) of \( P \) [6 Sec. 3.4].

**Proof.** Suppose that \( A \) is a hyperplane arrangement of \( k \leq n \) hyperplanes in \( \mathbb{R}^n \) and there is a bounded region, \( R \), of \( A \). The region \( R \) is a convex polytope and hence has a combinatorial dual \( P^* \) whose vertices are in bijective correspondence with (a subset of) the hyperplanes of \( A \). Since \( P^* \) is a convex polytope of dimension \( n \) and is the convex hull of its vertices, and the convex hull of \( k \) points has dimension at most \( k - 1 \), it follows that \( k \geq n + 1 \). □

**Lemma 9.5.** Let \( S = \{ S_1, \ldots, S_N \} \subseteq \mathbb{R}^n \) be a nondegenerate solution set arrangement with defining set, \( \{(W_i|b_i)\}_{i=1}^N \) of augmented weight/bias vectors as in Equation 2, and let \( A = \{H_1, \ldots, H_N\} \subseteq \mathbb{R}^n \) be its associated (possibly non-generic) hyperplane arrangement as in Definitions 2.12 and 3.16. Let \( \{H_{i_1}, \ldots, H_{i_n}\} \subseteq A \) be any rank \( n \) subarrangement of size \( n \). Then

\[
p = H_{i_1} \cap \ldots \cap H_{i_n}
\]

is a 0-cell (vertex) of the canonical polyhedral complex \( C(A) \). Conversely, every vertex \( p \) of \( C(A) \) can be realized as

\[
p = H_{i_1} \cap \ldots \cap H_{i_n}
\]

for some rank \( n \) subarrangement \( \{H_{i_1}, \ldots, H_{i_n}\} \subseteq A \).

**Proof.** Let \( \mathcal{A}' = \{H_{i_1}, \ldots, H_{i_n}\} \) be a rank \( n \), size \( n \) subarrangement of \( A \). From Lemma 2.11 it follows that \( \mathcal{A}' \) is a generic arrangement, and hence the \( n \)-fold intersection, \( H_{i_1} \cap \ldots \cap H_{i_n} \), is an affine subspace of \( \mathbb{R}^n \) of dimension 0. Indeed, since the \( (n-k) \)-dimensional affine subspaces of \( \mathbb{R}^n \) associated to \( k \)-fold intersections of \( k \)-element subsets of \( \mathcal{A}' \) are reverse-ordered by inclusion, we see that \( p = H_{i_1} \cap \ldots \cap H_{i_n} \) is the unique 0-cell in the boundary of all cells of the polyhedral complex \( C(\mathcal{A}') \). Since \( A \) is obtained from \( \mathcal{A}' \) by adding hyperplanes, \( C(A) \) is a polyhedral subdivision of \( C(\mathcal{A}') \), and so \( p \) is also a 0-cell (vertex) of \( C(A) \), as desired.

For the converse statement, we proceed by induction on \( n \). For the base case \( (n = 1) \), it follows directly from the definition of \( C(A) \) that every 0-cell
(vertex) is a hyperplane of \( A \). Now let \( n > 1 \) and suppose \( p \) is a 0–cell of \( C(A) \). We know that \( p \in K \) for some hyperplane \( K \in A \). Consider the restricted solution set arrangement

\[
S_K = \{ K \cap H \mid H \in A \setminus K \},
\]

from which we obtain a restricted hyperplane arrangement \( A_K \) by deleting the degenerate solution sets. Then \( p \) is also a 0–cell in the canonical polyhedral complex \( C(A_K) \). Since \( A_K \) is an \((n-1)\)–dimensional hyperplane arrangement, the inductive hypothesis tells us that there exist hyperplanes \( H_{i_1}, \ldots, H_{i_{n-1}} \in A \) such that \( p = (K \cap H_{i_1}) \cap \ldots \cap (K \cap H_{i_{n-1}}) \) in \( K \). Letting \( H_{i_n} = K \), it follows that

\[
p = H_{i_1} \cap \ldots \cap H_{i_n}.
\]

\( \{H_{i_1}, \ldots, H_{i_n}\} \) must therefore be rank \( n \), since otherwise its intersection would be an affine space of dimension \( > 0 \).

Corollary 9.6. Let \( A = \{ H_1, \ldots, H_N \} \subset \mathbb{R}^n \), \( \{(W_i | b_i)\}_{i=1}^N \) be as above. There is a canonical surjective map from the set of linearly-independent \( n \)–element subsets (subbases), \( \{W_{i_1}, \ldots, W_{i_n}\} \subseteq \{W_1, \ldots, W_N\} \), to the set of vertices of \( C(A) \).

Proof. Subbases of the set, \( \{W_1, \ldots, W_N\} \), of weight vectors are in canonical bijective correspondence with the set of rank \( n \), size \( n \) subarrangements of \( A \). By Lemma 9.5, there is a surjective map from the set of rank \( n \), size \( n \) subarrangements of \( A \) to the set of vertices of \( C(A) \), defined by taking the \( n \)–fold intersection of the hyperplanes in the subarrangement.

Lemma 9.7. Let \( A = \{ H_1, \ldots, H_N \} \subset \mathbb{R}^n \), \( \{(W_i | b_i)\}_{i=1}^N \) be as above, and let

\[
B_p = \{W_{i_1}, \ldots, W_{i_n}\} \quad \text{and} \quad B_q = \{W_{j_1}, \ldots, W_{j_n}\}
\]

be two subbases of \( \{W_1, \ldots, W_N\} \) with corresponding canonical vertices \( p \) and \( q \), respectively, as guaranteed by Corollary 9.6. If \( |B_p \cap B_q| = n - 1 \), then either \( p = q \) or \( p \cup q \) is the boundary of a 1–cell in \( C(A) \).

Proof. If

\[
B_p = \{W_{i_1}, \ldots, W_{i_n}\} \quad \text{and} \quad B_q = \{W_{j_1}, \ldots, W_{j_n}\}
\]

are as above, then (reordering \( j_1, \ldots, j_n \) if necessary) we may assume that

\[
i_k = j_k \quad \text{for} \quad k = 1, \ldots, n - 1 \quad \text{and} \quad i_n \neq j_n.
\]

Now (the proof of) Corollary 9.6 tells us that

\[
p = (H_{i_1} \cap \ldots \cap H_{i_{n-1}}) \cap H_{i_n} \quad \text{and} \quad q = (H_{i_1} \cap \ldots \cap H_{i_{n-1}}) \cap H_{j_n},
\]

which tells us that \( p \) and \( q \) are points on the same 1–dimensional affine space, \( (H_{i_1} \cap \ldots \cap H_{i_{n-1}}) \subseteq C(A) \). The conclusion follows.

Corollary 9.8. Let \( A = \{ H_1, \ldots, H_{n+1} \} \) be any (generic or non-generic) arrangement of hyperplanes in \( \mathbb{R}^n \). Every pair of 0–cells (vertices), \( p \neq q \), of \( C(A) \) is connected by some 1–cell (edge) of \( C(A) \). That is, all vertices are adjacent in the graph \( C(A)_1 \).

Proof. Every pair of \( n \)–element subsets of an \((n+1)\)–element set has a common \((n-1)\)–element subset. So if \( B_p, B_q \) are two subbases of \( \{W_1, \ldots, W_{n+1}\} \) and \( p \neq q \), then Lemma 9.7 tells us \( p \) and \( q \) are adjacent in \( C(A)_1 \).
We now consider a generic, ordered, co-oriented hyperplane arrangement $A = \{H_1, \ldots, H_n\}$ in $\mathbb{R}^n$. Note that $|A| = n$, so Lemma 9.3 applies.

Let $R_{\bar{1}} \subset \mathbb{R}^n$ denote the closure of the $\bar{1} = (1, \ldots, 1) \in \{0, 1\}^n$ region of $A$. Note that $R_{\bar{1}}$ is a polyhedral set of dimension $n$. The following lemma is immediate.

**Lemma 9.9.** Let $A = \{H_1, \ldots, H_n\}$ be a generic, ordered, co-oriented arrangement of $n$ hyperplanes in $\mathbb{R}^n$. Then the faces of $R_{\bar{1}}$ are in natural bijection with binary $n$–tuples. Explicitly, the map from $\{0, 1\}^n$ to the set of faces of $R_{\bar{1}}$ given by

$$\bar{\theta} \in \{0, 1\}^n \mapsto F_{\bar{\theta}} := \{\bar{v} \odot \bar{v} \mid \bar{v} \in R_{\bar{1}}\}$$

is a bijection.

**Remark 9.10.** In the above, $\bar{v} \odot \bar{v}$ denotes the Hadamard product (component-wise product) of $\bar{\theta}$ and $\bar{v}$. Accordingly, $F_{\bar{1}} = R_{\bar{1}}$, and $F_{\bar{0}} = \{(0, \ldots, 0)\}$. Moreover, $\dim(F_{\bar{\theta}}) = \sum_{i=1}^n \theta_i$.

Let $A^{st}$ be the standard ordered, co-oriented coordinate hyperplane arrangement in $\mathbb{R}^n$. That is, $A^{st} = \{H_i^{st}\}_{i=1}^n$, where

$$H_i^{st} := \{\bar{v} = (v_1, \ldots, v_n) \in \mathbb{R}^n \mid v_i = 0\},$$

do not-oriented in the direction of the non-negative half-space, $\{\bar{v} \in \mathbb{R}^n \mid v_i \geq 0\}$. We shall denote by $R_{\bar{1}}^{st}$ the closure of the $\bar{1}$ region of $A^{st}$, and by $F_{\bar{\theta}}^{st}$ its $\bar{\theta}$ face.

In other words, $R_{\bar{1}}^{st}$ (resp., $R_{\bar{0}}^{st}$) is the positive (resp., non-negative) orthant in $\mathbb{R}^n$.

**Lemma 9.11.** Let $A = \{H_1, \ldots, H_n\}$ be a generic, ordered, co-oriented arrangement of $n$ hyperplanes in $\mathbb{R}^n$ associated to a generic layer map $\sigma \circ A : \mathbb{R}^n \to \mathbb{R}^n$. Then $A$ maps the $A$ decomposition of $\mathbb{R}^n$ to the $A^{st}$ decomposition of $\mathbb{R}^n$, in the following sense:

- $A(H_i) = H_i^{st}$ for all $i = 1, \ldots, n$,
- $A(R_{\bar{\theta}}) = R_{\bar{\theta}}^{st}$ and $A(F_{\bar{\theta}}) = F_{\bar{\theta}}^{st}$ for all $\bar{\theta} \in \{0, 1\}^n$.

Moreover, $\sigma \circ A$ is the composition of the affine isomorphism $A$ realizing the above identification, followed by the projection

$$\bar{R}_{\bar{\theta}}^{st} \to F_{\bar{\theta}}^{st}$$

given by taking the Hadamard product with $\bar{\theta} \in \{0, 1\} \subseteq \mathbb{R}^n$.

**Proof.** Immediate from the definition of the ReLU function. $\square$

### 9.2. Regions of bent hyperplane arrangements and the $\nabla F$–oriented $1$–skeleton of the canonical polyhedral complex.

We can similarly endow the activation regions of a generic, transversal ReLU neural network with a binary labeling as follows. Recall that if

$$F : \mathbb{R}^{n_0} \xrightarrow{F_1} \mathbb{R}^{n_1} \xrightarrow{F_2} \cdots \xrightarrow{F_m} \mathbb{R}^{n_m} \xrightarrow{G} \mathbb{R}$$

is transversal and generic, Theorem 2 guarantees that the domain of the $(n_0 - 1)$–skeleton of $C(F)$ (resp., the $n_0$–cells) agrees with the bent hyperplane arrangement, $\mathcal{B}_F$, (resp., the closures of the activation regions of $\mathcal{B}_F$).
In this case, the image of every activation region of \( F \) (interior of an \( n_0 \)-cell of \( C(F) \)) is contained in a unique region of the co-oriented hyperplane arrangement in each layer:

**Definition 9.12.** Let

\[
F : \mathbb{R}^{n_0} \xrightarrow{F_1} \mathbb{R}^{n_1} \xrightarrow{F_2} \cdots \xrightarrow{F_m} \mathbb{R}^{n_m} \xrightarrow{G} \mathbb{R}
\]

be a transversal, generic ReLU neural network, and let \( A^{(i)} \) denote the co-oriented hyperplane arrangement associated to \( F_i \). The \((\vec{\theta}_1, \ldots, \vec{\theta}_m)\)-region of \( F \), denoted \( R_{(\vec{\theta}_1, \ldots, \vec{\theta}_m)} \), is the unique activation region of \( F \) satisfying the property that for each \( i \in \{1, \ldots, m\} \),

\[
F_{i-1} \circ \cdots \circ F_1 \left( R_{(\vec{\theta}_1, \ldots, \vec{\theta}_m)} \right) \subseteq R_{\vec{\theta}_i} \left( A^{(i)} \right).
\]

**Remark 9.13.** As with regions of classical hyperplane arrangements, the assignment of binary \((n_1, \ldots, n_m)\)-tuples to activation regions of a generic, transversal neural network is injective, but need not be surjective. If \( n_0 = n_1 = \ldots = n_m \), then the assignment is bijective, by Lemma 9.3.

**Lemma 9.14.** Let

\[
F : \mathbb{R}^{n_0} \xrightarrow{F_1} \mathbb{R}^{n_1} \xrightarrow{F_2} \mathbb{R}^{n_2} \xrightarrow{F_3} \cdots \xrightarrow{F_m} \mathbb{R}^{n_m} \xrightarrow{G} \mathbb{R}
\]

be a transversal, generic ReLU neural network with associated weight matrices \( W_1, \ldots, W_m, W_{m+1} \). Let \( R_{(\vec{\theta}_1, \ldots, \vec{\theta}_m)} \) be a region of \( B_F \) with associated sequence of binary tuples \( (\vec{\theta}_1, \ldots, \vec{\theta}_m) \), and let \( p \in \bar{R} \), where \( \bar{R} \) is the closure of \( R \). Then

\[
\frac{\partial F}{\partial x} \bigg|_{x=p} = W_{m+1} W_m \vec{\theta}_m \cdots W_1 \vec{\theta}_1,
\]

where we define \( W_k^{\vec{\theta}_k} \) to be the matrix obtained from \( W_k \) by replacing the \( i \)th row of \( W_k \) with 0’s when the \( i \)th entry of \( \vec{\theta}_k \) is 0.

**Proof.** Immediate from the definition of the affine linear function on \( R_{(\vec{\theta}_1, \ldots, \vec{\theta}_m)} \) and the chain rule for partial derivatives.

The 1-skeleton, \( C(F)_1 \), of the canonical polyhedral decomposition for a neural network \( F : \mathbb{R}^{n_0} \to \mathbb{R} \), is an embedded linear graph in \( \mathbb{R}^{n_0} \). This graph has a natural partial orientation, defined as follows.

**Definition 9.15.** Let \( F : \mathbb{R}^{n_0} \to \mathbb{R} \) be a neural network, denote by \( C(F)_1 \) the 1-skeleton of its canonical polyhedral complex, and let \( C \) be a 1-cell in \( C(F)_1 \).

- If \( F \) is nonconstant on \( C \), orient \( C \) in the direction in which \( F \) increases.
- If \( F \) is constant on \( C \), we will leave it unlabeled and refer to \( C \) as a flat edge.

We will refer to this (partial) orientation on \( C(F)_1 \) as the \( \text{grad}(F) \)-orientation or \( \nabla F \)-orientation.

**Remark 9.16.** Note that \( F \) is linear on \( C \) by Theorem [1].
For a transversal, generic ReLU neural network $F$,

$$F : \mathbb{R}^{n_0} \xrightarrow{F_1} \mathbb{R}^{n_1} \xrightarrow{F_2} \ldots \xrightarrow{F_m} \mathbb{R}^{n_m} \xrightarrow{G} \mathbb{R},$$

Lemma 9.17 provides a way to calculate the orientations on the 1–cells of $\mathcal{C}(F)_1$ combinatorially from the weight matrices of the neural network layers and the list of binary tuples in the regions adjacent to the 1–cells.

**Lemma 9.17.** Let

$$F : \mathbb{R}^{n_0} \rightarrow \ldots \rightarrow \mathbb{R}^{n_m} \rightarrow \mathbb{R}$$

be a transversal, generic ReLU neural network with associated weight matrices $W_1, \ldots, W_m, W_{m+1}$, and let $C$ be a 1–cell in $\mathcal{C}(F)_1$ with arbitrarily-chosen orientation. Let $v_C$ be the unit norm vector parallel to $C$ in the direction of the arbitrarily-chosen orientation. Let $\Theta(C)$ denote the set of binary tuples associated to regions $R$ for which $C$ is in $\partial R$, and let

$$\Theta(C ) = (\theta^1_1(C), \ldots, \theta^m_1(C)) := \bigoplus_{(\bar{\theta}_1, \ldots, \bar{\theta}_m) \in \Theta(C)} (\bar{\theta}_1, \ldots, \bar{\theta}_m)$$

be the Hadamard product of all of the binary tuple sequences in $\Theta(C)$. We recover the $\text{grad}(F)$–orientation on $C$ (Definition 9.15) by assigning to $C$:

- the orientation in the direction of $v_C$ if
  $$\left( W_{m+1} W_m^{\theta^2_m(C)} \ldots W_1^{\theta^1_1(C)} \right) \cdot v_C > 0,$$

- the orientation in the direction of $-v_C$ if
  $$\left( W_{m+1} W_m^{\theta^2_m(C)} \ldots W_1^{\theta^1_1(C)} \right) \cdot v_C < 0,$$

and

- no orientation if
  $$\left( W_m^{\theta^2_m(C)} \ldots W_1^{\theta^1_1(C)} \right) \cdot v_C = 0$$

**Proof.** Definition 9.15 tells us that if $F$ is nonconstant on $C$ then the orientation on $C$ is in the direction parallel to $C$ in which $F$ increases. Identify the tangent vectors along $C$ with $\pm v_C$, and the result follows from the fact that $F$ is linear on $C$ and agrees with the linear functions on all regions containing $C$ in their boundary. 

10. **Obstructions to Topological Expressiveness and Applications**

This section uses the framework developed in the previous sections to give an alternative perspective on the Hanin-Sellke, Johnson result that a width $n$ ReLU neural network $F : \mathbb{R}^n \rightarrow \mathbb{R}$ has decision regions that are either empty or unbounded. We also develop an architecture-based obstruction to the existence of multiple bounded connected components in a decision region.

Recall the statement of the Hanin-Sellke, Johnson result:
Theorem 5. \cite{11, 12} Let \( n \geq 2 \). Suppose
\[
F : \mathbb{R}^n \xrightarrow{F_1} \mathbb{R}^n \xrightarrow{F_2} \cdots \xrightarrow{F_m} \mathbb{R}^n \xrightarrow{G} \mathbb{R}
\]
is a width \( n \) ReLU neural network map and \( t \in \mathbb{R} \). Each of the sets
\[
N_F(t) := F^{-1}((\mathbb{R}^n, t)) \\
B_F(t) := F^{-1}(\{t\}) \\
Y_F(t) := F^{-1}((t, \mathbb{R}^n))
\]
is either empty or unbounded.

We will need some elementary facts about the image of a ReLU neural network in the width \( n \) case. We address the case of generic and non-generic layer maps separately.

Proposition 10.1. Let \( N = (F_m \circ \ldots \circ F_1) : \mathbb{R}^n \to \ldots \to \mathbb{R}^n \) be the composition of all but the final layer map of a generic (Definition 2.9) width \( n \) ReLU neural network in which every hidden layer has dimension \( n \). Then
\[
\text{Im}(N) \subseteq \overline{\mathbb{R}^n} \subseteq \mathbb{R}^n
\]
is the domain of a polyhedral complex, \( C \), with at most one cell of dimension \( n \). Explicitly,
\[
\text{Im}(N) = |C| = \mathcal{P} \cup \mathcal{Q},
\]
where \( \mathcal{P} \) is a (possibly empty) polyhedral set of dimension \( n \), and \( \mathcal{Q} \) is a union of polyhedral sets of dimension \( < n \). Moreover, if \( \mathcal{P} \) is nonempty, \( n \geq 2 \), and
\[
\mathcal{P} = H_1^+ \cap \ldots \cap H_m^+
\]
is an irredundant realization of \( \mathcal{P} \) as an intersection of closed half spaces, then the hyperplane arrangement \( \{H_1, \ldots, H_m\} \) has rank \( \geq 2 \).

Proof. We proceed by induction on the number, \( m \), of layers. If \( m = 1 \), \( \text{Im}(N) \) is \( \overline{\mathbb{R}^n} \), which is the domain of a polyhedral complex with a single \( n \)–cell, \( \mathcal{P} = \mathbb{R}_1^+ \) realizable as an irredundant intersection of \( n \) half-spaces. Moreover, if \( n \geq 2 \), the rank of the corresponding hyperplane arrangement, \( \{H_1^+, \ldots, H_m^+\} \) is \( \geq 2 \), as required.

Now consider \( m \geq 2 \) and suppose \( \mathcal{C}' \) is the polyhedral complex whose domain agrees with the image, \( \text{Im}(N') = \mathcal{P}' \cup \mathcal{Q}' \), of the first \( m − 1 \) layers of \( N \) as described. Let
\begin{itemize}
  \item \( \mathbf{A} \) be the ordered, co-oriented hyperplane arrangement associated to \( F_m \),
  \item \( \mathcal{C}(\mathbf{A}) \) be the associated polyhedral decomposition of the domain of \( F_m \) (Definition 3.16),
  \item and \( \mathcal{C}'_{\cap \mathcal{C}(\mathbf{A})} \) be the complex whose cells are pair-wise intersections of cells of \( \mathcal{C}' \) with cells of \( \mathcal{C}(\mathbf{A}) \).
\end{itemize}

By Lemma 9.11 \( F_m \) is linear on the cells of \( \mathcal{C}'_{\cap \mathcal{C}(\mathbf{A})} \). Indeed, it is immediate that we can alternatively characterize \( \mathcal{C}'_{\cap \mathcal{C}(\mathbf{A})} \) as the level set complex,
\(C_{\epsilon \in C(A^\text{st})} \) of \(F_m\) relative to the polyhedral decomposition associated to the standard hyperplane arrangement, \(A^\text{st}\), in the codomain.

Noting that the image of a polyhedral set under an affine linear map is a polyhedral set, we now define \(\mathcal{C}\) to be the complex whose cells are the images of cells of \(C_{\epsilon \in C(A^\text{st})}\) under \(F_m\).

It then follows immediately from Lemma \ref{lem:9.11} that all of the cells of \(\mathcal{C}\) have dimension < \(n\) except possibly \(F_m(\mathcal{P}' \cap \bar{R}_1(A))\). Further, since \(F_m\) is an affine isomorphism on \(\bar{R}_1(A)\), this cell will be \(n\)-dimensional if \(\mathcal{P}' \cap \bar{R}_1(A)\) is \(n\)-dimensional.

In this case, we claim that as long as \(n \geq 2\), an irredundant bounding hyperplane arrangement of the cell \(\mathcal{P}' \cap \bar{R}_1(A)\) will have rank \(\geq 2\), since both \(\mathcal{P}'\) and \(\bar{R}_1(A)\) have this property. To see this, note that the union of the bounding hyperplane arrangements for \(\mathcal{P}'\) and \(\bar{R}_1(A)\) yields a bounding hyperplane arrangement for \(\mathcal{P}' \cap \bar{R}_1(A)\), and it necessarily has rank \(\geq 2\).

If this union is irredundant, we are done. If not, we appeal to Farkas’ Lemma III, cf. \cite{23} Sec. 2], which says that any redundant inequality in a system of linear inequalities is a non-negative linear combination of the other linear inequalities in the system. This implies that the rank of any bounding hyperplane arrangement of a polyhedral set is equal to the rank of an irredundant bounding hyperplane arrangement.

Moreover, the image under \(F_m\) of an irredundant bounding hyperplane arrangement for \(\mathcal{P}' \cap \bar{R}_1(A)\) is also irredundant and has rank \(\geq 2\), since \(F_m\) is an affine isomorphism on \(\bar{R}_1(A)\). Defining \(\mathcal{P}\) to be

- \(F_m(\mathcal{P}' \in \bar{R}_1(A^\text{st}))\) if the polyhedral set \(\mathcal{P}' \in \bar{R}_1(A^\text{st})\) has dimension \(n\), and
- \(\emptyset\) otherwise,

and \(\mathcal{Q}\) to be the union of all other cells of \(\mathcal{C}\), the result follows.

\(\square\)

Lemma 10.2. Let

\(N = (F_m \circ \ldots \circ F_1) : \mathbb{R}^n \to \mathbb{R}^n \to \ldots \to \mathbb{R}^n\)

be the composition of all but the final layer map of a generic width \(n\) ReLU neural network in which every hidden layer has dimension \(n\), and let

\(\text{Im}(N) = |\mathcal{C}| = \mathcal{P} \cup \mathcal{Q}\)

as in Proposition \ref{prop:10.1}. If \(x \in |\mathcal{C}_{n-1}|\), then \(N^{-1}(\{x\})\) is unbounded.

Proof. We proceed again by induction on the number, \(m\), of layers. The result is clear when \(m = 1\), since in this case Lemma \ref{lem:9.11} tells us that \(\mathcal{Q} = \emptyset\) and \(\mathcal{P} = R^\text{st}_1\), and each point \(x \in |\mathcal{C}_{n-1}| = \partial \mathcal{P} = \partial (R^\text{st}_1)\) is in the image of the projection map \(R^\text{st}_\theta \to F^\text{st}_\theta\), hence has unbounded preimage.

Now suppose \(m > 1\) and the result holds for the image, \(|\mathcal{C}'| = \mathcal{P}' \cup \mathcal{Q}'\), of the first \(m - 1\) layers of \(N\). That is, each point in \(|\mathcal{C}'_{n-1}|\) has unbounded preimage.

Let \(x \in |\mathcal{C}_{n-1}| \subseteq \text{Im}(N)\). If \(x\) is in the image of \(|\mathcal{C}'_{n-1}|\), then it has unbounded preimage by the inductive hypothesis. So we may assume that \(x\) is in the image of \(\text{int}(\mathcal{P})\) and not in the image of \(\partial \mathcal{P}'\). But since \(x \in |\mathcal{C}_{n-1}|\),
Lemma 10.3 implies that $F^{-1}_m(\{x\}) \subseteq \mathcal{C}'$ is a ray contained in int($\mathcal{P}'$). Since int($\mathcal{P}'$) is the image of the interior of a polyhedral set in the domain under a composition of affine linear isomorphisms, the preimage of this ray is a ray in the domain, hence unbounded. The conclusion follows.

\[ \square \]

Lemma 10.3. Let $X$ be an affine hyperplane in $\mathbb{R}^n$, and let
\[ \mathcal{P} = H_1^+ \cap \ldots \cap H_m^+ \]
be an irredundant representation of a non-empty $n$-dimensional polyhedral set in $\mathbb{R}^n$ such that the hyperplane arrangement $\mathcal{A} = \{H_1, \ldots, H_m\}$ has rank $\geq 2$, and, for each $i$, let $F_i = \mathcal{P} \cap H_i$ be the facet in $\partial \mathcal{P}$ corresponding to the bounding hyperplane $H_i$. If $X \cap \mathcal{P} \neq \emptyset$, then $X \cap F_i \neq \emptyset$ for some $i$.

Proof. We proceed by induction on $m$, the base case being $m = 2$. Note also that the rank assumption implies that $n \geq 2$. In this case, if $X \cap \mathcal{P} \neq \emptyset$ and $X \cap F_1 = \emptyset$, then $X$ and $H_1$ must be parallel. But then the rank assumption implies that $X \cap F_2 \neq \emptyset$ as desired.

Now assume
\[ \mathcal{P} = H_1^+ \cap \ldots \cap H_m^+ \]
for $m > 2$ and $\mathcal{A} = \{H_1, \ldots, H_m\}$ has rank $\geq 2$. Reordering if necessary, we may assume $\{H_1, H_2\}$ has rank 2. If $X \cap F_m \neq \emptyset$, we’re done, so we may assume WLOG that $X \cap F_m = \emptyset$.

But then $\mathcal{P}' := \bigcap_{i=1}^{m-1} H_i^+$ is a necessarily irredundant representation of a polyhedral set with fewer facets, whose bounding hyperplane arrangement has rank $\geq 2$. So the inductive hypothesis tells us that there exists some $i \leq m - 1$ such that $X \cap F_i \neq \emptyset$, as desired.

\[ \square \]

Lemma 10.4. For any $n \in \mathbb{N}$, let
\[ N = (F_m \circ \ldots \circ F_1) : \mathbb{R}^n \to \cdots \to \mathbb{R}^n \]
be the composition of all but the final layer map of a non-generic width $n$ ReLU neural network. Then each point in $\text{Im}(N)$ has unbounded preimage.

Proof. Let $F_i$ be the first non-generic layer map in the composition $N = F_m \circ \ldots \circ F_1$. Since $F_i$ is non-generic, the affine map $A_i$ underlying $F_i$ is non-invertible, by Lemma 2.11. Indeed, the preimage of any point is an affine linear subspace of $\mathbb{R}^n$ of dimension $\geq 1$, hence unbounded. Recalling that $F_i = \sigma \circ A_i$ is a map that is linear on the cells of the canonical polyhedral decomposition $\mathcal{C}(F_{i-1} \circ \ldots \circ F_1)$ of $\mathbb{R}^n$, it follows immediately that the linear map on each cell is also non-invertible, hence the preimage of any point $p \in \text{Im}(F_i)$ is unbounded. Any point $q \in \text{Im}(N)$ is of the form $q = (F_m \circ \ldots \circ F_{i+1})(p)$ for some $p \in \text{Im}(F_i)$. So $N^{-1}(\{q\})$ is unbounded.

Recall that a threshold $t$ is transversal for a neural network $F$ (Definition 6.10) if it is transversal for $F$ with respect to its canonical polyhedral complex $\mathcal{C}(F)$.

Lemma 10.5. Let $t$ be a transversal threshold for a neural network $F : \mathbb{R}^n_0 \to \mathbb{R}$. Then
\[ B_F(t) = \partial N_F(t) = \partial Y_F(t). \]
Proof. In the case that \( B_F(t) = \emptyset \), either \( Y_F(t) = \mathbb{R}^{n_0} \) and \( N_F(t) = \emptyset \) or \( Y_F(t) = \emptyset \) and \( N_F(t) = \mathbb{R}^{n_0} \), so the statement holds.

Now suppose \( B_F(t) \neq \emptyset \). For each cell \( C \in \mathcal{C}(F) \) such that \( F^{-1}(\{t\}) \cap C \neq \emptyset \), Lemma 5.6 guarantees that \( \text{aff}(F^{-1}(\{t\}) \cap C) \) is a hyperplane that cuts \( C \). Denote by \( C^+ \) and \( C^- \) the intersections of \( C \) with the two open half-spaces that are the complement of this hyperplane. Since \( F \) is nonconstant on \( C \) (by Lemma 5.4), precisely one of \( C^+ \) and \( C^- \) must be contained in \( Y_F(t) \) and the other must be contained in \( N_F(t) \). Therefore \( B_F(t) \subseteq \partial Y_F(t) \) and \( B_F(t) \subseteq N_F(t) \). The reverse inclusions are obvious. \( \square \)

We are now ready for:

Proof of Theorem 2. Fix an integer \( n \geq 2 \) and let \( F : \mathbb{R}^n \to \mathbb{R} \) be a ReLU neural network whose hidden layers all have dimension \( \leq n \). We may then assume WLOG that every intermediate layer has dimension \( n \) (c.f. Remark 2.10). Decompose \( F \) as \( F = G \circ N \), where \( N : \mathbb{R}^n \to \mathbb{R}^n \) is the composition of all the layer maps except for the final one, and \( G : \mathbb{R}^n \to \mathbb{R} \) is the final layer map. If \( G \) is degenerate, it is immediate that the theorem holds. So assume that \( G \) is nondegenerate.

Step 1: We will prove that for every \( t \in \mathbb{R} \), the decision boundary \( B_F(t) \) is either empty or unbounded. Since \( G \) is nondegenerate, \( X_t := G^{-1}(\{t\}) \) is an affine hyperplane in the final hidden layer of \( F \). Note that

\[
B_F(t) = N^{-1}(G^{-1}(\{t\})) = N^{-1}(\text{Im}(N) \cap X_t).
\]

If \( \text{Im}(N) \cap X_t \) is empty, then \( B_F(t) \) is empty, as desired. So assume \( \text{Im}(N) \cap X_t \) is nonempty.

Case 1: We first consider the case that \( N \) is non-generic. If \( \text{Im}(N) \cap X_t \) is nonempty, then \( N^{-1}(\text{Im}(N) \cap X_t) \) is unbounded by Lemma 10.4 and if \( \text{Im}(N) \cap X_t \) is empty, then so is \( N^{-1}(\text{Im}(N) \cap X_t) \).

Case 2: Now consider the case that \( N \) is generic. By Proposition 10.1, \( \text{Im}(N) \) is the domain of a polyhedral complex \( \mathcal{C} \) that has a unique (possibly empty) \( n \)-cell \( \mathcal{P} \).

Subcase a: If \( X_t \cap \mathcal{P} = \emptyset \), then the assumption that \( \text{Im}(N) \cap X_t \neq \emptyset \) implies \( X_t \cap C_{n-1} \neq \emptyset \). Therefore \( B_F(t) \) is unbounded by Lemma 10.2.

Subcase b: If \( X_t \cap \mathcal{P} \neq \emptyset \), then \( \mathcal{P} \) is nonempty. Because \( n \geq 2 \), Proposition 10.1 guarantees that \( \mathcal{P} \) has rank \( \geq 2 \). Hence \( X_t \cap C_{n-1} \neq \emptyset \) by Lemma 10.3. Therefore \( B_F(t) \) is unbounded by Lemma 10.2.

Step 2: We will use the fact that \( B_F(t) \) is empty or unbounded to show \( N_F(t) \) and \( Y_F(t) \) are also.

Case 1: When \( t \in \mathbb{R} \) is a transversal threshold, it is now straightforward to see that the decision regions \( Y_F(t) \) and \( N_F(t) \) are also either empty or unbounded, since \( B_F(t) = \partial N_F(t) = \partial Y_F(t) \) by Lemma 10.5 and a bounded set cannot have unbounded closure.

Case 2: Suppose \( t \in \mathbb{R} \) is a non-transversal threshold. We will give an argument for \( Y_F(t) \); the argument for \( N_F(t) \) is analogous. Let \( X^+_t \) be the positive half-space associated to the co-oriented affine hyperplane \( X_t \). Then

\[
F^{-1}(t, \infty)) = N^{-1}(\text{Im}(N) \cap X^+_t).
\]

If this intersection is empty, then \( Y_F(t) \) is empty, as desired. If this intersection is nonempty, there are two subcases.
Subcase a: \( t < \max\{ t' \in \mathbb{R} : F^{-1}((t', \infty)) \neq \emptyset \} \). In this case, since \( F \) is continuous, there exists \( \epsilon > 0 \) such that \( (t, t+\epsilon) \subset \{ t' \in \mathbb{R} : F^{-1}((t', \infty)) \neq \emptyset \} \). Hence Lemma 5.7 implies there exists a transversal threshold \( t' > t \) for which \( F^{-1}\{ t' \} \) is non-empty. Noting that \( F^{-1}\{ t' \} = B_F(t') \), it follows from the first part of the proof that \( B_F(t') \) is unbounded. So \( Y_F(t) \supseteq B_F(t') \) must also be unbounded.

Subcase b: \( t = \max\{ t' \in \mathbb{R} : F^{-1}((t', \infty)) \neq \emptyset \} \). In this case \( Y_F(t) \) is empty, as desired.  

10.1. Obstructing multiple bounded connected components. As observed in [14], it is straightforward to construct, for every \( n \), a width \( n+1 \) neural network with a single hidden layer, \( \mathbb{R}^n \to \mathbb{R}^{n+1} \to \mathbb{R} \), that has a bounded decision region consisting of a single connected component. We prove that such a simple architecture cannot produce a decision region with more than one bounded connected component.

**Theorem 6.** Let \( F : \mathbb{R}^n \to \mathbb{R}^{n+1} \to \mathbb{R} \) be a ReLU neural network. Then a decision region \( Y_F(t) \) or \( N_F(t) \) associated to a transversal threshold \( t \) can have no more than one bounded connected component.

**Lemma 10.6.** Let \( P \subseteq \mathbb{R}^n \) be a polyhedral set, and let \( F : P \to \mathbb{R} \) be an affine linear map on \( P \). If \( F \) achieves a maximum (resp., minimum) on the interior of \( P \), then \( F \) achieves this maximum (resp., minimum) value on all of \( P \), and hence on all faces in its boundary.

**Proof.** This is a standard result in linear programming. The maximum (resp., minimum) value of an affine linear function on a polyhedral set is achieved when the dot product with a particular vector (the vector of weights of the affine linear function) is maximized (resp., minimized). But since \( P \) is a closed subset of a linear subspace of \( \mathbb{R}^n \), the maximum value of the dot product with a fixed vector is either attained on the boundary or on the entire set.  

**Corollary 10.7.** Let \( F : \mathbb{R}^{n_0} \to \mathbb{R} \) be a neural network, and \( C(F) \) be its canonical polyhedral complex. If \( P \) is a cell of \( C(F) \) with at least one vertex as a face, and \( F \) achieves a maximum (resp., minimum) on \( P \), then \( F \) achieves a maximum (resp., minimum) at a vertex of \( P \).

**Proof.** The function \( F \) is linear on \( P \) by Theorem 1. Under the given assumptions, every face of \( P \) will also be a polyhedral set with a vertex as a face. The result follows by strong induction on the dimension of \( P \), applying Lemma 10.6 in the inductive step.  

**Corollary 10.8.** Let \( F \) and \( C(F) \) be as above. If \( P \) is a bounded cell (polytope) of \( C(F) \) of any dimension, then \( F \) achieves a maximum (resp., minimum) at a vertex of \( P \).

\(^3\)Note that \( F \) needn’t be generic or transversal.
Proof. Every polytope $\mathcal{P} \subset \mathbb{R}^n$ (of any dimension) has at least one vertex. Moreover, it is bounded, hence compact, since cells are closed. The extreme value theorem then guarantees that $F$ achieves both a minimum and maximum value on $\mathcal{P}$. The result follows from Corollary 10.7.

Proposition 10.9. Let $t$ be a transversal threshold for a neural network $F : \mathbb{R}^{n_0} \to \mathbb{R}$, and let $S$ be a bounded connected component of $Y_F(t)$ (resp., $N_F(t)$). Then there exist non-empty bounded subgraphs $\mathcal{G}' \subseteq \mathcal{G} \subseteq \mathcal{C}(F)_1$ which, when endowed with the $\nabla F$-orientation (Definition 9.15), satisfy:

(i) $\mathcal{G}'$ is flat;
(ii) $\mathcal{G}' \subseteq \mathcal{G} \subseteq S$;
(iii) there is a non-empty collection, $\mathcal{E}$, of edges adjacent to $\mathcal{G}$, satisfying the property that every edge $e \in \mathcal{E}$ points towards $\mathcal{G}$ (resp., points away from $\mathcal{G}$) and has nonempty intersection with $\partial S$ and the other decision region, $N_F(t)$ (resp, $Y_F(t)$).

Remark 10.10. Note that for any graphs $G_1$ and $G_2$, the statement “$G_1$ is a subgraph of $G_2$” implies that the set of vertices (resp. edges) of $G_1$ is a subset of the set of vertices (resp. edges) of $G_2$. The vertices (resp. edges) of the graph $\mathcal{C}(F)_1$ are the 0-cells (resp. 1-cells) of $\mathcal{C}(F)$.

Remark 10.11. One can view the graph $\mathcal{G}'$ described in Proposition 10.9 as a PL analogue of a Morse critical point of index $n$ (resp., 0). Recall that if $f : M^n \to \mathbb{R}$ is a Morse function on a smooth $n$–dimensional manifold, any bounded connected component, $S$, of a superlevel set (resp., sublevel set) must contain a critical point of index $n$ (resp., of index 0) in its interior. Moreover, once the manifold has been endowed with a Riemannian metric, the gradient vector field, $\nabla f$, will be transverse to $\partial S$ (since it’s the preimage of a regular value) and will point into (resp., out of) $S$.

Proof. Let $\overline{S}$ denote the closure of $S$. Since $\overline{S}$ is closed and bounded, hence compact, the extreme value theorem tells us that $f$ attains its maximum (resp., minimum) value, $M \in \mathbb{R}$ (resp., $m \in \mathbb{R}$), on $\overline{S}$. I.e., there exists $x \in \overline{S}$ such that $f(x) = M$ and $f(y) \leq M$ for all $y \in \overline{S}$. But Lemma 10.6 implies that $f^{-1}(\{M\})$ contains a non-empty subgraph, $\mathcal{G}'$, of $\mathcal{C}(F)_1$, since a maximum value, if attained on the interior of a cell, is attained on the whole cell, including its boundary.

Moreover, $\mathcal{G}' \subset S$, for if $\mathcal{G}' \cap (\partial S \subseteq F^{-1}(t)) \neq \emptyset$ then $t = M$, which would imply that $t$ is not a transversal threshold since its preimage contains a vertex which by definition cannot have a nonconstant cellular neighborhood.

Let $\mathcal{G}$ be the maximal subgraph of $\mathcal{C}(F)_1 \cap S$ that both contains $\mathcal{G}'$ and is entirely contained in $S$. Properties (i) and (ii) are immediate by construction. To see Property (iii), note that that $\mathcal{C}(F)_1$ is connected and unbounded, so it follows that $\mathcal{C}(F)_1 \cap \partial S \neq \emptyset$. Since $t$ is a transversal threshold, all points in $\partial \overline{S}$ have nonconstant cellular neighborhood, hence all edges of $\mathcal{C}(F)_1$ intersecting $\partial S$ are oriented, and the orientations are toward (resp., away from) $\mathcal{G}$ if $S \subseteq Y_F(t)$ (resp., $S \subseteq N_F(t)$). 

□
Proof of Theorem \[6\]. We open by noting that since $F$ has a single hidden layer, its canonical polyhedral complex, $C(F)$, is simply the canonical polyhedral complex, $C(A)$, of the hyperplane arrangement, $A$, in $\mathbb{R}^n$ associated to the first layer map. We may assume without loss of generality that $|A| = n + 1$, for if the first layer map is degenerate then the neural network has width $n$, and hence its decision regions have no bounded connected components, by Theorem \[5\].

Now let $t \in \mathbb{R}$ be a transversal threshold for a (not necessarily generic, not necessarily transversal) ReLU network, $F : \mathbb{R}^n \to \mathbb{R}^{n+1} \to \mathbb{R}$. We will show that $Y_F(t)$ has no more than one bounded connected component. The argument for $N_F(t)$ is analogous.

Assume, aiming for a contradiction, that $Y_F(t)$ has more than one bounded connected component. Choose two of these, and call them $S_1$ and $S_2$. As described in Proposition \[10.9\] there exist non-empty bounded subgraphs $G_i \subset S_i \ (i = 1, 2)$ of the 1–skeleton of $C(A) = C(F)$ and associated non-empty collections, $\mathcal{E}_i$, of edges adjacent to $G_i$, equipped with $\nabla F$–orientation pointing towards $G_i$. For each $S_i$, choose an external vertex $p_i \subset G_i$. That is, choose a vertex $p_i \subset G_i$ in the boundary of an edge $e$ of $\mathcal{E}_i$.

Now Corollary \[9.8\] tells us that $p_1$ and $p_2$ are connected by an edge (1–cell), $e$, of $C(A)$. It follows that $e$ is in both $\mathcal{E}_1$ and $\mathcal{E}_2$. But this is impossible, since it would require $e$ to be oriented in two different directions at once. We conclude that one of $\mathcal{E}_1$ or $\mathcal{E}_2$ must be empty, hence Proposition \[10.9\] tells us that one of $S_1, S_2$ must be empty. The result follows.

\[\square\]
