EXTENSION QUIVER FOR LIE SUPERA LGBRA $q(3)$

NIKOLAY GRANTCHAROV AND VERA SERGAN NOVA

ABSTRACT. We describe all blocks of the category of finite-dimensional $q(3)$-supermodules by providing their extension quivers. We also obtain two general results about the representation of $q(n)$: we show that the Ext quiver of the standard block of $q(n)$ is obtained from the principal block of $q(n-1)$ by identifying certain vertices of the quiver and prove a “virtual” BGG-reciprocity for $q(n)$. The latter result is used to compute the radical filtrations of $q(3)$ projective covers.

INTRODUCTION

The “queer” Lie superalgebra $q(n)$ is an interesting super analogue of the Lie algebra $gl(n)$. Other related queer-type Lie superalgebras include the subsuperalgebra $sq(n)$ obtained by taking odd trace 0, and for $n \geq 3$, the simple Lie superalgebra $psq(n)$ obtained by taking the quotient of the commutator $[q(n), q(n)]$ by the center. These queer superalgebras have a rich representation theory, partly due to the Cartan subsuperalgebra $\mathfrak{h}$ not being abelian and hence having nontrivial representations, called Clifford modules.

Finite-dimensional representation theory of $q(n)$ was initiated in [Kac] and developed in [P]. Algorithms for computing characters of irreducible finite-dimensional representations were obtained in [PS1], [PS2] using methods of supergeometry and in [B1], [B2] using a categorification approach. Finite-dimensional representations of half-integer weights were studied in detail in [CK], [CKW], [B3]. In [Maz], the blocks in the category of finite-dimensional $q(2)$-modules semisimple over the even part were classified and described using quivers and relations. A general classification of blocks was obtained in [Ser-ICM] using translation functors and supergeometry.

In this paper, we describe the blocks in the category of finite-dimensional $q(3)$ and $sq(3)$ modules semisimple over the even part in terms of quiver and relations. We found that to describe blocks of $q(n)$ in general, it remains to consider the principal block. For $n = 3$, this is the first example of a wild block in $q$. Our main tools are relative Lie superalgebra cohomology and geometric induction.

In section 1, we describe some background information for $q(n)$ and quivers, and we formulate our main theorems, Theorem 1.5 and Theorem 1.6. In section 2, we introduce geometric induction and prove a “virtual” BGG reciprocity law, Theorem 2.2, that generalizes [GS2] to the queer Lie superalgebras. This result allows us to describe radical filtrations of all finite-dimensional indecomposable projective modules for $sq(3)$ and $q(3)$. Diagrams of these are provided in section 6, the appendix. In section 3, we prove a result on self extensions of simples for $g = q(n)$, Theorem 3.1 and for $g = sq(n)$, Theorem 3.2. In section 4, we show the standard block for $q(n)$ is closely related to the principal block of $q(n-1)$, Proposition 4.1.1 and in particular deduce the quiver for $sq(3), q(3)$ standard block. Finally in section 5, we compute the quiver for principal block of $sq(3), q(3)$.

1. Preliminaries and Main Theorem

1.1. General Definitions. Throughout we work with $\mathbb{C}$ as the ground field. We set $\mathbb{Z}_2 = \mathbb{Z}/2\mathbb{Z}$. Recall that a vector superspace $V = V_0 \oplus V_1$ is a $\mathbb{Z}_2$-graded vector space. Elements of $V_0$ and $V_1$ are called even and odd, respectively. If $V, V'$ are superspaces, then the space $\text{Hom}_{\mathbb{C}}(V, V')$ is naturally $\mathbb{Z}_2$ graded with grading $f \in \text{Hom}_{\mathbb{C}}(V, V')$, if $f(V_r) \subset V'_{r+s}$ for all $r \in \mathbb{Z}_2$.

A superalgebra is a $\mathbb{Z}_2$-graded, unital, associative algebra $A = A_0 \oplus A_1$ which satisfies $A_r A_s \subset A_{r+s}$. A Lie superalgebra is a superspace $g = g_0 \oplus g_1$ with bracket operation $[,] : g \otimes g \to g$ which preserves the graded version of the usual Lie bracket axioms. The universal enveloping algebra $U(g)$ is $\mathbb{Z}_2$-graded and satisfies a PBW type theorem \cite{Kac}. A $g$-module is a left $\mathbb{Z}_2$-graded $U(g)$-module. A morphism of $g$-modules $M \to M'$ is an element of $\text{Hom}_{\mathbb{C}}(M, M')_0$ satisfying $f(xm) = xf(m)$ for all $m \in M, x \in U(g)$. We denote by $g$-mod the category of $g$-modules. This is a symmetric monoidal category. The primary category of interest $\mathcal{F}$ consists of finite-dimensional $g$-modules which are semisimple over $g_0$. We stress that we only allow for parity preserving morphisms in $\mathcal{F}$. In this way, $\mathcal{F}$ is an abelian rigid symmetric monoidal category: for $V, W \in \mathcal{F}$, define $V \otimes W$ and $V^*$ using the coproduct and antipode of $U(g)$, respectively:

$$\delta(x) = x \otimes 1 + 1 \otimes x, \quad S(x) = -x \quad \forall x \in g.$$

For $V \in g$-mod, we denote by $S(V)$ the symmetric superalgebra. As a $g_0$-module, $S(V)$ is isomorphic to $S(V) = S(V_0) \otimes \Lambda(V_1)$, where $\Lambda(V_1)$ is the exterior algebra of $V_1$ in the category of vector spaces. For $V$ a $g_1$-module and $W$ a $g_2$-module, we define the outer tensor product $V \boxtimes W$ to be the $g_1 \oplus g_2$-module with the action for $(q_1, q_2) \in g_1 \oplus g_2$ given by

$$(q_1, q_2)(v \boxtimes w) := (-1)^{qr} (q_1 v \boxtimes q_2 w).$$

We define the (super)dimension of $V \in g$-mod as follows. Let $C[\varepsilon]$ be polynomial algebra with variable $\varepsilon$ and denote two-dimensional $C$-algebra $C[\varepsilon]/(\varepsilon^2 - 1)$ as $C$. Then

$$\dim(V) := \dim_{\mathbb{C}}(V_0) + \dim_{\mathbb{C}}(V_1)\varepsilon \in \tilde{C}.$$

The parity change functor $\Pi : A - \text{sm} \to A - \text{sm}$ is defined as follows: For $M \in A - \text{sm}$, $\Pi(M)_{0} := M_1$ and $\Pi(M)_1 := M_0$ and the action on $m \in \Pi(M)$ is $a \cdot m = (-1)^{a} m a$. Lastly, if $f : M \to N$ is a morphism of supermodules, then $\Pi f : \Pi M \to \Pi N$ is $\Pi f = f$.

1.2. The queer Lie superalgebra $q(n)$. By definition, the queer Lie superalgebra $q(n)$ is the Lie subsuperalgebra of $gl(n|n)$ leaving invariant an odd automorphism of the standard representation $p$ with the property $p^2 = -1$. In matrix form,

$$q(n) = \left\{ \begin{pmatrix} A & B \\ B & A \end{pmatrix} : A, B \in gl_n(\mathbb{C}) \right\}, \quad \text{if } p = \begin{pmatrix} 0 & 1_n \\ -1_n & 0 \end{pmatrix}.$$ 

Let $g = q(n)$. The even (resp. odd) subspace of $g$ consists of block matrices with $B = 0$ (resp. $A = 0$). For $1 \leq i, j \leq n$, we define the standard basis elements as

$$e_{i,j}^0 = \begin{pmatrix} E_{i,j} & 0 \\ 0 & E_{i,j} \end{pmatrix} \in g_0 \quad \text{and} \quad e_{i,j}^1 = \begin{pmatrix} 0 & E_{i,j} \\ E_{i,j} & 0 \end{pmatrix} \in g_1,$$

where $E_{i,j}$ denote the elementary matrix. Observe the odd trace $\text{otr}(\begin{pmatrix} A & B \\ B & A \end{pmatrix}) := \text{tr}(B)$ annihilates the commutator $[q(n), q(n)]$. Let

$$sq(n) = \{ X \in q(n) : \text{otr}(X) = 0 \}.$$

Furthermore, $\text{otr}(XY)$ defines a nondegenerate $g$-invariant odd bilinear form on $g$. In particular, we have an isomorphism $q(n)^* \cong \Pi q(n)$ of $q(n)$-modules.
All Borel Lie superalgebras $\mathfrak{b} \subset \mathfrak{g}$ are conjugate to the “standard” Borel, i.e., block matrices where $A, B \in \mathfrak{gl}(n)$ are upper triangular. The nilpotent subsuperalgebra $\mathfrak{n}$ consists of block matrices where $A, B$ are strictly upper triangular.

In the standard basis, the supercommutator has the form

$$[e_{ij}^\sigma, e_{kl}^\tau] = \delta_{jk} e_{il}^{\sigma+\tau} - (-1)^{\sigma \tau} \delta_{il} e_{kj}^{\sigma+\tau},$$

where $\sigma, \tau \in \mathbb{Z}_2$. The Cartan superalgebra $\mathfrak{h}$ has basis $e_{ii}^\sigma$ for $1 \leq i \leq n, \sigma \in \mathbb{Z}_2$. The elements $H_i := e_{ii}^0, \overline{H}_i := e_{ii}^1, 1 \leq i \leq n,$ form a basis for $\mathfrak{h}_0, \mathfrak{h}_1,$ respectively. Let $\{\epsilon_i | i = 1, \ldots, n\} \subset \mathfrak{h}_0^*$ denote the dual basis of $\{H_i\}$. There is a root decomposition of $\mathfrak{g}$ with respect to the Cartan subalgebra $\mathfrak{h}$ given by

$$\mathfrak{g} = \mathfrak{h} \oplus \bigoplus_{\alpha \in \Phi} \mathfrak{g}_\alpha,$$

where $\Phi = \{\epsilon_i - \epsilon_j | 1 \leq i \neq j \leq n\}$ is the same as the set of roots of $\mathfrak{gl}_n(\mathbb{C})$. For a root $\alpha = \epsilon_i - \epsilon_j$ we have $\dim \mathfrak{g}_\alpha = 1 + \varepsilon$ because $\mathfrak{g}_\alpha = \text{span}\{e_{ij}^\sigma : \sigma \in \mathbb{Z}_2\}$. The positive roots are $\Phi^+ := \{\epsilon_i - \epsilon_j : 1 \leq i < j \leq n\}$. The simple roots are $\{\epsilon_i - \epsilon_{i+1} : 1 \leq i \leq n - 1\}$. The Weyl group for $\mathfrak{q}(n)$ is $W = S_n$, the symmetric group on $n$ letters.

By $\mathfrak{h}'$ we denote the Cartan subalgebra of $\mathfrak{so}(n)$. A weight is by definition an element $\lambda \in \mathfrak{h}_0^*$ and we write it in the form $\lambda = (\lambda_1, \ldots, \lambda_n)$ with respect to the standard basis $(\epsilon_1, \ldots, \epsilon_n)$. We say $\lambda$ is integral if $\lambda_i \in \mathbb{Z}$ for all $1 \leq i \leq n$. We say $(\lambda_1, \ldots, \lambda_n) \in \mathfrak{h}_0^*$ is typical if $\lambda_i + \lambda_j \neq 0$ for all $1 \leq i \neq j \leq n$. We introduce partial ordering on $\mathfrak{h}_0^*$ via $\lambda \leq \mu$ if and only if $\mu - \lambda \in \mathbb{N}\Phi^+$. Finally, we define $\rho_0 := 1/2 \sum_{\alpha \in \Phi^+} \alpha$.

1.3. Irreducible $\mathfrak{h}$ and $\mathfrak{g}$-representations. Following [2] Prop.1, we now define for each $\lambda \in \mathfrak{h}_0^*$ a simple $\mathfrak{h}$-supermodule. Define an even superantisymmetric bilinear form $F_\lambda : \mathfrak{h}_\lambda \times \mathfrak{h}_\lambda \to \mathbb{C}$ as $F_\lambda(u, v) := \lambda([u, v])$. Let $K_\lambda = \text{Ker} F_\lambda$ and $E_\lambda = \mathfrak{h}_1/K_\lambda$. The restriction of $F_\lambda$ to $\mathfrak{h}'$ will be denoted by $F_\lambda'$ and we set $K'_\lambda = \text{Ker} F_\lambda'$ and $E'_\lambda = \mathfrak{h}'_1/K'_\lambda$.

**Lemma 1.3.1.** Let $\lambda = (\lambda_1, \ldots, \lambda_n) \in \mathfrak{h}_0^*$.

(a) If there exists $i$ such that $\lambda_i = 0$, then

$$\dim E_\lambda = \dim E_\lambda' = |\{i : \lambda_i \neq 0\}|.$$

(b) If all $\lambda_i \neq 0$ and $\frac{\lambda_1}{\lambda_1} + \cdots + \frac{\lambda_n}{\lambda_n} \neq 0$, then

$$\dim E_\lambda' = n - 1, \quad \dim E_\lambda = n.$$

(c) If all $\lambda_i \neq 0$ and $\frac{\lambda_1}{\lambda_1} + \cdots + \frac{1}{\lambda_n} = 0$, then

$$\dim E_\lambda' = n - 2, \quad \dim E_\lambda = n.$$

**Proof.** It is straightforward that $K_\lambda$ is the span of $\overline{H}_i$ for all $i$ such that $\lambda_i \neq 0$. Hence

$$\dim E_\lambda = |\{i : \lambda_i \neq 0\}|.$$

To compute $K'_\lambda$, consider the basis $\{\overline{H}_i - \overline{H}_{i+1} | i = 1, \ldots, n - 1\}$ of $\mathfrak{h}'_1$. Then

$$K'_\lambda = \{u \in \mathfrak{h}'_1 : \lambda([u, \overline{H}_i - \overline{H}_{i+1}] | i = 1, \ldots, n - 1\} = \{u_1, \ldots, u_n\} \subset \mathfrak{h}_1 : u_1 + \cdots + u_n = 0, u_i \lambda_i = u_{i+1} \lambda_{i+1} \text{ for all } 1 \leq i \leq n - 1\}.$$

Suppose without loss of generality $\lambda_1 = \cdots = \lambda_k = 0$, where $k \geq 1$. This forces $u_{k+1} = \cdots = u_n = 0$ and $u_1 + \cdots + u_k = 0$, so $K'_\lambda$ has a basis

$$\{\overline{H}_1 - \overline{H}_2, \ldots, \overline{H}_{k-1} - \overline{H}_k\}$$

and $\dim K'_\lambda = k - 1$. Thus, $\dim E'_\lambda = \dim \mathfrak{h}'_1 - \dim K'_\lambda = n - k$. 
Next, suppose all \( \lambda_i \neq 0 \). Then similarly we compute

\[
K'_{\lambda} = \begin{cases}
\mathbb{C}(\frac{1}{\lambda_1}, \frac{1}{\lambda_2}, \ldots, \frac{1}{\lambda_n}) & \text{if } \frac{1}{\lambda_1} + \ldots + \frac{1}{\lambda_n} = 0 \\
0 & \text{if } \frac{1}{\lambda_1} + \ldots + \frac{1}{\lambda_n} \neq 0.
\end{cases}
\]

Let \( \dim E_{\lambda} = m > 0 \). On the vector superspace \( E_{\lambda} \), \( F_{\lambda} \) induces a nondegenerate bilinear form, also denoted \( F_{\lambda} \). Let \( \text{Cliff}(\lambda) \) be the Clifford superalgebra defined by \( E_{\lambda} \) and \( F_{\lambda} \). Then \( (1) \) \( \text{Cliff}(\lambda) \) is isomorphic to \( \text{Cliff}(m) \), the Clifford superalgebra with generators \( e_1, \ldots, e_m \) and relations \( e_i^2 = 1 \), \( (2) \) \( \dim \text{Cliff}(\lambda) = 2^{m-1}(1+\varepsilon) \), and \( (3) \) the category \( \text{Cliff}(\lambda)-\text{mod} \) is semisimple (e.g. \cite{Mein}).

If \( m \) is odd, then there exists a unique simple \( \text{Cliff}(m) \)-module, denoted by \( v(m) \), which is invariant under parity change (this follows from existence of an odd automorphism). If \( m \) is even, then there exists 2 nonisomorphic simple \( \text{Cliff}(m) \)-modules \( v(m) \) and \( Hv(m) \) which are swapped by the parity change functor. Using the surjective homomorphism \( U(\mathfrak{h}) \to \text{Cliff}(\lambda) \) with kernel \( (H_i - \lambda_i, K_\lambda) \), we lift \( v(m) \) to an \( \mathfrak{h} \)-module which we denote by \( v(\lambda) \). Lemma \[3.1\] implies

\[
\dim v(\lambda) = \dim(v(m)) = 2^{(m-1)/2}(1+\varepsilon),
\]

where \([x]\) denotes the integer part of \( x \in \mathbb{R} \). Furthermore, this construction provides a complete irredundant collection of all finite-dimensional simple \( \mathfrak{h} \)-supermodule.

Next define the Verma module

\[
M_{\mathfrak{g}}(\lambda) := U(\mathfrak{g}) \otimes_{U(\mathfrak{h})} v(\lambda),
\]

where the action of \( \mathfrak{n}^+ \) on \( v(\lambda) \) is trivial.

Let

\[
\Lambda = \{ \lambda = (\lambda_1, \ldots, \lambda_n) \in \mathfrak{h}_0^* : \lambda_i - \lambda_{i+1} \in \mathbb{Z} \text{ and } \lambda_i = \lambda_j \Rightarrow \lambda_i = \lambda_j = 0 \}.
\]

The set of \( \mathfrak{g} \)-dominant integral weights is

\[
\Lambda^+ = \{ \lambda = (\lambda_1, \ldots, \lambda_n) \in \mathfrak{h}_0^* : \lambda_i - \lambda_{i+1} \in \mathbb{Z}_{\geq 0} \text{ and } \lambda_i = \lambda_j \Rightarrow \lambda_i = \lambda_j = 0 \}.
\]

Below is the main theorem about irreducible \( \mathfrak{g} \)-modules, first proven by V. Kac.

**Theorem 1.1.** [Kac]

1. For any weight \( \lambda \in \mathfrak{h}_0^* \), \( M_{\mathfrak{g}}(\lambda) \) has a unique maximal submodule \( N(\lambda) \), hence a unique simple quotient, \( L_{\mathfrak{g}}(\lambda) \).
2. For each finite dimensional irreducible \( \mathfrak{g} \)-module \( V \), there exists a unique weight \( \lambda \in \Lambda^+ \) such that \( V \) is a homomorphic image of \( M_{\mathfrak{g}}(\lambda) \).
3. \( L_{\mathfrak{g}}(\lambda) := M_{\mathfrak{g}}(\lambda)/N_{\mathfrak{g}}(\lambda) \) is finite dimensional if and only if \( \lambda \in \Lambda^+ \).

We will often omit the subscript \( \mathfrak{g} \) in the notation for Verma, simple, and projective modules.

1.4. The Category \( \mathcal{F} \). Let \( \mathfrak{g} = \mathfrak{g}(n) \). Denote by \( \mathcal{F}^n \), or simply \( \mathcal{F} \) the category consisting of finite-dimensional \( \mathfrak{g} \)-supermodules semisimple over \( \mathfrak{g}_0 \) (so the center of \( \mathfrak{g}_0 \) acts semisimply), with morphisms being parity preserving. The full subcategory of \( \mathcal{F} \) consisting of modules with integral weights is equivalent to the category of finite-dimensional \( G \)-modules, where \( G \) is the algebraic supergroup with \( \text{Lie}(G) = \mathfrak{g} \) and \( G_0 = GL(n) \).

Let \( Z(\mathfrak{g}) \) be the center of the universal enveloping algebra \( U(\mathfrak{g}) \). A central character is a homomorphism \( \chi : Z(U(\mathfrak{g})) \to \mathbb{C} \). We say that a \( \mathfrak{g} \)-module \( M \) has central character \( \chi \) if for any \( z \in Z(\mathfrak{g}) \), \( m \in M \), there exists a positive integer \( n \) such that \((z - \chi(z)\text{id})^n.m = 0 \). It is well known from linear algebra that any finite-dimensional indecomposable \( \mathfrak{g} \)-module has a central character, hence \( \mathcal{F}^n = \oplus \mathcal{F}^n_{\chi} \), where \( \mathcal{F}^n_{\chi} \) is the subcategory of modules admitting central character \( \chi \). In the most cases \( \mathcal{F}^n_{\chi} \) is indecomposable, i.e. a block in the category \( \mathcal{F}^n \). The only exception is \( \mathcal{F}^n_\chi \) for even \( n \) and typical central character \( \chi \). In this case \( \mathcal{F}^n_\chi \) is semisimple and has two non-isomorphic simple objects \( L(\lambda) \) and \( \Pi L(\lambda) \).
Similarly to the Lie algebra case, there is a canonical injective algebra homomorphism, the Harish-Chandra homomorphism:

\[ \text{HC} : Z(g) \hookrightarrow S(h_0)^W, \]

\[ \text{HC} : Z(g) \hookrightarrow S(h_0)^W, \]

(Serg, CW). Given any \( \lambda \in h_0^* \), we define \( \chi_\lambda : Z(g) \to C \) to be the unique homomorphism making

\[ Z(g) \xrightarrow{\chi_\lambda} S(h_0)^W \]

\[ \xrightarrow{\text{HC}} \]

\[ C \]

commute, where \( \lambda^W \) is the natural homomorphism induced by \( \lambda \in h_0^* \). If \( \chi = \chi_\lambda \) for some \( \lambda \), we denote \( \mathcal{F}_\chi \) by \( \mathcal{F}_\lambda \). Given a central character \( \chi_\lambda \) with \( \lambda = (\lambda_1,..,\lambda_n) \), we define its weight to be the formal sum

\[ \text{wt}(\lambda) := \delta_{\lambda_1} + \ldots + \delta_{\lambda_n}, \]

where \( \delta_i = -\delta_i - \delta_0 = 0 \). A fundamental result by Sergeev \( \text{Serg} \) implies:

**Theorem 1.2.** For \( \lambda, \mu \in h_0^* \), \( \chi_\lambda = \chi_\mu \) if and only if \( \text{wt}(\lambda) = \text{wt}(\mu) \).

The following classification theorem about blocks in \( \mathcal{F}^3 \) is important for us. It is an immediate consequence of [Ser-ICM Theorem 5.8].

**Theorem 1.3.** \( \lambda = (\lambda_1, \lambda_2, \lambda_3) \in \Lambda^+ \cap \mathbb{Z}^3 \) be a dominant integral weight and \( |\lambda| \) be the number of non-zero coordinates in \( \text{wt}(\lambda) \).

- (the strongly typical block) If \( |\lambda| = 3 \) then \( \mathcal{F}_\lambda^3 \) is semisimple and contains one up to isomorphism simple module;
- (the typical block) If \( |\lambda| = 2 \) then \( \mathcal{F}_\lambda^3 \) is equivalent to the block \( \mathcal{F}_{(0)}^1 \) for \( q(1) \);
- (the standard block) If \( |\lambda| = 1 \) then \( \mathcal{F}_\lambda^3 \) is equivalent to \( \mathcal{F}_{(1,0,0)}^3 \);
- (the principal block) If \( |\lambda| = 0 \) then \( \mathcal{F}_\lambda^3 \) is equivalent to \( \mathcal{F}_{(0,0,0)}^3 \).

Furthermore, if \( \lambda \in \Lambda^+ \) but \( \lambda \notin \mathbb{Z}^3 \), then either \( \lambda \) is typical, so \( \lambda_i + \lambda_j \neq 0 \) \( \forall i, j \), or \( \lambda \) has atypicality 1. In the former case the block is semisimple and has one up to isomorphism simple object. In the latter case all such blocks are equivalent to the “half-standard” block \( \mathcal{F}_{(3/2,1/2,-1/2)} \) by [B3] Theorem 5.21.

Finally, it is well known there are enough projective and injective objects in \( \mathcal{F} \) [Ser1]. Let \( P_\theta(\lambda) \) denote the projective cover of \( L_\theta(\lambda) \).

1.5. **Quivers.** Let \( \mathcal{F} \) be any abelian \( C \)-linear category with enough projectives, finite-dimensional morphism spaces, and finite-length composition series for all objects. For us, \( \mathcal{F} \) will be as in the previous subsection. The following properties are as stated in [Ger Sect. 1], which are just slight generalizations of results in [Ben Sect. 4.1].

An Ext-quiver \( Q \) for \( \mathcal{F} \) is a directed graph with vertex set consisting of isomorphism classes of finite-dimensional simple objects of \( \mathcal{F} \). In our case, \( Q = \{ L(\lambda), \Pi L(\lambda) \} \) for \( \lambda, \Pi \lambda \in \Lambda^+ \). We use the notation \( \Pi \lambda \in \Lambda^+ \) to distinguish the simple object \( \Pi L(\lambda) \) from \( L(\lambda) \) when they are nonisomorphic. The number of arrows between two objects \( \lambda, \mu \) will be \( d_{\lambda, \mu} := \dim \text{Ext}^1_C(L(\lambda), L(\mu)) \). We define a \( C \)-linear category \( CQ \) with objects being vertices of \( Q \) and morphisms \( \text{Hom}_{CQ}(\lambda, \mu) \) being space of formal linear combinations of paths between the two objects \( \lambda, \mu \). Composition of morphisms is concatenation of paths.

A system of relations on \( Q \) is a map \( R \) which assigns a subspace \( R(\lambda, \mu) \subset \text{Hom}_{CQ}(\lambda, \mu) \) to each pair of vertices \( (\lambda, \mu) \in \Lambda^+ \times \Lambda^+ \) such that for any \( \lambda, \mu, \nu \in \Lambda^+ \)

\[ R(\nu, \mu) \circ \text{Hom}_{CQ}(\lambda, \nu) \subset R(\lambda, \mu) \quad \text{and} \quad \text{Hom}_{CQ}(\nu, \mu) \circ R(\lambda, \nu) \subset R(\lambda, \mu). \]
A representation of $Q$ is a finite-dimensional $\Lambda^+$-graded vector space $V = \bigoplus_{\lambda \in \Lambda^+} V_\lambda$ together with linear maps $\phi|_V : V_\lambda \to V_\mu$ for every arrow $\phi : \lambda \to \mu$. Representations of $Q$ form an Abelian category denoted by $Q$-mod. Given quiver $Q$ and relations $R$, define the category $\mathcal{C}Q/R$ consisting of objects $\lambda \in \Lambda^+$ and morphisms $\text{Hom}_{\mathcal{C}Q/R}(\lambda, \mu) := \text{Hom}_{\mathcal{C}Q}(\lambda, \mu)/R(\lambda, \mu)$. We then denote by $\mathcal{C}Q/R$-mod the full subcategory of $\mathcal{C}Q$-mod consisting of representations $V$ such that for any vertices $\lambda, \mu$, we have $\text{Im}(R(\lambda, \mu)) \to \text{Hom}_{\mathcal{C}Q}(V_\lambda, V_\mu) = 0$.

The next proposition gives an explicit description of the relations of an Ext-quiver given the relations as defined in Proposition 1.5.1. Then there exists a unique well-defined family of linear maps

$$\overline{R}_{\lambda, \mu} : \text{Hom}_Q(\lambda, \mu) \to \text{Hom}_F(\mu, \lambda),$$

such that $\overline{R}_{\lambda, \mu}(\phi^i_{\lambda, \mu}) = R_{\lambda, \mu}(\phi^i_{\lambda, \mu})$ and which is compatible with composition.

Moreover, the map

$$R : (\lambda, \mu) \to \text{Ker}\overline{R}_{\lambda, \mu}$$

is a system of relations on $Q$ and the categories $\mathcal{C}Q/R$ and $\mathcal{G}^{\text{op}}$ are equivalent.

The system of relations is determined up to a choice of $R_{\lambda, \mu}$, which is not canonical in general. But, we may multiply the $R_{\lambda, \mu}(\phi^i_{\lambda, \mu})$ by nonzero scalars to make the relations “look nice.” There is then an additional proposition, [Ger, Proposition 1.2.2], which states $\mathcal{G}^{\text{op}}$ is equivalent to $\mathcal{F}$. This then implies the following important theorem of Ext-quivers we use.

**Theorem 1.4.** ([Ger, Theorem 1.4.1]) Let $\mathcal{F}$ be as above, Q its Ext-quiver, and $R$ be a system of relations as defined in Proposition 1.5.1. Then there exists an equivalence of categories

$$e : \mathcal{F} \xrightarrow{\sim} \mathcal{C}Q/R - \text{mod}$$

such that

$$e(M) = \bigoplus_{\lambda \in \Lambda^+} \text{Hom}_{\mathcal{F}}(P(\lambda), M)$$

**1.6. Main Theorem.** In the statement of the main theorems, we will provide the Ext-quivers of various blocks. The relations are given by labelling the $\dim \text{Ext}^1_{\mathcal{G}}(L(\lambda), L(\mu))$ arrows between $L(\lambda), L(\mu) \in Q$ by $\alpha \in \text{Hom}_{\mathcal{G}}(L(\lambda), L(\mu))$ which is then identified (by some choice of scalar) with $\alpha \in \text{Hom}_{\mathcal{G}}(P(\lambda), \text{rad}P(\mu)/\text{rad}^2P(\mu))$ via 1.5.1.

**Theorem 1.5.** Every block $\mathcal{F}_\lambda$ of the category $\mathcal{F}$ of finite dimensional sq(3)-modules semisimple over sq(3)$_0$ is equivalent to the category of finite dimensional modules over one of the following algebras given by a quiver and relations:

(1) A typical block $\lambda = (\lambda_1, \lambda_2, \lambda_3)$ such that $\lambda_i + \lambda_j \neq 0$ for any $i \neq j$, and $\frac{1}{\lambda_1} + \frac{1}{\lambda_2} + \frac{1}{\lambda_3} \neq 0$ or exactly one $\lambda_i = 0$. 

•
Theorem 1.6. Every block $F_\lambda$ of the category $F$ of finite dimensional $\mathfrak{q}(3)$-modules semisimple over $\mathfrak{q}(3)_0$ is equivalent to the category of finite dimensional modules over one of the following algebras given by quiver and relations:

1. A strongly typical block $\lambda = (\lambda_1, \lambda_2, \lambda_3)$ such that $\lambda_i + \lambda_j \neq 0, \lambda_i \neq 0$ for any $i, j$

   \begin{align*}
   &\begin{array}{c}
   \vcenter{\hbox{\begin{tikzpicture}
   \begin{scope}[scale=0.5]
   \node (a) at (0,0) {$a$};
   \node (b) at (1,0) {$b$};
   \node (x) at (2,0) {$x$};
   \node (y) at (3,0) {$y$};
   \draw (a) -- (b);
   \draw (b) -- (x);
   \draw (x) -- (y);
   \draw (a) -- (x);
   \draw (y) -- (b);
   \end{scope}
   \end{tikzpicture}}}
   \end{array}
   \end{align*}

   with relations

   \begin{align*}
   ab &= ba = 0.
   \end{align*}

2. A typical block $\lambda = (\lambda_1, \lambda_2, \lambda_3)$ such that some $\lambda_i = 0$ and $\lambda_j + \lambda_k \neq 0$ for any $j, k$

   \begin{align*}
   &\begin{array}{c}
   \vcenter{\hbox{\begin{tikzpicture}
   \begin{scope}[scale=0.5]
   \node (a) at (0,0) {$a$};
   \node (b) at (1,0) {$b$};
   \draw (a) -- (b);
   \draw (b) -- (a);
   \end{scope}
   \end{tikzpicture}}}
   \end{array}
   \end{align*}

   with relations

   \begin{align*}
   ab &= ba = 0.
   \end{align*}
(3) The “half-standard” block $\lambda = (\frac{3}{2}, -\frac{1}{2})$

\[ \begin{array}{c}
\bullet \quad a \quad b \\
n & \bullet & a \\
\end{array} \quad \begin{array}{c}
\bullet \quad a \quad b \\
n & \bullet & a \\
\end{array} \quad \begin{array}{c}
\bullet \quad a \quad b \\
n & \bullet & a \\
\end{array} \cdots \]

where vertices are labeled $L(\frac{3}{2}, -\frac{1}{2}), L(\frac{5}{2}, \frac{3}{2}, -\frac{5}{2}), L(\frac{7}{2}, \frac{3}{2}, -\frac{7}{2}), \cdots$ with relations

\[ a^2 = b^2 = 0, ab = ba. \]

(4) The standard block $\lambda = (1, 0, 0)$

\[ \begin{array}{c}
\bullet \quad a \\
\bullet \quad x \\
\bullet \quad y \\
\end{array} \quad \begin{array}{c}
\bullet \quad a \\
\bullet \quad x \\
\bullet \quad y \\
\end{array} \quad \begin{array}{c}
\bullet \quad a \\
\bullet \quad x \\
\bullet \quad y \\
\end{array} \cdots \]

where vertices are labeled $L(1, 0, 0), L(2, 1, -2), L(3, 1, -3), \cdots$ with relations

\[ x^2 = y^2 = 0, \quad xa = by = ab = 0 \]
\[ h^2 = 0, \quad xy = yx, \quad bah = hba. \]

(5) The principal block $\lambda = (0, 0, 0)$

\[ \begin{array}{c}
\bullet \quad a \\
\bullet \quad b \\
\bullet \quad x \\
\bullet \quad y \\
\end{array} \quad \begin{array}{c}
\bullet \quad a \\
\bullet \quad b \\
\bullet \quad x \\
\bullet \quad y \\
\end{array} \quad \begin{array}{c}
\bullet \quad a \\
\bullet \quad b \\
\bullet \quad x \\
\bullet \quad y \\
\end{array} \cdots \]

where vertices are labeled $L(1, 0, -1), L(0), L(2, 0, -2), L(3, 0, -3), \cdots$ in top row and $\Pi L(1, 0, -1), \Pi L(0, 0, 0), \Pi L(2, 0, -2), \Pi L(3, 0, -3), \cdots$ in bottom row. Then labelling all vertical arrows by $\theta$, the relations are:

\[ x^2 = y^2 = 0, \quad xb = dy = bd = ca = 0 \]
\[ xy = yx, \quad yx = bacd, \quad dbac = acdb \]
\[ \theta^2 = 0, \theta \gamma = \gamma \theta \text{ for } \gamma \in \{a, b, c, d, x, y\}. \]

**Corollary 1.6.1.** All blocks of $\text{sq}(3)$ are tame. The typical and standard $q(3)$ blocks are tame. The principal $q(3)$ block is wild.

**Proof.** Observe that all blocks of $\text{sq}(3)$ have special biserial quivers and hence are tame [Erd]. The same holds for the two typical and standard blocks of $q(3)$. We show the $q(3)$ principal block is wild by “duplicating the quiver” [GS3, Chap. 9]. Namely, label the vertices of the quiver by $Q_0 = \{1, 2, 3, \ldots\} \cup \{-1, -2, -3, \ldots\}$ corresponding to top and bottom row, respectively. Let $Q_1$ denote the arrows and $R$ the relations. Define $Q'_0 := Q_0 \cup \{1', 2', 3', \ldots\} \cup \{-1', -2', -3', \ldots\}$ and set of arrows as

\[ Q'_1 = \{(i \to j') : (i \to j) \in Q_1\}. \]

Let $Q = (Q_0, Q_1, R)$ and $Q' = (Q'_0, Q'_1)$. Then $k(Q)/R'$, $R'$ being relation defined by any product of 2 arrows is 0, is a quotient of $k(Q)/R$. Note that the indecomposable representations of $(Q_0, Q_1, R')$ are in bijection with that of $Q'$. But $Q'$ is not a union of affine and Dynkin diagrams of type $A, D, E$ (each vertex $i, i > 3$ has 3 edges coming out), so it is wild and this implies $Q$ is wild. \qed
2. Geometric Preliminaries and BGG Reciprocity

2.1. Relative cohomology of Lie superalgebras. Let \( t \subset \mathfrak{g} \) be a Lie subsuperalgebra and \( M \) a \( \mathfrak{g} \)-module. For \( p \geq 0 \), define

\[
C^p(\mathfrak{g}, t; M) = \text{Hom}_t(\wedge^p(\mathfrak{g}), M).
\]

where \( \wedge^p(\mathfrak{g}) \) is the super wedge product. The differential maps \( d^p : C^p(\mathfrak{g}, t; M) \rightarrow C^{p+1}(\mathfrak{g}, t; M) \) are defined in the same way as for Lie algebras, see for example [BKN] Section 2.2]. The relative cohomology are defined by

\[
H^p(\mathfrak{g}, t; M) = \text{Ker} d^p / \text{Im} d^{p-1}.
\]

We will be interested in the case when \( t = \mathfrak{g}_0 \). Then the relative cohomology describe the extension groups in the category \( F \) of finite-dimensional \( \mathfrak{g} \)-modules semisimple over \( \mathfrak{g}_0 \). More precisely, we have the following relation:

\[
\text{Ext}^p_{\mathfrak{g}}(M, N) \cong H^p(\mathfrak{g}, \mathfrak{g}_0; M^* \otimes N).
\]

From here on out, we will use \( \text{Ext}^i_{\mathfrak{g}}(-, -) \) to denote \( \text{Ext}^i_{\mathfrak{g}}(-, -) \). For conciseness, we often write \( \text{Ext}_q \) or \( \text{Ext}_{sq} \) to denote \( \text{Ext}_{\mathfrak{g}(n)} \) or \( \text{Ext}_{sq(n)} \).

**Theorem 2.1.** Let \( \mathfrak{g} = \mathfrak{g}(n) \). Then

\[
\text{Ext}^i_{\mathfrak{g}(n)}(C, C) \cong \begin{cases} S^i(\mathfrak{g}_0^*)^{\mathfrak{g}_0} & \text{if } i \text{ even} \\ 0 & \text{else} \end{cases}
\]

and

\[
\text{Ext}^i_{\mathfrak{g}(n)}(C, \Pi C) \cong \begin{cases} S^i(\mathfrak{g}_0^*)^{\mathfrak{g}_0} & \text{if } i \text{ odd} \\ 0 & \text{else} \end{cases}
\]

**Proof.** Note that \( \mathfrak{g}_1 \cong \Pi \mathfrak{g}_1 \) as a \( \mathfrak{g}_0 \)-module and therefore \( \Lambda^i(\mathfrak{g}_1^*) \cong \Pi^i S^i(\mathfrak{g}_0^*) \). Therefore

\[
C^i(\mathfrak{g}, \mathfrak{g}_0; C) \cong \begin{cases} S^i(\mathfrak{g}_0^*)^{\mathfrak{g}_0} & \text{if } i \text{ even} \\ 0 & \text{else} \end{cases}
\]

and

\[
C^i(\mathfrak{g}, \mathfrak{g}_0; \Pi C) \cong \begin{cases} S^i(\mathfrak{g}_0^*)^{\mathfrak{g}_0} & \text{if } i \text{ odd} \\ 0 & \text{else} \end{cases}
\]

The differential is obviously zero and the statement follows.

**Remark 1.** One can also use the \( \mathbb{Z}_2 \)-graded version of relative cohomology like in [BKN]. It is more suitable for the supervision of the category \( F \) where odd morphisms are allowed.

2.2. Geometric induction. We next provide a few fact about geometric induction following the exposition in [GS],[PS1]. Let \( p \) be any parabolic subsuperalgebra of \( \mathfrak{g} \) containing \( \mathfrak{b} \). Let \( G = Q(n) \), and \( P, B \) be the corresponding Lie supergroups of \( p, b \). For a \( P \)-module \( V \), we denote by the calligraphic letter \( V \) the vector bundle \( G \times_p V \) over the generalized grassmannian \( G/P \). See [Man] for the construction. Note that the space of sections of \( V \) on any open set has a natural structure of \( \mathfrak{g} \)-module; in other words the sheaf of sections of \( V \) is a \( \mathfrak{g} \)-sheaf. Therefore the cohomology groups \( H^i(G/P, V) \) are \( \mathfrak{g} \)-modules. Define the geometric induction functor \( \Gamma_i \) from category of \( p \)-modules to category of \( \mathfrak{g} \)-modules as

\[
\Gamma_i(G/P, V) := H^i(G/P, V^*)^*.
\]

It is also possible to define \( \Gamma_i(G/P, V) \) without the need of proving the rather technical question of existence of \( G/P \). Namely, consider the Zuckerman functor from the category of \( P \)-modules to \( G \)-modules defined by:

\[
H^0(G/P, V) := \Gamma_{\mathfrak{g}_0}(\text{Hom}_{U(p)}(U(\mathfrak{g}), V)),
\]

where \( \Gamma_{\mathfrak{g}_0}(M) \) denotes the set of \( \mathfrak{g}_0 \)-finite vectors of \( \mathfrak{g} \)-module \( M \). One can show easily that \( H^0(G/P, V) \) has a unique \( G \)-module structure compatible with the \( \mathfrak{g} \)-action. It is also straightforward that \( H^0(G/P, V) \) is left exact and the right adjoint to the restriction functor \( G - \text{mod} \rightarrow P - \text{mod} \). We define \( H^i(G/P, -) \) to be its right derived functors. Using this definition we can define \( \Gamma_i(G/P, V) \) for any \( V \) whose weights are in \( \Lambda \).

We state some well known results.

**Proposition 2.2.1.** [Jan],[GS] The functor \( \Gamma_i \) satisfies the following properties.
(1) For any short exact sequence of $P$-modules
\[ 0 \to U \to V \to W \to 0, \]
there is a long exact sequence of $\mathfrak{g}$-modules
\[ \cdots \to \Gamma_1(G/P, W) \to \Gamma_0(G/P, U) \to \Gamma_0(G/P, V) \to \Gamma_0(G/P, W) \to 0. \]
(2) For a $P$-module $V$ and a $\mathfrak{g}$-module $M$,
\[ \Gamma_i(G/P, V \otimes M) = \Gamma_i(G/P, V) \otimes M. \]
(3) $\Gamma_0(G/P, V)$ is the maximal finite-dimensional quotient of $M_p(V) := U(\mathfrak{g}) \otimes_{U(\mathfrak{p})} V$ in the sense that any finite-dimensional quotient of $M_p(V)$ is a quotient of $\Gamma_0(G/P, V)$.

If $G = Q(n)$ then all parabolic subgroups containing the standard Borel subgroup $B$ are in bijection with those of $GL(n)$. Hence they are enumerated by partitions. The Levi subgroup $L$ of parabolic $P$ is isomorphic to $Q(m_1) \times \cdots \times Q(m_k)$ with $m_1 + \cdots + m_k = n$. A weight $\lambda = (\lambda_1, \ldots, \lambda_n)$ is called $\mathfrak{p}$-typical if
\[ \lambda_i + \lambda_j = 0 \text{ implies } m_1 + \cdots + m_s < i, j \leq m_1 + \cdots + m_{s+1}. \]

**Proposition 2.2.2.** (Typical Lemma) [PS1] Thm 2 Let $P$ be any parabolic supergroup containing $B$ and suppose $\lambda \in \Lambda^+$ is $\mathfrak{p}$-typical, where $\mathfrak{p} := \text{Lie}(P)$. Then
\[ \Gamma_i(G/P, L_\mathfrak{p}(\lambda)) = \begin{cases} L(\lambda) & \text{if } i = 0 \\ 0 & \text{if } i > 0 \end{cases} \]

Now, for any parabolic supergroup $P$ containing $B$, define the multiplicity
\[ m^i_P(\lambda, \mu) := [\Gamma_i(G/P, L_\mathfrak{p}(\lambda)) : L_\mathfrak{g}(\mu)]. \]

**Proposition 2.2.3.** If $\lambda > \mu$, then
\[ m^0_B(\lambda, \mu) \geq \dim \text{Ext}^1_\mathfrak{g}(L(\lambda), L(\mu)). \]

**Proof.** Suppose $0 \to L(\mu) \to V \to L(\lambda) \to 0$ is an extension. Then $V$ contains a highest weight vector $v_\lambda$ of weight $\lambda$ coming from the inverse image of that of $L(\lambda)$. Since $V$ is indecomposable, $V$ is generated by $v_\lambda$ and since $\mu < \lambda$, $V = U(\mathfrak{g}) v_\lambda$ is annihilated by $n^+$. Thus $V$ is a highest weight module of weight $\lambda$, so it is a finite-dimensional quotient of $M(\lambda)$ and consequently by Proposition 2.2.1(3), it is a quotient of $\Gamma_0(G/B, L_\mathfrak{b}(\lambda))$. Each such isomorphism class of extension $V$ thus gives rise to a distinct subquotient $L(\mu)$ in $\Gamma_0(G/B, L_\mathfrak{b}(\lambda))$. Consequently, $\dim \text{Ext}^1_\mathfrak{g}(L(\lambda), L(\mu)) \leq [\Gamma_0(G/B, L_\mathfrak{b}(\lambda)) : L(\mu)] = m_0^B(\lambda, \mu).$ \hfill $\Box$

**Remark 2.** In [PS1], the authors work in $\mathfrak{g}^{\Pi}$-mod consisting of $\Pi$-invariant $\mathfrak{g}$-modules (and even morphisms) and define $m^\Pi_P(\lambda, \mu)$ accordingly. For $\mathfrak{g} = \mathfrak{q}(n)$, the simple $\mathfrak{g}^{\Pi}$-modules are $L(\lambda)$ when $|\{i : \lambda_i \neq 0\}|$ is odd and $L(\lambda) \oplus \Pi L(\lambda)$ when $|\{i : \lambda_i \neq 0\}|$ is even.

**Proposition 2.2.4.** Let $P$ be the parabolic subgroup of $Q(3)$ defined by roots $\{\varepsilon_1 - \varepsilon_2, \varepsilon_1 - \varepsilon_3, \varepsilon_2 - \varepsilon_3, \varepsilon_3 - \varepsilon_2\}$. Suppose $\lambda \in \Lambda^+ \setminus \{(t, a, -a)\}$. Then for all $\mu \in \Lambda^+$,
\[ m^i_P(\lambda, \mu) = m^i_B(\lambda, \mu). \]

**Proof.** There is a canonical projection $G/B \to G/P$ with kernel $P/B = Q(2)/B \cap Q(2)$. By our assumption, the weights $\lambda$ is $B$-typical in $P$. Thus the Leray spectral sequence
\[ H^i(G/P, H^j(P/B, L_b(\lambda))) \Rightarrow H^{i+j}(G/B, L_b(\lambda)) \]
collapses by the typical lemma. \hfill $\Box$
2.3. **Virtual BGG Reciprocity.** We now formulate a “virtual” BGG reciprocity theorem for \( g = \mathfrak{g}(n) \) or \( \mathfrak{q}(n) \) which will be used to compute composition factors of indecomposable projective covers, \( P_{\mathfrak{g}}(\lambda) \) of \( L_{\mathfrak{g}}(\lambda) \). This result is a generalization of Theorem 1 in [GS2] in the case when Cartan subalgebra is not purely even. In this section we consider the quotient \( K^H(\mathcal{F}) \) of the Grothendieck ring \( K(\mathcal{F}) \) by the relation \([X] = [\Pi X]\). Then \( K^H(\mathcal{F}) \) has a basis \( \{L(\lambda) \mid \lambda \in \Lambda^+\} \) and \([X : L(\lambda)]_\Pi\) is the coefficient \( a_\lambda \) in the decomposition \([X] = \sum a_\lambda[L(\lambda)]\).

For \( M \in \mathcal{F}^H \), define \( \mathcal{R} := \mathbb{Z}[e^\mu]_{\mu \in \Lambda} \) and the character of \( M \)

\[
\text{Ch}(M) := \sum_{\mu \in \Lambda} \dim(M_\mu)e^\mu \in \mathcal{R},
\]

where we put \( \dim X := \dim X_0 + \dim X_1 \). Then \( \text{Ch} \) defines an injective homomorphism \( K^H(\mathcal{F}) \rightarrow \mathcal{R} \).

For any \( \lambda \in \Lambda \) we define an Euler characteristic as

\[
\mathcal{E}(\lambda) := \sum_{\mu \in \Lambda} \sum_{i=0}^{\dim(G/B)_0} (-1)^i[\Gamma_i(G/B, v(\lambda)) : L(\mu)]_\Pi[L(\mu)],
\]

where \( \Gamma_i \) is the dual to geometric induction functor as defined in section 2.2. It is straightforward to check (see e.g [Bi 1, Theorem 4.25]) that for \( \lambda \in \Lambda \) such that \( \text{wt}(\lambda) = \gamma \), then \([\mathcal{E}(\lambda)] \in K^H(\mathcal{F}_\gamma)\).

We comment that this Euler characteristic is different to the one defined in [Bi2]. There, the author considered an induction from the maximal parabolic \( P_\lambda \) to which \( v(\lambda) \) extends, i.e

\[
\mathcal{E}_p(\lambda) := \sum_{\mu \in \Lambda} \sum_{i=0}^{\dim(G/P_\lambda)_0} (-1)^i[\Gamma_i(G/P_\lambda, v(\lambda)) : L(\mu)][L(\mu)].
\]

The following result is a straightforward generalization of [GS] Lemma 1,2.

**Lemma 2.3.1.** The Euler characteristic \( \mathcal{E}(\lambda) \) satisfies

\[(1) \quad \text{Ch}(\mathcal{E}(\lambda)) = \dim v(\lambda)D \sum_{w \in S_n} \varepsilon(w)e^{w \cdot \lambda}\]

where

\[
D = \prod_{\alpha \in \Phi^+} \frac{e^{\alpha/2} + e^{-\alpha/2}}{e^{\alpha/2} - e^{-\alpha/2}}.
\]

\[(2) \quad \text{For all } w \in W, \quad \mathcal{E}(\lambda) = \varepsilon(w)\mathcal{E}(w \cdot \lambda)\]

\[(3) \quad \text{Let } \Lambda_0^+ \text{ denote the set regular dominant weights with respect to } g_0. \text{ The set}
\]

\[
\{\text{Ch}(\mathcal{E}(\lambda)), \lambda \in \Lambda_0^+\}
\]

is linearly independent in the ring \( \mathcal{R} \).

We call a simple \( \mathfrak{g} \)-module \( L(\lambda) \) of Type M if \( \Pi L(\lambda) \) is not isomorphic to \( L(\lambda) \) and of Type Q if \( \Pi L(\lambda) \cong L(\lambda) \). Note that the type of \( L(\lambda) \) is the same as the type of \( v(\lambda) \). Furthermore, for \( \mathfrak{g} = \mathfrak{q}(n) \) the type depends on the number of non-zero entries in \( \lambda \): the type is M, if this number is even, and Q if it is odd. For example, \( L(1, 0, 0) \) is of type Q and \( L(0) \) is of type M. We set

\[
t(\nu) = \begin{cases} 
1 & \text{if } L(\nu) \text{ Type M} \\
0 & \text{if } L(\nu) \text{ Type Q}.
\end{cases}
\]
**Theorem 2.2.** Let $g = q(n)$ or $sq(n)$. Let $\mu \in \Lambda^+$ and $b_{\mu, \lambda}$ be the coefficients occurring in the expansion
\[
E(\mu) = \sum_{\lambda \in \Lambda^+} b_{\mu, \lambda}[L(\lambda)].
\]
Then there exists coefficients $a_{\lambda, \mu}$ such that
\[
[P(\lambda)] = \sum_{\mu \in \Lambda^+_0} a_{\lambda, \mu}E(\mu).
\]
and
\[
a_{\lambda, \mu} = 2^{t(\mu) - t(\lambda)} \gamma_\mu b_{\mu, \lambda}
\]
where
\[
\gamma_\mu = \begin{cases} 
1 & \text{if } \mu = q(n) \text{ and } \prod \mu_i \neq 0, \text{ or } \mu = sq(n) \text{ and } \sum \frac{1}{\mu_i} \neq 0 \\
2 & \text{otherwise}.
\end{cases}
\]

**Proof.** We follow the proof of [GS2][Theorem 1]. First, we have the Bott reciprocity formula
\[
(2.3.1) \quad \dim \text{Hom}_g(P(\lambda), \Gamma_i(V)) = \dim \text{Ext}_B^i(V, P(\lambda)) = \dim H^i(b, h_0; V^* \otimes P(\lambda)).
\]
Let $C^i(n, -)$ stand for the $i$-th term of the cochain complex computing $H^\bullet(n, -)$. Note that $P(\lambda)$ and hence $C^i(n; V^* \otimes P(\lambda))$ is projective and injective in the category of $\mathfrak{g}$-modules semisimple over $h_0$. Hence $H^i(h, h_0; C^i(n, V^* \otimes P(\lambda))) = 0$ for any $i$ and $j \geq 1$. Therefore the first term of the spectral sequence for the pair $(b, h)$ implies that
\[
(2.3.2) \quad \sum_{i=0}^\infty (-1)^i \dim \text{Ext}_B^i(v(\mu), P(\lambda)) = \sum_{i=0}^\infty (-1)^i \dim \text{Hom}_g(v(\mu), C^i(n, P(\lambda))).
\]
Furthermore, we have
\[
(2.3.3) \quad [M : L(\lambda)]_\Pi = \begin{cases} 
\dim \text{Hom}_g(P(\lambda) \oplus \Pi P(\lambda), M) & \text{if } L(\lambda) \text{ Type M} \\
\dim \text{Hom}_g(P(\lambda), M) & \text{if } L(\lambda) \text{ Type Q}.
\end{cases}
\]
Define $b^j_{\mu, \lambda}$ by
\[
b^j_{\mu, \lambda} := \begin{cases} 
\dim \text{Hom}_g(v(\mu) \oplus \Pi v(\mu), C^j(n, P(\lambda))) & \text{if } L(\lambda) \text{ Type M} \\
\dim \text{Hom}_g(v(\mu), C^j(n, P(\lambda))) & \text{if } L(\lambda) \text{ Type Q}.
\end{cases}
\]
By application of (2.3.2) and (2.3.3) we obtain
\[
b_{\mu, \lambda} = \sum_{i=0}^\infty (-1)^i b^i_{\mu, \lambda}.
\]
For any module $M \in \mathcal{F}$ projective over $\mathfrak{h}$ we have the equality
\[
(2.3.4) \quad \frac{\dim M_\mu}{\dim \hat{v}(\mu)} = \begin{cases} 
\dim \text{Hom}_g(v(\mu) \oplus \Pi v(\mu), M) & \text{if } \mu \text{ Type M} \\
\dim \text{Hom}_g(v(\mu), M) & \text{if } \mu \text{ Type Q}
\end{cases}
\]
where $\hat{v}(\mu)$ is the corresponding indecomposable injective $\mathfrak{h}$-module. In other words we get
\[
\text{Ch}(M) = \sum_{\mu \text{ type M}} \dim \text{Hom}_g(v(\mu) \oplus \Pi v(\mu), M)e^\mu + \sum_{\mu \text{ type Q}} \dim \text{Hom}_g(v(\mu), M)e^\mu.
\]
If $\lambda$ is of type Q we obtain
\[
\text{Ch}(C^i(n, P(\lambda))) = \sum_{\mu \text{ type M}} 2b^i_{\mu, \lambda} \dim \hat{v}(\mu)e^\mu + \sum_{\mu \text{ type Q}} b^i_{\mu, \lambda} \dim \hat{v}(\mu)e^\mu = \sum_\mu 2^{t(\mu) - t(\lambda)} b^i_{\mu, \lambda} \dim \hat{v}(\mu)e^\mu.
\]
If $\lambda$ is of type $M$ we obtain
\[
\text{Ch}(C^i(n, P(\lambda))) = \sum_{\mu \text{ type } M} b_{i,\mu,\lambda}^i \dim \hat{v}(\mu)e^\mu + \sum_{\mu \text{ type Q}} \frac{1}{2} b_{i,\mu,\lambda}^i \dim \hat{v}(\mu)e^\mu = \sum_{\mu} \beta(\mu - \lambda) b_{i,\mu,\lambda} \dim \hat{v}(\mu)e^\mu.
\]
Taking alternating sum over $i$ we get
\[
\sum_{i=1}^\infty (-1)^i \text{Ch}(C^i(n, P(\lambda))) = \sum_{\mu} 2^{\beta(\mu - \lambda)} b_{\mu,\lambda} \dim \hat{v}(\mu)e^\mu.
\]
On the other hand, we have
\[
\sum_{i=1}^\infty (-1)^i \text{Ch}(C^i(n, P(\lambda))) = \text{Ch}(P(\lambda)) \prod_{\alpha \in \Phi^+} \frac{1 - e^{-\alpha}}{1 + e^{-\alpha}} = D^{-1} \text{Ch}(P(\lambda)).
\]
This implies
\[
\text{Ch}(P(\lambda)) = D \sum_{\mu \in \Lambda} b_{\mu,\lambda} \dim \hat{v}(\mu)2^{\beta(\mu - \lambda)} e^\mu.
\]
By $S_n$-invariance of $\text{Ch}(P(\lambda))$, we get
\[
b_{\mu,\lambda} = e(w)b_{w,\mu,\lambda} \quad \forall w \in S_n.
\]
This together with $\dim \hat{v}(\mu) = \dim \hat{v}(w,\mu)$ implies
\[
\text{Ch}(P(\lambda)) = D \sum_{w \in W} \sum_{\mu \in \Lambda^+} b_{\mu,\lambda}(w) \dim \hat{v}(\mu)2^{\beta(\mu - \lambda)} e^{w,\mu} = \sum_{\mu \in \Lambda^+} \frac{\dim \hat{v}(\mu)}{\dim \hat{v}(\mu)} 2^{\beta(\mu - \lambda)} b_{\mu,\lambda} \text{Ch}(E(\mu)).
\]
Therefore we obtain the relation
\[
a_{\lambda,\mu} = \frac{\dim \hat{v}(\mu)}{\dim \hat{v}(\mu)} 2^{\beta(\mu - \lambda)} b_{\mu,\lambda}.
\]
Since $\mu \in \Lambda^+_0$ at most one $\mu_i = 0$. Therefore, we get: for $\mathfrak{g} = \mathfrak{q}(n)$, $v(\mu) = \hat{v}(\mu)$ if all $\mu_i \neq 0$; for $\mathfrak{g} = \mathfrak{sq}(n)$, $v(\mu) = \hat{v}(\mu)$ if $\sum_{i=1}^n \frac{1}{\mu_i} \neq 0$. In remaining cases $\frac{\dim \hat{v}(\mu)}{\dim v(\mu)} = 2$. \hfill $\square$

**Remark 3.** Theorem 2.2 holds for any Lie superalgebra $\mathfrak{g}$ such that $\mathfrak{h} = \mathfrak{h}_0$ and $\mathfrak{g}_1 = \mathfrak{g}_1^\circ$. In this case, we get $\gamma_\mu = 1$.

Let $K^H_F(F)$ be the subgroup of $K^H(F)$ generated by the classes of all projective modules. It is an ideal in $K^H(F)$ since tensor product of projective with any finite-dimensional module is projective. Let $K^H_E(F)$ be the subgroup of $K^H(F)$ generated by the Euler characteristics. Then $K^H_P(F) \subset K^H_E(F) \subset K^H(F)$ and the inclusions are in general strict. The $b_{\nu,\mu}$ express a basis of $K^H_P(F)$ in terms of the basis of $K^H(F)$ and $a_{\lambda,\nu}$ express the basis of $K^H_P(F)$ in terms of basis of $K^H_E(F)$. Thus for two $\mathfrak{g}$-dominant weights $\lambda, \mu$, we have
\[
[P(\lambda) : L(\mu)]_P = \sum_{\nu \in \Lambda^+_0} a_{\lambda,\nu} b_{\nu,\mu}.
\]

**2.4. General lemma.** To study relations between block for $\mathfrak{sq}(n)$ and $\mathfrak{q}(n)$ we consider the induction and restriction functors
\[
\text{Ind} : \mathcal{F}_{\mathfrak{sq}(n)} \to \mathcal{F}_{\mathfrak{q}(n)}, \quad M \mapsto \text{Ind}_{\mathfrak{sq}(n)}^{\mathfrak{q}(n)} M;
\]
\[
\text{Res} : \mathcal{F}_{\mathfrak{q}(n)} \to \mathcal{F}_{\mathfrak{sq}(n)}, \quad M \mapsto \text{Res}_{\mathfrak{sq}(n)}^{\mathfrak{q}(n)} M.
\]
The Frobenius reciprocity implies that Ind is left adjoint of Res.

**Lemma 2.4.1.** Let $M$ be a projective $\mathfrak{sq}(n)$-module with $\Pi M \cong M$ and let $\mathcal{A} = \text{End}_{\mathfrak{sq}(M)}(M), \mathcal{A}' = \text{End}_{\mathfrak{q}(\text{Ind} M)}$. Assume that there exists $\theta \in \mathcal{A}'$ such that $\ker \theta = \text{im} \theta$ and $\ker \theta \cap (1 \otimes M) = \{0\}$. Then $\mathcal{A}' \cong \mathcal{A} \otimes C[\theta]/(\theta^2)$. 

Proof. Note that our assumptions imply $\text{Res Ind } M = M \oplus M$. Consider injective homomorphism $\text{Ind} : A \to A'$ and $\text{Res} : A' \to \text{Mat}_2 \otimes A$. Furthermore, for $\gamma \in A$, we have
\[
\text{Res Ind } \gamma = \begin{pmatrix} \gamma & \gamma' \\ 0 & \gamma \end{pmatrix}
\]
for some $\gamma' \in A$. The condition $\theta^2 = 0$ implies
\[
\text{Res } \theta = \begin{pmatrix} 0 & 0 \\ \text{Id} & 0 \end{pmatrix}.
\]
The Frobenius reciprocity implies for any $\varphi \in A'$,
\[
\text{if } \text{Res } \varphi = \begin{pmatrix} 0 & \sigma \\ 0 & \tau \end{pmatrix} \text{ then } \text{Res } \varphi = 0.
\]
We have
\[
[\text{Res Ind } \gamma, \text{Res } \theta] = \begin{pmatrix} \gamma' & 0 \\ 0 & -\gamma' \end{pmatrix},
\]
\[
[\text{Res Ind } \gamma, \text{Res } \theta] - \text{Res Ind } \gamma' = \begin{pmatrix} 0 & -\gamma'' \\ 0 & -2\gamma' \end{pmatrix},
\]
hence $\gamma' = 0$.

Thus, we have proved that $\text{Ind}(A)$ commutes with $\theta$. Thus there is an injective homomorphism $A \otimes C[\theta] / (\theta^2) \to A$. The dimension argument implies that it is an isomorphism. \(\square\)

3. SELF EXTENSIONS

The goal of this section is to prove the following theorem.

**Theorem 3.1.** Let $\lambda = (\lambda_1, ..., \lambda_k, 0, ..., 0, -\lambda_{k+m+1}, ..., -\lambda_n)$ such that all $\lambda_i > 0$ be a dominant integral weight in $q(n)$. Then
\[
\text{Ext}^1_{q(n)}(L(\lambda), \Pi L(\lambda)) = \begin{cases} C & \text{if } m > 0 \\ 0 & \text{if } m = 0. \end{cases}
\]

If $L(\lambda) \neq \Pi L(\lambda)$, then
\[
\text{Ext}^1_{q(n)}(L(\lambda), L(\lambda)) = 0.
\]

Theorem 3.1 implies parts (1) and (2) of our main theorem 1.6. Namely, $\text{Ext}^1(L(\lambda), L(\mu)) \neq 0 \Rightarrow \text{wt}(\lambda) = \text{wt}(\mu)$. Thus, by Theorem 3.1, there are no extensions in the strongly typical block, and there is a unique extension $L(\lambda) \otimes L(\lambda)$ in the typical block. Thus in the typical block, the projective cover of $L(\lambda)$ is $P(\lambda) = L(\lambda) / L(\lambda)$ (Theorem 2.2). Then $a \in \text{Hom}_q(P(\lambda), \Pi P(\lambda))$ implies $a^2 = 0$.

**Proof.** The key idea is to take parabolic invariants to reduce the problem to finding extensions between trivial modules. Let $\lambda$ be as in the theorem. Define the parabolic subalgebra of $g$ by
\[
p := h \oplus \bigoplus_{1 < i < j \leq n} g_{\epsilon_i - \epsilon_j} \oplus \bigoplus_{k < i < j \leq k+m} g_{\epsilon_j - \epsilon_i}.
\]
Its Levi subalgebra $l \subset p$ is isomorphic to $q(m) \oplus h'$ where $h' \subset h$ is the centralizer of $q(m)$ in $h$. Let
\[
n_p := \bigoplus_{i \leq k < j \leq n} g_{\epsilon_i - \epsilon_j} \oplus \bigoplus_{k \leq i < k+m < j \leq n} g_{\epsilon_i - \epsilon_j}
\]
be the nilpotent radical of $p$.

We first observe that taking $n_p$ invariants is a functor from $q(n)$-mod to $l$-mod. Next, suppose $L(\lambda)^{n_p}$ had a nontrivial $l$-invariant subspace $N$. Because $l$ preserves the $\lambda$-weight space, and the lower parabolic nilpotent part only lowers the $\lambda$-weight space, we must have $U(q(n))N_\lambda \subseteq L(\lambda) \lambda \Rightarrow$
Lemma 3.0.3. Suppose \( U(q(n))N \subseteq L(\lambda) \Rightarrow N = 0 \), contradiction. Thus \( L(\lambda)^{n_p} \) is simple \( \lambda \)-module. On the other hand, \( L(\lambda)_\lambda \) is also an irreducible \( \lambda \)-module of highest weight. So by the characterization of the simple highest weight \( \lambda \)-modules, \( L(\lambda)^{n_p} = L(\lambda)_\lambda \).

**Lemma 3.0.1.** Using the above notation, the following linear maps are injective

\[
\text{Ext}^1_{q(n)}(L(\lambda), L(\lambda)) \hookrightarrow \text{Ext}^1_{q(n)}(L(\lambda)^{n_p}, L(\lambda)^{n_p}),
\]

\[
\text{Ext}^1_{q(n)}(L(\lambda), \Pi \lambda(L)) \hookrightarrow \text{Ext}^1_{q(n)}(L(\lambda)^{n_p}, \Pi \lambda(\lambda)^{n_p}).
\]

**Proof.** Suppose we had a sequence of \( q(n) \)-modules \( 0 \to L(\lambda) \to M \to L(\lambda) \to 0 \) such that taking \( n_p \) invariants results in a split short exact sequence of \( \lambda \)-modules

\[
0 \to L(\lambda)^{n_p} \xrightarrow{\phi} M^{n_p} \xrightarrow{\psi} L(\lambda)^{n_p} \to 0.
\]

From before, we know this sequence is the same as

\[
0 \to L(\lambda)_\lambda \xrightarrow{\phi} M_\lambda \xrightarrow{\psi} L(\lambda)_\lambda \to 0.
\]

Existence of a splitting maps means there exists an \( \lambda \)-module homomorphism \( \delta : L(\lambda)_\lambda \to M_\lambda \) such that \( \psi \circ \delta = \text{id}_{L(\lambda)_\lambda} \). Thus, we know

\[
M_\lambda = \phi(L(\lambda)_\lambda) \oplus \delta(L(\lambda)_\lambda).
\]

Let \( L' = U(q(n)) \delta(L(\lambda)_\lambda) \). Then

\[
M = U(q(n)) \delta(L(\lambda)_\lambda) = U(q(n)) \phi(L(\lambda)_\lambda) \oplus \delta(L(\lambda)_\lambda)
\]

\[
\subset U(q(n)) \phi(L(\lambda)_\lambda) + U(q(n)) \delta(L(\lambda)_\lambda)
\]

\[
= \phi(L(\lambda)) + L'
\]

where in the last line we use that \( \phi \) is a \( q(n) \)-module homomorphism and \( U(q(n))L(\lambda)_\lambda = L(\lambda) \). Thus \( M = \phi(L(\lambda)) + L' \).

To show the sum is direct, observe \( \phi \) injective and \( L(\lambda) \) simple implies \( \phi(L(\lambda)) \) is simple, so \( \phi(L(\lambda)) \cap L' = 0 \) or \( \phi(L(\lambda)) \). The case \( \phi(L(\lambda)) \cap L' = \phi(L(\lambda)) \) is impossible, as

\[
(L' \cap \Phi(L(\lambda)))_\lambda = L'_\lambda \cap \Phi(L(\lambda))_\lambda = 0.
\]

This shows that the sequence of \( q(n) \) modules splits also. \( \square \)

If \( m = 0 \), then \( \text{Ext}^1_{q(n)}(L(\lambda), L(\lambda)) = 0 \). This follows from

\[
\dim \text{Ext}^1_{q(n)}(L(\lambda), \Pi \lambda(L)) \leq \dim \text{Ext}^1_{h(n)}(L(\lambda)^{n_p}, \Pi \lambda(\lambda)^{n_p}) = 0,
\]

where we used \( m = 0 \Rightarrow I = h \) and lemma 3.0.1 for the first step, and the well known fact that Clifford supermodules are semisimple when \( \lambda \) is nondegenerate, for the second step [Mein].

**Lemma 3.0.2.** If \( \lambda \) is as in Theorem 3.74 and \( m > 0 \) and \( v(\lambda) \) is considered as a simple \( \lambda \)-modules, then \( \text{Ext}^1(\nu(\lambda), \Pi \nu(\lambda)) = 0 \) and \( \text{Ext}^1(\nu(\lambda), \nu(\lambda)) = 0 \) if \( v(\lambda) \) is of Type M.

**Proof.** We start with general observation.

**Lemma 3.0.3.** Suppose \( g = A \oplus B \), where \( A, B \) are Lie superalgebras and \( M = M_A \boxtimes M_B \) is a \( g \)-supermodule. Then

\[
H^1(g, g_0; M) = H^1(A, A_0; M_A) \boxtimes H^0(B, B_0; M_B) \oplus H^1(A, A_0; \Pi M_A) \boxtimes H^0(B, B_0; \Pi M_B) \oplus H^0(A, A_0; M_A) \boxtimes H^1(B, B_0; M_B) \oplus H^1(A, A_0; \Pi M_A) \boxtimes H^1(B, B_0; \Pi M_B).
\]
Now write \( v(\lambda) = C \otimes v(\lambda') \) for \( I = q(m) \oplus h' \). Then since \( v(\lambda') \) is a projective \( h' \)-module we have
\[
\text{Ext}^1_i(v(\lambda), \Pi v(\lambda)) = \text{Ext}^1_{q(m)}(C, C) \otimes \text{Hom}_{h'}(v(\lambda'), \Pi v(\lambda')) \oplus \text{Ext}^1_{q(m)}(C, C) \otimes \text{Hom}_{h'}(v(\lambda'), v(\lambda'))
\]
and
\[
\text{Ext}^1_i(v(\lambda), v(\lambda)) = \text{Ext}^1_{q(m)}(C, C) \otimes \text{Hom}_{h'}(v(\lambda'), v(\lambda')) \oplus \text{Ext}^1_{q(m)}(C, C) \otimes \text{Hom}_{h'}(v(\lambda'), \Pi v(\lambda')).
\]
By Theorem 2.1 we have \( \text{Ext}^1_{q(m)}(C, C) = 0 \) and \( \text{Ext}^1_{q(m)}(C, C) = C \). The lemma follows.

By Lemma 3.0.1 and Lemma 3.0.2 we have that
\[
\dim \text{Ext}^1_{q(n)}(L(\lambda), \Pi L(\lambda)) \leq 1
\]
and
\[
\text{Ext}^1_{q(n)}(L(\lambda), L(\lambda)) = 0
\]
if \( L(\lambda) \) is not isomorphic to \( \Pi L(\lambda) \).

It remains to show that there exists a non-trivial extension between \( L(\lambda) \) and \( \Pi L(\lambda) \). For this we consider an indecomposable \((1|1)\)-dimensional \( q(n) \)-module \( U \) with a basis \( u \in U_0, \bar{u} \in U_1 \) and with action given by
\[
X \bar{u} = 0, \quad X u = \text{otr} X \bar{u}, \quad \forall X \in q(n).
\]
Then we have an exact sequence of \( q(n) \)-modules
\[
0 \rightarrow \Pi L(\lambda) \rightarrow L(\lambda) \otimes U \rightarrow L(\lambda) \rightarrow 0.
\]
To see that it does not split take \( p \) such that \( \lambda_p = 0 \). On the weight space \( (L(\lambda) \otimes U)_\lambda \) the odd basis element \( \bar{H}_p \) acts non-trivially while its action on \( (L(\lambda) \oplus \Pi L(\lambda))_\lambda \) is obviously trivial. The proof of Theorem 3.1 is complete.

**Theorem 3.2.** Let \( \lambda = (\lambda_1, \ldots, \lambda_k, 0, \ldots, 0, -\lambda_{k+m+1}, \ldots, -\lambda_m) \) such that all \( \lambda_i > 0 \) be a dominant integral weight in \( q(n) \).

1. \( \text{Ext}^1_{q(n)}(L_{q(n)}(\lambda), L_{q(n)}(\lambda')) = 0 \) if \( L(\lambda) \neq \Pi L(\lambda) \);
2. \( \text{Ext}^1_{q(n)}(L_{q(n)}(\lambda), \Pi L_{q(n)}(\lambda)) = \text{Ext}^1_{q(n)}(L_{q(n)}(\lambda), L_{q(n)}(\lambda)) = 0 \) if \( m > 0 \) or \( m = 0 \) and \( \frac{1}{\lambda_1} + \cdots + \frac{1}{\lambda_m} \neq 0 \);
3. \( \text{Ext}^1_{q(n)}(L_{q(n)}(\lambda), \Pi L_{q(n)}(\lambda)) = C \) if \( \frac{1}{\lambda_1} + \cdots + \frac{1}{\lambda_m} = 0 \).

**Proof.** Note that 3.0.1 can be generalized to the case of \( \mathfrak{so}(n) \), namely if \( p' = p \cap \mathfrak{so}(n) \), \( l' = l \cap \mathfrak{so}(n) \) and \( v'(\lambda) \) is the irreducible \( l' \)-module, the map
\[
\text{Ext}^1_{\mathfrak{so}(n)}(L_{\mathfrak{so}(n)}(\lambda), (\Pi)L_{\mathfrak{so}(n)}(\lambda)) \hookrightarrow \text{Ext}^1_{l'}(v'(\lambda), (\Pi)v'(\lambda))
\]
is injective. We claim that \( \text{Ext}^1_{l'}(v'(\lambda), (\Pi)v'(\lambda)) = 0 \) for all \( \lambda \) which do not satisfy (3). Indeed, if \( m > 0 \), then \( \mathfrak{so}(m) \) is an ideal in \( l' \) which acts trivially on \( v'(\lambda) \) and \( \Pi v'(\lambda) \) and the quotients \( l'/\mathfrak{so}(m) \cong l/q(m) \cong h' \). Since
\[
\text{Ext}^1_{\mathfrak{so}(m)}(C, C) = \text{Ext}^1_{\mathfrak{so}(m)}(C, C) = 0,
\]
using spectral sequence we get
\[
H^1(l', l'_0, v'(\lambda)^* \otimes (\Pi)v'(\lambda)) \cong H^1(h', h'_0, v'(\lambda)^* \otimes (\Pi)v'(\lambda)) = 0.
\]
It remains to consider the case \( \frac{1}{\lambda_1} + \cdots + \frac{1}{\lambda_m} = 0 \). In this case one-dimensional \( K_{\lambda}' \) lies in the radical of the corresponding Clifford algebra, therefore we have
\[
\text{Ext}^1_{l'}(v'(\lambda), (\Pi)v'(\lambda)) = C.
\]
To construct a non-trivial extension over $\mathfrak{sq}(n)$ consider the induced module $\text{Ind}_{\mathfrak{sq}(n)}^q L_{\mathfrak{sq}(n)}(\lambda)$ isomorphic to $L(\lambda) = L_{\mathfrak{sq}(n)}(\lambda)$. It is the middle term of an exact sequence of $\mathfrak{sq}(n)$-modules

$$0 \to L_{\mathfrak{sq}(n)}(\lambda) \xrightarrow{\varphi} L(\lambda) \to \Pi L_{\mathfrak{sq}(n)}(\lambda) \to 0.$$  

Let us check that the sequence does not split. Using Frobenius reciprocity, we compute

$$\text{Hom}_{\mathfrak{sq}(n)}(\Pi L_{\mathfrak{sq}(n)}(\lambda), L(\lambda)) = \text{Hom}_{q(n)}(\Pi L(\lambda), L(\lambda)).$$

If $n$ is odd, then $L_{\mathfrak{sq}(n)}(\lambda)$ is isomorphic to $\Pi L_{\mathfrak{sq}(n)}(\lambda)$ and $L(\lambda)$ is isomorphic to $\Pi L(\lambda)$ as a $q(n)$-module. So

$$C \varphi = \text{Hom}_{\mathfrak{sq}(n)}(\Pi L_{\mathfrak{sq}(n)}(\lambda), L(\lambda)) = \text{Hom}_{q(n)}(\Pi L(\lambda), L(\lambda)).$$

If $n$ is even then $L_{\mathfrak{sq}(n)}(\lambda)$ is not isomorphic to $\Pi L_{\mathfrak{sq}(n)}(\lambda)$ and $L(\lambda)$ is not isomorphic to $\Pi L(\lambda)$ as an $q(n)$-module. Therefore

$$\text{Hom}_{\mathfrak{sq}(n)}(\Pi L_{\mathfrak{sq}(n)}(\lambda), L(\lambda)) = \text{Hom}_{q(n)}(\Pi L(\lambda), L(\lambda)) = 0.$$  

In both cases, the sequence does not split. \qed

**Corollary 3.0.1.** Let $\lambda$ be a dominant integral weight. Let $\text{Res}, \text{Ind}$ denote $\text{Res}_{\mathfrak{sq}}, \text{Ind}_{\mathfrak{sq}}$ respectively.

(a) If there exists $i$ such that $\lambda_i = 0$, then

$$\text{Res} L(\lambda) = L_{\mathfrak{sq}}(\lambda), \quad \text{Ind} L_{\mathfrak{sq}}(\lambda) = \frac{L(\lambda)}{\Pi L(\lambda)}$$

(b) If all $\lambda_i \neq 0$ and $\frac{1}{\lambda_1} + \cdots + \frac{1}{\lambda_n} \neq 0$, then

$$\text{Res} L(\lambda) = L_{\mathfrak{sq}}(\lambda) \oplus \Pi L_{\mathfrak{sq}}(\lambda), \quad \text{Ind} L_{\mathfrak{sq}}(\lambda) = L(\lambda)$$

(c) If all $\lambda_i \neq 0$ and $\frac{1}{\lambda_1} + \cdots + \frac{1}{\lambda_n} = 0$, then

$$\text{Res} L(\lambda) = \frac{\Pi L_{\mathfrak{sq}}(\lambda)}{L_{\mathfrak{sq}}(\lambda)}, \quad \text{Ind} L_{\mathfrak{sq}}(\lambda) = L(\lambda)$$

**Proof.** By PBW theorem for $\mathfrak{g}(n), \mathfrak{sq}(n)$, given a finite-dimensional $\mathfrak{sq}(n)$ module $M$, $\dim \text{Res} \text{Ind} M = 2 \dim M$. Suppose we are in case (a). By Lemma 1.3.1(a), $\text{Res} L(\lambda) = L_{\mathfrak{sq}}(\lambda)$ and $\text{Ind} L_{\mathfrak{sq}}(\lambda)$ is the middle term of the exact sequence of $\mathfrak{q}(n)$ modules

$$0 \to L(\lambda) \xrightarrow{\varphi} \text{Ind} L_{\mathfrak{sq}}(\lambda) \to \Pi L(\lambda) \to 0.$$  

Now, since there some $\lambda_i = 0$, $L_{\mathfrak{sq}}(\lambda) \cong \Pi L_{\mathfrak{sq}}(\lambda)$ if and only if $L(\lambda) \cong \Pi L(\lambda)$. Then repeating the argument from Theorem 3.2, we conclude the sequence is nonsplit. For case (b), note that Lemma 1.3.1(b) implies $L(\lambda) \cong \Pi L(\lambda)$ if and only if $L_{\mathfrak{sq}}(\lambda) \not\cong \Pi L_{\mathfrak{sq}}(\lambda)$, and Theorem 3.2 implies there is no self extension $\frac{L_{\mathfrak{sq}}(\lambda)}{\Pi L_{\mathfrak{sq}}(\lambda)}$. Finally, case (c) was done in Theorem 3.2. \qed

4. Standard Block

In this section, we compute the Ext-quiver for the standard block of $\mathfrak{g} = \mathfrak{q}(3)$ and $\mathfrak{g} = \mathfrak{sq}(3)$.
4.1. Induction and Restriction Functors. Our goal is to establish a connection between the standard block $\mathcal{F}_{1,0,\ldots,0}^n$ and the principal block $\mathcal{F}_{0}^{n-1}$. As a first step we use the geometric induction in the case when it is an exact functor.

Consider the parabolic subalgebra

$$p = h \oplus \bigoplus_{2 \leq i \leq n} g_{\varepsilon_i - \varepsilon_i} \oplus \bigoplus_{2 \leq i \neq j \leq n} g_{\varepsilon_i - \varepsilon_j}.$$ 

Its Levi subalgebra $\mathfrak{l}$ is isomorphic to $\mathfrak{q}(1) \oplus \mathfrak{q}(n-1)$. Let

$$n_p = \bigoplus_{2 \leq i \leq n} g_{\varepsilon_i - \varepsilon_i}$$

denote the nilpotent radical of $p$.

Let $t$ be a positive integer. A dominant integral weight $\lambda$ of $\mathfrak{q}(n)$ is called $t$-admissible if $\lambda = (t, \lambda_2, \ldots, \lambda_n)$ such that $t + \lambda_i \neq 0$, in other words the first mark of $\lambda$ is $t$ and $\lambda$ is $p$-typical.

Let $\mathcal{F}_t(t)$ denote the category of finite-dimensional $t$-modules on which $H_1$ acts by $t$ and all weights of $\mathfrak{q}(n-1)$ have integral marks strictly less than $t$. Let $\mathcal{F}^n(t)$ denote the Serre subcategory of $\mathcal{F}_t^n$ generated by $L(\lambda)$ for all $t$-admissible $\lambda$. Define the functors

$$\Gamma^t : \mathcal{F}_t(t) \rightarrow \mathcal{F}^n(t), \quad R^t : \mathcal{F}^n(t) \rightarrow \mathcal{F}_t(t)$$

by

$$\Gamma^t(M) := \Gamma_0(G/P,M), \quad R^t := \text{Ker}(H_1 - t).$$

**Proposition 4.1.1.** The functors $\Gamma^t$ and $R^t$ define an equivalence between $\mathcal{F}_t(t)$ and $\mathcal{F}^n(t)$.

**Proof.** By Proposition 2.2.2, $\Gamma_t(G/P,M) = 0$ for $i > 0$ and every $M \in \mathcal{F}_t(t)$. Furthermore, $\Gamma_0(G/P,M)$ is simple if $M$ is simple. On the other hand, $R^t(N) = H^0(p,N)$ for any $N \in \mathcal{F}_t^n(t)$. That implies $\Gamma^t$ is left adjoint to $R^t$, both functors are exact and establish bijection on the sets of isomorphism classes of simple objects in both categories. Hence these functors provide an equivalence between the two categories.

4.2. Reduction to $\mathfrak{q}(n-1)$. Note that every module in $\mathcal{F}_t(t)$ is of the form $L_{\mathfrak{q}(1)} \boxtimes M$ for some $M \in \mathcal{F}_{0}^{n-1}$.

**Corollary 4.2.1.** Let $\lambda = (\lambda_1, \ldots, \lambda_k, 1, 0, \ldots, 0, -\lambda_k, \ldots, -\lambda_1), \mu = (\mu_1, \ldots, \mu_{k'}, 1, 0, \ldots, 0, -\mu_{k'}, \ldots, -\mu_1)$ be $\mathfrak{q}(n)$ dominant weights in the standard block. For $t >> \max\{\lambda_1, \mu_1\}$,

$$\text{Ext}^1_{\mathfrak{q}(n)}(L(\lambda), L(\mu)) = \text{Ext}^1_{\mathfrak{q}(n)}(L(t, \tilde{\lambda}), L(t, \tilde{\mu}))$$

$$= \text{Ext}^1_{\mathfrak{q}(1) \oplus \mathfrak{q}(n-1)}(L(t) \boxtimes L(\tilde{\lambda}), L(t) \boxtimes L(\tilde{\mu}))$$

$$= \text{Ext}^1_{\mathfrak{q}(n-1)}(L(\tilde{\lambda}), L(\tilde{\mu})) \oplus \text{Ext}^1_{\mathfrak{q}(n-1)}(L(\tilde{\lambda}), \Pi L(\tilde{\mu}))$$

where $\tilde{\lambda} = (\lambda_1 - 1, \ldots, \lambda_k - 1, 1, 0, \ldots, 1 - \lambda_k, \ldots, 1 - \lambda_1)$ and $\tilde{\mu} = (\mu_1 - 1, \ldots, \mu_{k'} - 1, 0, \ldots, 0, 1 - \mu_{k'}, \ldots, 1 - \mu_1)$. If $k = 0$, then $\lambda = (1, 0, \ldots, 0)$ and $\tilde{\lambda} = 0$, and similarly for $k' = 0$.

**Proof.** The first equality follows from [Ser-ICM Lemma 5.12], which shows there is an equivalence of categories between $\mathcal{F}_t^n(1,0,\ldots,0)$ (“standard block”) and $\mathcal{F}_t^n(t,0,\ldots,0)$ given by a composition of translation functors. Under this equivalence, $L(\lambda)$ maps to $L(t, \tilde{\lambda})$. The second equality follows from Proposition 4.1.1. The last equality follows from Lemma 3.0.3.

Now, using the $\mathfrak{q}(2)$ Ext quiver in Maz Theorem 27, this corollary computes all extensions occurring in Theorem 1.9 (4).
Remark 4. In the standard block, the \( \mathfrak{sq}(3) \) extensions are the same as the \( \mathfrak{q}(3) \) extensions. Indeed, Lemma [7.0.7] shows if \( \lambda = (a, 1, -a), \mu = (b, 1, -b) \), then \( \text{Res} L(\lambda) = L_{\mathfrak{sq}}(\lambda) \oplus \Pi L_{\mathfrak{sq}}(\lambda) \) and \( \text{Ind} L_{\mathfrak{sq}}(\lambda) = L(\lambda) \). Now Shapiro’s lemma implies
\[
\text{Ext}_1^\Omega(\text{Ind} L_{\mathfrak{sq}}(\lambda), L(\mu)) = \text{Ext}_1^\Omega(L_{\mathfrak{sq}}(\lambda), L_{\mathfrak{sq}}(\mu) \oplus \Pi L_{\mathfrak{sq}}(\mu)), \quad \text{and}
\]
\[
\text{Ext}_1^\Omega(\text{Ind} \Pi L_{\mathfrak{sq}}(\lambda), L(\mu)) = \text{Ext}_1^\Omega(\Pi L_{\mathfrak{sq}}(\lambda), L_{\mathfrak{sq}}(\mu) \oplus \Pi L_{\mathfrak{sq}}(\mu)).
\]
Since \( L(\lambda) = \Pi L(\lambda) \), we have \( \text{Ext}_1^\Omega(L(\lambda), L(\mu)) = \text{Ext}_1^\Omega(L_{\mathfrak{sq}}(\lambda), L_{\mathfrak{sq}}(\mu)) \). Also \( \text{Res} L(1, 0, 0) = L_{\mathfrak{sq}}(1, 0, 0) \), hence \( \text{Ind} L_{\mathfrak{sq}}(\lambda) = \text{Ind} \Pi L_{\mathfrak{sq}}(\lambda) \) implies by Shapiro’s lemma
\[
\text{Ext}_1^\Omega(L(\lambda), L(1, 0, 0)) = \text{Ext}_1^\Omega(L_{\mathfrak{sq}}(\lambda), L_{\mathfrak{sq}}(1, 0, 0)) = \text{Ext}_1^\Omega(\Pi L_{\mathfrak{sq}}(\lambda), L_{\mathfrak{sq}}(1, 0, 0)).
\]

4.3. Relations.

4.3.1. \( \mathfrak{g} = \mathfrak{sq}(3) \). All irreducible modules and projective covers considered here will be for \( \mathfrak{sq}(3) \), and we will omit the subscripts from \( L_{\mathfrak{sq}}(\lambda) \) and \( P_{\mathfrak{sq}}(\lambda) \). If \( \lambda \neq (1, 0, 0), \mu = (a, 1, -a), a > 1 \), then \( [P(\lambda) : E(\mu)] = [E(\mu) : L(\lambda)] \) by Theorem [2.2]. We note \( L_{\mathfrak{sq}}(a, 1, -a) \neq \Pi L_{\mathfrak{sq}}(a, 1, -a) \). If \( \lambda = (1, 0, 0) \), then \( [P(\lambda) : E(\mu)] = 2[E(\mu) : L(\lambda)] \). Now, the character formula for \( L(\lambda) : \lambda = (\lambda_1, \lambda_2, \lambda_3) \in \Lambda^+ \) is shown in [PS1] to equal the generic character formula for all \( \lambda \neq (1, 0, 0) \). This combined with character formula for \( E(\lambda) \) (3.3.1) implies
\[
E(1, 0, 0) = 0; \quad E(2, 1, -2) = [L(1, 0, 0)] + [L(2, 1, -2)]; \quad E(a, 1, -a) = [L(a, 1, -a)] + [L(a-1, 1, -a+1)].
\]
Thus, using (2.3.5), we find
\[
[P(1, 0, 0)] = 2[L(1, 0, 0)] + 2[L(2, 1, -2)]
\]
\[
[P(2, 1, -2)] = [L(1, 0, 0)] + 2[L(2, 1, -2)] + [L(3, 1, -3)]
\]
\[
[P(a, 1, -a)] = [L(a-1, 1, 1-a)] + 2[L(a, 1, -a)] + [L(a+1, 1, -a-1)] \quad \text{for } a > 2.
\]
This forces the radical filtrations for \( P(\lambda) \) to be as shown in the Appendix Section 6.1, since we know all possible extensions of simples, and hence \( \text{rad}P(\lambda)/\text{rad}^2P(\lambda) \).

Let \( V \in \mathcal{F} \) have radical filtration \( V = \text{rad}^0(V) \supset \text{rad}^1(V) \supset \cdots \supset \text{rad}^k(V) = 0 \). Let \( \text{rad}_i = \text{rad}^i/\text{rad}^{i+1} \) and denote the radical filtration by
\[
\text{rad}_0V = \text{rad}_1V \cdots \text{rad}_{k-1}V.
\]
Let \( a_1 \in \text{Hom}_Q(L(1, 0, 0), L(2, 1, -2)), b_1 \in \text{Hom}_Q(L(2, 1, -2) L(1, 0, 0)), a_1 \in \text{Hom}_Q(L(t, 1, -t), L(t+1, 1, -t-1)), b_1 \in \text{Hom}_Q(L(t+1, 1, -t-1), L(t, 1, -t)) \) be paths on the quiver. We identify each \( \gamma \in \text{Hom}_Q(L(\lambda), L(\mu)) \) with a corresponding element of \( \text{Hom}_\mathfrak{g}(P(\lambda), \text{rad}P(\mu)/\text{rad}^2P(\mu)) \) as in Proposition [1.5.1]. Then using the radical filtrations in Section 6.1,
\[
\text{im}(a_1b_1) = \text{im}(a_1)(L(2, 1, -2)L(1, 0, 0)) = L(2, 1, -2)
\]
and
\[
\text{im}(a_1b_2) = \text{im}(b_2)(L(2, 1, 2)L(3, 1, -3)) = L(2, 1, -2).
\]
and hence \( a_1b_1 = b_2a_2 \). Likewise we find \( a_2a_1 = b_1b_2 = 0, a_{t+1}a_t = b_tb_{t+1} = 0 \) and \( b_ta_t = a_{t-1}b_{t-1} \) for \( t \geq 3 \). The computation for \( a'_t \in \text{Hom}_Q(\Pi L(t+1, 1, -t-1), \Pi L(t, 1, 1)) \) and \( b'_t \in \text{Hom}_Q(\Pi L(t, 1, -t), \Pi L(t+1, 1, -t-1)) \) is identical.

4.3.2. Translation functor from the principal to the standard block. Consider the translation functors:
\[
TV = \text{pr}_1(V \otimes L(1, 0, 0)) \quad \text{and} \quad T^*W = \text{pr}_2(W \otimes L(0, 0, -1)),
\]
where \( \text{pr}_1 \) is projection to standard block and \( \text{pr}_2 \) is projection to principal block. It is well known \( T, T^* \) are both exact and left and right adjoint to each other.

Lemma 4.3.1. We have \( TL_{\mathfrak{q}}(1, 0, -1) = 0 \) and \( TL_{\mathfrak{q}}(a, 0, -a) \cong L_{\mathfrak{q}}(a, 1, -a) \) for \( a \geq 2 \).
Proof. For the first assertion we use
\[ \text{Hom}_q((L_\lambda(1,0,0), TL_\lambda(1,0,-1)) = \text{Hom}_q(T^*L_\lambda(1,0,0), L_\lambda(1,0,-1)) = 0.} \]
Since all simple constituents of \( TL_\lambda(1,0,-1) \) are isomorphic to \( L_\lambda(1,0,0) \) by the weight argument, the statement follows.

For the second assertion, use Lemma 2.2.1 (2) to check that
\[ TG_0(G/B, v(a,0,-a)) = \Gamma_0(G/B, v(a,1,-a)). \]
Information about the multiplicities of simple modules in \( \Gamma_0(G/B, v(a,0,-a)) \) and \( \Gamma_0(G/B, v(a,1,-a)) \) allows to conclude that
\[ T(\text{Top} \Gamma_0(G/B, v(a,0,-a))) = \text{Top} \Gamma_0(G/B, v(a,1,-a)). \]

4.3.3. \( g = q(3) \). As before, we use BGG reciprocity to find
\[ [P(1,0,0)] = 4[L(1,0,0)] + 2[L(2,1,-2)] \]
\[ [P(2,1,-2)] = 2[L(1,0,0)] + 2[L(2,1,-2)] + [L(3,1,-3)] \]
\[ [P(a,1,-a)] = [L(a-1,1,1-a)] + 2[L(a,1,-a)] + [L(a+1,1,-a-1)] \quad \text{for} \ a > 2 \]

Recall functors Res, Ind from Section 2.4. It is easy to verify the following isomorphisms
\[ P_q(\lambda) \cong \text{Ind} P_{sq}(\lambda), \quad \text{Res}_q(\lambda) \cong P_{sq}(\lambda) \oplus \Pi P_{sq}(\lambda). \]
Furthermore, we have an isomorphism \( P_{sq}(\lambda) \cong \Pi P_{sq}(\lambda) \) only for \( \lambda = (1,0,0) \). Moreover, from relations for \( sq(3) \) we know
\[ \text{Hom}_{sq}(P_{sq}(\lambda), \Pi P_{sq}(\mu)) = 0 \]
if both \( \lambda \) and \( \mu \) are not equal to \( (1,0,0) \). This implies
\[ \text{Ind} : \text{Hom}_{sq}(P_{sq}(\lambda), P_{sq}(\mu)) \to \text{Hom}_q(P_q(\lambda), P_q(\mu)) \]
is an isomorphism if \( \lambda, \mu \neq (1,0,0) \). Therefore we have unique lift of the arrows \( a_t, b_t \) to \( \tilde{a}_t, \tilde{b}_t \) for \( t \geq 2 \) and the relations between them are the same as for \( sq(3) \). For the arrows \( a_1 : P_{sq}(1,0,0) \to P_{sq}(2,1,-2) \) and \( b_1 : P_{sq}(2,1,-2) \to P_{sq}(1,0,0) \) we define
\[ \tilde{a}_1 = \text{Ind}(a_1 + \Pi b_1), \quad \tilde{b}_1 = \text{Ind}(b_1 + \Pi a_1). \]
Then we immediately obtain \( \tilde{a}_1 \tilde{b}_1 = 0 \) and \( \tilde{a}_2 \tilde{a}_1 = \tilde{b}_1 \tilde{b}_2 = 0 \) from the relations for \( sq(3) \). From multiplicities of simple modules in projectives and information about \( \text{Ext}^{1}_{q} \), one can compute the layers of the radical filtration in projective modules which are listed in Section 6.2.

There is one additional loop arrow \( h : P_q(1,0,0) \to P_q(1,0,0) \). Let us show that we can choose \( h \) in such a way that \( h^2 = 0 \). We claim that there exists a \( q(3) \)-module \( R \) with radical filtration
\[ L_q(1,0,0) \mid L_q(2,1,-2) \mid L_q(1,0,0). \]
Indeed, it is proven independently in Section 5 that there exists a \( q \)-module \( R' \) with the radical filtration
\[ \Pi C \mid L_q(2,0,-2) \mid C. \]
Set \( R = TR' \) where \( T \) is the translation functor from the principal to the standard block. Lemma 4.3.1 ensures that the composition factors of \( R \) are as desired. Furthermore, \( R' \) is a quotient of \( P_q(0) \) and hence \( R \) is a quotient of \( P_q(1,0,0) \). That settles the radical filtration of \( R \).

Now we can use an exact sequence
\[ 0 \to R \to P_q(1,0,0) \to R \to 0 \]
to construct \( h \in \text{End}_q(P_q(1,0,0)) \) with image and kernel isomorphic to \( R \). In fact from the radical filtration of \( R \) we know that \( \text{Res} R \cong P_{sq}(1,0,0) \).

Now we can use Lemma 2.4.1 with \( M = R, \ P_q(1,0,0) = \text{Ind} R \) and \( \theta = h \). The algebra \( \text{End}_q(P_q(1,0,0)) \) is generated \( h \) and \( u := \tilde{b}_1 \tilde{a}_1 \) with \( u^2 = 0 \). Lemma 2.4.1 implies \( hu = uh \).
4.4. “Half-Standard” Block. We can compute the Ext quiver for \( \mathfrak{q}(3) \) half-standard block by just computing the radical filtrations of the projective covers. The character formula for \( L(\lambda) \) when \( \text{wt}(\lambda) = \delta_3 \) is the same as the generic character formula. Hence, we find
\[
[\mathcal{E}(\lambda)] = [L(\lambda)] + [L(\lambda + 1)] + [L(\lambda + 2)] + \cdots
\]
where \( \delta_3 \) is the same as the generic character formula. Hence, we find
\[
\mathcal{E}(a, b) = \begin{cases} 
 [L(a, b)] & \text{if } a > b \\
 [L(a, b)] + [L(a, b + 1)] & \text{if } a = b \\
 [L(a, b)] + [L(a, b + 1)] + [L(a, b + 2)] & \text{if } a < b
\end{cases}
\]

Now by our BGG reciprocity result, \( [\mathcal{E}(\mu) : \mathcal{E}(\lambda)] = [\mathcal{E}(\mu) : \mathcal{E}(\lambda)] \) whenever \( \text{wt}(\mu) = \text{wt}(\lambda) = \delta_3 \).

Remark 5. Using a minor improvement of the arguments given in [Ser-ICM], we find there is an equivalence of categories \( F_X \) with \( \text{wt}(\lambda) = \delta_3 \) and \( F_X \) with \( \text{wt}(\lambda) = \delta_{3a+1} \) for any \( t > 0 \) given by a composition of translation functors. Then using the typical lemma (which holds for half-integral typical weights), we find an equivalence of categories between \( F_1(t) \) and \( F_0(t) \) just as in Proposition 4.1.7. Thus, we have an analogue of Corollary 4.2.7 for the half-standard block.

5. Principal Block

5.1. Ext quiver for the principal block for \( \mathfrak{g}(3) \). In this subsection we use the notations
\[
\mathfrak{g} = \mathfrak{g}(3), \quad L(a) = L_{\mathfrak{g}(3)}(a, 0, -a), \quad P(a) = P_{\mathfrak{g}(3)}(a, 0, -a).
\]

We start with the following

Lemma 5.1.1. If \( a > 0 \) then \( L(a) \cong \Pi L(a) \) and \( P(a) \cong \Pi P(a) \). Furthermore, \( P(0) \cong P(0) \).

Proof. If the highest weight \( \mathfrak{h} \)-module of \( L(a) \) is \( v(a, 0, -a) \) then the highest weight \( \mathfrak{h} \)-module of \( L(a) \) is \( v(-a, 0, a) \) [Fre]. The first assertion follows from the isomorphism \( L_v(a, 0, -a) \cong L_v(-a, 0, a) \) of \( \mathfrak{h} \)-modules when \( a > 0 \). If \( I(L), P(L) \) denote the injective, projective hull of a simple \( \mathfrak{g} \)-module \( L \) respectively, then by [Ser1]
\[
I(L) \cong P(L) \otimes T
\]
where \( T \cong S^{top}(\mathfrak{g}) \). In our case \( S^{top}(\mathfrak{g}) = S^8(\mathfrak{g}) \) is the trivial \( \mathfrak{g}_0 \)-module. Hence we have \( I(L) \cong P(L) \). On the other hand \( P(L) \cong P(L) \). Hence if \( a > 0 \), \( P(L) \cong P(L) \). If \( a = 0 \), then \( L(0) = L(0) \) and consequently \( P(L(0)) \cong P(L(0)) \cong P(L(0)) \).

Corollary 5.1.1. If \( a, b > 0 \) then
\[
\text{Ext}^1_{\mathfrak{g}}(L(a), L(b)) \cong \text{Ext}^1_{\mathfrak{g}}(L(b), L(a)), \quad \text{Ext}^1_{\mathfrak{g}}(L(a), L(0)) \cong \text{Ext}^1_{\mathfrak{g}}(L(0), L(a)).
\]

Note, in the case \( \mathfrak{g} = \mathfrak{g}(3) \) and \( \mu = (a, 0, -a), a > 0 \), we have \( [\mathcal{E}(\mu) : \mathcal{E}(\lambda)] = [\mathcal{E}(\mu) : \mathcal{E}(\lambda)] \) by Theorem 2.2. Now, using the character formula for \( L(a, 0, -a) \) [PS2] and \( \mathcal{E}(a, 0, -a) \) [2.3.1], we find
\[
\mathcal{E}(0) = 0; \quad \mathcal{E}(1, 0, -1) = [L(1)]; \quad \mathcal{E}(2, 0, -2) = [L(2)] + [L(1)] + [L(1)] + 2[C]
\]
\[
\mathcal{E}(a, 0, -a) = [L(a)] + [L(a - 1)] \quad \text{if } a > 2.
\]
Thus, using (5.1.6) we find
\[ [P(0)] = 4[C] + 2[L(1)] + 2[L(2)] \]
\[ [P(1)] = 2[C] + 2[L(1)] + [L(2)] \]
\[ [P(2)] = 2[C] + [L(1)] + 2[L(2)] + [L(3)] \]
\[ [P(a)] = [L(a - 1)] + 2[L(a)] + [L(a + 1)] \quad \text{for} \ a > 2. \]

Furthermore, it follows from [PS2] that \( \Gamma_i(G/B, v(a, 0, -a)) = 0 \) if \( a \geq 2 \) and \( i \geq 1 \). Therefore if \( a \geq 3 \), we obtain a non-split exact sequence
\[ 0 \to L(a - 1) \to \Gamma_0(G/B, v(a, 0, -a)) \to L(a) \to 0, \]
which gives a non-trivial extension \( \text{Ext}^1_\mathfrak{g}(L(a), L(a - 1)) \). There are no more by Proposition (5.1.3).

**Lemma 5.1.2.** Let \( a \geq 3 \), then
\[ \text{Ext}^1_\mathfrak{g}(L(a), L(a - 1) \cap L(a)) = \text{Ext}^1_\mathfrak{g}(L(a - 1), L(a)) = C \]
and \( \text{Ext}^1_\mathfrak{g}(L(a), L) = 0 \) for all simple \( L \) not isomorphic to \( L(a - 1) \).

**Proof.** We do not have self-extensions by Theorem (3.2). If \( b < a \), then a non-trivial extension of \( L(a) \) by \( L(b) \) or \( \Pi L(b) \) is a quotient of \( \Gamma_0(G/B, v(a, 0, -a)) \) by Proposition (2.2.1). That forces \( b = a - 1 \) and also implies \( \text{Ext}^1_\mathfrak{g}(L(a), \Pi L(b)) = 0 \). The case \( b > a \) follows by Corollary 5.1.1. \( \square \)

**Remark 6.** Our choice of labeling \( \Pi L(a) \) vs \( L(a) \) for \( a \geq 2 \) is determined by the above lemma. For \( a = 1 \) we assume that \( L(1) \) is dual to the adjoint representation in \( \mathfrak{psq}(3) \). For \( a = 2 \) the choice will be clear from the following lemma. Note that in the same way using
\[ [\Gamma_0(v(2, 0, -2)) : L(1)]_\Pi = 1, \]
we obtain
(5.1.1) \[ \dim \text{Ext}^1(L(2), L(1) \oplus \Pi L(1)) = \dim \text{Ext}^1(L(1) \oplus \Pi L(1), L(2)) \leq 1. \]

**Lemma 5.1.3.**
(5.1.2) \[ \text{Ext}^1_\mathfrak{g}(L(1), C) = C \quad \text{and} \quad \text{Ext}^1_\mathfrak{g}(\Pi L(1), C) = 0, \]
(5.1.3) \[ \text{Ext}^1_\mathfrak{g}(L(2), C) = 0 \quad \text{and} \quad \text{Ext}^1_\mathfrak{g}(\Pi L(2), C) = C, \]
(5.1.4) \[ \text{Ext}^1_\mathfrak{g}(L(1), L(2)) = 0 \quad \text{and} \quad \text{Ext}^1_\mathfrak{g}(\Pi L(1), L(2)) = 0. \]

**Proof.** Identify \( \Pi L(1) \) with the simple Lie superalgebra \( \mathfrak{psq}(3) \), then \( \text{Der} \mathfrak{psq}(3) = \Pi C, \ [Kac] \). This implies (5.1.2) by use of duality and Lemma 5.1.1.

In order to prove remaining relations we consider the projective module \( P(0) \). We know all its simple constituents: \( L(1), \ \Pi L(1), L(2), \ \Pi L(2) \) and \( L(0), \ \Pi L(0) \), the last two appear with multiplicity 2. Since \( P(0) \) is projective, we know its super dimension is 0, so \( L(0) \) and \( \Pi L(0) \) occur with same multiplicity. Assume for the sake of contradiction that
\[ \text{Ext}^1_\mathfrak{g}(L(2), C) = \text{Ext}^1_\mathfrak{g}(\Pi L(2), C) = 0. \]

That would imply that
\[ P(0)/\text{rad} P(0) = L(0), \quad \text{rad} P(0)/\text{rad}^2 P(0) = L(1). \]

Furthermore, since \( \mathfrak{g}(3)^* \) is a quotient of \( P(0) \) we know that \( \text{rad}^2 P(0)/\text{rad}^3 P(0) \) contains \( \Pi L(0) \). But it must contain \( L(2) \) or \( \Pi L(2) \) (otherwise \( L(2) \) will not appear in \( P(0) \)). We have the inequality
\[ [\text{rad}^2 P(0)/\text{rad}^3 P(0) : L] \leq \dim \text{Ext}^1_\mathfrak{g}(L(1), L) \]
for any simple \( L \). Therefore \( \text{rad}^2 P(0)/\text{rad}^3 P(0) \) contains only one copy of \( \Pi L(0) \) and one copy of either \( L(2) \) or \( \Pi L(2) \), 5.1.1. Without loss of generality we may assume
\[ \text{rad}^2 P(0)/\text{rad}^3 P(0) = \Pi L(0) \oplus \Pi L(2). \]
Let $M = P(0)/\operatorname{rad}^3P(0)$. Then by our assumption we have $M^* \subset P(0)^* \cong P(0)$, and we have the exact sequence

$$0 \to M^* \to P(0) \to M \to 0.$$ 

Furthermore, it also follows from our assumptions that the radical and socle filtrations on $M$ are the same. In particular, it follows that $M^*/\operatorname{rad}M^* = \Pi L(0) \oplus L(2)$. That would imply $\operatorname{Ext}^1_\mathcal{O}(\Pi L(2) \oplus \Pi L(0), L(2) \oplus \Pi L(0)) \neq 0$. But that contradicts our original assumption.

The above argument implies that $\operatorname{Ext}^1_\mathcal{O}(C, \Pi L(2)) = C$. Therefore

$$\operatorname{rad}P(0)/\operatorname{rad}^2P(0) = L(1) \oplus \Pi L(2) \quad \text{or} \quad \operatorname{rad}P(0)/\operatorname{rad}^2P(0) = L(1) \oplus \Pi L(2) \oplus L(2).$$

However, it is easy to see that the latter case is impossible since otherwise by self-duality of $P(0)$ we have $\operatorname{soc}^2P(0)/\operatorname{soc}P(0) = \Pi L(1) \oplus \Pi L(2) \oplus L(2)$ and that would imply $[P(0) : L(2)]_{\Pi} > 2$. Therefore we have $\operatorname{rad}P(0)/\operatorname{rad}^2P(0) = L(1) \oplus \Pi L(2)$, and that implies (5.1.3).

Moreover, we obtain the radical filtration of $P(0)$ as shown in the appendix. Since $\Pi \nu(2, 0, -2)$ is the highest weight $\mathfrak{h}$-submodule of $P(0)$, we have a homomorphism $\gamma : \Gamma_0(G/B, \Pi \nu(2, 0, -2)) \to P(0)$ and from the socle filtration of $P(0)$ (in this case we have $\operatorname{soc}^kP(0) = \operatorname{rad}^{k-2}P(0)$) we obtain that $\gamma$ is injective. The socle filtration of $\Gamma_0(G/B, \Pi \nu(2, 0, -2))$ is inherited from that of $P(0)$. We get

$$\operatorname{soc}\Gamma_0(G/B, \Pi \nu(2, 0, -2)) = L(0),$$

$$\operatorname{soc}^2\Gamma_0(G/B, \Pi \nu(2, 0, -2))/\operatorname{soc}\Gamma_0(G/B, \Pi \nu(2, 0, -2)) = \Pi L(1),$$

$$\operatorname{soc}^3\Gamma_0(G/B, \Pi \nu(2, 0, -2))/\operatorname{soc}^2\Gamma_0(G/B, \Pi \nu(2, 0, -2)) = \Pi L(0),$$

$$\operatorname{soc}^4\Gamma_0(G/B, \Pi \nu(2, 0, -2))/\operatorname{soc}^3\Gamma_0(G/B, \Pi \nu(2, 0, -2)) = \Pi L(2).$$

That proves (5.1.4) \hfill $\square$

Note that Lemma 5.1.2 and Lemma 5.1.3 prove that the ext quiver for the principal block for $\mathfrak{sq}(3)$ coincides with one in Theorem 1.3.

5.2. Relations for the principal block for $\mathfrak{g} = \mathfrak{sq}(3)$. We first compute the radical filtration of all indecomposable projectives. Using the self-duality (up to parity) of $P(a)$ and fact that we know all possible extensions of simples, we automatically know the top 2 and bottom 2 layers. It turns out the other layers are fixed as well, as shown below. Diagrams are in the Appendix Section 6.2.

For $P(0)$, we just obtained in the proof of Lemma 5.1.3

For $P(1)$, $\text{Top}P(1) = L(1)$ and $\operatorname{rad}P(1)/\operatorname{rad}^2P(1) = \Pi C$. The only extension with $\Pi C$ is $L(2)$.

For $P(2)$, $\text{Top}P(2) = L(2)$ and $\operatorname{rad}P(2)/\operatorname{rad}^2P(2) = L(0)+L(3)$. Considering possible extensions of $L(0)$ and $L(3)$, we find $L(1)$ is subquotient of $\operatorname{rad}^2P(2)$ and $\operatorname{soc}^2P(2) = L(2)$. Finally, there only exists an extension $L(1) \oplus C$ and not $L(1) \oplus C$.

For $P(a), a \geq 3$, $\text{Top}P(a) = L(a)$ and $\operatorname{rad}P(a)/\operatorname{rad}^2P(a) = L(a-1) + L(a+1)$.

Now, we will use the radical filtrations to compute all relations. Note in all cases,

$$\dim \operatorname{Hom}_\mathfrak{g}(P(a, 0, -a), M) = [M : L(a, 0, -a)].$$

Let $a \in \operatorname{Hom}_\mathfrak{g}(P(1), P(0)), c \in \operatorname{Hom}_\mathfrak{g}(P(0), \Pi P(1)), d \in \operatorname{Hom}_\mathfrak{g}(P(2), \Pi P(0)), b \in \operatorname{Hom}_\mathfrak{g}(P(0), P(2))$, and the $a', b', c', d'$ be the corresponding parity-changed arrows. Since $[P(1) : \Pi L(1)] = [P(2) : \Pi L(2)] = 0$, we obtain $bd' = ca = b'd' = c'a' = 0$.

Let $a_t \in \operatorname{Hom}_\mathfrak{g}(P(t, P(t+1)), b_t \in \operatorname{Hom}_\mathfrak{g}(P(t+1), P(t))$. Then $[\Pi P(0) : L(3)] = [P(3) : L(0)] = 0$ and $[P(t+1) : L(t) = [P(t-1) : L(t+1)] = 0$ for $t \geq 3$ implies the relations $db_2 = a_2b = 0$ and $a_{t+1}a_t = b_{t+1}b_t = 0, t \geq 2$. By symmetry, we get the parity-changed analogues of these relations.

Next consider the cycle paths in $P(0) : ac'a'c, d'b'a'c, d'c'db, ac'db$. We know from previous paragraph that $ac'a'c = 0 = db'db$. Also, since $\dim \operatorname{Hom}_\mathfrak{g}(P(0), \Pi P(0)) = 2$, $ac'$ and $db$ are not scalar multiples. Thus

$$\text{im}(d'b'a'c) = L(0) = \text{im}(ac'db)$$
and \( \dim \text{End}_q(P(0)) = 2 \), implies \( d'b'a'c = \lambda_0 a'c' db \) for \( \lambda_0 \in \mathbb{C}^* \). Similarly we find \( dbac' = \lambda'_0 a'c' d'b' \).

Next consider the nontrivial cycle paths in \( P(2) : b_2 a_2, ba'c' \). Since
\[
\text{im}(b_2 a_2) = L(2) = \text{im}(bac'd),
\]
and \( \dim \text{End}_q(P(2)) = 2 \), we conclude \( b_2 a_2 = \lambda_2 bac'd, \lambda_2 \in \mathbb{C}^* \).

Finally, for \( t \geq 3 \), we find cycle paths in \( P(a) \) are \( a_t b_t, b_{t+1} a_{t+1} \). Both have image \( L(t) \), hence \( a_t b_t = \lambda_t b_{t+1} a_{t+1} \). Observe we can sufficiently scale all arrows and hence normalize all \( \lambda_t, \lambda'_t \in \mathbb{C}^* \) to equal 1. The remaining dim \( \text{Hom}_q(P(a), P(b)) \) calculations shows there are no other relations.

5.3. The principal block of \( q(3) \). We start with the following general statement.

**Lemma 5.3.1.** Let \( \lambda, \mu \) be two distinct weights in the principal block such that there exists \( i, j : \lambda_i = \mu_j = 0 \). If \( \dim \text{Ext}^1_{q(n)}(L_{sq}(\lambda), L_{sq}(\mu)) + \dim \text{Ext}^1_{q(n)}(L_{sq}(\lambda), \Pi L_{sq}(\mu)) \leq 1 \), then
\[
\text{Ext}^1_{q(n)}(L_{sq}(\lambda), L_{sq}(\mu)) = \text{Ext}^1_{q(n)}(L(\lambda), L(\mu)).
\]

**Proof.** By Cor. 3.0.1, \( \text{Res} L(\lambda) = L_{sq}(\lambda) \) and \( \text{Ind} L_{sq}(\lambda) = \frac{\Pi L_{sq}(\lambda)}{L(\lambda)} \). The nonsplit short exact sequence
\[
0 \to L(\lambda) \to V \to \Pi L(\lambda) \to 0 \quad \text{of } q(n)\text{-modules, which exists by Theorem 3.1,}
\]
gives rise to long exact sequences \((\mu \neq \lambda)\)
\[
0 \to \text{Ext}^1_{q(n)}(L(\lambda), L(\mu)) \to \text{Ext}^1_{q(n)}(L_{sq}(\lambda), L_{sq}(\mu)) \to \text{Ext}^1_{q(n)}(L(\lambda), L(\mu)) \to \text{Ext}^2_{q(n)}(L(\lambda), L(\mu)) \to \cdots
\]
\[
0 \to \text{Ext}^1_{q(n)}(L(\lambda), \Pi L(\mu)) \to \text{Ext}^1_{q(n)}(L_{sq}(\lambda), \Pi L_{sq}(\mu)) \to \text{Ext}^1_{q(n)}(L(\lambda), \Pi L(\mu)) \to \text{Ext}^2_{q(n)}(L(\lambda), \Pi L(\mu)) \to \cdots
\]
Now the lemma follows from Shapiro’s lemma, \( \text{Ext}^1_{q(n)}(V, L(\mu)) = \text{Ext}^1_{q(n)}(L_{sq}(\lambda), L_{sq}(\mu)) \), and the hypotheses. \( \square \)

Lemma 5.3.1 implies that the Ext quiver for the principal block of \( q(3) \) is obtained from that of \( sq(3) \) by adding a single arrow between each \( L(a) \) and \( \Pi L(a) \) (Theorem 5.1).

**Lemma 5.3.2.** Let \( q = q(3) \) and \( \theta \in \text{Hom}_q(P(\lambda), \Pi P(\lambda)) \) be the unique self extension for each \( \lambda \) in the principal \( q \)-block. Let \( \mathbb{P}_{sq} \) (resp., \( \mathbb{P}_q \)) denote the direct sum of all indecomposable projectives in the principal block for \( sq(3) \) (resp., \( q(3) \)); \( \mathcal{A} = \text{End}_{sq}(\mathbb{P}_{sq}) \) denote the algebra defined by the quiver with relations in principal \( sq(3) \)-block. Then the algebra defined by quiver with relations in principal \( q(3) \)-block is
\[
\mathcal{A}' = \text{End}_{q}(\mathbb{P}_q) \cong \mathcal{A} \otimes \mathbb{C}[\theta]/(\theta^2).
\]

**Proof.** Recall the functors \( \text{Res} \) and \( \text{Ind} \) from Section 2.4. We would like to show that \( M = \mathbb{P}_{sq} \) satisfies the assumptions of Lemma 2.4.1. Cor. 3.0.1 implies \( \mathbb{P}_q \cong \text{Ind} M \). It remains to show the existence of \( \theta \). The BGG reciprocity implies for \( \lambda, \mu \) in principal block, \( [P_q(\lambda) : L(\mu)] = 2[P_{sq}(\lambda) : L_{sq}(\mu)] \). Since \( \text{Ind} P_{sq}(\lambda) \) is projective,
\[
\text{Ind} P_{sq}(\lambda) = P_q(\lambda) \quad \text{and} \quad \text{Res} P_q(\lambda) = P_{sq}(\lambda) \oplus \Pi P_{sq}(\lambda).
\]
If \( \lambda \neq 0 \) then \( \text{Hom}_{sq}(\Pi P_{sq}(\lambda), P_{sq}(\lambda)) = 0 \) and therefore the above decomposition is unique.

By Frobenius reciprocity and fact that \( \text{Hom}_{sq}(P_{sq}(\lambda), \Pi P_{sq}(\lambda)) = 0 \) for \( \lambda \neq 0 \), we have for \( \lambda \neq 0 \)
\[
\text{Hom}_q(\text{Ind} P_{sq}(\lambda), \text{Ind} \Pi P_{sq}(\lambda)) = \text{Hom}_{sq}(P_{sq}(\lambda), \text{Res} \text{Ind} \Pi P_{sq}(\lambda))
\]
\[
= \text{Hom}_{sq}(P_{sq}(\lambda), P_{sq}(\lambda) \oplus \Pi P_{sq}(\lambda))
\]
\[
= \text{Hom}_{sq}(P_{sq}(\lambda), \text{Res} \text{Ind} P_{sq}(\lambda)) = \mathbb{C}.
\]

We choose \( \theta_\lambda : P_q(\lambda) \to \Pi P_q(\lambda) \) corresponding to the identity map in \( \text{Hom}_{sq}(P_{sq}(\lambda), P_{sq}(\lambda)) \) and set \( \tilde{P}(\lambda) = \text{Im} \theta \). Then we have an exact sequence
\[
0 \to \Pi P(\lambda) \to P_q(\lambda) \to \tilde{P}(\lambda) \to 0,
\]
with \( \text{Res} \bar{P}(\lambda) \cong P_{\text{sq}}(\lambda) \). Now let us prove that for \( \lambda = 0 \) we also have \( \theta : P_{\text{sq}}(0) \to \Pi P_{\text{sq}}(0) \) with \((\Pi \theta)\theta = 0\) and hence the exact sequence

\[
0 \to \Pi \bar{P}(0) \to P_{\text{sq}}(\lambda) \to \bar{P}(0) \to 0.
\]

We use that \( P_{\text{sq}}(0) = pr(\text{Ind}_{q(3)}^{q(3)} C) \) where \( pr \) denote the projection on the principal block. Let \( l = q(3)_0 \otimes C \bar{H} \) where \( \bar{H} = \bar{H}_1 + \bar{H}_2 + \bar{H}_3 \). Since \( \bar{H}^2 \) acts by zero on the modules of our block we have an exact sequence of \( l \)-modules

\[
0 \to \Pi C \to \text{Ind}_{q(3)}^l C \to C \to 0,
\]

and therefore the exact sequences

\[
0 \to \Pi \text{Ind}_{q(3)}^l C \to \text{Ind}_{q(3)}^l C \to \text{Ind}_{q(3)}^l C \to 0,
\]

\[
0 \to \text{Ind}_{q(3)}^l C \text{ } \xrightarrow{\Pi \alpha} \Pi \text{Ind}_{q(3)}^l C \xrightarrow{\Pi \beta} \Pi \text{Ind}_{q(3)}^l C \to 0.
\]

By setting \( \theta = pr(\Pi \alpha \beta) pr \) we obtain the desired claim.

To finish the proof we just use Lemma [2,4.1]

\[\square\]

6. Appendix: Radical filtrations for \( P_{\text{sq}}(\lambda) \) when \( g = \text{sq}(3), q(3) \).

In all radical filtrations, an edge denotes an extension. Observe for \( P_{q(3)}(a, 0, -a) \), the “left half” corresponds to \( \ker \theta \) and the “right half” corresponds to \( \text{im} \theta \).

6.1. \( g = \text{sq}(3) \). The radical filtrations are \((a \geq 3)\):

\[
P(1, 0, 0) \quad P(2, 1, -2) \quad P(a, 1, -a)
\]

\[
L(1, 0, 0) \quad L(2, 1, -2) \quad L(a, 1, -a)
\]

\[
\Pi L(2, 1, -2) \quad L(2, 1, -2) \quad L(a + 1, 1, -a - 1)
\]

\[
L(1, 0, 0) \quad L(2, 1, -2) \quad L(a, 1, a)
\]
6.2. $\mathfrak{g} = \mathfrak{q}(3)$. The radical filtrations are $(a \geq 3)$:

\[
\begin{array}{ccc}
P(1,0,0) & P(2,1,-2) & P(a,1,-a) \\
L(1,0,0) & L(2,1,-2) & L(a,1,-a) \\
L(1,0,0) & L(2,1,-2) & L(a,1,-a) \\
L(2,1,-2) & L(1,0,0) & L(a,1,1,-a-1) \\
L(1,0,0) & L(2,1,-2) & L(a-1,1,1-a)
\end{array}
\]

The following radical filtrations are deduced from the fact that $\theta : P(a) \rightarrow \Pi P(a)$ corresponds to $\text{id} : P_{sq}(a) \rightarrow P_{sq}(a)$ as seen from Lemma 5.3.2.
