**Abstract**

This paper is devoted to establish nontrivial effective lower bounds for the least common multiple of consecutive terms of a sequence \((u_n)_{n \in \mathbb{N}}\) whose general term has the form \(u_n = r[n]_q + u_0\), where \(q, r\) are positive integers and \(u_0\) is a non-negative integer such that \(\gcd(u_0, r) = \gcd(u_1, q) = 1\). For such a sequence, we show that for all positive integer \(n\), we have \(\text{lcm}\{u_1, u_2, \ldots, u_n\} \geq c_1 \cdot c_2 \cdot q^{n^2} 4\), where \(c_1\) and \(c_2\) are positive constants depending only on \(q, r\) and \(u_0\). This can be considered as a \(q\)-analog of the lower bounds already obtained by the author (in 2005) and by Hong and Feng (in 2006) for the arithmetic progressions.

**Keywords:** Least common multiple, \(q\)-analogs, arithmetic progressions.

**1 Introduction and the main results**

Throughout this paper, we let \(\mathbb{N}^*\) denote the set \(\mathbb{N} \setminus \{0\}\) of positive integers. For \(t \in \mathbb{R}\), we let \([t]\) denote the integer part of \(t\). We say that an integer \(a\) is a multiple of a non-zero rational number \(r\) if the quotient \(a/r\) is an integer. The letter \(q\) always denotes a positive integer; besides, it is assumed if necessary that \(q \geq 2\) (this assumption is needed in §2.2). Let us recall the standard notations of \(q\)-calculus (see e.g., [10]). For \(n, k \in \mathbb{N}\), with \(n \geq k\), we have by definition:

\[
[n]_q := \frac{q^n - 1}{q - 1} \quad \text{for } q \neq 1 \text{ and } [n]_1 := n, \\
[n]_q! := [n]_q[n-1]_q \cdots [1]_q \quad \text{(with the convention } [0]_q! = 1),
\]
The numbers $\binom{n}{k}_q$ are called the $q$-binomial coefficients (or the gaussian binomial coefficients) and it is well-known that they are all positive integers (see e.g., [10]). From this last fact, we derive the important property stating that:

For all $a, b \in \mathbb{N}$, the positive integer $\binom{a+b}{a}_q \binom{b}{a}_q$ divides the positive integer $\binom{a+b}{a}_q \binom{b}{a}_q$.  \hspace{1cm} (1.1)

Indeed, for $a, b \in \mathbb{N}$, we have $\binom{a+b}{a}_q \binom{b}{a}_q = \binom{a+b}{a}_q \in \mathbb{N}^*$.

The study of the least common multiple of consecutive positive integers began with Chebyshev’s work [4] in his attempts to prove the prime number theorem. The latter defined $\psi(n) := \log \text{lcm}(1, 2, \ldots, n) \ (\forall n \geq 2)$ and showed that $\frac{\psi(n)}{n}$ is bounded between two positive constants, but he failed to prove that $\psi(n) \sim_{n \to \infty} n$, which is equivalent to the prime number theorem. Quite recently, Hanson [7] and Nair [12] respectively obtained in simple and elegant ways that $\text{lcm}(1, 2, \ldots, n) \leq 3^n \ (\forall n \in \mathbb{N}^*)$ and $\text{lcm}(1, 2, \ldots, n) \geq 2^n \ (\forall n \geq 7)$. Later, the author [5, 6] obtained nontrivial effective lower bounds for the least common multiple of consecutive terms in an arithmetic progression. In particular, he proved that for any $u_0, r, n \in \mathbb{N}^*$, with $\gcd(u_0, r) = 1$, we have $\text{lcm}(u_0, u_0 + r, \ldots, u_0 + nr) \geq u_0(r + 1)^{n-1}$. By developing the author’s method, Hong and Feng [8] managed to improve this lower bound to the optimal one:

$$\text{lcm}(u_0, u_0 + r, \ldots, u_0 + nr) \geq u_0(r + 1)^n \ (\forall n \in \mathbb{N}),$$

which is already conjectured by the author [5, 6]. It is interesting to note that the method used to obtain (1.2) is based on the following fundamental theorem:

**Theorem 1** ([6, Theorem 2]). Let $I$ be a finite non-empty set of indices and $(u_i)_{i \in I}$ be a sequence of non-zero integers. Then the integer

$$\text{lcm}\{u_i, \ i \in I\} \cdot \text{lcm}\left\{\prod_{i \in I} |u_i - u_j|, \ j \in I \right\}$$

is a multiple of the integer $\prod_{i \in I} u_i$.

Furthermore, several authors obtained improvements of (1.2) for $n$ sufficiently large in terms of $u_0$ and $r$ (see e.g., [9, 11]). Concerning the asymptotic estimates and the effective upper bounds for the least common multiple of an arithmetic progression, we can cite the work of Bateman et al. [1] and the very recent work of Bousla [2].

In this paper, we apply and adapt the author’s method [5, 6] (slightly developed by Hong and Feng [8]) to establish nontrivial effective lower bounds for the least common multiple of consecutive terms in a sequence that we called a $q$-arithmetic progression; that is a sequence $(u_n)_n$ with general term has the form $u_n = r[n]_q + u_0 \ (\forall n \in \mathbb{N})$, where $r \in \mathbb{N}^*$, $u_0 \in \mathbb{N}$ and $r, u_0, q$ satisfy some technical conditions. Our main results are the following:
Theorem 1.1 (The crucial result). Let $q$ and $r$ be two positive integers and $u_0$ be a non-negative integer. Let $(u_n)_{n \in \mathbb{N}}$ be the sequence of natural numbers whose general term $u_n$ is given by: $u_n = r[n]_q + u_0$. Suppose that $\gcd(u_0, r) = \gcd(u_1, q) = 1$. Then, for any positive integers $n$ and $k$ such that $n \geq k$, the positive integer $\text{lcm}\{u_k, u_{k+1}, \ldots, u_n\}$ is a multiple of the rational number $\frac{u_k u_{k+1} \cdots u_n}{[n-k]_q}$.

Theorem 1.2. In the situation of Theorem 1.1, set
\[ A := \max\left(0, \frac{u_0(q-1) + 1 - r}{2r}\right). \]
Then, for any positive integer $n$, we have
\[ \text{lcm}\{u_1, u_2, \ldots, u_n\} \geq u_1 \left(\frac{r + 1}{\sqrt{r(A + 1)}}\right)^{n-1} q^{\frac{(n-1)(n-4)}{4}}. \]

Theorem 1.3. In the situation of Theorem 1.1, set
\[ B := \max\left(r, \frac{u_0(q-1) + 1 - r}{2}\right). \]
Then, for any positive integer $n$, we have
\[ \text{lcm}\{u_1, u_2, \ldots, u_n\} \geq u_1 \left(\frac{r + 1}{2\sqrt{B}}\right)^{n-1} q^{\frac{(n-1)(n-4)}{4}}. \]

Note that Theorem 1.1 is a $q$-analog of a result due to the author (see [5, Théorème 2.3] or [6, Theorem 3]). Furthermore, Theorems 1.2 and 1.3 are derived from Theorem 1.1 by optimizing a certain specific expression, and they can be considered as $q$-analogs of the results by the author [5, 6] and those by Hong and Feng [8].

From Theorems 1.2 and 1.3, we immediately derive the two following corollaries:

Corollary 1.4. Let $q$, $a$ and $b$ be integers such that $q \geq 2$, $a \geq 1$ and $b \geq -a$ and let $(v_n)_{n \in \mathbb{N}}$ be the sequence of natural numbers whose general term $v_n$ is given by:
\[ v_n = aq^n + b \quad (\forall n \in \mathbb{N}). \]
Suppose that $\gcd(aq, b) = \gcd(a + b, q - 1) = 1$ and set
\[ A' := \max\left(0, \frac{b}{2a} + \frac{1}{2a(q-1)}\right). \]
Then, for any positive integer $n$, we have
\[ \text{lcm}\{v_1, v_2, \ldots, v_n\} \geq (aq + b) \left(\frac{a(q-1) + 1}{\sqrt{a(q-1)(A' + 1)}}\right)^{n-1} q^{\frac{(n-1)(n-4)}{4}}. \]

Corollary 1.5. In the situation of Corollary 1.4, set
\[ B' := \max\left(a(q-1), \frac{b(q-1) + 1}{2}\right). \]
Then, for any positive integer $n$, we have
\[ \text{lcm}\{v_1, v_2, \ldots, v_n\} \geq (aq + b) \left(\frac{a(q-1) + 1}{2\sqrt{B'}}\right)^{n-1} q^{\frac{(n-1)(n-4)}{4}}. \]
2 The proofs

Throughout the following, we fix $q, r \in \mathbb{N}^*$ and $u_0 \in \mathbb{N}$ such that $\gcd(u_0, r) = \gcd(u_1, q) = 1$ and we let $(u_n)_{n \in \mathbb{N}}$ denote the sequence of natural numbers defined by its general term $u_n := r[n]_q + u_0 \ (\forall n \in \mathbb{N})$.

2.1 Proof of Theorem 1.1

To prove Theorem 1.1, we need the three following lemmas:

**Lemma 2.1.** For all $i, j \in \mathbb{N}$, we have

$$|u_i - u_j| = rq^\min(i,j)[|i - j|]_q,$$

*Proof.* Let $i, j \in \mathbb{N}$. Because the two sides of the equality of the lemma are both symmetric (in $i$ and $j$), we may suppose without loss of generality that $i \geq j$. Doing so, we have

$$|u_i - u_j| = u_i - u_j = \left( r[i]_q + u_0 \right) - \left( r[j]_q + u_0 \right)$$

$$= r \left( [i]_q - [j]_q \right)$$

$$= r \left( \frac{q^i - 1}{q - 1} - \frac{q^j - 1}{q - 1} \right)$$

$$= r \left( \frac{q^i - q^j}{q - 1} \right)$$

$$= rq^j \left( \frac{q^{i-j} - 1}{q - 1} \right)$$

$$= rq^j[|i-j|]_q$$

$$= rq^\min(i,j)[|i - j|]_q,$$

as required. The lemma is proved. \(\square\)

**Lemma 2.2.** For all $n \in \mathbb{N}$, we have

$$\gcd(u_n, r) = 1.$$  

If in addition $n \geq 1$, then we have

$$\gcd(u_n, q) = 1.$$  

*Proof.* Let $n \in \mathbb{N}$ and let us show that $\gcd(u_n, r) = 1$. This is equivalent to show that $d = 1$ is the only positive common divisor of $u_n$ and $r$. So, let $d$ be a positive common divisor of $u_n$ and $r$ and let us show that $d = 1$. The hypothesis $d|u_n$ and $d|r$ imply $d|(u_n - r[n]_q) = u_0$. Hence $d$ is a positive common divisor of $u_0$ and $r$. But since $\gcd(u_0, r) = 1$, it follows that $d = 1$, as required. Consequently, we have $\gcd(u_n, r) = 1$.  

4
2.1 Proof of Theorem 1.1

Next, let $n \in \mathbb{N}^*$ and let us show that $\gcd(u_n, q) = 1$. Equivalently, we have to show that $d = 1$ is the only positive common divisor of $u_n$ and $q$. So, let $d$ be a positive common divisor of $u_n$ and $q$ and let us show that $d = 1$. The hypothesis $d|u_n$ and $d|q$ imply $d|(rq^n + u_0q) - (q - 1)u_n = r + u_0 - u_1$. So, $d$ is a positive common divisor of $u_1$ and $q$. But since $\gcd(u_1, q) = 1$, we conclude that $d = 1$, as required. Consequently, we have $\gcd(u_n, q) = 1$. This completes the proof of the lemma.

**Lemma 2.3.** For any positive integers $n$ and $k$ such that $n \geq k$ and any $j \in \{k, k+1, \ldots, n\}$, we have

$$\sum_{\substack{k \leq i \leq n \\ i \neq j}} \min(i, j) \leq \frac{(n-k)(n+k-1)}{2}.$$ 

**Proof.** Let $n$ and $k$ be positive integers such that $n \geq k$ and let $j \in \{k, k+1, \ldots, n\}$. We have

$$\sum_{\substack{k \leq i \leq n \\ i \neq j}} \min(i, j) = \sum_{k \leq i < j} \min(i, j) + \sum_{j < i \leq n} \min(i, j)$$

$$= \sum_{k \leq i < j} i + \sum_{j < i \leq n} j$$

$$= \frac{(j - k)(j + k - 1)}{2} + (n - j)j$$

$$= \frac{2nj - j^2 - k^2 - j + k}{2}$$

$$= \frac{(n-k)(n+k-1) + (n-j) - (n-j)^2}{2}$$

$$\leq \frac{(n-k)(n+k-1)}{2}$$

(since $n - j \leq (n-j)^2$, because $n - j \in \mathbb{N}$). The lemma is proved. □

Now, we are ready to prove the crucial theorem 1.1:

**Proof of Theorem 1.1.** Let $n$ and $k$ be positive integers such that $n \geq k$. By applying the fundamental theorem 1 to the set of indices $I = \{k, k+1, \ldots, n\}$ and to the sequence $(u_i)_{i \in I} = \{u_k, u_{k+1}, \ldots, u_n\}$, we find that the positive integer

$$\text{lcm}\{u_k, u_{k+1}, \ldots, u_n\} \cdot \text{lcm}\left\{ \prod_{\substack{k \leq i \leq n \\ i \neq j}} |u_i - u_j| ; j = k, \ldots, n \right\}$$

is a multiple of the positive integer $u_ku_{k+1} \cdots u_n$. Now, let us find a simple multiple for the positive integer $\text{lcm}\left\{ \prod_{\substack{k \leq i \leq n \\ i \neq j}} |u_i - u_j| ; j = k, \ldots, n \right\}$. According to Lemma 2.1, we have for any $j \in \{k, k+1, \ldots, n\}$:

$$\prod_{\substack{k \leq i \leq n \\ i \neq j}} |u_i - u_j| = \prod_{\substack{k \leq i \leq n \\ i \neq j}} \left( rq^{\min(i,j)}[|i - j|_q] \right)$$

5
2.2 Proofs of Theorems 1.2 and 1.3 and their corollaries

To deduce Theorems 1.2 and 1.3 from Theorem 1.1, we need some additional preparations. Since, for \( q = 1 \), Theorems 1.2 and 1.3 are immediate consequences of (1.2), we may suppose for the sequel that \( q \geq 2 \). Next, we naturally extend the definition of \( u_n \) to negative indices \( n \) and we define for all \( n, k \in \mathbb{Z} \) such that \( n \geq k \):

\[
C_{n,k} := \frac{u_k u_{k+1} \cdots u_n}{(n-k)!}. 
\]

Furthermore, for a given positive integer \( n \), the problem of determining the positive integer \( k \leq n \) which maximizes \( C_{n,k} \) leads us to introduce the function \( f : \mathbb{R} \to \mathbb{R} \), defined by:

\[
f(x) := q^{r-1} (rq^{r-1} + u_0(q - 1) + 1 - r) \quad (\forall x \in \mathbb{R}).
\]

It is immediate that \( f \) increases, tends to 0 as \( x \) tends to \( (-\infty) \) and satisfies, for all \( n \in \mathbb{N}^* \), the property:

\[
\forall k \in \mathbb{Z} : \quad k > n \implies f(k) > q^n.
\]

For a given positive integer \( n \), these properties ensure the existence of a largest \( k_n \in \mathbb{Z} \) satisfying \( f(k_n) \leq q^n \), and show, in addition, that \( k_n \leq n \). From the increase of \( f \) and the definition of \( k_n \) \((n \in \mathbb{N}^*)\), we derive that:

\[
\forall k \in \mathbb{Z} : \quad k \leq k_n \iff f(k) \leq q^n. \quad (2.1)
\]
Now, since for any \( n \in \mathbb{N}^* \) and any \( k \in \mathbb{Z} \), we have
\[
 f(k) \leq q^n \iff q^{k-1} (rq^{k-1} + u_0(q-1) + 1 - r) \leq q^n \\
\iff rq^{k-1} + u_0(q-1) + 1 - r \leq q^{n-k+1} \\
\iff \frac{q^{n-k+1} - 1}{q - 1} \geq \frac{q^{k-1} - 1}{q - 1} + u_0 \\
\iff [n - k + 1]_q \geq u_{k-1},
\]
then Property (2.1) is equivalent to:
\[
 \forall k \in \mathbb{Z} : \ k \leq k_n \iff [n - k + 1]_q \geq u_{k-1}. \quad (2.2)
\]

For a given positive integer \( n \), we set
\[
 \ell_n := \max(1, k_n).
\]

Since \( k_n \leq n \), we have that: \( \ell_n \in \{1, 2, \ldots, n\} \).

Next, it is immediate that \( f \) satisfies the following inequality:
\[
 f(x - 1) \leq \frac{1}{q} f(x) \quad (\forall x \in \mathbb{R}). \quad (2.3)
\]

For a fixed \( n \in \mathbb{N}^* \), the following lemmas aim to maximize the quantity \( C_{n,k} (1 \leq k \leq n) \) appearing in Theorem 1.1. Precisely, we shall determine two simple upper bounds for \( \max_{1 \leq k \leq n} C_{n,k} \) from which we derive our theorems 1.2 and 1.3.

**Lemma 2.4.** Let \( n \) be a fixed positive integer. The sequence \( (C_{n,k})_{k \in \mathbb{Z}, 1 \leq k \leq n} \) is non-decreasing until \( k = k_n \) then it decreases. So, it reaches its maximal value at \( k = k_n \).

**Proof.** For any \( k \in \mathbb{Z} \), with \( k \leq n \), we have
\[
 C_{n,k} \geq C_{n,k-1} \iff \frac{C_{n,k}}{C_{n,k-1}} \geq 1 \\
\iff \frac{u_k u_{k+1} \cdots u_n}{[n-k]_q!} / \frac{u_{k-1} u_k \cdots u_n}{[n-k+1]_q!} \geq 1 \\
\iff \frac{[n-k+1]_q}{u_{k-1}} \geq 1 \\
\iff [n-k+1]_q \geq u_{k-1} \\
\iff k \leq k_n \quad (\text{according to (2.2)}),
\]
which concludes to the result of the lemma. \( \square \)

From the last lemma, we obviously derive the following:

**Lemma 2.5.** Let \( n \) be a fixed positive integer. Then the sequence \( (C_{n,k})_{1 \leq k \leq n} \) reaches its maximal value at \( k = \ell_n \). \( \square \)
If \( n \in \mathbb{N}^* \) is fixed, we have from Lemma 2.5 above that \( \max_{1 \leq k \leq n} C_{n,k} = C_{n,\ell_n} \); however, the exact value of \( C_{n,\ell_n} \) (in terms of \( n, q, r, u_0 \)) is complicated. The lemmas below provide studies of the sequences \((k_n)_n\), \((\ell_n)_n\) and \((C_{n,\ell_n})_n\) in order to find a good lower bound for \( C_{n,\ell_n} \) which has a simple expression in terms of \( n, q, r, u_0 \).

**Lemma 2.6.** For all positive integer \( n \), we have

\[ k_n \leq k_{n+1} \leq k_n + 1. \]

In other words, we have

\[ k_{n+1} \in \{k_n, k_n + 1\}. \]

**Proof.** Let \( n \) be a fixed positive integer. By definition of the integer \( k_n \), we have

\[ f(k_n) \leq q^n \leq q^{n+1}, \]

which implies (by definition of the integer \( k_{n+1} \)) that:

\[ k_{n+1} \geq k_n. \]

On the other hand, we have (according to (2.3) and to the definition of the integer \( k_{n+1} \)):

\[ f(k_{n+1} - 1) \leq \frac{1}{q} f(k_{n+1}) \leq \frac{1}{q} q^{n+1} = q^n, \]

which implies (by definition of the integer \( k_n \)) that:

\[ k_n \geq k_{n+1} - 1; \]

that is

\[ k_{n+1} \leq k_n + 1. \]

This completes the proof of the lemma.

**Lemma 2.7.** For all positive integer \( n \), we have

\[ \ell_{n+1} \in \{\ell_n, \ell_n + 1\}. \]

In addition, in the case when \( \ell_{n+1} = \ell_n + 1 \), we have \( \ell_n = k_n \) and \( \ell_{n+1} = k_{n+1} = k_n + 1 \).

**Proof.** Let \( n \) be a fixed positive integer. By Lemma 2.6, we have that:

\[ k_n \leq k_{n+1} \leq k_n + 1. \]

Hence

\[ \max(1, k_n) \leq \max(1, k_{n+1}) \leq \max(1, k_n + 1) = \max(0, k_n) + 1 \leq \max(1, k_n) + 1; \]

therefore

\[ \ell_n \leq \ell_{n+1} \leq \ell_n + 1. \]
This confirms the first part of the lemma.

Now, let us show the second part of the lemma. So, suppose that \( \ell_{n+1} = \ell_n + 1 \) and show that \( \ell_n = k_n \) and \( \ell_{n+1} = k_{n+1} = k_n + 1 \). Since \( \ell_n = \max(1, k_n) \geq 1 \) and \( \ell_{n+1} = \ell_n + 1 \) then \( \ell_{n+1} \geq 2 \). This implies that \( \ell_{n+1} \neq 1 \); thus \( \ell_{n+1} = k_{n+1} \) (since \( \ell_{n+1} = \max(1, k_{n+1}) \in \{1, k_{n+1}\} \)). Using this and Lemma 2.6 above, we derive that: \( \ell_n = \ell_{n+1} - 1 = k_{n+1} - 1 \leq (k_n + 1) - 1 = k_n \); that is \( \ell_n \leq k_n \). But since \( \ell_n = \max(1, k_n) \geq k_n \), we conclude that \( \ell_n = k_n \). This completes the proof of the second part of the lemma and achieves this proof. \( \square \)

**Lemma 2.8.** For all positive integer \( n \), we have

\[
C_{n+1, \ell_{n+1}} \geq (r + 1)q^{\ell_n - 1}C_{n, \ell_n}.
\]

*Proof.* Let \( n \) be a fixed positive integer. By Lemma 2.7, we have that \( \ell_{n+1} \in \{\ell_n, \ell_{n+1}\} \). So, we have to distinguish two cases:

1st case: (if \( \ell_{n+1} = \ell_n \))

In this case, we have

\[
C_{n+1, \ell_{n+1}} = C_{n+1, \ell_n} = \frac{u_{\ell_n}u_{\ell_{n+1}}\cdots u_nu_{n+1}}{[n + 1 - \ell_n]_q!} = \frac{u_{\ell_n}u_{\ell_{n+1}}\cdots u_n}{[\ell_n - \ell_n]_q!} \cdot \frac{u_{n+1}}{[n + 1 - \ell_n]_q} = C_{n, \ell_n} \cdot \frac{u_{n+1}}{[n + 1 - \ell_n]_q}.
\]

Next, we have

\[
u_{n+1} - (r + 1)q^{\ell_n - 1}[n + 1 - \ell_n]_q = r[n + 1]_q + u_0 - (r + 1)q^{\ell_n - 1}\left(\frac{q^{n+1-\ell_n} - 1}{q - 1}\right)
\]

\[
= r\left(\frac{q^{n+1} - 1}{q - 1}\right) + u_0 - (r + 1)\left(\frac{q^n - q^{\ell_n - 1}}{q - 1}\right)
\]

\[
= \frac{r(q^{n+1} - 1) + u_0(q - 1) - (r + 1)(q^n - q^{\ell_n - 1})}{q - 1}
\]

\[
= \frac{rq^{n+1} - (r + 1)q^n + (r + 1)q^{\ell_n - 1} - r + u_0(q - 1)}{q - 1}
\]

\[
= \frac{(r(q - 1) - 1)q^n + [(r + 1)q^{\ell_n - 1} - r] + u_0(q - 1)}{q - 1}
\]

\[
\geq 0
\]

(since \( q \geq 2, r \geq 1, u_0 \geq 0 \) and \( \ell_n \geq 1 \)). Thus

\[
\frac{u_{n+1}}{[n + 1 - \ell_n]_q} \geq (r + 1)q^{\ell_n - 1}.
\]

By reporting this into (2.4), we get

\[
C_{n+1, \ell_{n+1}} \geq (r + 1)q^{\ell_n - 1}C_{n, \ell_n},
\]

as required.
2nd case: (if \( \ell_{n+1} = \ell_n + 1 \))

In this case, we have (according to Lemma 2.7): \( \ell_n = k_n \) and \( \ell_{n+1} = k_{n+1} = k_n + 1 \). Thus, we have

\[
C_{n+1,k_{n+1}} = C_{n+1,k_n} = \frac{u_{k_n+1}u_{k_n+2} \cdots u_{n+1}}{[n-k_n]!} = C_{n,k_n} \cdot \frac{u_{n+1}}{u_k} = C_{n,\ell_n} \cdot \frac{u_{n+1}}{u_k}. \tag{2.5}
\]

Next, according to the inequality of the right-hand side of (2.2) (applied for \( n + 1 \) instead of \( n \) and \( k_{n+1} \) instead of \( k \)), we have (since \( k_{n+1} \leq k_n \)):

\[
u_k = u_{k+1} \leq [(n+1) - k_{n+1} + 1] = [n - k_n + 1].
\]

Hence:

\[
u_{n+1} - (r+1)q^{\nu_n}u_k = u_{n+1} - (r+1)q^{\nu_n}u_k \geq u_{n+1} - (r+1)q^{\nu_n}[n-k_n + 1] = r\left(\frac{q^{n+1} - 1}{q-1}\right) + u_0 - (r+1)q^{\nu_n-1}\left(\frac{q^{n-k_n+1} - 1}{q-1}\right) = \frac{r(q^{n+1} - 1) + u_0(q-1) - (r+1)(q^n - q^{\nu_n-1})}{q-1} = \frac{(r(q-1) - 1)q^n + u_0(q-1) + (r+1)q^{\nu_n-1} - r}{q-1} \geq 0
\]

(since \( q \geq 2, r \geq 1, u_0 \geq 0 \) and \( k_n = \ell_n \geq 1 \)). Thus

\[
u_{n+1} \geq (r+1)q^{\nu_n-1}.
\]

By reporting this into (2.5), we get

\[
C_{n+1,\ell_{n+1}} \geq (r+1)q^{\nu_n-1}C_{n,\ell_n},
\]

as required. The proof of the lemma is complete. \( \Box \)

By induction, we derive from Lemma 2.8 above the following:

**Corollary 2.9.** For all positive integer \( n \), we have

\[
C_{n,\ell_n} \geq u_1(r+1)^{n-1}q^{\sum_{i=1}^{n-1}(\ell_i-1)}.
\]

**Proof.** Let \( n \) be a positive integer. From Lemma 2.8, we have

\[
C_{n,\ell_n} = C_{1,\ell_1} \prod_{i=1}^{n-1} \frac{C_{i+1,\ell_{i+1}}}{C_{i,\ell_i}} \geq C_{1,\ell_1} \prod_{i=1}^{n-1} \{(r+1)q^{\ell_i-1}\} = C_{1,\ell_1}(r+1)^{n-1}q^{\sum_{i=1}^{n-1}(\ell_i-1)}.
\]

Next, since \( k_1 \leq 1 \), we have \( \ell_1 = \max(1, k_1) = 1 \); hence \( C_{1,\ell_1} = C_{1,1} = \frac{u_1}{[0]q} = u_1 \). Consequently, we have

\[
C_{n,\ell_n} \geq u_1(r+1)^{n-1}q^{\sum_{i=1}^{n-1}(\ell_i-1)},
\]

as required. The corollary is proved. \( \Box \)
From Theorem 1.1 and Corollary 2.9 above, we immediately deduce the following:

**Corollary 2.10.** For all positive integer \( n \), we have
\[
\text{lcm}\{u_1, u_2, \ldots, u_n\} \geq u_1(r+1)^{n-1}q^\sum_{i=1}^{n-1}(\ell_i-1).
\]

**Proof.** Let \( n \) be a fixed positive integer. Since the positive integer \( \text{lcm}\{u_1, u_2, \ldots, u_n\} \) is obviously a multiple of the positive integer \( \text{lcm}\{u_{\ell_n}, u_{\ell_n+1}, \ldots, u_n\} \), which is a multiple of the rational number \( \frac{u_{\ell_n}u_{\ell_n+1}^{1-\ell_n}}{|n-\ell_n|!} = C_{n, \ell_n} \) (according to Theorem 1.1), then we have
\[
\text{lcm}\{u_1, u_2, \ldots, u_n\} \geq C_{n, \ell_n}.
\]
The result of the corollary then follows from Corollary 2.9. The proof is achieved. \( \square \)

**Remark.** If we allow to take \( q = 1 \) in Corollary 2.10, then we exactly obtain the result of Hong and Feng [8] (recalled in (1.2)).

Now, in order to derive from Corollary 2.10 above an explicit lower bound for \( \text{lcm}\{u_1, u_2, \ldots, u_n\} \) \( (n \geq 1) \), it remains to bound from below the \( \ell_i \)'s in terms of \( n, q, r \) and \( u_0 \). We just give here two ways to bound from below the \( \ell_i \)'s, but there are certainly other ways (perhaps more intelligent) to do this. We have the following lemmas:

**Lemma 2.11.** Let
\[
A := \max\left(0, \frac{u_0(q-1)+1-r}{2r}\right).
\]
Then, for all positive integer \( n \), we have
\[
\ell_n > \frac{1}{2} \left( n - \log r + 2 \log(A+1) \right).
\]

**Proof.** Let \( n \) be a fixed positive integer. Since the inequality of the lemma is obvious for \( \frac{\log r + 2 \log(A+1)}{\log q} \leq n \), we may assume for the sequel that \( n > \frac{\log r + 2 \log(A+1)}{\log q} \). Now, for any \( x \geq 1 \), we have
\[
f(x) := q^{x-1} \left( rq^{x-1} + u_0(q-1) + 1 - r \right)
= r \left\{ \left( q^{x-1} + \frac{u_0(q-1) + 1 - r}{2r} \right)^2 - \left( \frac{u_0(q-1) + 1 - r}{2r} \right)^2 \right\}
\leq r \left( q^{x-1} + \frac{u_0(q-1) + 1 - r}{2r} \right)^2
\leq r \left( q^{x-1} + A \right)^2
\leq r \left( q^{x-1} + Aq^{x-1} \right)^2
= r(A+1)^2q^{2(x-1)}.
\]
By applying this for
\[
x_0 := \frac{1}{2} \left( n - \frac{\log r + 2 \log(A+1)}{\log q} \right) + 1
\]
(which is > 1 according to our assumption $n > \frac{\log r + 2\log(A+1)}{\log q}$), we get

$$f(x_0) \leq r(A+1)^2 q^{n - \frac{\log r + 2\log(A+1)}{\log q}} = q^n.$$  

Then, since $f$ is increasing and $|x_0| \leq x_0$, we derive that:

$$f([x_0]) \leq f(x_0) \leq q^n,$$

which implies (according to the definition of $k_n$) that:

$$k_n \geq |x_0| > x_0 - 1.$$  

Hence:

$$\ell_n := \max(1, k_n) \geq k_n > x_0 - 1,$$

that is

$$\ell_n > \frac{1}{2} \left( n - \frac{\log r + 2\log(A+1)}{\log q} \right),$$

as required. The lemma is proved. □

**Lemma 2.12.** Let

$$B := \max\left( r, \frac{u_0(q-1) + 1 - r}{2} \right).$$

Then, for all positive integer $n$, we have

$$\ell_n > \frac{1}{2} \left( n - \frac{\log(4B)}{\log q} \right).$$

**Proof.** Let $n$ be a fixed positive integer. Since the inequality of the lemma is obvious for $n \leq \frac{\log(4B)}{\log q}$, we may assume for the sequel that $n > \frac{\log(4B)}{\log q}$. Now, for any $x \geq 1$, we have

$$f(x) := q^{x-1} (r q^{x-1} + u_0(q-1) + 1 - r)$$

$$\leq q^{x-1} (B q^{x-1} + 2B)$$

$$< B (q^{x-1} + 1)^2$$

$$\leq B (2q^{x-1})^2$$

$$= 4Bq^{2(x-1)}.$$

By applying this for

$$x_1 := \frac{1}{2} \left( n - \frac{\log(4B)}{\log q} \right) + 1$$

(which is > 1 according to our assumption $n > \frac{\log(4B)}{\log q}$), we get

$$f(x_1) \leq 4Bq^{\frac{\log(4B)}{\log q}} = q^n.$$  

Then, since $f$ is increasing and $|x_1| \leq x_1$, we derive that:

$$f([x_1]) \leq f(x_1) \leq q^n,$$

12
which implies (according to the definition of $k_n$) that:

$$k_n \geq \lfloor x_1 \rfloor > x_1 - 1 = \frac{1}{2} \left( n - \frac{\log(4B)}{\log q} \right).$$

Hence

$$\ell_n := \max(1, k_n) \geq k_n > \frac{1}{2} \left( n - \frac{\log(4B)}{\log q} \right),$$

as required. The lemma is proved.

We are now ready to prove Theorems 1.2 and 1.3 announced in §1.

**Proof of Theorem 1.2.** By using successively Corollary 2.10 and Lemma 2.11, we have for all $n \in \mathbb{N}^*$:

$$\text{lcm} \{u_1, u_2, \ldots, u_n\} \geq u_1(r + 1)^{n-1}q^{\sum_{i=1}^{n-1}(\ell_i-1)}$$

$$\geq u_1(r + 1)^{n-1}q^{\frac{(n-1)(n-4)}{4} - \frac{1}{2}\log r + 2\log(\frac{A+1}{q})}$$

$$= u_1 \left( \frac{r + 1}{\sqrt{B(A+1)}} \right)^{n-1}q^{\frac{(n-1)(n-4)}{4}},$$

as required.

**Proof of Theorem 1.3.** By using successively Corollary 2.10 and Lemma 2.12, we have for all $n \in \mathbb{N}^*$:

$$\text{lcm} \{u_1, u_2, \ldots, u_n\} \geq u_1(r + 1)^{n-1}q^{\sum_{i=1}^{n-1}(\ell_i-1)}$$

$$\geq u_1(r + 1)^{n-1}q^{\frac{(n-1)(n-4)}{4} - \frac{1}{2}\log(4B)}$$

$$= u_1 \left( \frac{r + 1}{\sqrt{B}} \right)^{n-1}q^{\frac{(n-1)(n-4)}{4}},$$

as required.

**Proof of Corollary 1.4.** It suffices to remark that $v_n = a(q - 1)[n]_q + a + b$ ($\forall n \in \mathbb{N}$) and then to apply Theorem 1.2 for the sequence $(v_n)_{n \in \mathbb{N}}$. We just specify that the imposed conditions $\gcd(aq, b) = 1$ ($\forall n \in \mathbb{N}$) guarantee the conditions $\gcd(v_0, r) = 1$ required in Theorem 1.2 (with $r := a(q - 1)$).

**Proof of Corollary 1.5.** We simply apply Theorem 1.3 for the sequence $(v_n)_{n \in \mathbb{N}}$, after noticing that its general term can be written as: $v_n = a(q - 1)[n]_q + a + b$.

3 Numerical examples and remarks

By applying our main results, we get for example the following nontrivial effective estimates:

- $\text{lcm}\{2^1 - 1, 2^2 - 1, \ldots, 2^n - 1\} \geq 2^{\frac{n(n-1)}{4}}$ ($\forall n \geq 1$)

  (Apply Theorem 1.2 for $u_n = [n]_2 = 2^n - 1$).
• \( \text{lcm}\{2^1 + 1, 2^2 + 1, \ldots, 2^n + 1\} \geq 3 \cdot 2^{\frac{(n-1)(n-4)}{4}} \) \((\forall n \geq 1)\).

(Apply one of the two corollaries 1.4 or 1.5 for \( v_n = 2^n + 1 \)).

• \( \text{lcm}\{3^1 + 1, 3^2 + 1, \ldots, 3^n + 1\} \geq 4 \cdot 3^{\frac{(n-1)(n-4)}{4}} \) \((\forall n \geq 1)\).

(Remark that \( \text{lcm}\{3^1 + 1, 3^2 + 1, \ldots, 3^n + 1\} = 2 \text{lcm}\{\frac{3^1+1}{2}, \frac{3^2+1}{2}, \ldots, \frac{3^n+1}{2}\} \) and apply one of the two theorems 1.2 or 1.3 for \( u_n = n_3 + 1 = \frac{3^n+1}{2} \)).

Remarks.

1. Theorems 1.2 and 1.3 are incomparable in the sense that there are situations where Theorem 1.2 is stronger than Theorem 1.3 and other situations where we have the converse. For example, it is easy to verify that if \( u_0(q-1) + 1 - r \leq 0 \) then Theorem 1.2 is stronger than Theorem 1.3, while if \( u_0(q-1) + 1 - 3r > 0 \) then Theorem 1.3 is stronger than Theorem 1.2.

2. By refining the arguments of bounding from below the \( \ell_i \)'s (that is the arguments of the proofs of Lemmas 2.11 and 2.12), it is perhaps possible to obtain a lower bound for \( \text{lcm}\{u_1, u_2, \ldots, u_n\} \) \((n \geq 1)\) of the form:

\[
\text{lcm}\{u_1, u_2, \ldots, u_n\} \geq c \left( \frac{r+1}{\sqrt{r}} \right)^{n-1} q^{\frac{(n-1)(n-4)}{4}},
\]

where \( c \) is a positive constant depending only on \( q, r \) and \( u_0 \). It appears that this is the best that can be expected from this method!

3. It is remarkable that our lower bounds of \( \text{lcm}\{u_1, u_2, \ldots, u_n\} \), for the considered sequences \((u_n)_n\), are quite close to \( \sqrt{u_1u_2 \cdots u_n} \). More precisely, we can easily deduce from our main results that in the same context, we have \( \text{lcm}\{u_1, u_2, \ldots, u_n\} \geq c_3 c_4^n \sqrt{u_1u_2 \cdots u_n} \), for some suitable positive constants \( c_3 \) and \( c_4 \), depending only on \( q, r \) and \( u_0 \).

4. There is something in common between our results and the recent result by Bousla and Farhi [3] providing effective bounds for \( \text{lcm}(U_1, U_2, \ldots, U_n) \), when \((U_n)_{n \in \mathbb{N}}\) is a particular Lucas sequence; precisely, when \((U_n)_n\) is recursively defined by: \( U_0 = 0, U_1 = 1 \) and \( U_{n+2} = PU_{n+1} - QU_n \) \((\forall n \in \mathbb{N})\) for some \( P, Q \in \mathbb{Z}^* \), with \( P^2 - 4Q > 0 \) and \( \gcd(P, Q) = 1 \). Indeed, if we take \( P = q+1 \) and \( Q = q \) (for some integer \( q \geq 2 \)), we obtain that \( U_n = [n]_q \) and the Bousla-Farhi lower bound then gives:

\[
\text{lcm}\left(\left[1\right]_q, \left[2\right]_q, \ldots, \left[n\right]_q\right) \geq q^{\frac{q^2 - q}{2} - 1} \quad (\forall n \geq 1),
\]

which is almost the same as what obtained in this paper.
