Constructive Spherical Codes by Hopf Foliations

Henrique K. Miyamoto, Student Member, IEEE, Sueli I. R. Costa, Member, IEEE and Henrique N. Sá Earp

Abstract

We present a new systematic approach to constructing spherical codes in dimensions $2^k$, based on Hopf foliations. Using the fact that a sphere $S^{2n-1}$ is foliated by manifolds $S^{n-1}_{\cos \eta} \times S^{n-1}_{\sin \eta}$, $\eta \in [0, \pi/2]$, we distribute points in dimension $2^k$ via a recursive algorithm from a basic construction in $\mathbb{R}^4$. Our procedure outperforms some current constructive methods in several small-distance regimes and constitutes a compromise between achieving a large number of codewords for a minimum given distance and effective constructiveness with low encoding computational cost. Bounds for the asymptotic density are derived and compared with other constructions. The encoding process has storage complexity $O(n)$ and time complexity $O(n \log n)$. We also propose a sub-optimal decoding procedure, which does not require storing the codebook and has time complexity $O(n \log n)$.

I. INTRODUCTION

A spherical code $C(M, n, d) := \{x_1, x_2, ..., x_M\} \subset S^{n-1}$ is a set of $M$ points on the unit Euclidean sphere in $\mathbb{R}^n$ with minimum Euclidean distance at least $d$, cf. [2]. Problems with spherical codes involve finding optimal distributions of points relative to some parameter of interest, and they lend themselves to several applications. From a practical point of view, it is also desirable that a code exhibits algebraic or geometric structures and has low complexity for the coding and decoding processes. The spherical packing problem in spherical code design can be considered in the following presentation: given a minimum Euclidean distance $d > 0$, to find the largest possible number $M$ of points on $S^{n-1}$ with all mutual distances at least $d$. The solution is trivial for $n = 2$, namely a...
regular polygon, but few optimal solutions are known for higher dimensions. Special codes and some best known codes for a given distance in selected dimensions are presented in [2] and [3].

Among the most well-known constructive spherical codes, we highlight the so-called apple-peeling [4], wrapped [5] and laminated [6] methods, the last two being asymptotically dense. The torus layers spherical codes (TLSC) [7], while not asymptotically dense, have a more homogeneous structure and have been shown to compare favorably with other codes for non-asymptotic minimum distances. This method foliates the sphere $S^{2n-1}$ by flat manifolds $S^1 \times \cdots \times S^1$ and distributes points using good packing density lattices in the half-dimension [8], [9]. Other recent contributions to this topic include codes obtained by partitioning the sphere into regions of equal area [10], bounds for constructible codes near the Shannon bound [11], commutative group codes [12], [13] and cyclic group codes [14]. One main challenge for the application of spherical codes is the effective constructiveness for a large range of distances at a reasonable computational cost, which we propose to address in this work.

Classical applications of spherical codes in communications include channel coding, as a generalization of PSK modulation, and source coding, using shape-gain vector quantizers [15], [16]. The problem of optimal constellation design for signalling in non-coherent communications can be formulated as a sphere packing on the Grassmannian manifold of lines [17], which, in turn, is associated to an antipodal spherical code [18]. A recent example of such approach can be found in [19]. Furthermore, spherical codes have been used in schemes to improve power efficiency of communication systems in the context of MIMO communications [20], [21].

In the context of coherent optical communications, four-dimensional modulations have been considered in order to exploit the physical nature of the electromagnetic field. In [22], [23], [24] the performance of four-dimensional modulations is studied and spherical codes are also considered. In [25], the authors observe that, at low spectral efficiencies, in dimensions two and four, spherical codes have optimal or close to optimal performance. The performance of modulations in dimensions 8 and 16 has also been addressed in [26], [27].

We propose a construction of spherical codes inspired by the TLSC method and the Hopf fibration, which gives a somewhat ‘natural’ foliation of $S^3$, $S^7$ and $S^{15}$, and which also appears in problems in physics and communications [24], [28], [29]. Our procedure exploits Hopf foliations in dimensions $2^k$ to construct a family of spherical codes by Hopf foliations (SCHF), by means of a recursive algorithm for any given minimum distance $d \in \{0, 2\}$. The initial step is a flat model in $\mathbb{R}^4$, for which this construction is equivalent to TLSC via special lattices in dimension two. For higher dimensions, the construction is qualitatively different and, besides defining a much simpler algorithm, for certain minimum distances, it outperforms known TLSC implementations in terms of code cardinality. Although we focus on codes in dimensions $2^k$ with basic dimension 4, the procedure presented here can be applied to any even dimension $2n$, if provided with a family of spherical codes in dimension $n$. The performance analysis of the proposed codes includes the comparison with other known constructions, determining their asymptotic density, and computing the complexity of the encoding and decoding processes.

This paper is organized as follows: Section II is an introduction to Hopf foliations. Section III introduces the SCHF, and derives some of their properties and the recursive construction procedure. In Section IV we present numerical results for constructions in dimensions 4, 8, 16, 32 and 64. In Section V we derive asymptotic density bounds for our family of codes, showing that those can be approached for not so small minimum distances.
Section VI discusses the encoding complexity, showing that this construction has storage complexity $O(n)$ and time complexity $O(n \log n)$. In Section VII we provide a suboptimal decoding algorithm with time complexity $O(n \log n)$ and storage complexity $O(1)$ which avoids the high-complexity of the ML decoder, while keeping reasonable decoding capacity. Finally, in Section VIII we draw some conclusions and perspectives for subsequent work.

II. HOPF FIBRATION AND SPHERE FOLIATIONS

We denote the Euclidean sphere of $\mathbb{R}^n$, with radius $r$, centered at the origin, by

$$S^{n-1}_r := \{ x \in \mathbb{R}^n : \|x\| = r \},$$

and the unit sphere simply by $S^{n-1} := S^{n-1}_1$.

For $n \in \{1, 2, 4, 8\}$, the Hopf fibration is the map

$$h : S^{2n-1} \rightarrow S^n$$

$$(z_0, z_1) \mapsto (2z_0 \overline{z_1}, |z_0|^2 - |z_1|^2)$$

in which $z_0, z_1$ are elements of a normed division algebra $\mathbb{A}$, which can be chosen to be the real numbers $\mathbb{R}$, the complex numbers $\mathbb{C}$, the quaternions $\mathbb{H}$ or the octonions $\mathbb{O}$, respectively in real dimensions $n = 1, 2, 4, 8$, cf. [30], [31], [32] (see Fig. 1).

Identifying $\mathbb{R}^{2n} \cong \mathbb{A}^2$ by $(x_0, \ldots, x_{n-1}; x_n, \ldots, x_{2n-1}) \leftrightarrow (z_0; z_1)$ and $\mathbb{R}^{n+1} \cong \mathbb{A} \times \mathbb{R}$ by $(x_0, \ldots, x_n) \leftrightarrow (z, x)$, the unit $(2n-1)$- and $n$-spheres are described respectively by

$$S^{2n-1} = \{(z_0, z_1) \subset \mathbb{A}^2 : |z_0|^2 + |z_1|^2 = 1 \}$$

and

$$S^n = \{(z, x) \subset \mathbb{A} \times \mathbb{R} : |z|^2 + x^2 = 1 \}.$$

It is well-known that each Hopf map endows $S^{2n-1}$ with a fiber bundle structure $S^{n-1} \hookrightarrow S^{2n-1} \xrightarrow{h} S^n$: the preimage $h^{-1}(P)$ of each point $P \in S^n$ under the Hopf fibration is a great sphere $S^{n-1} \subset S^{2n-1}$.

Each set $h^{-1}(P) \cong S^{n-1}$ is called the fiber of $h$ over $P$. Consider a point $P$ on a fixed parallel slice $S^{n-1}_{\sin \frac{\pi}{2}} \subset S^n$ given by a fixed coordinate $x_i = \cos \frac{\pi}{2} \eta$, $\eta \in [0, \pi/2]$. Varying $P$ over such parallel slice (i.e., varying $\eta \in [0, \pi/2]$) spans a pre-image comprising the union of corresponding fibers in the total space $S^{2n-1}$, which is therefore a product $S^{n-1}_{\cos \eta} \times S^{n-1}_{\sin \eta} \subset S^{2n-1}$. Hence, by considering all such slices in the base sphere $S^n$, we foliate $S^{2n-1}$ by product manifolds $T^{n-2}_{\eta} := (S^{n-1}_{\cos \eta} \times S^{n-1}_{\sin \eta})_{\eta} := S^{n-1}_{\cos \eta} \times S^{n-1}_{\sin \eta}$.

As it turns out, this foliation which we call Hopf foliation is not restricted to the cases $n \in \{1, 2, 4, 8\}$, indeed it extends to any $n \in \mathbb{N}^*$, even if there is not an associated normed division algebra in that dimension.

**Assertion 1.** For every $n \in \mathbb{N}^*$, the sphere $S^{2n-1} \subset \mathbb{R}^{2n}$ is foliated by manifolds $(S^{n-1}_{\cos \eta} \times S^{n-1}_{\sin \eta})_{\eta}$.

Indeed, write $x = (x_1, \ldots, x_{2n}) \in S^{2n-1} \subset \mathbb{R}^{2n}$ as

$$x = \left( \frac{\alpha (x_1, \ldots, x_n)}{\alpha} ; \frac{\beta (x_{n+1}, \ldots, x_{2n})}{\beta} \right)$$

(3)
for $\alpha := \|\langle x_1, \ldots, x_n \rangle\|$ and $\beta := \|\langle x_{n+1}, \ldots, x_{2n} \rangle\|$ and $\alpha, \beta \neq 0$. For $\alpha = 0$ or $\beta = 0$, we have degenerated manifolds $0 \times S_{\sin \eta}^{n-1}$ or $S_{\cos \eta}^{n-1} \times 0$. Since for any $x \in S^{2n-1}$ we have $\alpha^2 + \beta^2 = 1$, there is a unique $\eta \in [0, \pi/2]$ such that $\alpha = \cos \eta$ and $\beta = \sin \eta$, so

$$x = (\cos \eta v_1; \sin \eta v_2), \quad v_1, v_2 \in S^{n-1}.$$  

This describes the foliation of the unit sphere $S^{2n-1} \subset \mathbb{R}^{2n}$ by products of spheres $S_{\cos \eta}^{n-1} \times S_{\sin \eta}^{n-1}$ of radii $\cos \eta$ and $\sin \eta$.

In particular, the Hopf fibration in dimension 4 ($n = 2$) gives a foliation of $S^3$ by two-dimensional flat tori $T^2_{\eta} = S_{\cos \eta}^{1} \times S_{\sin \eta}^{1}$:

$$\iota : \left[0, \frac{\pi}{2}\right] \times \left[0, 2\pi\right]^2 \rightarrow S^3$$

$$(\eta; \xi_1, \xi_2) \mapsto (e^{i\xi_1} \cos \eta, e^{i\xi_2} \sin \eta).$$

For each angle $\eta$, the induced map $\iota_{\eta} : [0, 2\pi]^2 \rightarrow S^3$ spans the torus $T_{\eta} := S_{\cos \eta}^{1} \times S_{\sin \eta}^{1} = \text{im} \iota_{\eta} \subset S^3$ of Euclidean radii $\cos \eta$ and $\sin \eta$. When $\eta \notin \{0, \pi/2\}$, the parametrization describes circles, which are degenerated tori. Taking $\eta \notin \{0, \pi/2\}$ and $c = (c_1, c_2) := (\cos \eta, \sin \eta)$, the image $\iota_{\eta}(u/\cos \eta, v/\sin \eta) = \Phi_c(u, v)$ coincides with the flat tori map defined in [7]. Moreover, $\iota_{\eta}([0, 2\pi]^2) = \Phi_c([0, 2\pi c_1] \times [0, 2\pi c_2])$ and $\Phi_c$ is a local isometry, which maps the rectangle into the flat torus in $\mathbb{R}^4$ by gluing its parallel boundary segments.

III. CONSTRUCTION OF SPHERICAL CODES

Our construction of spherical codes, inspired by the Hopf fibration, uses the foliations of Assertion [1] to algorithmically distribute points on spheres $S^{n-1} \subset \mathbb{R}^n$, given a minimum mutual Euclidean distance $d \in [0, 2]$. Each
part of the code constructed on a Cartesian product \((S^{n-1} \times S^{n-1})_\eta\) corresponds to a direct sum \([2\text{ Section 1.7}]\) of codes on each copy of \(S^{n-1}\). We construct each code \(C(M, n, d)\) as the union of several such products.

**A. Choosing the leaves**

The next result, obtained by straightforward calculation, is used to choose the layers of leaves \((S^{n-1} \times S^{n-1})_\eta\), all along our recursive procedure. We remark that, restricted to \(n = 2\), this proposition is the same as \([2\text{ Proposition 1}]\).

**Proposition 1.** The minimum distance between two leaves \(T^{2n-2}_\eta = (S^{n-1} \times S^{n-1})_\eta\) and \(T^{2n-2}_{\eta'} = (S^{n-1} \times S^{n-1})_{\eta'}\) is

\[
d(T^{2n-2}_\eta, T^{2n-2}_{\eta'}) = 2 \sin \left( \frac{\eta - \eta'}{2} \right),
\]

which coincides with the Euclidean distance between two points of angles \(\eta\) and \(\eta'\) on the first quadrant of \(S^1\).

**Proof:** Adopting the notation \(v_1 := (v_1, \ldots, v_n)\) and \(v_2 := (v_{n+1}, \ldots, v_{2n})\), take two points

\[
x = (\cos \eta v_1; \sin \eta v_2) \in (S^{n-1} \times S^{n-1})_\eta
\]

and

\[
x' = (\cos \eta' v'_1; \sin \eta' v'_2) \in (S^{n-1} \times S^{n-1})_{\eta'},
\]

with \(\|v_i\| = \|v'_i\| = 1\), for \(i \in \{1, 2\}\). For the squared Euclidean distance \(d^2(x, x')\) we have

\[
d^2(x, x') = \|x - x'\|^2 = \|x\|^2 + \|x'\|^2 - 2 \langle x, x' \rangle
\]

\[
= 2 - 2(\cos \eta \cos \eta' \langle v_1, v'_1 \rangle + \sin \eta \sin \eta' \langle v_2, v'_2 \rangle)
\]

\[
\geq 2 - 2(\cos \eta \cos \eta' + \sin \eta \sin \eta')
\]

\[
= 2[1 - \cos(\eta - \eta')]
\]

\[
= 2 \left[ 1 - 2 \sin^2 \left( \frac{\eta - \eta'}{2} \right) \right]
\]

\[
= 4 \sin^2 \left( \frac{\eta - \eta'}{2} \right),
\]

and equality holds if, and only if, \(v_1 = v'_1\) and \(v_2 = v'_2\). Therefore the minimum distance between the sets \((S^{n-1} \times S^{n-1})_\eta\) and \((S^{n-1} \times S^{n-1})_{\eta'}\) is \(d(T^{2n-2}_\eta, T^{2n-2}_{\eta'}) = 2 \sin \left( \frac{\eta - \eta'}{2} \right)\), which is the chordal distance between points determined by angles \(\eta\) and \(\eta'\) on the first quadrant of the circle \(S^1 \subset \mathbb{R}^2\) (see Fig. 2).

**Corollary 1.** In the context of Proposition \([7]\)

1) The minimum angular interval between \(\eta\) and \(\eta'\) respecting the minimum distance \(d\) is

\[
\Delta \eta := |\eta - \eta'| = 2 \arcsin(d/2).
\]

2) The maximum number of disjoint intervals of measure \(\Delta \eta\) fitting in the interval \([0, \pi/2]\) is

\[
t(d) = \left\lfloor \frac{\pi}{4 \arcsin(d/2)} \right\rfloor.
\]
3) We may then choose the leaves $S_{\cos \eta}^{n-1} \times S_{\sin \eta}^{n-1}$ far apart by at least $d$, considering
   
   a) $\eta = \eta_0 + k\Delta \eta$, for $k \in [0, t(d)]$ and $0 \leq \eta_0 \leq (\pi/2 - t(d)\Delta \eta)/2$, or
   
   b) $\eta = \pi/4 + k\Delta \eta$, for $k \in [0, \lfloor t(d)/2 \rfloor]$, 

   In the latter case, leaves are symmetrically chosen around $\eta = \pi/4$, the leaf of greatest ‘area’. 

   Once the leaves have been chosen with a guaranteed minimum mutual distance $d$, we proceed to construct a spherical code in $S^{2n-1}$, by considering codes on each leaf $T_{\eta}^{2n-2}$ with the desired minimum distance. We illustrate this idea with an example, to show that there are several ways of choosing these leaves.

**Example 1.** For minimum distance $d = 1$, we have $\Delta \eta = \pi/3$ and $t(1) = 1$. We can choose different sets of leaves: either $\eta = \frac{\pi}{3}$, $\eta \in \{0, \frac{\pi}{3}\}$ or $\eta \in \{\frac{\pi}{12}, \frac{5\pi}{12}\}$. In dimension $n = 4$, we can construct one of the following codes:

1) Case $\eta = \frac{\pi}{3}$ (only one leaf). consider the code in $S_{\frac{\pi}{3}}^{1} \times S_{\frac{\pi}{3}}^{1}$ as the product code $C = C_{\text{pen}} \times C_{\text{ant}}$, where $C_{\text{pen}}$ is the biorthogonal code in $S_{\frac{\pi}{3}}^{1}$, given as the set of all permutations of $(\pm \sqrt{1/2}, 0)$, which has minimum distance 1 and 16 codewords.

2) Case $\eta \in \{0, \frac{\pi}{3}\}$ (two leaves). For $\eta = 0$, consider the code $C_1 = \{(0, 0)\} \times C_{\text{hex}}$, where $C_{\text{hex}}$ is the hexagonal code in $S_{\frac{\pi}{3}}^{1}$. For $\eta = \frac{\pi}{3}$, consider $C_2 = C_{\text{pen}} \times C_{\text{ant}}$, where $C_{\text{pen}}$ is the pentagon in $S_{\frac{\pi}{3}}^{1}$ and $C_{\text{ant}}$ is the set of two antipodal points in $S_{\frac{\pi}{3}}^{1}$. The final code $C = C_1 \cup C_2$ is a spherical code with 16 codewords.

3) For $\eta \in \{\frac{\pi}{12}, \frac{5\pi}{12}\}$ (two symmetrical leaves), consider the codes $C_1 = C_{\text{one}} \times C_{\text{pen}}$ and $C_2 = C_{\text{pen}} \times C_{\text{one}}$, where $C_{\text{one}}$ is a single-point code on $S_{\sin(\pi/12)}^{1} = S_{\cos(5\pi/12)}^{1}$ and $C_{\text{pen}}$ is the pentagonal code on $S_{\cos(\pi/12)}^{1} = S_{\sin(5\pi/12)}^{1}$. Each $C_1, C_2$ has 5 points, and the final code $C = C_1 \cup C_2$ has 10 points, which is less than the 12 points obtained by taking $\eta \in \{0, \frac{\pi}{3}\}$.

4) Note that Proposition \[\text{[7]}\] provides a sufficient condition for the minimum distance. But in this case we can see that, besides the codewords of item \[\text{[7]}\], we can also consider points in the degenerated tori defined by $\eta \in \{0, \frac{\pi}{3}\}$, i.e., the codewords $(0, 0, \pm \sqrt{1/2}, \pm \sqrt{1/2})$ and $(\pm \sqrt{1/2}, \pm \sqrt{1/2}, 0, 0)$, and still have minimum distance 1 between the 24 codewords. This spherical code is the best known for $d = 1$ in $\mathbb{R}^4 \[\text{[2]}\]$ and a similar code for this distance with $(\binom{n}{2})$ codewords can be obtained in $\mathbb{R}^n$.

In the algorithm we will formulate shortly, we set a procedure based on Proposition \[\text{[1]}\] considering different
choices for the leaves, such as the ones in items 1, 2 and 3, and a few special codes such as the one in item 4. These examples illustrate the fact that the general construction by leaves is complex, as it requires choosing good codes in the half-dimension. This motivates us to propose a recursive procedure for dimensions $2^k$, using dimension $n = 4$ as the basic case.

**B. Basic case: spherical codes in $\mathbb{R}^4$**

Given a minimum distance $d \in [0, 2]$, our procedure is based on a two-step process:

1) To choose a set of parameters $\eta \in [0, \pi/2]$, generating a family of tori $T^2_\eta = S^1_{\cos \eta} \times S^1_{\sin \eta}$ mutually distant by at least $d$, as sets in $\mathbb{R}^4$, cf. Corollary 1–3).

2) On each torus $T^2_\eta$, to distribute points with minimal mutual distance $d$, following three steps:
   a) choose $n$ internal circles mutually distant by at least $d$;
   b) on each such circle, distribute $m$ equidistant points;
   c) possibly choose an angle of displacement between the distributions of consecutive internal circles, so as to bring those circles closer and improve the point density.

An example is illustrated in Fig. 3. The next result provides an algorithm to determine the number $n$ of internal circles and the number $m$ of points on each such circle, within each $T^2_\eta$, assuming internal circles of radius $\cos \eta$ which are generated by horizontal lines of constant angle $\xi$ and an angle of displacement.

**Proposition 2.** On each torus $T^2_\eta$:

1) The distance between the image by $\iota_\eta$ of two points, determined by angles $\xi_1$ and $\xi_1 + \Delta \xi_1$ on the same internal circle given by $\iota_\eta(\xi_1, \xi_2)$ for a fixed $\xi_2$, is

$$d(\iota_\eta(\xi_1, \xi_2), \iota_\eta(\xi_1 + \Delta \xi_1, \xi_2)) = 2 \cos \eta \sin[(\Delta \xi_1)/2].$$

2) The maximum number $m$ of points that can be distributed on a internal circle, respecting the minimum mutual distance $d$, is

$$m(d, \eta) = \begin{cases} \frac{\pi}{\arcsin(d/2 \cos \eta)}, & \text{if } d \leq 2 \cos \eta, \\ 1, & \text{else}. \end{cases}$$

3) The distance between the image by $\iota_\eta$ of two points, one on each of two consecutive internal circles, with point distributions displaced by $\Delta \xi_1/2 = \pi/m$, $m = m(d, \eta)$, is

$$d(\iota_\eta(\xi_1, \xi_2), \iota_\eta(\xi_1 + \Delta \xi_1/2, \xi_2 + \Delta \xi_2)) = \left(4 \cos^2 \eta \sin^2 \frac{\pi}{2m} + 4 \sin^2 \eta \sin^2\frac{\Delta \xi_2}{2}\right)^{\frac{1}{2}}.$$  

4) The distance between the image by $\iota_\eta$ of two points aligned with respect to $\xi_1$ in two internal circles parametrized by $\xi_2$ and $\xi_2 + 2\Delta \xi_2$ is

$$d(\iota_\eta(\xi_1, \xi_2), \iota_\eta(\xi_1, \xi_2 + 2\Delta \xi_2)) = 2 \sin \eta \sin \Delta \xi_2.$$  

5) The maximum number $n$ of internal circles that can be distributed on $T_\eta$, with consecutive displacement $\pi/m$, $m = m(d, \eta)$, such that the mutual distance among their points is at least $d$, is

$$n(d, \eta) = \max(n, 1),$$
with \( \tilde{n} = 2\left\lfloor \min\{n_1, n_2\} / 2 \right\rfloor \) and
\[
\begin{align*}
n_1 &= \left\lfloor \frac{\pi}{\arcsin \left( \frac{(d^2/4) \csc^2 \eta - \cot^2 \eta \sin^2(\pi/2m)}{2} \right) } \right\rfloor, \\
n_2 &= \begin{cases} 
\frac{2\pi}{\arcsin(d/2 \sin \eta)}, & \text{if } d \leq 2 \sin \eta, \\
1, & \text{else}.
\end{cases}
\end{align*}
\] (13) (14)

**Proof:** The calculations are straightforward using:

\[
d^2(\iota_\eta(\xi_1, \xi_2), \iota_\eta(\xi_1', \xi_2')) = |e^{i\xi_1 \cos \eta} - e^{i\xi_1' \cos \eta}|^2 + |e^{i\xi_2 \sin \eta} - e^{i\xi_2' \sin \eta}|^2.
\]

For 2), note that \( m = \lfloor 2\pi / \Delta \xi_1 \rfloor \), where \( \Delta \xi_1 = 2 \arcsin(d/2 \cos \eta) \) is obtained by inverting (8) and setting the distance to \( d \). For 5), note that \( n_1 = \lfloor 2\pi / \Delta \xi_2 \rfloor \) with \( \Delta \xi_2 = 2 \arcsin \left[ \frac{(d^2/4) \csc^2 \eta - \cot^2 \eta \sin^2(\pi/2m)}{2} \right] \) obtained by inverting (10), setting the distance to \( d \). Similarly, \( n_2 = \lfloor 2\pi / \Delta \xi_2 \rfloor \) with \( \Delta \xi_2 = \arcsin(d/\sin \eta) \) obtained from (11). As we have to ensure minimum distances both in (10) and in (11), we choose the minimum between \( n_1 \) and \( n_2 \). Notice moreover that, if we put more than one internal circle, the number of circles \( \tilde{n} \) effectively has to be even, so that first and last circles have different displacements, thus ensuring minimum mutual distance between their points.

It is possible to describe the generation of points in complex variables, once again referring to the Hopf foliation and noticing that a rotation in \( \mathbb{R}^2 \cong \mathbb{C} \) corresponds to multiplication by a unitary complex number. Thus, on each torus \( T^2_\eta \), points take the form
\[
(z_0, z_1) = (e^{i\xi_1 \cos \eta} e^{i\xi_2 \sin \eta}, e^{i\xi_1' \cos \eta} e^{i\xi_2' \sin \eta}),
\]
with \( j \in [0, m - 1] \) and \( k \in [0, n - 1] \). This description compares favorably for instance to the use of rotation matrices in [7], because it reduces several matrix products to scalar and complex products, as one can empirically ascertain from the simulations in Fig. 4.

**C. Recursive generalization: spherical codes in \( \mathbb{R}^{2^k} \)**

With the generalized foliation of Assertion [1] the following natural two-step algorithm for \( S^{2n-1} \subset \mathbb{R}^{2n} \) emerges:

1Using Wolfram Mathematica 12.1 Student Edition on a 8GB RAM, Intel Core i5-7200U @ 2.50GHz machine.
1) To vary the parameter $\eta \in [0, \pi/2]$, generating a family of leaves $S^{n-1}_{\cos \eta} \times S^{n-1}_{\sin \eta}$ mutually distant of at least $d$.

2) On each leaf $S^{n-1}_{\cos \eta} \times S^{n-1}_{\sin \eta}$, to distribute points recursively on each of the spheres $S^{n-1}_{\cos \eta}$ and $S^{n-1}_{\sin \eta}$, at scaled minimum distances $d / \cos \eta$ and $d / \sin \eta$, respectively.

We shall focus on dimensions $2^k$, $k \geq 2$, starting from $\mathbb{R}^4$. For instance, to construct a spherical code in $S^7 \subset \mathbb{R}^8$, we foliate it by manifolds $(S^3 \times S^3)_{\eta}$, and each copy of $S^3 \subset \mathbb{R}^4$ is known from the basic case.

In our implementation, the standard algorithm exploits in particular the symmetry of the leaves $(S^3 \times S^3)_{\eta}$ around $\eta = \pi/4$. The first chosen leaf is $\eta_0 = \pi/4$, the distribution is done for $\eta \in [\pi/4, \pi/2]$ and the points for $\eta \in [0, \pi/4]$ are obtained by coordinate permutations.

As a direct result of the proposed construction, we immediately derive the following Proposition 3:

**Proposition 3.** The cardinality $M(n, d)$ of the SCHF $C_{SCHF}(M, n, d)$ with minimum distance $d$, constructed by our standard procedure, is given by a recursive expression as follows:

$$M(2n, d) = \begin{cases} [M(n, \sqrt{2}d)]^2 + 2 \sum_{i=1}^{[t/2]} M(n, d/\cos \eta_i)M(n, d/\sin \eta_i), & \text{for } n > 2 \quad (15) \\ m_0n_0 + 2 \sum_{i=1}^{[t/2]} m_in_i, & \text{for } n = 2 \quad (16) \end{cases}$$

with $\eta_i := \pi/4 + i\Delta \eta$ as in (6), $t := t(d)$ as in (7), $m_i := m(d, \eta_i)$ as in (9) and $n_i := n(d, \eta_i)$ as in (12).

**Example 2.** To construct a code in $\mathbb{R}^8$ with minimum distance $d = 0.5$ by our standard procedure, we consider the foliation of $S^7$ by $(S^3 \times S^3)_{\eta}$ and use Proposition 7 to choose the set of parameters $\eta \in \{0.5053, \pi/4, 1.2907\}$. Next, for each leaf $S^3_{\cos \eta} \times S^3_{\sin \eta}$, we take the Cartesian product of codes in the 3-spheres of radii $\cos \eta$ and $\sin \eta$ in $\mathbb{R}^3$. On each of these 3-spheres, we apply the basic-case algorithm for minimum distances $d/\cos \eta$ and $d/\sin \eta$, namely: to choose a family of tori $T^2_{\eta}$ and to distribute points on each. For instance, $(S^3 \times S^3)_{1.2907} = S^3_{0.2763} \times S^3_{0.9610}$.
On the right-sphere, we choose the tori with \( \eta \in \{0.5263, \pi/4, 1.3117\} \). On the left-sphere, it is only possible to choose one torus, with \( \eta = \pi/4 \). Due to the symmetry about \( \eta = \pi/4 \) in both cases, it suffices to calculate half of the points and obtain the symmetric ones by permuting their coordinates. Summing across all the leaves, there are 2,608 points in total.

D. Modifications

One can consider some small modifications of the previous standard procedure, in order to improve the cardinality of the code.

1) When choosing leaves, in the context of Corollary 1, we may choose not only symmetrically distributed leaves around \( \eta = \pi/4 \), but consider the following choices – and even a combination of them – in different dimensions:
   a) \( \eta = \pi/4 \pm k\Delta \eta \), for \( k \in [0, \lfloor t(d)/2 \rfloor] \);
   b) \( \eta = k\Delta \eta \), for \( k \in [0, \lfloor t(d) \rfloor] \);
   c) \( \eta = \pi/2 - k\Delta \eta \), for \( k \in [0, \lfloor t(d) \rfloor] \).

2) When distributing points on a torus \( T_\eta \), in the context of Proposition 2, we may consider ‘diagonal’ inner circles (the fibres of points under the Hopf map \( h \)), whenever that is more advantageous than the standard distribution. As those circles have unitary radius, the number of points that can be placed on them, respecting minimum mutual distance \( d \), is \( \lfloor \pi / \arcsin(d/2) \rfloor \).

3) Whenever possible and more advantageous, we can consider explicit ad hoc constructions [2]: optimal codes in \( \mathbb{R}^4 \) for cardinalities 2, 3, 4 5, 8, 10 and 24 (minimum distances \( 2, \sqrt{3}, \sqrt{8/3}, \sqrt{8/2}, \sqrt{2}, \sqrt{5/2}, 1 \), respectively), as well as the biorthogonal codes which place \( 2n \) points with minimum distance \( \sqrt{2} \) in any dimension \( n \).

Remark 1. In the proposed standard procedure, any dimension \( n \) can be considered as a basic case for codes in \( \mathbb{R}^2n \), so long as good constructive codes are available in \( \mathbb{R}^n \) for a wide range of minimum distances. However much this may provide greater density, as discussed in Section V in this paper we focus on the construction in \( \mathbb{R}^{2k} \) with basic case \( \mathbb{R}^4 \) due to its effective constructiveness and low complexity.

IV. Non-asymptotic Performance Analysis

We compare the cardinality of our codes with other constructive spherical codes, in different dimensions, for many non-asymptotic minimum distance regimes. In dimension 4, we compare our results with apple-peeling [4], wrapped [5], laminated [6] and TLSC [7] (Table I). In higher dimensions, we compare with two TLSC implementations by Naves [33] that differ in the choice of the subcode: either with \( k \) elements or on polygon layers (Table II). In these dimensions, we have also considered EQPA codes [10] (Table III), concatenated MPSK [34, p. 36], commutative group codes (CGC) [12, 13] (Tables IV and V) and some codes from [3]. The SCHF considered in these tables

* unknown values

use the modifications introduced in Section III-D. The proposed SCHF construction was implemented in Wolfram Mathematica and Python.

We see that the performance of SCHF in $\mathbb{R}^4$ is, as expected, similar to TLSC and not far from some of the best known spherical codes. In higher dimensions, SCHF can achieve a higher cardinality than TLSC ($k$ elements) in most regimes and, in many of them, higher than TLSC (polygon layers) too. Commutative group codes, which have a powerful algebraic structure, are outperformed by SCHF in nearly all considered minimum distance regimes.

A more complete picture is given on Fig. 5, 6, 7, 8, showing the binary rate per dimension $R = (\log_2 M)/n$ for codes in dimensions 4, 8, 16 and 32, respectively. These computations for the proposed recursive SCHF, both

</table>
with and without the modifications of Section III-D show in each dimension and for small values of \(d\) a good approximation of the asymptotic bounds derived in Section V. Indeed, SCHF generally outperforms the other plotted constructions.

We also acknowledge the recent appearance, on a somewhat different vein, of some Hopf fibration formalism in the context of optical communications [24]. A design for higher order modulations is presented, based on an interesting use of the Hopf preimage under the so-called sampled discrete Hopf fibration and in close relation to physical properties of light. That construction relies on the choice of a polytope on the base space (such as the tetrakis hexahedron) and apparently does not address the spherical packing problem for any given minimum distance. Particularities aside, SCHF outperform the two four-dimensional modulations presented in [24] at the same minimum distance, cf. Table VI.
Fig. 6. Binary rate per dimension for different codes in dimension 8.

Fig. 7. Binary rate per dimension for different codes in dimension 16.

V. ASYMPTOTIC DENSITY

We now analyze the density of our spherical codes. Consider the gamma function $\Gamma(x) = \int_0^\infty e^{-t}t^{x-1}dt$. The Euclidean $(n-1)$-dimensional volume (hypersurface area) of the sphere $S^{n-1} \subset \mathbb{R}^n$ is given [8] by

$$S_n := \frac{n\pi^{n/2}}{\Gamma(1 + n/2)}.$$  

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
and the corresponding $n$-dimensional volume of the ball bounded by $S^{n-1}$ is

$$V_n := \frac{\pi^{n/2}}{\Gamma(1 + n/2)}.$$  

Note that the spherical code with minimum distance $d$ has minimum angular separation $\theta(d) = 2 \arcsin(d/2)$. The $(n-1)$-dimensional volume of a spherical cap on the sphere $S^{n-1}$ with angular radius $\theta(d)/2$ is

$$S_C(n, d) := \int_0^{\theta(d)/2} \sin^{n-2} x \, dx.$$  

Hence the density $\Delta(C)$ of an $n$-dimensional spherical code $C(M, n, d)$ is the ratio of the total area covered by the $M(n, d)$ spherical caps, with angular radius $\theta(d)/2$ centered at the codewords, by the total surface area

$$\Delta(C(n, d)) := \frac{M(n, d) S_C(n, d)}{S_n}. \quad (17)$$

In what follows, we will write $f(d) \simeq g(d)$ when

$$\lim_{d \to 0} \frac{f(d)}{g(d)} = 1.$$  

For small values of $d$, $S_C(n, d)$ can be approximated [5] by

$$S_C(d, n) = V_{n-1} \left( \frac{d}{2} \right)^{n-1} + O(d^{n+1}),$$

which implies $S_C(n, d) \simeq V_{n-1} \left( \frac{d}{2} \right)^{n-1}$ and

$$\Delta(C(n, d)) \simeq \frac{M(n, d) V_n}{S_n} \left( \frac{d}{2} \right)^{n-1}. \quad (18)$$

The asymptotic center density $\Delta_c$ of a family of spherical codes $C(M, n, d)$, constructed for different minimum distances $d$, is defined as

$$\Delta_c(C(n)) := \lim_{d \to 0} \frac{M(n, d)}{S_n} \left( \frac{d}{2} \right)^{n-1}. \quad (19)$$

It provides a means of comparing packings of different constructions in a given dimension, for small $d$.  

Fig. 8. Binary rate per dimension for different codes in dimension 32.
Lemma 1. The asymptotic center density of the SCHF in dimension 4 is
\[ \Xi_c(SCHF[4]) = \frac{1}{4\sqrt{3}}. \] (20)

Proof: In \( \mathbb{R}^4 \), the asymptotic SCHF and TLSC coincide, and their densities can be approached by the density of the lattice product \( A_2 \times \mathbb{Z} \) [7 Proposition 6]. Considering the well-known center densities of lattices \( A_2 \) and \( \mathbb{Z} \) [8], we then have:
\[ \Xi_c(SCHF[4]) = \Delta_c(A_2 \times \mathbb{Z}) = \Delta_c(A_2) \cdot \Delta_c(\mathbb{Z}) = \frac{1}{2\sqrt{3}} \cdot \frac{1}{2} = \frac{1}{4\sqrt{3}}. \]

Proposition 4. The asymptotic center density of the SCHF in dimension \( 2n \), constructed from a family of codes \( C(n) \) in dimension \( n \), which achieves asymptotic density \( \Xi_c(C(n)) \) is
\[ \Xi_c(SCHF[2n; C(n)]) = \frac{1}{2}(\Xi_c(C(n)))^2. \]

Proof: For small \( d \), we have
\[ \Xi_c(SCHF[2n; C(n)]) \approx \frac{M(2n, d)}{S_{2n}} \left( \frac{d}{2} \right)^{2n-1} \] (21) and
\[ \Xi_c(C(n)) \approx \frac{M(n, d)}{S_n} \left( \frac{d}{2} \right)^{n-1}. \] (22)

From (22), we have
\[ M(n, d) \approx S_n \left( \frac{2}{d} \right)^{n-1} \Xi_c(C(n)). \] (23)

From the construction of SCHF, we have
\[
M(2n, d) = \sum_{i=1}^{\lfloor t(d) \rfloor} M(n, d/\cos \eta_i)M(n, d/\sin \eta_i)
\]
\[
\approx \sum_{i} \left[ S_n \left( \frac{2\cos \eta_i}{d} \right)^{n-1} \Xi_c(C(n)) \right] \left[ S_n \left( \frac{2\sin \eta_i}{d} \right)^{n-1} \Xi_c(C(n)) \right]
\]
\[
= \Xi_c(C(n))^2(S_n)^2 \frac{2^{n-1}}{d^{2n-2}} \sum_{i} [\sin(2\eta_i)]^{n-1}. \]

Therefore, from (21),
\[ \Xi_c(SCHF[2n; C(n)]) \approx \frac{\Xi_c(C(n))^2(S_n)^2}{2^n} \frac{\lfloor t(d) \rfloor}{S_{2n}} \sum_{i} [\sin(2\eta_i)]^{n-1}d. \]

For small \( d \), we have \( \Delta \eta \approx d, \eta_i \approx id \) and \( t(d) \approx \pi/2d \), hence the last summation approaches the corresponding integral, what implies
\[ \Xi_c(SCHF[2n; C(n)]) = \frac{\Xi_c(C(n))^2(S_n)^2}{2^n} \frac{\pi/2}{S_{2n}} \int_0^{\pi/2} (\sin 2\eta)^{n-1} d\eta \]
\[ = \frac{\Xi_c(C(n))^2(S_n)^2}{2^{n+1}} \frac{\pi}{S_{2n}} \int_0^{\pi} (\sin x)^{n-1} dx. \] (24)
On the other hand, since the sphere $S^{2n-1}$ is foliated by manifolds $S^{n-1}_{\cos \eta} \times S^{n-1}_{\sin \eta}$, for small $d$ we have

\[
S_{2n} \simeq \sum_i t(d) \Vol(S^{n-1}_{\cos \eta}) \Vol(S^{n-1}_{\sin \eta}) \Delta \eta
= \sum_i S_n(\cos \eta_i)^{n-1} S_n(\sin \eta_i)^{n-1} \Delta \eta
= \frac{(S_n)^2}{2^{n-1}} \sum_i |\sin(2\eta_i)|^{n-1} \Delta \eta.
\]

and, when $d \to 0$ as in (24),

\[
S_{2n} = \frac{(S_n)^2}{2^n} \int_0^\pi (\sin x)^{n-1} \, dx.
\] (25)

Substituting (25) in (24) yields the claim:

\[
\bar{\Delta}_c(\text{SCHF}[2n; C(n)]) = \frac{1}{2} \left( \bar{\Delta}_c(C(n)) \right)^2.
\] (26)

**Remark 2.** Since the maximum asymptotic center density for spherical codes in $S^{n-1} \subset \mathbb{R}^n$ is the highest center packing density of $\mathbb{R}^{n-1}$ (cf. Proposition 4), the asymptotic density of a SCHF in $S^{2n-1} \subset \mathbb{R}^{2n}$ is bounded above and asymptotic to

\[
\bar{\Delta}_c(\text{SCHF}[2n; C(n)]) \leq \frac{1}{2} \left( \bar{\Delta}_c(\mathbb{R}^{n-1}) \right)^2.
\] (27)

By recursively applying Proposition 4 in dimensions $2^k$, for $k \geq 2$ (cf. Lemma 1), we get

**Corollary 2.** The asymptotic center density of the recursive SCHF in dimension $n = 2^k$, $k \geq 2$ is

\[
\bar{\Delta}_c(\text{SCHF}[2^k]) = \bar{\Delta}_c(\text{SCHF}[2^k; \text{SCHF}[2^{k-1}; \cdots \text{SCHF}[4]]]) = (2)^{1-(3)2^{k-2}} (3)^{-2^k}. \] (28)

Moreover, using (23) and Corollary 2, we get:

**Corollary 3.** The cardinality $M(n,d)$ of the recursive SCHF in dimension $n = 2^k$ is bounded above and, as $d \to 0$, asymptotic to

\[
M(2^k, d) \simeq \frac{2^{k+2^{k-2}} 3^{-2^{k-1}} \pi^{2^{k-1}}}{(2^{k-1})! \ d^{2^{k-1}}}. \] (29)

**Proof:** For small values of $d$, we have the approximation

\[
\bar{\Delta}_c \simeq \frac{M(n,d)}{S_n} \left( \frac{d}{2} \right)^{n-1}.
\]

Using (29), we get

\[
M(2^k, d) = \bar{\Delta}_c(\text{SCHF}[2^k]) S_{2^k} \left( \frac{2}{d} \right)^{2^k-1}
= \left( (2)^{1-(3)2^{k-2}} (3)^{-2^k} \right) \frac{2^k \pi^{2^{k-1}}}{(2^{k-1})!} \left( \frac{2}{d} \right)^{2^k-1}
= \frac{2^{k+2^{k-2}} 3^{-2^{k-1}} \pi^{2^{k-1}}}{(2^{k-1})! \ d^{2^{k-1}}}. \]
TABLE VII
ASYMPTOTIC CENTER DENSITY FOR DIFFERENT $n$-DIMENSIONAL SPHERICAL CODES. $\Delta_n$ DENOTES THE HIGHEST CENTER DENSITY OF A SPHERE IN $\mathbb{R}^n$: $\Delta_n := \Delta_n(\mathbb{R}^{n-1})$. FOR DIMENSIONS 8, 16 AND 32 THE CALCULATIONS ASSUME THE BEST KNOWN CENTER DENSITIES.

</table>

For a fixed dimension $n$, the asymptotic center density of different spherical code constructions allows one to compare their respective numbers of codewords for the same small minimum distance $d$, cf. [23].

Table VII compares some asymptotic center densities for spherical codes in dimensions 4, 8, 16 and 32. We consider both the SCHF recursive procedure with basic case $\mathbb{R}^d$ (Corollary 2) and the SCHF procedure that uses asymptotic dense codes in the half dimension (Remark 2). For each dimension, we also include the TLSC upper bound as in [7, Proposition 6], the apple-peeling bound as in [5, Lemma 3] and highest asymptotic center density for spherical codes (from the best known packing in the previous dimension) [8, 35].

We can see that the ratios between the center densities of these different constructions show how much smaller the number of codewords achieved by recursive SCHF construction is, when compared to SCHF in half dimension, TLSC, apple-peeling and, of course, the highest possible asymptotic density in each dimension, which can be theoretically achieved by wrapped or laminated codes. The trade-off to emphasise here is the high constructibility of recursive SCHF for any given minimum distance and its low complexity in the encoding and decoding processes, which will be discussed in Sections VI and VII.

One should also point out that there may be a difference between asymptotic density bounds and the density effectively achieved, specially for higher dimensions. This is due to the characteristics of each of the analyzed constructions. Half dimension SCHF depend on the existence of good codes in the half dimension; TLSC require the use of the best codes and lattices in the half dimension; wrapped codes rely on the choice of a lattice in the previous dimension; laminated codes have been approached in dimensions from 2 to 49 and may have slower convergence than wrapped codes; apple-peeling construction is based on spherical codes in the previous dimension. We note that, in the case of TLSC, the implementations carried out so far do not seek to construct the densest theoretically possible codes, but rather good, feasible ones – as in [35], who proposes different approaches for the construction of the subcodes. On the other hand, in dimensions $2^k$, the construction of recursive SCHF does not depend on any choice, can be constructed for any given minimum distance $d$ and the asymptotic bound is indeed approached for not-so-small minimum distances (cf. Fig. 5, 6, 7, 8).
The construction of SCHF using better available constructions in the half dimension offers an easy way of obtaining good codes. One could consider, for instance, using a family of wrapped codes in dimension 25 (as in [15], based on the Leech lattice) to construct codes in dimension 50 by Hopf foliations, with low addition in encoding complexity, cf. Section VI (a wrapped spherical code in this dimension would require the use of a good lattice in dimension 49).

Finally, it is also interesting to compare the asymptotic behavior of recursive SCHF with the more structured spherical commutative group codes (CGC). From [12, Proposition 7], the number $M(n,d)$ of codewords of a CGC in dimension $n$ is bounded above by

$$M(n,d) < \Delta_c(\Lambda_{n/2}) \left( \frac{4\pi}{d\sqrt{n/2}} \right)^{n/2},$$

where $\Delta_c(\Lambda_{n/2})$ is the maximum center density of a lattice packing in $\mathbb{R}^{n/2}$. This implies that the asymptotic center density is equal to zero, which is expected, since those codes must be contained in a $n$-dimensional flat torus. Note that, for a fixed dimension $n = 2^k$, the cardinality of a CGC grows with $O(1/d^{2k-1})$, while for a recursive SCHF (cf. Corollary 3), it grows with $O(1/d^{2k-1})$, i.e., there exists a value $d$ beyond which the cardinality of SCHF outperforms CGC (see Tables IV and V).

VI. Encoding Complexity Analysis

We now present a complexity analysis of the encoding algorithm for the standard SCHF construction. Lachaud and Stern [36] propose the following definition for polynomial complexity of a spherical code. Let $\Sigma$ be a finite alphabet and consider spherical codes $C = C(M,n,d) \subset S^{n-1}$ that are image of maps $F : \Sigma^k \to S^{n-1}$. We say that a family $(C_i)$ of spherical codes is polynomially constructible if there is a sequence $(F_i)$ of maps $F_i : \Sigma^{k_i} \to S^{n_i-1}$ such that: (i) $F_i$ is one-to-one from $\Sigma^{k_i}$ to $C_i$, and (ii) for every $a \in \Sigma^{k_i}$, the point $F_i(a)$ is computable from $i$ and $a$ in polynomial time, with respect to the dimension $n_i$ of $C_i$.

A. Basic case $\mathbb{R}^4$

We first analyze the encoding complexity in dimension $n = 4$. The injection $F$ can be decomposed as $F = \iota \circ \chi$, where $\iota$ is as in (4) and $\chi(a) = (\eta, \xi_1, \xi_2)$ as in Algorithm 1. We assume that, in the construction of the code $C(M,4,d)$, we store a table that contains information on each leaf $T_\eta$: each line contains the index $i$ of the leaf, the parameter $\eta_i$ and the number of points in that leaf $M_i$. The length of this table is $t(d) = \lceil \pi/[4 \arcsin(d/2)] \rceil$ (Corollary 1), hence the storage complexity is $O(t)$. We assume that accessing data in this table has constant complexity.

Each individual line of Algorithm 1 has constant complexity (constant number of additions, multiplications, trigonometric functions etc.). In the worst-case scenario, the main loop (line 3) will be executed $t = t(d)$ times. Note that

$$t(d) = \left\lfloor \frac{\pi}{4 \arcsin(d/2)} \right\rfloor \leq \frac{\pi}{4 \arcsin(d/2)} \leq \frac{\pi}{2d},$$

so the computational complexity of the algorithm is $O(t) = O(d^{-1})$. 
Algorithm 1: Encoding algorithm for $\mathbb{R}^4$ (map $F = \iota \circ \chi$).

\textbf{Input:} $a$, $d$

\textbf{Output:} $(x_1, x_2, x_3, x_4)$

1 $t \leftarrow \lfloor \pi/4 \arcsin(d/2) \rfloor$

2 for $i \in [-\lfloor t/2 \rfloor, \lfloor t/2 \rfloor]$ do

3 $M_i \leftarrow \text{consult } i\text{-th line of table}$

4 if $a \geq M + M_i$ then

5 $M \leftarrow M + M_i$

6 $i \leftarrow i + 1$

else

7 $\eta \leftarrow \pi/4 + 2i \arcsin d/2$

8 $m \leftarrow \text{as in Proposition 2, item 2}$

9 $n \leftarrow \text{as in Proposition 2, item 5}$

10 $j \leftarrow (a - M) \mod m$

11 $k \leftarrow \lfloor (a - M)/m \rfloor$

12 $\xi_1 \leftarrow j \frac{2\pi}{m} + k \frac{\pi}{m}$

13 $\xi_2 \leftarrow k \frac{2\pi}{n}$

14 \textbf{return} $\left( \cos \eta \cos \xi_1, \cos \eta \sin \xi_1, \sin \eta \cos \xi_2, \sin \eta \sin \xi_2 \right)$

end

end

B. General case $\mathbb{R}^{2n}$

We consider now the algorithm that implements the map $F(a) = (x_1, \ldots, x_{2n}) \in C(M, 2n, d)$. This injection can be decomposed with the help of the following maps:

$$\sigma : \Sigma \rightarrow \left[0, \frac{\pi}{2}\right] \times \Sigma_1 \times \Sigma_2$$

$$a \mapsto (\eta, a_1, a_2), \quad \text{with} \quad \Sigma_j = \{0, \ldots, M_j - 1\}, j \in \{\emptyset, 1, 2\} \quad (31)$$

$$\iota \circ \chi : \Sigma \rightarrow C(M, 4, d)$$

$$a \mapsto (\cos \eta \cos \xi_1, \cos \eta \sin \xi_1, \sin \eta \cos \xi_2, \sin \eta \sin \xi_2), \quad \text{with} \quad \Sigma_j = \{0, \ldots, M_j - 1\}, j \in \{\emptyset, 1, 2\} \quad (32)$$

and

$$\Phi : \left[0, \frac{\pi}{2}\right] \times C(M_1, n, d/\cos \eta) \times C(M_2, n, d/\sin \eta) \rightarrow C(M_1 M_2, 2n, d)$$

$$(\eta, (x_1, \ldots, x_n), (y_1, \ldots, y_n)) \mapsto (\cos \eta (x_1, \ldots, x_n), \sin \eta (y_1, \ldots, y_n)) .$$
Fig. 9. Decomposition tree for $S^{2n-1}$. Note that the number of nodes is $\sum_{i=0}^{k-2} 2^i = 2^{k-1} - 1 = n - 1$, with $k = \log_2(2n)$.

We also assume that we have stored tables with information on each leaf $(S^{n-1} \times S^{n-1})_{\eta}$, for dimensions $\tilde{n} \in \{n, n/2, \ldots, 2\}$, during the construction of the code. Each line of this table contains the index $i$ of the leaf, its parameter $\eta_i$, and the number of points $M_1$ and $M_2$ on each of the half-dimension spheres $S^{\tilde{n}-1}_{\cos \eta}$ and $S^{\tilde{n}-1}_{\sin \eta}$, respectively (see Table VIII).

**TABLE VIII**

**EXAMPLE OF STORAGE TABLE FOR $C(M, 2n, d)$**.

</tbody>
</table>

The length of each table is equal to the number $\tilde{t}$ of leaves in the corresponding dimension. For $S^{2n-1}$, this number is $t(d) = \lfloor \pi/4 \arcsin(d/2) \rfloor$ (Corollary 1). There will be $n - 1$ tables, one for each sphere (node) of the decomposition tree (Fig. 9). Note that, when halving the dimension of the sphere ($S^{2n-1} \rightarrow S^{n-1}$), the size of the table in the new dimension cannot increase:

$$d \leq \min \left\{ \frac{d}{\cos \eta}, \frac{d}{\sin \eta} \right\}$$

$$\Rightarrow \frac{\pi}{4 \arcsin(d/2)} \geq \max \left\{ \frac{\pi}{4 \arcsin(d/2 \cos \eta)}, \frac{\pi}{4 \arcsin(d/2 \sin \eta)} \right\}.$$ 

Thus the storage space needed is no greater than $(n - 1)t(d)$, and the storage complexity is $O(nt) = O(nd^{-1})$, which is linear in the dimension $n$.

The algorithm that implements $\nu \circ \chi$ (32) is the same as for the basic case $\mathbb{R}^4$, and it has complexity $O(t)$. The map $\sigma$ (31) is similarly implemented by Algorithm 2. Each individual line has constant complexity and, in the worst-case scenario, the main loop (line 3) is repeated $\tilde{t} \leq t$ times, so it has complexity $O(t) = O(d^{-1})$. 
Algorithm 2: Algorithm that implements map $\sigma$.

**Input:** $a, d$

**Output:** $\eta, a_1, a_2$

1. $M \leftarrow 0$
2. $\tilde{t} \leftarrow \lfloor \pi/4 \arcsin(d/2) \rfloor$
3. for $i \in [-\lfloor \tilde{t}/2 \rfloor, \lfloor \tilde{t}/2 \rfloor]$ do
   4. $(M_{i,1}, M_{i,2}) \leftarrow$ consult $i$-th line of table
   5. if $a > M + M_{i,1}M_{i,2}$ then
   6. $M \leftarrow M + M_{i,1}M_{i,2}$
   7. $i \leftarrow i + 1$
   8. else
   9. $\eta \leftarrow \frac{\tilde{t}}{2} + 2i \arcsin \frac{d}{2}$
   10. $a_1 \leftarrow ((a - M) \mod M_{i,1})$
   11. $a_2 \leftarrow \lfloor (a - M)/M_{i,1} \rfloor$
   12. return $(\eta, a_1, a_2)$
4. end

Finally, the implementation of map $F$ is represented in Algorithm 3. The general step for dimension $n$ computes $\sigma(a, d)$ with $O(d^{-1})$ (line 4), calls itself twice with parameter $n/2$ (lines 5 and 6), and performs $n$ multiplications (line 7). If we have a good family of codes in dimension $n/2$, with encoding complexity $O(f(n))$, and we apply one iteration of Algorithm 3 to double the dimension with SCHF construction, the encoding complexity of the new code with respect to the dimension $n$ will be $O(\max(2f(n), n))$. In the recursive case, the number of steps of the recurrence is characterized by

$$T(n) = 2T \left( \frac{n}{2} \right) + O(n) + O(d^{-1}).$$

Using Master theorem, we find that, for fixed $d$, this algorithm has complexity $O(n \log n)$.

We can compare this complexity with known TLSC implementations. Codes obtained via a subcode with $k$ elements have linear time complexity; in spite of the low complexity, they have the weakest performance among TLSC implementations and are outperformed by recursive SCHF in most scenarios (see Section IV). Codes on polygon layers have the best performance among TLSC implementations and the closest to SCHF; nonetheless, their exact complexity has not been established and, based on the code structure and computing time required for tested examples, seems to be higher than recursive SCHF.
**Algorithm 3:** Encoding algorithm for $\mathbb{R}^n$ (map $F$).

**Input:** $n$, $a$, $d$

**Output:** $x = (x_1, \ldots, x_n)$

1. **if** $n = 4$ **then**
   2. **return** $x \leftarrow \iota \circ \chi(a, d)$

3. **else**
   4. $(\eta, a_1, a_2) \leftarrow \sigma(a, d)$
   5. $(w_1, \ldots, w_{n/2}) \leftarrow F(n/2, a_1, d/\cos \eta)$
   6. $(z_1, \ldots, z_{n/2}) \leftarrow F(n/2, a_2, d/\sin \eta)$
   7. **return** $x \leftarrow \left(\cos \eta(w_1, \ldots, w_{n/2}), \sin \eta(z_1, \ldots, z_{n/2})\right)$

8. **end**

**VII. Decoding**

Given a vector $y \in \mathbb{R}^n$ and a spherical code $C(M, n, d)$, the maximum likelihood (ML) decoding consists in finding the vector $x \in C(M, n, d)$ such that

$$x = \arg \min_{x_i \in C} \|y - x_i\|. \quad (33)$$

As shown in [7], to decode a received vector $y$ in a spherical code, we can consider $y$ to be unitary and the problem is equivalent to

$$x = \arg \max_{x_i \in C} \langle x_i, y \rangle. \quad (34)$$

For small codes, it is feasible to obtain (34) by computing all inner products and choosing the minimizing value. But to avoid high-complexity of ML decoding on larger codes, we introduce a sub-optimal decoding algorithm for standard SCHF construction, which is inspired by [7] and does not require storage of the whole codebook. As previously, we start with a procedure for the basic case $\mathbb{R}^4$ and then generalize it recursively to $\mathbb{R}^{2n}$.

**A. Basic case: spherical code in $\mathbb{R}^4$**

Using the Hopf foliation, a unit vector $y = (y_1, y_2, y_3, y_4)$ may be written as

$$(y_1 + iy_2, y_3 + iy_4) = (e^{i\xi_1} \cos \eta, e^{i\xi_2} \sin \eta),$$

where

$$\eta = \arctan \left( \sqrt{\frac{y_2^2 + y_3^2}{y_1^2 + y_2^2}} \right), \quad (35)$$

$$\xi_1 = \arctan(y_2/y_1), \quad (36)$$

$$\xi_2 = \arctan(y_4/y_3). \quad (37)$$
In general, however, the triplet \((\eta; \xi_1, \xi_2)\) does not parametrize a point of the codebook. So our objective is to find the triplet \((\hat{\eta}; \hat{\xi}_1, \hat{\xi}_2)\) which parametrizes the codeword closest to \(x\). Let us denote our guess by \(\hat{x} = (e^{i\hat{\xi}_1} \cos \hat{\eta}, e^{i\hat{\xi}_2} \sin \hat{\eta})\).

1) The first step is to search for the torus \(T_{\hat{\eta}}\) closest to received point \(y\). Thanks to Proposition \[\text{[1]}\] this is equivalent to finding

\[
\hat{\eta} = \arg \min_{\eta' \in H} |\eta' - \eta|,
\]

where \(H = \{\frac{\pi}{4} + 2i \arcsin \frac{d}{2}, -|t(d)/2| \leq i \leq |t(d)/2|\}\) is the set of \(\eta\) parameters used in the code.

2) Once \(\hat{\eta}\) is determined, we project \(y\) on \(T_{\hat{\eta}}\), obtaining \((e^{i\hat{\xi}_1} \cos \hat{\eta}, e^{i\hat{\xi}_2} \sin \hat{\eta})\). This is the point on \(T_{\hat{\eta}}\) which is closest to the received vector \(y\). To obtain \(\hat{\xi}_1\) and \(\hat{\xi}_2\), we compute

\[
\hat{k} = \left\lfloor \frac{\xi_2 / \Delta \xi_2}{\Delta \xi_2} \right\rfloor \mod n, \quad (39)
\]

\[
\hat{j} = \left\lfloor \frac{\xi_1 - \hat{k} \Delta \xi_1 / 2}{\Delta \xi_1} \right\rfloor \mod m, \quad (40)
\]

where \(\lfloor \cdot \rfloor\) denotes the rounding function and \(\Delta \xi_1 = 2\pi/m, \Delta \xi_2 = 2\pi/n\). Then

\[
\hat{\xi}_1 = \hat{j} \Delta \xi_1 + \hat{k} \Delta \xi_2, \quad (41)
\]

\[
\hat{\xi}_2 = \hat{k} \Delta \xi_2. \quad (42)
\]

To further approach minimum distance solution, additional steps can be considered. If \(\hat{d} := \|\hat{x} - y\| < d/2\), the decoding is finished. Otherwise, the closest point \(x^*\) may be on another torus \(T_{\eta_i}\). We can look for the set of tori with parameters \(\{\eta_1, \ldots, \eta_\nu\}\) for which \(d_i = \|\hat{x}_i - y\| < \hat{d}\), where

\[
\hat{x}_i = (e^{i\xi_1,i} \cos \eta_i, e^{i\xi_2,i} \sin \eta_i)
\]

is the projection on torus \(T_{\eta_i}, i \in \{1, \ldots, \nu\}\) and we choose \(x^* = \hat{x}_i\) that minimizes \(d_i\). As for the coding design, in dimension 4, this procedure approaches the one proposed for TLSC \[\text{[7]}\].

B. Recursive generalization to \(\mathbb{R}^{2^k}\)

Let us generalize the decoding procedure for higher dimensions, i.e., to any \(S^{2n-1}\), \(n = 4, 8, 16, \ldots\) As before, write the arbitrary received vector \(y \in S^{2n-1}\) as

\[
y = (\cos \eta (y_1, \ldots, y_n), \sin \eta (y_{n+1}, \ldots, y_{2n}))
\]

with

\[
\eta = \arctan \left( \frac{\sum_{i=n+1}^{2n} y_i^2}{\sum_{j=1}^{n} y_j^2} \right). \quad (43)
\]

1) Find the closest leaf \((S^{n-1} \times S^{n-1})_{\eta}\) to point \(y\), i.e., the value \(\hat{\eta}\) that parametrizes a leaf used in the code closest to \(\eta\), as in \[\text{[38]}\].

2) We can then split \(S^{2n-1}\) into \(S^{n-1}_{\cos \eta}\) and \(S^{n-1}_{\sin \eta}\) and recursively apply the procedure all the way down to the basic case \(S^3 \subset \mathbb{R}^4\). The additional steps can also be applied for each leaf \((S^{n-1} \times S^{n-1})_{\eta}\).
C. Decoding performance

We analyze the performance of the decoding for the standard SCHF procedure. The only information required to store are minimum distance and dimension, so this algorithm has storage complexity $O(1)$.

The number of operations $T(n)$ in the general loop of Algorithm 5 follows the recursive expression

$$T(n) = 2T\left(\frac{n}{2}\right) + O(n),$$

where $O(n)$ accounts for computing $y$ (line 4), $\eta$ from (43) (line 5) and the products in line 9. Using Master theorem [37], it follows that this algorithm has complexity $O(n \log n)$. Compare this with the complexity of a brute-force ML decoder, which has time complexity $O(Mn)$ and storage complexity $O(M)$. In [34], two decoding algorithms are proposed for laminated spherical codes: one uses $O(\sqrt{M})$ space and $O(\log M)$ time and the other uses $O(1)$ space and $O(\sqrt{M})$ time.

Algorithm 4: Decoding algorithm in $\mathbb{R}^d$.

Input: $y$, $d$

Output: $\hat{x}$

1. $y \leftarrow y/\|y\|$
2. $(\eta, \xi_1, \xi_2) \leftarrow$ as in (35), (36), (37)
3. $\hat{\eta} \leftarrow \left\lfloor \frac{\eta - \pi/4}{\Delta \eta} \right\rfloor \Delta \eta + \frac{\pi}{\Delta \eta}$, with $\Delta \eta = 2 \arcsin(d/2)$
4. $m \leftarrow$ as in Proposition 2
5. $n \leftarrow$ as in Proposition 2
6. $(\hat{\xi}_1, \hat{\xi}_2) \leftarrow$ as in (39), (40), (41), (42)
7. return $(\cos \hat{\eta} \cos \hat{\xi}_1, \cos \hat{\eta} \sin \hat{\xi}_1, \sin \hat{\eta} \cos \hat{\xi}_2, \sin \hat{\eta} \sin \hat{\xi}_2)$

To analyze the performance of this sub-optimal decoder, we have performed the following test: for a given code $C(M, n, d)$, we add i.i.d. centered Gaussian noises $z_i \sim \mathcal{N}(0, \sigma^2)$ to each point $x_i$ in the code and decode each $y_i = x_i + z_i$. We compute the symbol error rate (SER) for different signal-to-noise ratios (SNR), as well as the average CPU time required for decoding one codeword for the proposed algorithm without additional steps, with some additional steps (if $\hat{d} \geq d/2$, we consider the two adjacent leaves $\eta \pm \Delta \eta$), and the brute force ML decoder. Results are presented in Fig. 10 and Table IX.

While the SER of the proposed decoder without additional steps is higher than brute-force ML for high SNR, the average time required to decode one codeword required by the latter method can be up to ten times higher. On the other hand, when allowing simple additional steps, the decoding performance practically matches brute force ML, while keeping low time complexity. This justifies the use of the proposed sub-optimal decoder.

4 Using Python 3.7.6 on a 8GB RAM, Intel Core i5-7200U @ 2.50GHz machine.
Algorithm 5: Decoding algorithm in $\mathbb{R}^n$.

**Input:** $y, d, n$

**Output:** $\hat{x} = (\hat{x}_1, \ldots, \hat{x}_n)$

1. if $n = 4$ then
2. 
   Apply Algorithm 4 to $y$ and $d$
3. else
4. 
   $y \leftarrow y/\|y\|$
5. Compute $\eta$ from $y$ using (43)
6. $\tilde{\eta} \leftarrow \left[ \frac{\eta - \pi/4}{\Delta \eta} \right] \Delta \eta + \frac{\pi}{4}$, with $\Delta \eta = 2 \arcsin(d/2)$
7. $(w_1, \ldots, w_{n/2}) \leftarrow$ apply decoding in $\mathbb{R}^{n/2}$ to $(x_1, \ldots, x_{n/2})$ with $d/\cos \eta$
8. $(z_1, \ldots, z_{n/2}) \leftarrow$ apply decoding in $\mathbb{R}^{n/2}$ to $(x_{(n/2)+1}, \ldots, x_n)$ with $d/\sin \eta$
9. return $\hat{x} \leftarrow (\cos \tilde{\eta}(w_1, \ldots, w_{n/2}), \sin \tilde{\eta}(z_1, \ldots, z_{n/2}))$
10. end

**VIII. CONCLUSION**

We propose a construction for spherical codes in dimensions $2^k$ by a recursive procedure that is based on the Hopf foliations of $S^{2n-1}$ by $(S^{n-1} \times S^{n-1})_\eta$ and uses $\mathbb{R}^4$ as basic case. In fact, this construction can be applied to any even dimension $2n$ as long as a family of spherical codes is provided in dimension $n$.

Given a minimum distance $d > 0$, the standard method chooses leaves $S^{n-1}_{\cos \eta} \times S^{n-1}_{\sin \eta}$, parametrized by $\eta \in [0, \pi/2]$, that foliate $S^{2n-1}$ while mutually distant by at least $d$. On each leaf, we recursively distribute points on each of the spheres $S^{n-1}_{\cos \eta}$ and $S^{n-1}_{\sin \eta}$, with scaled minimum distances and combine the results as Cartesian product. On the

basic case $\mathbb{R}^4$, the sphere $S^3$ is foliated by tori $T^2_d$, each of which is divided in internal circles mutually distant by $d$, where points are equidistantly distributed.

In non-asymptotic regime, SCHF compare favorably to other constructive methods. The asymptotic upper bounds for the recursive and half dimension SCHF are derived and compared with other constructions. An encoding algorithm is presented, the time and storage complexities of which are respectively $O(n \log n)$ and $O(n)$. A suboptimal decoder with time complexity $O(n \log n)$ and storage complexity $O(1)$ is also proposed. We verify in some examples that, by allowing additional steps, its SER is close to that of ML decoder, while keeping the time required significantly lower.

Perspectives for the extension of this work include investigating, in several $2n$ dimensions, SCHF constructed from good available codes in dimension $n$; considering the structure of quaternions and octonions in the construction of codes; and analyzing the proposed SCHF for vector quantitation of Gaussian sources.

ACKNOWLEDGMENT

The authors are grateful for some generous contributions by C. Torezzan, V. Vaishampayan, L. Naves, as well as to J. Hamkins and K. Zeger, for sharing their apple-peeling implementation.
