Universal integral quadratic forms over dyadic local fields

Constantin-Nicolae Beli

Abstract

We give necessary and sufficient conditions for an integral quadratic form over a dyadic local field to be universal.

1 Introduction

Let $F$ be a local non-archimedean field of characteristic zero. Let $\mathcal{O}$ be the ring of integers and let $\mathfrak{p}$ be the prime ideal of $F$. The group of units of $\mathcal{O}$ is $\mathcal{O}^\times = \mathcal{O} \setminus \mathfrak{p}$. We have $\mathfrak{p} = \pi \mathcal{O}$, where $\pi$ is a prime element of $\mathcal{O}$. If $\mathfrak{a}$ is an ideal of $F$ then we define its order $\text{ord} \mathfrak{a} \in \mathbb{Z} \cup \{\infty\}$ by $\text{ord} \mathfrak{a} = R$ if $\mathfrak{a} = \mathfrak{p}^R$ for some $R \in \mathbb{Z}$ and $\text{ord} \mathfrak{a} = \infty$ if $\mathfrak{a} = 0$. If $a \in F$ we denote by $\text{ord} a = \text{ord} a \mathcal{O}$, i.e. $\text{ord} a$ is the value of $a$. We have $\text{ord} a = R$ if $a = \pi^R \varepsilon$ with $\varepsilon \in \mathcal{O}^\times$ and $\text{ord} a = \infty$ if $a = 0$.

We denote by $(\cdot, \cdot)_p : \hat{F}/\hat{F}^2 \times \hat{F}/\hat{F}^2 \to \{\pm 1\}$ the Hilbert symbol.

All quadratic spaces and lattices in this paper will be assumed to be non-degenerate.

If $V$ is a quadratic space and $x_1, \ldots, x_n$ is an orthogonal basis with $Q(x_i) = a_i$, then we say that $V \cong [a_1, \ldots, a_n]$ relative to the orthogonal basis $x_1, \ldots, x_n$. For the quadratic lattice $L = \mathcal{O} x_1 \perp \cdots \perp \mathcal{O} x_n$ we write $L \cong \langle a_1, \ldots, a_n \rangle$.

Recall that if $b \in \hat{F}$ then $b$ is represented by $[a_1, a_2]$ iff $(a_1 b, -a_1 a_2)_p = 1$ and it is represented by $[a_1, a_2, a_3]$ iff $b \notin -a_1 a_2 a_3 \hat{F}^2$ or $[a_1, a_2, a_3]$ is isotropic. We also have that $[a_1, a_2, a_3]$ is isotropic iff $-a_1$ is represented by $[a_2, a_3]$, which is equivalent to $(-a_1 a_2, -a_2 a_3)_p = 1$.

If $V, W$ are two quadratic spaces, we denote by $W \rightarrow V$ the fact that $V$ represents $W$. Similarly for lattices.

If $L$ is a quadratic lattice, with $FL = V$, and $Q : V \rightarrow F$ is the corresponding quadratic form, then we say that $L$ is integral if $Q(L) \subseteq \mathcal{O}$ and we say that it is universal if $Q(L) = \mathcal{O}$. In [XZ] the authors gave necessary and sufficient conditions for a quadratic lattice to be universal in the case when $F$ is non-dyadic. In the more complicated dyadic case they solved the same problem, but only for binary and ternary lattices.

In this paper we completely solve this problem for dyadic quadratic lattices in arbitrary dimensions. Unlike in [XZ], where the quadratic lattices are described in terms of Jordan compositions, here we use BONGs (bases of norm generators), which we introduced in [B1]. Since the BONGs are not widely known and used, we now give a brief review. A summary of the results from [B1] we use here can be found in [B3, §1].

From now on $F$ is a dyadic field, i.e. a finite extensions of $\mathbb{Q}_2$. We denote by $e$ the ramification index of the extension $F/\mathbb{Q}_2$, i.e. $e = \text{ord} 2$. 

1
1.1 The map \( d : \hat{F}/\hat{F}^2 \to \{0, 1, 3, 5, \ldots, 2e - 1, 2e, \infty\} \)

The quadratic defect, introduced in [OM, §6A], of an element \( \varepsilon \in F \) is the ideal \( \mathfrak{d}(a) = \cap_{x \in F}(a - x^2)\mathcal{O} \). We denote by \( \Delta = 1 - 4p \) a fixed element with \( \mathfrak{d}(\Delta) = 4\mathcal{O} \).

In [B1, §1] we introduced the order of the relative quadratic defect \( d : \hat{F}/\hat{F}^2 \to \mathbb{Z} \cup \{\infty\} \), \( d(a) = \text{ord} \ a^{-1}\mathfrak{d}(a) \). Let \( a = \pi^k \varepsilon \), with \( \varepsilon \in \mathcal{O}^\times \). If \( R \) is even \( d(a) = d(\varepsilon) = \text{ord} \mathfrak{d}(\varepsilon) \in \{1, 3, 5, \ldots, 2e - 1, 2e, \infty\} \). If \( R \) is odd then \( d(a) = 0 \).

We have \( d(a) = 0 \) iff \( \text{ord} \ a \) is odd, \( d(a) \geq 1 \) iff \( \text{ord} \ a \) is even, \( d(a) = 2e \) iff \( a \in \Delta \hat{F}^2 \) and \( d(a) = \infty \) iff \( a \in \hat{F}^2 \).

The map \( d \) has the following properties:

1. \( d(ab) \geq \min\{d(a), d(b)\} \) \( \forall a, b \in \hat{F} \).
2. If \( d(a) + d(b) > 2e \) then \( (a, b)_p = 1 \).
3. If \( a \in \hat{F} \setminus F^2 \) then there is \( b \in F \) with \( d(b) = 2e - d(a) \) such that \( (a, b)_p = -1 \). Moreover, if \( d(a) < 2e \) then we can choose \( b \in \mathcal{O}^\times \).

(For the last statement note that if \( d(a) < 2e \) then \( d(b) = 2e - d(a) > 0 \) so \( b \in \mathcal{O}^\times \hat{F}^2 \). Since both \( d(b) \) and \( (a, b)_p \) depend only on \( b \) modulo \( \hat{F}^2 \), we may assume that \( b \in \mathcal{O}^\times \).)

1.2 BONGs and good BONGs

Let \( V \) be a quadratic space over \( F \), with the quadratic form \( Q : V \to F \) and the corresponding bilinear symmetric form \( B : V \times V \to F, B(x, y) = \frac{1}{2}(Q(x + y) - Q(x) - Q(y)) \).

Let now \( L \) be a lattice over \( V \). The norm \( nL \) of \( L \) is the fractionary ideal generated by \( Q(L) \) and the scale \( sL \) of \( L \) is the fractionary ideal \( B(L, L) \).

**Bases of norm generators (BONGs)**

The bases of norm generators (BONGs), introduced in [B1, §2], were defined recursively as follows. A norm generator of \( L \) is and element \( x \in L \) such that \( Q(x)\mathcal{O} = nL \). A basis of norm generator (BONG) of \( L \) is an orthogonal basis \( x_1, \ldots, x_n \) of \( V = FL \) such that \( x_1 \) is a norm generator for \( L \) and \( x_2, \ldots, x_n \) are a BONG for \( pr_{x_1}L \). (Here \( pr_{x_1} : V \to x_1^\perp \) is the projection on the orthogonal complement \( x_1^\perp \) of \( x_1 \).)

A BONG uniquely determines a lattice. We write \( L = \prec x_1, \ldots, x_n \succ \) to denote the fact that \( x_1, \ldots, x_n \) is a BONG for \( L \) and we say that \( L \cong \prec a_1, \ldots, a_n \succ \) relative to the BONG \( x_1, \ldots, x_n \) if \( Q(x_i) = a_i \).

**The binary case**

If \( n = 2 \) then an orthogonal basis \( x_1, x_2 \) of \( V \) with \( Q(x_i) = a_i \) is the BONG of a lattice iff \( a_2/a_1 \in A \), where \( A \subset \hat{F}/\mathcal{O}^2 \), \( A = \{a \in \hat{F} : a \in 1/4\mathcal{O}, \ v(-a) \subseteq \mathcal{O}\} \).

If \( a \in \hat{F} \) with \( \text{ord} a = R \), then \( a \in A \) iff \( R + d(-a) \geq 0 \) and \( R \geq -2e \). Hence if \( \text{ord} a_i = R_i \) then \( a_2/a_1 \in A \) iff \( R_2 - R_1 \geq -2e \) and \( R_2 - R_1 + d(-a_1a_2) \geq 0 \). (See [B1, Lemmas 3.5 and 3.6].)

If \( R_2 > R_1 \) then we have the Jordan splitting \( L = \mathcal{O}x_1 \perp \mathcal{O}x_2 \) and the scales of the Jordan components are \( n\mathcal{O}x_1 = p^{R_1} \) and \( n\mathcal{O}x_2 = p^{R_2} \).

If \( R_2 \leq R_1 \) then \( L = \mathcal{O}^{R_1+R_2}/2 \)-modular with \( nL = p^{R_1} \). In particular, if \( R_2 - R_1 = -2e \), then \( sL = p^{(R_1+R_2)/2} = p^{R_1+e} = 1/2p^{R_1} = 1/2\mathcal{O}L. \) Hence \( L \cong 1/2p^{R_1}A(0, 0) \) or \( 1/2p^{R_1}A(2, 2\rho) \).

If \( a \in A \), with \( \text{ord} a = R \), then \( g(a) \leq \mathcal{O}^\times/\mathcal{O}^\times \) is defined by \( g(a) = \mathcal{O}^\times \) if \( R = -2e \),
\[ g(a) = \mathcal{O} \times 2 \text{ if } R > 2e \text{ and } g(a) = \begin{cases} (1 + p^{R/2 + e}) \mathcal{O} \times 2 & d(-a) > e - R/2 \\ (1 + p^{R + d(-a)}) \mathcal{O} \times 2 \cap N(-a) & d(-a) \leq e - R/2 \end{cases} \]

if \(-2e < R \leq 2e\).

Then if \(L \cong \langle a_1, a_2 \rangle \) and \(\eta \in \mathcal{O} \times \), we have \(L \cong L^0\), i.e. \(\langle a_1, a_2 \rangle \cong \langle \eta a_1, \eta a_2 \rangle\), iff \(\eta \in g(a_2/a_1)\). (See [B1, Lemma 3.11].)

**Good BONGs**

A BONG \(x_1, \ldots, x_n\) of \(L\) is called good if ord \(Q(x_i) \leq\) ord \(Q(x_{i+2})\) for \(1 \leq i \leq n - 2\).

If \(x_1, \ldots, x_n\) is an orthogonal basis of \(V\), with \(Q(x_i) = a_i\) and ord \(a_i = R_i\) then \(x_1, \ldots, x_n\) is the good BONG of a lattice \(L\) with \(FL = V\) iff \(R_i \leq R_{i+2}\) for \(1 \leq i \leq n - 2\) and \(a_{i+1}/a_i \in A\) for \(1 \leq i \leq n - 1\). The second condition writes as \(R_{i+1} - R_i \geq -2e\) and \(R_{i+1} - R_i + d(-a_i a_{i+1}) \geq 0\). (See [B1, Lemma 4.3(ii)].)

In particular, if \(R_{i+1} - R_i\) is odd then ord \(a_i a_{i+1} = R_i + R_{i+1}\) is odd so \(R_{i+1} - R_i = R_{i+1} - R_i + d(-a_i a_{i+1}) \geq 0\). Thus \(R_{i+1} - R_i\) cannot be odd and negative.

If \(R_{i+1} - R_i = -2e\) then \(R_{i+1} - R_i + d(-a_i a_{i+1}) \geq 0\) implies \(d(-a_i a_{i+1}) \geq 2e\) so \(-a_1 a_2 \in \hat{F}^2\) or \(\Delta \hat{F}^2\), corresponding to \(d(-a_1 a_2) = \infty\) or \(2e\), accordingly.

Every quadratic lattice has a good BONG. Good BONGs can be obtained with the help of the so-called maximal norm splittings. (See [B1, Lemmas 4.3(iii) and 4.6] and [B3, §7].)

**Similarities with orthogonal bases**

Unlike in the non-dyadic case, in the dyadic case lattices usually don’t have orthogonal bases. The BONGs, especially the good BONGs, are a good substitute, as the they preserve many of the properties of the orthogonal bases.

Suppose that \(x_1, \ldots, x_n\) are an orthogonal basis of a quadratic space, with \(Q(x_i) = a_i\) and ord \(a_i = R_i\).

If \(x_1, \ldots, x_n\) is a good BONG for \(L\) then \(L \cong \langle x_1, \ldots, x_k \rangle \cong \langle x_{k+1}, \ldots, x_n \rangle\) holds iff \(R_k \leq R_{k+1}\). Equivalently, \(\langle a_1, \ldots, a_n \rangle \cong \langle a_1, \ldots, a_k \rangle \cong \langle a_{k+1}, \ldots, a_n \rangle\) if \(R_k \leq R_{k+1}\).

Conversely, if \(x_1, \ldots, x_k\) and \(x_{k+1}, \ldots, x_n\) are good BONGs for the lattices \(L'\) and \(L''\) then \(x_1, \ldots, x_n\) is a good BONG for \(L' \perp L''\) iff \(R_k \leq R_{k+1}\), \(R_{k-1} \leq R_{k+1}\) and \(R_k \leq R_{k+2}\). (If \(k = 1\) we ignore \(R_{k-1} \leq R_{k+1}\); if \(k = n - 1\) we ignore \(R_k \leq R_{k+2}\).)

If \(x_1, \ldots, x_n\) is a good BONG and for some \(1 \leq k \leq l \leq n\), \(x_k, \ldots, y_l\) is another good BONG for \(\langle y_k, \ldots, y_l \rangle\), then \(x_1, \ldots, x_{k-1}, y_k, \ldots, y_l, x_{l+1} \ldots, x_n\) is a good BONG for \(L\). Consequently, if \(L \cong \langle a_1, \ldots, a_n \rangle\) and \(\langle a_k, \ldots, a_l \rangle \cong \langle b_k, \ldots, b_l \rangle\) relative to good BONGs, then \(L \cong \langle a_1, \ldots, a_{k-1}, b_k, \ldots, b_l, a_{l+1} \ldots, a_n \rangle\) relative to a good BONG.

In particular, if \(\eta \in g(a_{k+1}/a_k)\) then \(\langle a_k, a_{k+1} \rangle \cong \langle \eta a_k, \eta a_{k+1} \rangle\) so \(\langle a_1, \ldots, a_n \rangle \cong \langle a_1, \ldots, a_{k-1}, \eta a_k, \eta a_{k+1}, a_{k+2} \ldots a_n \rangle\).

If \(L \cong \langle a_1, \ldots, a_n \rangle\) relative to the good BONG \(x_1, \ldots, x_n\), then \(L^2 \cong \langle a_1^{-1}, \ldots, a_n^{-1} \rangle\) relative to the good BONG \(x_1^2, \ldots, x_n^2\), where \(x^2 := Q(x)^{-1} x\) for every \(x \in V\) with \(Q(x) \neq 0\).

(See [B1, Lemmas 4.8 and 4.9, Corollary 4.4].)

**1.3 The invariants \(R_i(L)\) and \(\alpha_i(L)\) and the clasification theorem**

Suppose now that \(L \cong \langle a_1, \ldots, a_n \rangle\) relative to some good BONG and let \(R_i = \text{ord } a_i\). In [B3, §2] we defined, for every \(1 \leq i \leq n - 1\), the number \(\alpha_i\) as the minimum of the set.
The numbers \( R_i \), with \( 1 \leq i \leq n \), and \( \alpha_i \), with \( 1 \leq i \leq n-1 \), are invariants of the lattice \( L \), so we denote them by \( R_i(L) \) and \( \alpha_i(L) \). If \( L \) has a Jordan decomposition \( L = L_1 \perp \cdots \perp L_t \), then the numbers \( R_i = R_i(L) \) are in one-to-one correspondence with \( t \), rank \( L_i \), \( sL_i \) and \( nL_i^{gL_i} \) with \( 1 \leq i \leq t \). In particular, \( nL = p_i^{d_i} \) and \( sL = p_i^{\min\{R_i/(R_i + R_2)/2\}} \). The numbers \( \alpha_i = \alpha_i(L) \) are in one-to-one correspondence with the invariants \( \mathbf{w}_i = \mathbf{w}_i^{sL_i} \), with \( 1 \leq i \leq t \), and \( f_i \), with \( 1 \leq i \leq t-1 \), of \( L \). (See \[B1, Lemma 4.7\] and \[B3, Lemmas 2.13(i), 2.15 and 2.16\].)

Here are some properties of the invariants \( \alpha_i \), which appear in \[B3, Lemmas 2.2 and 2.7, Corollaries 2.8 and 2.9, Remark 2.6\].

1. The sequence \( R_i + \alpha_i \) is increasing and the sequence \(-R_{i+1} + \alpha_i \) is decreasing.
2. \( \alpha_i \geq 0 \), with equality iff \( R_{i+1} - R_i = -2e \).
3. If \( R_{i+1} - R_i \leq 2e \) then \( \alpha_i \geq R_{i+1} - R_i \) with equality iff \( R_{i+1} - R_i = 2e \) or it is odd.
4. If \( R_{i+1} - R_i \in \{-2e, 2e - 2\} \) or \( R_{i+1} - R_i \geq 2e \) then \( \alpha_i = (R_{i+1} - R_i)/2 + e \).
5. \( \alpha_i \) is an odd integer unless \( \alpha_i = (R_{i+1} - R_i)/2 + e \).
6. \( \alpha_i \) is an integer unless \( R_{i+1} - R_i \) is odd and \( > 2e \).
7. \( \alpha_i \) is invariant to scaling.
8. \( \alpha_i \in ([0, 2e] \cap \mathbb{Z}) \cup ((2e, \infty) \cap \frac{1}{2}\mathbb{Z}) \).
9. \( \alpha_i = \min\{(R_{i+1} - R_i)/2 + e, R_{i+1} - R_i + d(-a_i a_{i+1}), R_{i+1} - R_i + \alpha_{i-1}, R_{i+1} - R_i + \alpha_{i+1}\} \).

(If \( i = 1 \) we ignore \( R_{i+1} - R_i + \alpha_{i-1} \), as \( \alpha_0 \) is not defined. If \( i = n-1 \) then we ignore \( R_{i+1} - R_i + \alpha_{i+1} \), as \( \alpha_n \) is not defined.)

10. \( \alpha_i \) are invariant to scaling.
11. \( R_i(L^2) = -R_{n+1-i} \) and \( \alpha_i(L^2) = \alpha_{n-i}(L) \).

We now state O’Meara’s classification theorem \[OM, Theorem 93:28\] in terms of BONGs. This result is \[B3, Theorem 3.1\].

**Theorem 1.1.** Let \( L, K \) be two quadratic lattice with \( FL \cong FK \) and let \( L \cong \alpha a_1, \ldots, a_n \) and \( K \cong \alpha b_1, \ldots, b_n \) relative to good BONGs. Let \( R_i = R_i(L) \), \( S_i = R_i(K) \), \( \alpha_i = \alpha_i(L) \) and \( \beta_i = \alpha_i(K) \). Then \( L \cong K \) if:

\( i \) \( R_i = S_i \) for \( 1 \leq i \leq n \).

\( ii \) \( \alpha_i = \beta_i \) for \( 1 \leq i \leq n - 1 \).

\( iii \) \( d(a_1 \cdots a_i b_1 \cdots b_i) \geq \alpha_i \) for \( 1 \leq i \leq n - 1 \).

\( iv \) \([b_1, \ldots, b_{i-1}] \rightarrow [a_1, \ldots, a_i] \) for every \( 1 < i \leq n \) such that \( \alpha_{i-1} + \alpha_i > 2e \).

### 1.4 The invariants \( d[\varepsilon a_{i,j}] \) and \( d[\varepsilon a_{1,i}b_{1,j}] \)

For convenience, if \( a_1, a_2, \ldots \in \hat{F} \) and \( 1 \leq i \leq j + 1 \) then we denote by \( a_{i,j} = a_i \cdots a_j \). By convention, \( a_{i,i-1} = 1 \).

If \( L \cong \alpha a_1, \ldots, a_n \) relative to a good BONG and \( \alpha_i = \alpha_i(L) \), then for every \( 0 \leq i - 1 \leq j \leq n \) and \( \varepsilon \in \hat{F} \), then we define

\[
d[a_{i,j}] = \min\{d(a_{i,j}), \alpha_{i-1}, \alpha_j\}.
\]
If $i - 1 \in \{0, n\}$ $\alpha_{i-1}$ is not defined so it is ignored. Similarly $\alpha_j$ is ignored if $j \in \{0, n\}$.

In particular, since $d[-a_{i,i+1}] = \min \{d(-a_{i,i+1}), \alpha_{i-1}, \alpha_{i+1}\}$, the property (9) of §1.3 can be written as

$$\alpha_i = \min \{(R_{i+1} - R_i)/2 + e, R_{i+1} - R_i + d[-a_{i,i+1}]\}.$$

If $M \cong \prec a_1, \ldots, a_m \succ$ and $N \cong \prec b_1, \ldots, b_n \succ$ relative to good BONGs, $\alpha_i = \alpha_i(M)$ and $\beta_i = \alpha_i(N)$, then for every $0 \leq i \leq m$, $0 \leq j \leq m$, we define

$$d[\varepsilon a_{1,j}b_{1,j}] = \min \{d(\varepsilon a_{1,j}b_{1,j}), \alpha_i, \beta_j\}.$$

(If $i \in \{0, m\}$ then we ignore $\alpha_i$. If $j \in \{0, n\}$ then we ignore $\beta_j$.)

As a consequence of condition (iii) of Theorem ..., $d[\varepsilon a_{i,j}]$ and $d[\varepsilon a_{1,j}b_{1,j}]$ are independent of the choice of the good BONGs. Also $d[\varepsilon a_{i,j}]$ are a particular case of the expression $d[\varepsilon a_{1,j}b_{1,j}]$. Indeed, if we take $M = N = L$, so that $b_i = a_i$ and $\beta_i = \alpha_i$ then in $\hat{F}/\hat{F}^2$ we have $a_{1,j}b_{1,i-1} = a_{1,j}a_{1,i-1} = a_{1,j}$ so $d(\varepsilon a_{1,j}b_{1,i-1}) = d(\varepsilon a_{1,j})$. Therefore

$$d[\varepsilon a_{1,j}b_{1,i-1}] = \min \{d(\varepsilon a_{1,j}b_{1,i-1}), \alpha_j, \beta_{i-1}\} = \min \{d(\varepsilon a_{1,j}), \alpha_j, \alpha_{i-1}\} = d(\varepsilon a_{1,j}).$$

The invariants $d[\cdot]$ satisfy a similar domination principle as $d(\cdot)$. Namely, if we have a third lattice $K \cong \prec c_1, \ldots, c_k \succ$ and $\varepsilon', \varepsilon'' \in \hat{F}$ then in $\hat{F}/\hat{F}^2$ we have $(\varepsilon a_{1,j}b_{1,j})((\varepsilon' b_{1,j}c_{1,k}) = \varepsilon' a_{1,j}c_{1,k}$ and so $d(\varepsilon' a_{1,j}c_{1,k}) \geq \min \{d(\varepsilon a_{1,j}b_{1,j}), d(\varepsilon' b_{1,j}c_{1,k})\}$. Similarly, we have

$$d[\varepsilon' a_{1,j}c_{1,k}] \geq \min \{d[\varepsilon a_{1,j}b_{1,j}], d[\varepsilon' b_{1,j}c_{1,k}]\}.$$

Note that both $d$ and $\alpha_i$ take nonnegative values so $d[\varepsilon a_{1,j}b_{1,j}]$ is always nonnegative. If $\text{ord } \varepsilon a_{1,j}b_{1,j}$ is odd then $d(\text{ord } \varepsilon a_{1,j}b_{1,j}) = 0$ and so $d[\text{ord } \varepsilon a_{1,j}b_{1,j}] = 0$.

### 1.5 The representation theorem

We now state the representation theorem, which was announced in [B2, Theorem 4.5].

Let $M, N$ be quadratic lattices, with $M \cong \prec a_1, \ldots, a_m \succ$ and $N \cong \prec b_1, \ldots, b_n \succ$ relative to good BONGs and $m \geq n$. Let $R_i = R_i(M)$, $S_i = R_i(N)$, $\alpha_i = \alpha_i(M)$ and $\beta_i = \alpha_i(N)$. If $1 \leq i \leq \min \{m - 1, n\}$, then we define $A_i = A_i(M, N)$ as

$$A_i = \min \{(R_{i+1} - S_i)/2 + e, R_{i+1} - S_i + d[-a_{1,i+1}b_{1,i-1}], R_{i+1} + R_{i+2} - S_{i-1} - S_i + d[a_{1,i+2}b_{1,i-2}]\}.$$

(If $i = 1$ or $m - 1$, then the term $R_{i+1} + R_{i+2} - S_{i-1} - S_i + d[a_{1,i+2}b_{1,i-2}]$ is not defined so it is ignored.)

If $n \leq m - 2$ we assume that $S_{n+1} \gg 0$. Then, formally, we have

$$S_{n+1} + A_{n+1} = \min \{(R_{n+2} + S_{n+1})/2 + e, R_{n+2} + d[-a_{1,n+2}b_{1,n}], R_{n+2} + R_{n+3} - S_n + d[a_{1,n+3}b_{1,n-1}]\}.$$

Since $(R_{n+2} + S_{n+1})/2 + e \to \infty$ as $S_{n+1} \to \infty$, we can ignore it in the above formula and we define

$$S_{n+1} + A_{n+1} = \min \{R_{n+2} + d[-a_{1,n+2}b_{1,n}], R_{n+2} + R_{n+3} - S_n + d[a_{1,n+3}b_{1,n-1}]\}.$$

(If $n = m - 2$ then $R_{n+2} + R_{n+3} - S_n + d[a_{1,n+3}b_{1,n-1}]$ is not defined, so we ignore it.)
Theorem 1.2. Assume that \( FM \rightarrow FN \). Then \( M \rightarrow N \) iff:

(i) For \( 1 \leq i \leq n \) we have \( R_i \leq S_i \) or \( 1 < i < m \) and \( R_i + R_{i+1} \leq S_{i-1} + S_i \).

(ii) For \( 1 \leq i \leq \min\{m-1, n\} \) we have \( d[a_1, b_{i-1}] \geq A_i \).

(iii) For any \( 1 < i \leq \min\{m-1, n+1\} \) such that \( R_{i+1} > S_{i-1} \) and \( A_{i-1} + A_i > 2e + R_i - S_i \) we have \( [b_1, \ldots, b_{i-1}] \rightarrow [a_1, \ldots, a_i] \).

(iv) For any \( 1 < i \leq \min\{m-2, n\} \) such that \( R_{i+1} \leq S_{i-1}, R_{i+2} \leq S_i \) and \( R_{i+2} - S_{i-1} > 2e \) we have \( [b_1, \ldots, b_{i-1}] \rightarrow [a_1, \ldots, a_i] \). (If \( i = n + 1 \) we ignore the condition \( R_{i+2} \leq S_i \).)

Note that if \( n \leq m - 2 \) and \( i = n + 1 \) then \( S_{n+1} \) and \( A_{n+1} \) are not defined, but \( A_{n+1} \) is. Thus the condition \( A_n + A_{n+1} > 2e + R_{n+1} - S_{n+1} \) from (iii) should be read as \( A_n + (S_{n+1} + A_{n+1}) > 2e + R_{n+1} \).

Remarks

1. We have \( R_i - S_{i-1} + d[-a_{i-1}, b_{i-1}] \geq A_i - 1 \) and \( R_{i+1} - S_i + d[-a_{i+1}, b_{i-1}] \geq A_i \), by the definition of \( A_i \). So if \( A_{i-1} + A_i > 2e + R_i - S_i \) then \( R_i - S_{i-1} + d[-a_{i-1}, b_{i-1}] + R_{i+1} - S_i + d[-a_{i+1}, b_{i-1}] \geq 2e + R_i - S_i \) so \( d[-a_{i-1}, b_{i-2}] + d[-a_{i+1}, b_{i-1}] > 2e + S_{i-1} - R_{i+1} \). But one can prove that if \( M \) and \( N \) satisfy the conditions (i) and (ii) of Theorem 1.2 and \( R_{i+1} > S_{i-1} \), then \( A_{i-1} + A_i > 2e + R_i - S_i \) is equivalent to \( d[-a_{i-1}, b_{i-2}] + d[-a_{i+1}, b_{i-1}] > 2e + S_{i-1} - R_{i+1} \). Hence the condition (iii) of Theorem 1.2 can be replaced by:

   \( (iii') \) For any \( 1 < i \leq \min\{m-1, n+1\} \) such that \( R_{i+1} > S_{i-1} \) and \( d[-a_{i-1}, b_{i-1}] + d[-a_{i+1}, b_{i-1}] > 2e + S_{i-1} - R_{i+1} \) we have \( [b_1, \ldots, b_{i-1}] \rightarrow [a_1, \ldots, a_i] \).

2. In some cases conditions (ii) and (iii) (or its equivalent (iii')) of Theorem 1.2 need not be verified. Namely, an index \( 1 \leq i \leq \min\{m, n+1\} \) is called essential if \( R_{i+1} > S_{i-1} \) and \( R_{i+1} + R_{i+2} > S_{i-2} + S_{i-1} \). The inequalities that do not make sense because \( R_{i+1}, R_{i+2}, S_{i-2} \) or \( S_{i-1} \) is not defined are ignored. Then condition (ii) is vacuous at an index \( i \) if both \( i \) and \( i + 1 \) are not essential and condition (iii) is vacuous at an index \( i \) if \( i \) is not essential.

3. Condition (iv) of Theorem 1.2 can be replaced by a stronger condition, where the inequalities \( R_{i+1} \leq S_{i-1} \) and \( R_{i+2} \leq S_i \) are ignored.

   We have an even more general reasult. If \( N \rightarrow M \) and \( R_l - S_j > 2e \) for some \( 1 \leq l \leq m, 1 \leq j \leq n \), then \( [b_1, \ldots, b_j] \rightarrow [a_1, \ldots, a_{l-1}] \). In all cases but the one described in condition (iv), this follows from conditions (i), (ii) and (iii).

   In particular, if \( R_{i+1} - S_i > 2e \) then \( [b_1, \ldots, b_i] \cong [a_1, \ldots, a_i] \). By taking determinants we get that in \( \hat{F} / \hat{F}^2 \) we have \( a_{1,i} = b_{1,i} \) or, equivalently \( d(a_{1,i}, b_{1,i}) = \infty \).

   In fact, we have an even stronger result. If \( N \rightarrow M \) and \( R_l - S_j > 2e \) then \( \langle b_1, \ldots, b_j \rangle \rightarrow \langle a_1, \ldots, a_{l-1} \rangle \).

2 The main result

Theorem 2.1. Let \( M \) be an integral quadratic lattice with \( M \cong \langle a_1, \ldots, a_m \rangle \) relative to a good BONG and let \( R_i = R_i(M) \) for \( 1 \leq i \leq m \), \( \alpha_i = \alpha_i(M) \) for \( 1 \leq i \leq m - 1 \).

Then \( M \) is universal if and only if \( m \geq 2, R_1 = 0 \) and we have one of the cases below:

- (a) \( \alpha_1 = 0 \) or, equivalently, \( R_2 = -2e \).
- (b) If \( m = 2 \) or \( R_3 > 1 \), then \( [a_1, a_2] \) is isotropic.
Lemma 2.3. If \( m \geq 3 \), \( R_3 = 1 \) and either \( m = 3 \) or \( R_4 > 2e + 1 \), then \([a_1, a_2]\) is isotropic.

II. (a) \( m \geq 3 \) and \( \alpha_1 = 1 \).
(b) If \( R_2 = 1 \) or \( R_3 > 1 \), then \( m \geq 4 \) and \( \alpha_3 \leq 2(e - \lfloor \frac{R_4 - R_3}{2} \rfloor) - 1 \).
(c) If \( R_2 \leq 0 \), \( R_3 \leq 1 \) and either \( m = 3 \) or \( R_4 - R_3 > 2e \), then \([a_1, a_2, a_3]\) is isotropic.

Remark By §1.3, property (2), we have \( \alpha_1 = 0 \) iff \( R_2 - R_1 = -2e \). So if \( R_1 = 0 \) then \( \alpha_1 = 0 \) is equivalent to \( R_2 = -2e \).

The condition that \( M \) is integral, i.e. that \( Q(M) \subseteq \mathcal{O} \), is equivalent to \( nM \subseteq \mathcal{O} \). But \( nL = p^{R_1} \) so we have:

**Lemma 2.2.** \( M \) is integral iff \( R_1 \geq 0 \).

As noted in [XZ, Lemma 2.2], an integral lattice \( M \) is universal iff it represents all elements of \( \mathcal{O}^\times \cup \pi \mathcal{O}^\times \), i.e. the elements \( b \in \hat{F} \) with \( \text{ord} b = 0 \) or \( 1 \). In terms of Theorem 1.2, this means that \( M \) represents every unary lattice \( N \cong \prec b_1 \succ \) with \( S_1 = \text{ord} b_1 \in \{0, 1\} \).

Then Theorem 1.2 in the case \( n = 1 \) implies that:

**Lemma 2.3.** The integral lattice \( M \) is universal iff for every \( N \cong \prec b_1 \succ \) with \( S_1 \in \{0, 1\} \) we have \( FN \rightarrow FM \) and:

(i) \( R_1 \leq S_1 \).
(ii) \( d[a_1b_1] \geq A_1 \).
(iii') If \( m \geq 3 \), \( R_3 > S_1 \) and \( d[-a_{1,2}] + d[-a_{1,3}b_1] > 2e + S_1 - R_3 \) then \([b_1] \rightarrow [a_1, a_2] \).
(iv) If \( m \geq 4 \), \( R_3 \leq S_1 \) and \( R_4 - S_1 > 2e \) then \([b_1] \rightarrow [a_1, a_2, a_3] \).

Note that for (iii') we used the fact that \( d[-a_{1,2}b_1,0] = d[-a_{1,2}] \). As a consequence of this, we also have \( A_1 = \min\{(R_2 - S_1)/2 + e, R_2 - S_1 + d[-a_{1,2}]\} \).

**Lemma 2.4.** The condition that \( FN \rightarrow FM \) holds for all \( N \) iff \( FM \) is universal.

*Proof.* The condition that \( FM \) represents every \( FN \cong [b_1] \) with \( \text{ord} b_1 \in \{0, 1\} \) is equivalent to \( b_1 \rightarrow FM \) for every \( b_1 \in \hat{F} \), i.e. to \( FM \) being universal. \( \square \)

**Lemma 2.5.** If \( M \) is integral, the condition (i) of Lemma 2.3 holds for all \( N \) iff \( R_1 = 0 \).

*Proof.* Since \( M \) is integral, we have \( R_1 \geq 0 \). Condition (i) holds for every \( N \) iff \( R_1 \leq S_1 \) for \( S_1 \in \{0, 1\} \). Hence the conclusion. \( \square \)

**Lemma 2.6.** If \( R_1 \leq S_1 \) then \( \alpha_1 \geq A_1 \), with equality when \( R_1 = S_1 \).

Consequently, if \( R_1 \leq S_1 \) then \( d[a_1b_1] \geq A_1 \) is equivalent to \( d(a_1b_1) \geq A_1 \).

*Proof.* We have \( A_1 = \min\{(R_2 - S_1)/2 + e, R_2 - S_1 + d[-a_{1,2}]\} \) and, by §1.4, we also have \( \alpha_1 = \min\{(R_2 - R_1)/2 + e, R_2 - R_1 + d[-a_{1,2}]\} \). So if \( R_1 \leq S_1 \) then \( \alpha_1 \geq A_1 \) and if \( R_1 = S_1 \) then \( \alpha_1 = A_1 \).

Assume now that \( R_1 \leq S_1 \) so \( \alpha_1 \geq A_1 \). Then, since \( d[a_1b_1] = \min\{d(a_1b_1), \alpha_1\} \), we have \( d[a_1b_1] \geq A_1 \) iff \( d(a_1b_1) \geq A_1 \). \( \square \)
Lemma 2.7. If $R_1 = 0$ then condition (ii) of Lemma 2.3 holds for all $N$ with $S_1 = 0$ iff $\alpha_1 \leq 1$.

Proof. By Lemma 2.6, if $S_1 = 0 = R_1$ then $A_1 = \alpha_1$ and the condition (ii) of Lemma 2.3, $d[a_1b_1] \geq A_1$, writes as $d(a_1b_1) \geq A_1 = \alpha_1$.

Since $|a_1b_1| = R_1 + S_1 = 0$ is even, we have $d(a_1b_1) \geq 1$, so the condition that $1 \geq \alpha_1$ is sufficient. For the necessity, let $\varepsilon \in \mathcal{O}^\times$ with $d(\varepsilon) = 1$ and let $b_1 = \varepsilon a_1$. Then $S_1 = \text{ord } b_1 = \text{ord } a_1 = 0$ and in $\hat{F}/F^2$ we have $a_1 b_1 = \varepsilon$ so $d(a_1b_1) = d(\varepsilon) = 1$. Hence we must have $1 = d(a_1b_1) \geq \alpha_1$. □

Lemma 2.8. (i) If $\alpha_i = 0$ then $d[-a_{i,i+1}] \geq 2e$.

(ii) If $\alpha_i = 1$ then $-2e < R_{i+1} - R_i \leq 1$ or, equivalently, either $R_{i+1} - R_i = 1$ or $R_{i+1} - R_i$ is even and $2 - 2e \leq R_{i+1} - R_i \leq 0$. Moreover, $d[-a_{i,i+1}] \geq R_i - R_{i+1} + 1$, with equality if $R_{i+1} - R_i \neq 2 - 2e$.

(iii) If $R_{i+1} - R_i \in \{2 - 2e, 1\}$ then $\alpha_i = 1$ unconditionally. If $2 - 2e < R_{i+1} - R_i \leq 0$ then $\alpha_i = 1$ iff $d[-a_{i,i+1}] = R_i - R_{i+1} + 1$.

Proof. By 1.3, property (2), we have $\alpha_i = 0$ iff $R_{i+1} - R_i = -2e$.

Assume that $\alpha_i = 1$. By §1.2, we have $R_{i+1} - R_i \geq -2e$. But we cannot have $R_{i+1} - R_i = -2e$, since this would imply $\alpha_i = 0$. So $R_{i+1} - R_i > 2e$. We cannot have $R_{i+1} - R_i > 2e$, since by §1.3, property (5), this would imply $\alpha_i > 2e$. So $R_{i+1} - R_i \leq 2e$, which, by property (3), implies $1 = \alpha_i \geq R_{i+1} - R_i$. So $-2e < R_{i+1} - R_i \leq 1$. By §1.2, $R_{i+1} - R_i$ cannot be odd and negative. So we have either $R_{i+1} - R_i = 1$ or $R_{i+1} - R_i$ is even and $2 - 2e < R_{i+1} - R_i \leq 0$.

We now use the relation $\alpha_i = \min\{(R_{i+1} - R_i)/2 + e, R_{i+1} - R_i + d[-a_{i,i+1}]\}$. This implies that $\alpha_i \leq R_{i+1} - R_i + d[-a_{i,i+1}]$, so $d[-a_{i,i+1}] \geq R_i - R_{i+1} + \alpha_i$, with equality if $\alpha_i < (R_{i+1} - R_i)/2 + e$. If $\alpha_i = 0$, so $R_{i+1} - R_i = -2e$, we get $d[-a_{i,i+1}] \geq R_i - R_{i+1} = 2e$, which concludes the proof of (i). If $\alpha_i = 1$ we get $d[-a_{i,i+1}] \geq R_i - R_{i+1} + 1$, with equality if $1 < (R_{i+1} - R_i)/2 + e$, i.e. if $R_{i+1} - R_i > 2 - 2e$. This concludes the proof of (ii).

(iii) By §1.3, properties (3) and (4), if $R_{i+1} - R_i = 1$ then $\alpha_i = R_{i+1} - R_i = 1$ and if $R_{i+1} - R_i = 2 - 2e$ then $\alpha_i = (R_{i+1} - R_i)/2 + e = 1$. If $2 - 2e < R_{i+1} - R_i \leq 0$, then the necessity of $d[-a_{i,i+1}] = R_i - R_{i+1} + 1$ follows from (ii). Conversely, assume that $d[-a_{i,i+1}] = R_i - R_{i+1} + 1$. Then $R_{i+1} - R_i + d[-a_{i,i+1}] = 1$ and, since $R_{i+1} - R_i > 2 - 2e$, we also have $(R_{i+1} - R_i)/2 + e > 1$. It follows that $\alpha_i = \min\{(R_{i+1} - R_i)/2 + e, R_{i+1} - R_i + d[-a_{i,i+1}]\} = 1$.

We are interested in the case when $R_1 = 0$ and $i = 1$. We get:

Corollary 2.9. Assume that $m \geq 2$ and $R_1 = 0$. Then we have:

(i) If $\alpha_1 = 0$ then $d[-a_{1,2}] \geq 2e$.

(ii) If $\alpha_1 = 1$ then $-2e < R_2 \leq 1$ or, equivalently, either $R_2 = 1$ or $R_2$ is even and $2 - 2e \leq R_2 \leq 0$. Moreover, $d[-a_{1,2}] \geq 1 - R_2$, with equality if $R_2 \neq 2 - 2e$.

(iii) If $R_2 \in \{2 - 2e, 1\}$ then $\alpha_i = 1$ unconditionally. If $2 - 2e < R_2 \leq 0$ then $\alpha_1 = 1$ iff $d[-a_{1,2}] = 1 - R_2$.

We define the following statement, which is slightly stronger than II (a):
Lemma 2.10. Assume that \( FM \) is universal and \( R_1 = 0 \). Then condition (ii) of Lemma 2.3 holds for every \( N \) iff we have I (a) or II (a').

Proof. By Lemma 2.7, the condition (ii) of Lemma 2.3 in the case \( S_1 = 0 \) is equivalent to \( \alpha_1 \leq 1 \). We must prove that, assuming that \( R_1 = 0 \) and \( \alpha_1 \leq 1 \), the condition (ii) of Lemma 2.3 holds for every \( N \) with \( S_1 = 1 \) iff the additional conditions from II (a'), \( m \geq 3 \) and \( d[-a_{i,1}] = 1 - R_2 \), hold.

Since \( \ord a_1 b_1 = R_1 + S_1 = 1 \) is odd, we have \( d[a_1 b_1] = 0 \), so condition (ii) of Lemma 2.3 writes as \( 0 \geq A_1 \). If \( \alpha_1 = 0 \), so \( R_2 = -2e \), then \( A_1 \leq (R_2 - S_1) + 2 + e = 0 \), and we are done. If \( \alpha_1 = 1 \) and \( d[-a_{1,2}] = 1 - R_2 \) then \( A_1 \leq R_2 - S_1 + d[-a_{1,2}] = R_2 - 1 + (1 - R_2) = 0 \), so again we are done.

So we have the sufficiency of the condition \( d[-a_{1,2}] = 1 - R_2 \) from II (a'). For the necessity, assume that \( \alpha_1 = 1 \) and \( d[-a_{1,2}] \neq 1 - R_2 \). By Corollary 2.9(ii), this means that \( R_2 = 2 - 2e \) and \( d[-a_{1,2}] > 1 - R_2 \). Then \( R_2 - S_1 + d[-a_{1,2}] > R_2 - 1 + (1 - R_2) = 0 \) and \( (R_2 - S_1)/2 + e = (2-2e)/2 + e = 1/2 > 0 \). It follows that \( A_1 = \min\{(R_2 - S_1)/2 + e, R_2 - S_1 + d[-a_{1,2}]\} > 0 \), so the condition (ii) of Lemma 2.3 doesn't hold.

To complete the proof, we show that the remaining condition, \( m \geq 3 \), from II (a'), follows from the fact that \( FM \) is universal. If \( m = 2 \), then \( d(-a_{1,2}) = d[-a_{1,2}] = 1 - R_2 < \infty \) so \( -a_{1,2} \notin \hat{F}^2 \). It follows that \( FM \cong [a_1, a_2] \) is not isotropic and so it is not universal. □

Lemma 2.11. Assume that \( R_1 = 0 \) and \( R_2 = -2e \).

(i) We have \( a_{1,2} \in \hat{F}^2 \) or \( -\Delta \hat{F}^2 \). In the first case \( [a_1, a_2] \) is isotropic. In the second case \( [a_1, a_2] \) represents precisely the elements of \( \hat{F} \) with even orders.

In particular, in both cases \( [a_1, a_2] \) represents the elements of \( \hat{F} \) with even orders.

(ii) Assume that \( m \geq 3 \). If \( R_3 = 0 \) then \( [a_1, a_2, a_3] \) is isotropic. If \( R_3 = 1 \) then \( [a_1, a_2, a_3] \) is isotropic iff \( [a_1, a_2] \) is isotropic.

Proof. (i) By 1.2, as a consequence of \( R_2 - R_1 = -2e \), we have \( -a_{1,2} \in \hat{F}^2 \) or \( \Delta \hat{F}^2 \).

In the first case \( [a_1, a_2] \) is binary of determinant \(-1\) so it is isotropic. In the second case, for every \( b \in \hat{F} \) we have \( b \mapsto [a_1, a_2] \) iff \( (a_1 b, -a_{1,2})_p = (a_1 b, 1)_p = 1 \). But this happens iff \( \ord a_1 b = \ord b \) is even. (Recall that \( \ord a_1 = R_1 = 0 \).)

(ii) We have that \( [a_1, a_2, a_3] \) is isotropic iff \( -a_3 \mapsto [a_1, a_2] \). If \( R_3 = 0 \) then \( \ord a_3 = R_3 \) is even so \( -a_3 \) is represented by \( [a_1, a_2] \) in both cases from (i). Hence \( [a_1, a_2, a_3] \) is isotropic.

Suppose now that \( [a_1, a_2, a_3] \) is isotropic and \( R_3 = 1 \). Then \( [a_1, a_2] \) represents \( -a_3 \) and, since \( \ord a_3 = R_3 \) is odd, this is possible only if \( [a_1, a_2] \) is isotropic. The reverse implication is trivial. □

Lemma 2.12. If \( m \geq 3 \) and \( R_1 = 0 \) then \( R_3 \geq 0 \). If moreover \( R_2 = 1 \), then \( R_3 \geq 1 \).

Proof. By the properties of the good BONGs, \( R_3 \geq R_1 = 0 \). If \( R_2 = 1 \) then we cannot have \( R_3 = 0 \), since \( R_3 - R_2 \) cannot be odd and negative. So in this case \( R_3 \geq 1 \). □
Lemma 2.13. If $FM$ is universal, $R_1 = 0$ and $M$ satisfies $I(a)$ or $II(a')$ then the condition (iii') of Lemma 2.3 is satisfied for every $N$ iff $M$ satisfies $I(b)$ or $II(b)$, accordingly.

Proof. Suppose that we have $I(a)$. Then $\alpha_1 = 0$, $R_2 = -2e$ and, by Corollary 2.9(i), $d[-a_{1,2}] \geq 2e$.

By Lemma 2.11(i), $[a_1, a_2]$ represents all units so if $S_1 = \text{ord } b_1 = 0$ then $b_1 \mapsto [a_1, a_2]$ so (iii') holds trivially.

Suppose now that $S_1 = 1$. If $m = 2$ then $FM \cong [a_1, a_2]$ must be isotropic because it is universal. If $R_3 \leq S_1 = 1$ then (iii') holds trivially. Suppose now that $R_3 > 1$. Hence $R_3 > S_1$ and we also have $d[-a_{1,2}] + d[-a_{1,3}b_1] \geq d[-a_{1,2}] \geq 2e > 2e + S_1 - R_3$. Hence condition (iii') holds iff $b_1 \mapsto [a_1, a_2]$. Since ord $b_1 = S_1$ is odd, by Lemma 2.11(i), this can only happen if $[a_1, a_2]$ is isotropic. Conversely, if $[a_1, a_2]$ is isotropic then it is universal so (iii') holds trivially.

In conclusion, the condition (iii') holds iff $M$ satisfies $I(b)$.

Suppose now that we have $II(a')$. By Lemma 2.12, $R_3 \geq 0$ and if $R_2 = 1$ then $R_3 \geq 1$.

Suppose first that $R_2 \leq 0$ and $R_3 \leq 1$. We prove that the condition (iii') of Lemma 2.3 holds unconditionally. By Corollary 2.9(ii), $R_2$ is even and $2 - 2e \leq R_2 \leq 0$. If $R_3 = 0$ then $R_3 \leq S_1$ so (iii') holds trivially. Suppose now that $R_3 = 1$. If $S_1 = 1$ then $R_3 \leq S_1$ so (iii') holds trivially. If $S_1 = 0$ then $\text{ord } a_{1,3}b_1 = R_1 + R_2 + R_3 + S_1$ is odd so $d[-a_{1,3}b_1] = 0$. (We have $R_1 = S_1 = 0$, $R_3 = 1$ and $R_2$ is even.) Hence $d[-a_{1,2}] + d[-a_{1,3}b_1] = 1 - R_2 + 0 \leq 2e - 1 = 2e + S_1 - R_3$ so again (iii') holds trivially.

So we are left with the case when $R_2 = 1$ or $R_3 > 1$.

We claim that $d[[-a_{1,2}] = 1 - R_2$. If $R_2 = 1$ then $\text{ord } a_{1,2} = R_1 + R_2 = 1$ so $d[-a_{1,2}] = 0 = 1 - R_2$. Suppose now that $R_2 \leq 0$ and $R_3 > 1$. Since $R_2 \geq 2 - 2e$, we have $1 - R_2 \leq 2e - 1$. If $R_3 - R_2 > 2e$ then, by 1.3, property (5), we have $\alpha_2 > 2e > 1 - R_2$. If $R_3 - R_2 \leq 2e$ then, by the property (3), we have $\alpha_2 \geq R_3 - R_2 > 1 - R_2$. So we have

$\min\{d[-a_{1,2}], \alpha_2\} = d[-a_{1,2}] = 1 - R_2$ and $\alpha_2 > 1 - R_2$. It follows that $d[-a_{1,2}] = 1 - R_2$.

Suppose first that $S_1 \equiv R_2 + R_3 \pmod{2}$. Recall that if $R_2 = 1$ then $R_3 \geq 1$ and if $R_2 \leq 0$ then $R_3 > 1$. So, with the exception of the case $R_2 = R_3 = 1$, we have $R_3 > 1 \geq S_1$. If $R_2 = R_3 = 1$ then $S_1 \equiv R_2 + R_3 \equiv 0 \pmod{2}$ and $S_1 \in \{0, 1\}$ so $S_1 = 0 < R_3$. Hence in this case the inequality $R_3 > S_1$ from Lemma 2.3(iii') is satisfied. Condition (iii') states that if moreover $d[-a_{1,2}] + d[-a_{1,3}b_1] > 2e + S_1 - R_3$, then $b_1 \mapsto [a_1, a_2]$.

Note that $d[-a_{1,3}b_1] = \min\{d[-a_{1,3}b_1], \alpha_3\}$, with $\alpha_3$ ignored if $m = 3$.

If $m = 4$ then $d[-a_{1,3}b_1] \leq \alpha_3$ so if $d[-a_{1,2}] + \alpha_3 \leq 2e + S_1 - R_3$ then also $d[-a_{1,2}] + d[-a_{1,3}b_1] \leq 2e + S_1 - R_3$ so condition (iii') holds trivially.

Suppose now that $m = 3$ or $m \geq 4$ and $d[-a_{1,2}] + \alpha_3 > 2e + S_1 - R_3$. Then, by the formula $d[-a_{1,3}b_1] = \min\{d[-a_{1,3}b_1], \alpha_3\}$, $d[-a_{1,2}] + d[-a_{1,3}b_1] > 2e + S_1 - R_3$ is equivalent to $d[-a_{1,2}] + d[-a_{1,3}b_1] > 2e + S_1 - R_3$. So, for (iii') to hold, $[a_1, a_2]$ must represent every $b_1 \in \hat{F}$ with ord $b_1 = S_1$ and $d[-a_{1,2}] + d[-a_{1,3}b_1] > 2e + S_1 - R_3$. We have $R_2 \geq 2 - 2e$ so $d[-a_{1,2}] = 1 - R_2 \leq 2e - 1$. Then, by \S 1.1, that there is $\varepsilon \in \mathcal{O}^\times$ such that $d(\varepsilon) = 2e - d[-a_{1,2}] = 2e - d[-a_{1,2}]$ and $(\varepsilon, -a_{1,2}) = -1$. Since ord $a_{1,3} = R_1 + R_2 + R_3 = R_2 + R_3 \equiv S_1 \pmod{2}$, there is $b \in \hat{F}$, say, $b = -\pi^{S_1 - R_2 - R_3}a_{1,3}$, such that ord $b = S_1$ and $b \in -a_{1,3}\hat{F}^2$. It follows that $-a_{1,3}b \in \hat{F}$ and $-a_{1,3}b \varepsilon \in \varepsilon\hat{F}^2$ so $d[-a_{1,3}b] = \infty$ and $d[-a_{1,3}b \varepsilon] = d(\varepsilon) = 2e - d[-a_{1,2}]$. In both cases when $b_1 = b$ or $b \varepsilon$, we have ord $b_1 = \text{ord } b = S_1$ and $d[-a_{1,3}b_1] \geq 2e - d[-a_{1,2}]$, which implies $d[-a_{1,2}] + d[-a_{1,3}b_1] \geq 2e > 2e + S_1 - R_3$. So in both cases we have $b_1 \mapsto [a_1, a_2]$. 

which is equivalent to \((a_1b_1, -a_{1,2})_p = 1\). We get \((a_1b, -a_{1,2})_p = (a_1b\varepsilon, -a_{1,2})_p = 1\), which implies \((\varepsilon, -a_{1,2})_p = 1\). But this contradicts the choice of \(\varepsilon\).

So the condition that \(m \geq 4\) and \(d[-a_{1,2}] + \alpha_3 \leq 2e + S_1 - R_3\) is not only sufficient, but also necessary. Since \(d[-a_{1,2}] = 1 - R_2\), this inequality writes as \(\alpha_3 \leq 2e - 1 + S_1 + R_2 - R_3\). We have \(S_1 \equiv R_3 - R_2 \pmod{2}\) and \(S_1 \in \{0, 1\}\), so \(S_1 = R_3 - R_2 - 2[R_3 - R_2]\). It follows that \(2e - 1 + S_1 + R_2 - R_3 = 2(e - \left(\frac{R_3 - R_2}{2}\right)) - 1\).

So we have proved that if \(R_2 = 1\) or \(R_3 > 1\) then the condition that \(m \geq 4\) and \(\alpha_3 \leq 2(e - \left(\frac{R_3 - R_2}{2}\right)) - 1\) is necessary and sufficient for condition (iii’) of Lemma 2.3 to hold in the case when \(S_1 \equiv R_2 + R_3 \pmod{2}\). To conclude the proof, we show that this condition is also sufficient for (iii’) to hold in the case when \(S_1 \equiv R_2 + R_3 + 1 \pmod{2}\). So assume that \(\alpha_3 \leq 2(e - \left(\frac{R_3 - R_2}{2}\right)) - 1\) and \(S_1 \equiv R_2 + R_3 + 1 \pmod{2}\). Suppose that \(d[-a_{1,2}] + d[-a_{1,3}b_1] > 2e + S_1 - R_3\). We have \(d[-a_{1,2}] = 1 - R_2\) and \(\text{ord } a_{1,3}b_1 = R_1 + R_2 + R_3 + S_1 = R_2 + R_3 + S_1 \equiv 1 \pmod{2}\) so \(d[-a_{1,3}b_1] = 0\). Hence \((1 - R_2) + 0 > 2e + S_1 - R_3 \geq 2e - R_3\), which implies \(R_3 - R_2 > 2e - 1\), so \(R_3 - R_2 > 2e\). It follows that \(\alpha_3 \leq 2(e - \left(\frac{R_3 - R_2}{2}\right)) - 1 \leq 2(2 - \left(\frac{2e}{2}\right)) - 1 = -1\). But \(\alpha_3 \geq 0\), by §1.3, property (2). Contradiction. Hence \(d[-a_{1,2}] + d[-a_{1,3}b_1] \leq 2e + S_1 - R_3\) and so (iii’) holds trivially. □

**Lemma 2.14.** If \(FM\) is universal, \(R_1 = 0\) and \(M\) satisfies I (a) or II (a’) then the condition (iv) of Lemma 2.3 is satisfied for every \(N\) iff \(M\) satisfies I (c) or II (c), accordingly.

**Proof.** Recall that \(b_1 \rightarrow [a_1, a_2, a_3]\) iff \(b_1 \not\in a_{1,3}F^2\) or \([a_1, a_2, a_3]\) is isotropic.

Let \(S \in \{0, 1\}\) such that \(S \equiv R_2 + R_3 \pmod{2}\). We claim that condition (iv) of Lemma 2.3 holds for every \(N\) iff the following statement holds.

(*) If \(m \geq 3\), \(R_3 \leq S\) and either \(m = 3\) or \(R_1 - S > 2e\) then \([a_1, a_2, a_3]\) is isotropic.

Assume first that \(m \geq 4\).

If \(S_1 \equiv R_2 + R_3 + 1 \pmod{2}\) then \(\text{ord } b_1 = S_1\) and \(\text{ord } a_{1,3} = R_1 + R_2 + R_3 = R_2 + R_3\) have opposite parities so we cannot have \(b_1 \in -a_{1,3}F^2\). Therefore \(b_1 \rightarrow [a_1, a_2, a_3]\) so in this case condition (iv) of Lemma 2.3, holds unconditionally.

Suppose now that \(S_1 \equiv R_2 + R_3 \pmod{2}\), i.e. that \(S_1 = S\). If \(R_3 > S_1 = S\) or \(R_4 - S = R_4 - S_1 \leq 2e\), then (iv) holds trivially. So we assume that \(R_3 \leq S = S_1\) and \(R_4 - S = R_4 - S_1 > 2e\). Then condition (iv) of Lemma 2.3 states that \(b_1 \rightarrow [a_1, a_2, a_3]\). So \([a_1, a_2, a_3]\) must represent all elements of \(F\) of order \(S_1 = S\). Since \(\text{ord } a_{1,3} = R_1 + R_2 + R_3 = R_2 + R_3 \equiv S \pmod{2}\) there is \(b_1 \in -a_{1,3}F^2\) with \(\text{ord } b_1 = S\), say, \(b_1 = -\pi s_{-R_2-R_3}\). Then

\[
b_1 \rightarrow [a_1, a_2, a_3] \text{ and } b_1 \in -a_{1,3}F^2, \text{ so } [a_1, a_2, a_3] \text{ is isotropic.}
\]

Conversely, if \([a_1, a_2, a_3]\) is isotropic, then it is universal, so (iv) holds.

If \(m \leq 3\) then (iv) is vacuous, but the case when \(m = 3\) and \(R_3 \leq S\) can still be included here because when \(m = 3\) we have that \(FM \equiv [a_1, a_2, a_3]\) is universal, so isotropic.

Suppose first that we have I (a). If \(R_3 > 1\) then \(R_3 > S\) so (*) holds trivially. If \(R_3 = 0\) then, by Lemma 2.11(ii), \([a_1, a_2, a_3]\) is isotropic, so (*) holds unconditionally. We are left with the case \(R_3 = 1\). Then \(R_2 + R_3 = 1 - 2e\) is odd so \(S = 1\) and \(R_3 \leq S\) holds. The inequality \(R_4 - S > 2e\) writes as \(R_4 > 2e + 1\). Therefore (*) is equivalent to:

I (c’) If \(m \geq 3\), \(R_3 = 1\) and either \(m = 3\) or \(R_4 > 2e + 1\), then \([a_1, a_2, a_3]\) is isotropic.

But when \(R_3 = 1\), by Lemma 2.11(ii), \([a_1, a_2, a_3]\) is isotropic iff \([a_1, a_2]\) is isotropic. Hence I (c’) is equivalent to I (c).

Assume now that \(M\) satisfies II (a’).
Suppose first that $R_3 > 1$. Since $S \leq 1$ we get $R_3 > S$ so (*) holds trivially. So we may assume that $R_3 \leq 1$. Next suppose that $R_2 = 1$. By Lemma 2.12, $R_3 \geq 1$, so $R_3 = 1$. Since $R_2 + R_3 = 2$ is even, we get $S = 0$ and again $R_3 > S$, so (*) holds trivially.

Since for $R_2 = 1$ or $R_3 > 1$ (*) holds unconditionally, we are left with the case when $R_2 \leq 0$ and $R_3 \leq 1$. Since $R_2 \leq 0$ we have that $R_2$ is even and so $S \equiv R_2 + R_3 \equiv R_3 \pmod{2}$. Since $R_3, S \in \{0, 1\}$ and $R_3 \equiv S \pmod{2}$, we have $S = R_3$. In particular, $R_3 \geq S$ holds. So, in order that (*) holds we need that $[a_1, a_2, a_3]$ is isotropic if $m = 3$ or $m \geq 4$ and $R_4 - R_3 = R_4 - S > 2e$. So (*) writes as follows. If $m \geq 3$, $R_2 \leq 0$ and $R_3 \leq 1$ and either $m = 3$ or $m \geq 4$ and $R_4 - R_3 > 2e$, then $[a_1, a_2, a_3]$ is isotropic. But the condition that $m \geq 3$ is part of II (a’) so it can be dismissed. So we get II (c). □

**Proof of Theorem 2.1.** By Lemmas 2.2, 2.5, 2.10, 2.13 and 2.14, $FM$ is universal iff $FM$ is universal, $R_1 = 0$ and we have either I (a), (b) and (c) or II (a’), (b) and (c). Since $FM$ is universal, we have $m \geq 2$. Then, to conclude the proof, we must show that II (a’) can be replaced by II (a) and that the condition that $FM$ is universal is superfluous, as if $m \geq 2$ and $R_1 = 0$ then it follows both from I and from II.

First we prove that the extra condition from II (a’), that $d[-a_{1,2}] = 1 - R_2$, is superfluous, as it follows from II (a) and (b). Since $R_1 = 0$ and $\alpha_1 = 1$, by Corollary 2.1(ii), $d[-a_{1,2}] \geq 1 - R_2$, with equality if $R_2 \neq 2 - 2e$. So we only have to consider the case $R_2 = 2 - 2e$, when we only have $d[-a_{1,2}] \geq 1 - R_2 = 2e - 1$. Assume that $R_3 > 1$. Then, by II (b), we have that $m \geq 4$ and $\alpha_3 \leq 2(e - \lfloor R_3/R_2 \rfloor) - 1$. But $R_3 \geq 2$ so $R_3 - R_2 = R_3 - (2 - 2e) \geq 2e$. Then $\alpha_3 \leq 2(e - \lfloor 2e/2 \rfloor) - 1 \leq 2(e - \lfloor 2e/2 \rfloor) - 1 = -1$. But, by §1.3, property (2), we have $\alpha_3 \geq 0$. Contradiction. Hence $R_3 \leq 1$. If $R_3 = 0$ then $R_3 - R_2 = 2e - 2$ so, by §1.3, property (4), $\alpha_2 = (R_3 - R_2)/2 + e = 2e - 1$. If $R_3 = 1$ then $R_3 - R_2 = 2e - 1$ is odd and $< 2e$ so, by the property (3), $\alpha_2 = R_3 - R_2 = 2e - 1$. Then $2e - 1 \leq d[-a_{1,2}] = \min\{d(a_{1,2}), \alpha_2\} \leq \alpha_2 = 2e - 1$ so $d[-a_{1,2}] = 2e - 1 = 1 - R_2$.

Next we prove that if $m \geq 2$, $R_1 = 0$ and we have I or II, then $FM$ is universal. If $m = 2$ then we are in case of I and we have by I (b) that $FM = [a_1, a_2]$ is isotropic and so it is universal. Suppose now that $m = 3$. We consider first case I. If $R_3 > 1$ then $[a_1, a_2, a_3]$ is isotropic by I (b), if $R_3 = 1$ then it is isotropic by I (c) and if $R_3 = 0$ it is isotropic by Lemma 2.11(ii). If we are in the case II then we cannot have $R_2 = 1$ or $R_3 > 1$, since by II (b) this implies that $m \geq 4$. In the remaining case, $R_2 \leq 0$ and $R_3 \leq 1$, since $m = 3$ we have by I (c) that $[a_1, a_2, a_3]$ is isotropic. So, in all cases, $FM = [a_1, a_2, a_3]$ is isotropic and so universal. If $m \geq 4$ then $FM$ is universal unconditionally. □

**Remark.** If we make the convention that $R_i \gg 0$ for $i > m$ then conditions I and II can be written in a more compact way, without reference to the value of $n$. Namely one can write them as:

I (a) $\alpha_1 = 0$ or, equivalently, $R_2 = -2e$.
(b) If $R_3 > 1$, then $[a_1, a_2]$ is isotropic.
(c) If $R_3 = 1$ and $R_4 > 2e + 1$, then $[a_1, a_2]$ is isotropic.

II (a) $\alpha_1 = 1$.
(b) If $R_2 = 1$ or $R_3 > 1$, then $m \geq 4$ and $\alpha_3 \leq 2(e - \lfloor R_4/R_2 \rfloor) - 1$.
(c) If $R_2 \leq 0$, $R_3 \leq 1$ and $R_4 - R_3 > 2e$, then $[a_1, a_2, a_3]$ is isotropic.
3 Main result in terms of Jordan decompositions

We now give, without a proof, a translation of Theorem 2.1, in terms of Jordan decompositions.

Theorem 3.1. Let $M = M_1 \perp \cdots \perp M_t$ be a Jordan decomposition, with $sM_k = p^{r_k}$, $nM^{sL_k} = u_k$ and $wM^{sM_k} = w_k$ for $1 \leq k \leq t$. For $1 \leq k \leq t - 1$ we consider the ideal $f_k$ defined in [OM, §93E]. Then $M$ is universal if $\operatorname{rank} M \geq 2$, $nM = \mathcal{O}$, or, equivalently, $u_1 = 0$, and one of the following happens:

1. $\operatorname{rank} M_1 \geq 4$ and $w_1 \supseteq p$.
2. $\operatorname{rank} M_1 = 3$, $w_1 = p$ and one of the following happens:
   1.1. $t \geq 2$ and $u_2 \leq 2e$.
   1.2. $M_1$ is isotropic.
3. $\operatorname{rank} M_1 = 2$ and one of the following happens:
   3.1. $sM_1 = 2\mathcal{O}$ and one of the following happens:
   3.1.1. $t \geq 2$ and $u_2 = 0$.
   3.1.2. $t \geq 2$, $w_2 = 1$ and either $\operatorname{rank} M_2 \geq 2$ or $\operatorname{rank} M_2 = 1$, $t \geq 3$ and $u_3 \leq 2e + 1$.
   3.1.3. $M_1 \cong \mathcal{A}(0, 0)$.
4. $\operatorname{rank} M_1 = 1$, $u_2 = 1$, $m \geq 3$ and one of the following happens:
   4.1. $u_2 > 1$, $\operatorname{rank} M_2 \geq 2$ and $w_2 \supseteq 4p^{r_1+u_2-2(u_2/2)}$.
   4.2. $u_2 > 1$, $\operatorname{rank} M_2 = 1$, $t \geq 3$ and $f_2 \supseteq 4p^{r_1-2(u_2/2)}$.
   4.3. $u_2 \leq 1$ and $\operatorname{rank} M_2 \geq 2$.
   4.4. $u_2 \leq 1$, $\operatorname{rank} M_2 = 1$, $t \geq 3$ and $u_3 \leq u_2 + 2e$.
   4.5. $u_2 \leq 1$, $\operatorname{rank} M_2 = 1$ and $M_1 \perp M_2$ is isotropic.
5. $\operatorname{rank} M_1 = 1$, $u_2 = 1$, $m \geq 4$ and one of the following happens:
   5.1. $\operatorname{rank} M_2 \geq 3$.
   5.2. $\operatorname{rank} M_2 = 2$ and $u_3 \leq 2e$.
   5.3. $\operatorname{rank} M_2 = 1$ and one of the following happens:
   5.3.1. $\operatorname{rank} M_3 \geq 2$ and $w_3 \supseteq 4p^{r_3-2(u_3-1)/2}$.
   5.3.2. $\operatorname{rank} M_3 = 1$ and $f_3 \supseteq 4p^{-2(u_3-1)/2}$.
