WEIGHTED SHARING AND UNIQUENESS OF $L$-FUNCTION WITH CERTAIN CLASS OF MEROMORPHIC FUNCTION

ABHIJIT BANERJEE AND ARPITA KUNDU

Abstract. The purpose of the paper is to study the uniqueness problem of a $L$ function in the Selberg class sharing one or two sets with an arbitrary meromorphic function having finite poles. We manipulate the notion of weighted sharing of sets to improve one result of Yuan-Li-Yi [Value distribution of $L$-functions and uniqueness questions of F. Gross, Lithuanian Math. J., 58(2)(2018), 249-262]. More importantly, we have pointed out a number of gaps in all the results of Sahoo-Halder [Results on $L$-functions and certain uniqueness question of Gross, Lithuanian Math. J., 60(1)(2020), 80-91] which actually makes the validity of the same paper under question. As an attempt to rectify the results of Sahoo-Halder we have presented the accurate forms and proof of the results in a compact and convenient manner.

1. INTRODUCTION

By a meromorphic function we shall always mean a meromorphic function in the complex plane. We adopt the standard notations of Nevanilinna theory of meromorphic functions as explained in [5].

Let $f$ and $g$ be two non-constant meromorphic functions and let $S$ be a subset of distinct elements in the complex plane. For some $a \in \mathbb{C} \cup \{\infty\}$, we define $E_f(S) = \bigcup_{a \in S} \{z : f(z) - a = 0\}$, where each point is counted according to its multiplicity. If we do not count the multiplicity then the set $\bigcup_{a \in S} \{z : f(z) - a = 0\}$ is denoted by $E_f(S)$. If $E_f(S) = E_g(S)$ then we say $f$ and $g$ share the $S$ CM. On the other hand, if $E_f(S) = E_g(S)$ then we say $f$ and $g$ share the $S$ IM. This paper deals with the uniqueness problems of value sharing and set sharing related to $L$-functions and an arbitrary meromorphic function in $\mathbb{C}$.

In 1989, Selberg [13] introduced a new class of Dirichlet series, called the Selberg class, which later became an important field of research in analytic number theory. In this paper, by an $L$-function we mean a Selberg class function with the Riemann zeta function $\zeta(s) = \sum_{n=1}^{\infty} \frac{1}{n^s}$ as the prototype. The Selberg class $S$ of $L$-functions is the set of all Dirichlet series $L(s) = \sum_{n=1}^{\infty} a(n)n^{-s}$ of a complex variable $s$ that satisfy the following axioms (see [13]):

(i) Ramanujan hypothesis: $a(n) \ll n^c$ for every $c > 0$.
(ii) Analytic continuation: There is a non-negative integer $k$ such that $(s - 1)^k L(s)$ is an entire function of finite order.
(iii) Functional equation: $L$ satisfies a functional equation of type

$$\Lambda_L(s) = \omega \Lambda_L(1 - s),$$

where

$$\Lambda_L(s) = L(s)Q^s \prod_{j=1}^{K} \Gamma(\lambda_j s + \nu_j)$$

with positive real numbers $Q$, $\lambda_j$ and complex numbers $\nu_j, \omega$ with $Re\nu_j \geq 0$ and $|\omega| = 1$.

(iv) Euler product hypothesis : $L$ can be written over prime as

$$L(s) = \prod_{p} \exp \left( \sum_{k=1}^{\infty} \frac{b(p^k)}{p^{ks}} \right)$$

Key words and phrases: Meromorphic function, $L$ function, uniqueness, weighted sharing.

Type set by AMSTeX
with suitable coefficients $b(p^k)$ satisfying $b(p^k) \ll p^{\theta}$ for some $\theta < 1/2$ where the product is taken over all prime numbers $p$.

The Ramanujan hypothesis implies that the Dirichlet series $\mathcal{L}$ converges absolutely in the half-plane $\text{Re}(s) > 1$ and then is extended meromorphically. The degree $d_{\mathcal{L}}$ of an $L$-function $\mathcal{L}$ is defined to be

$$d_{\mathcal{L}} = 2 \sum_{j=1}^{K} \lambda_j,$$

where $\lambda_j$ and $K$ are respectively the positive real number and the positive integer as in axiom (iii) above. For the last couple of years or so, the researchers have given priority to the investigations on the value distributions of $L$-functions (see [3, 6, 9, 10, 14]). The value distribution of an $L$-function $\mathcal{L}$ concerns about the roots of the equation $\mathcal{L}(s) = c$ for some $c \in \mathbb{C} \cup \{\infty\}$. In case we talk about the sharing of sets by an $L$-function, we refer the reader to the first paragraph of this paper where all the definitions discussed also applicable to an $L$-function. Regarding uniqueness problem of two $\mathcal{L}$ functions, in 2007, Steuding [p. 152, [14]] proved that the number of shared values can be reduced significantly. Below we invoke the result.

**Theorem A.** If two $L$-functions $\mathcal{L}_1$ and $\mathcal{L}_2$ with $a(1) = 1$ share a complex value $c \neq \infty$ CM, then $\mathcal{L}_1 = \mathcal{L}_2$.

**Remark 1.1.** Providing a counterexample, Hu and Li [6] have pointed out that Theorem A is not true when $c = 1$.

Since $L$-functions possess meromorphic continuations, it is quite natural to investigate up to which extent an $L$-function can share values with an arbitrary meromorphic function. In 2010, Li [9] observed that Theorem A no longer holds for an $L$-function and a meromorphic function, which is clear from the following example.

**Example 1.1.** For an entire function $g$, the functions $\zeta$ and $\zeta e^g$ share $0$ CM, but $\zeta \neq \zeta e^g$.

However, considering two distinct complex values, Li [9] proved the following uniqueness result.

**Theorem B.** Let $f$ be a meromorphic function in $\mathbb{C}$ having finitely many poles, and let $a$ and $b$ be any two distinct finite complex values. If $f$ and a non-constant $L$-function $\mathcal{L}$ share a CM and $b$ IM, then $f = \mathcal{L}$.

Next to streamline all the results we are going to demonstrate onward, let us define the two polynomials $P(w), P_1(w)$ as follows:

$$P(w) = w^n + aw^m + b \quad \text{and} \quad P_1(w) = w^n + aw^{n-m} + b$$

where $a, b \in \mathbb{C} \setminus \{0\}$ and $n, m$ are two positive integers such that $\gcd(n, m) = 1$.

In view of Lemma [2,4] proved afterwards, we see that both $P(w)$ and $P_1(w)$ can have at most one multiple zero. Next corresponding to the polynomials $P(w), P_1(w)$, let us define two sets $S$ and $S_1$ as follows:

$$S = \{w : P(w) = 0\} = \{\alpha_1, \alpha_2, \ldots, \alpha_l\}$$

and

$$S_1 = \{w : P_1(w) = 0\} = \{\beta_1, \beta_2, \ldots, \beta_l\}$$

where $n - 1 \leq l \leq n$.

Inspired by the famous question of Gross [4] for meromorphic functions, Yuan-Li-Yi [15] proposed the question “what can be said about the relationship between a meromorphic function $f$ and an $L$-function $\mathcal{L}$ if $f$ and $\mathcal{L}$ share one or two finite sets?” In this respect, to find the relationship between a meromorphic function $f$ and an $L$-function $\mathcal{L}$ sharing one or two finite sets, Yuan-Li-Yi [15] proved the following uniqueness result.

**Theorem C.** [15] Let $f$ be a meromorphic function having finitely many poles in $\mathbb{C}$ and let $\mathcal{L}$ be a non-constant $L$-function. Let $S$ be defined as in [1.7] and $n(\geq 5) > m$ and $c \in \mathbb{C} \setminus S \cup \{0\}$. If $f$ and $\mathcal{L}$ share $S$ CM and $c$ IM, then $f = \mathcal{L}$. 
Theorem D. Let $f$ and $L$ be a defined as in Theorem C. Let $S$ be defined as in (17) where $n > 2m + 4$. If $f$ and $L$ share $S = \{w : P(w) = 0\}$ CM, then $f = L$.

Sahoo-Halder proved a supplementary result corresponding to Theorems C, D for IM sharing. Sahoo-Halder proved the following result.

Theorem E. Let $f$ be a meromorphic function having finitely many poles in $\mathbb{C}$ and $L$ be a non-constant $L$-function. Also let $S$ and $c$ be defined same as in Theorem C and $n > 4k + 9$ where $k = n - m \geq 1$. Then if $f$ and $L$ share $S$ IM and $c$ IM, then $f = L$.

Theorem F. Let $f$ be a meromorphic function having finitely many poles in $\mathbb{C}$ and $L$ be a non-constant $L$-function. Let $S$ be given as in (17), where $n > \max\{2m + 4, 4k + 9\}$ such that $k = n - m \geq 1$. If $f$ and $L$ share $S = \{w : P(w) = 0\}$ IM, then $f = L$.

We now observe some severe errors in [12] as follows:

Remark 1.2. In [12] Sahoo-Halder gave a restriction on choice of $m$, whereas if we consider the polynomial for $m = 1, 2, \ldots$ then putting $m = 1, 2$ ($m = n - 1, n - 2$) we get $n > 4n + 5$ and $n > 4n + 1$ respectively, which is a contradiction. So in general the theorem cease to hold for any arbitrary value of $m$ (or $k$). A careful observation shows that $n > 4k + 9$ holds only when $\frac{3n^2 + 3}{4} < m < n (1 \leq k \leq \frac{n - 10}{4})$.

Next in the proof of Theorem E in [12] [p.10, l.10 from bottom] the authors concluded that if $f$ and $L$ share $c$ IM then $P(f)$ and $P(L)$ also share $P(c)$ IM. With the help of this argument they finally set up $P(f) = P(L)$ and proved the rest part of the theorem. But this conclusion is true only when $P(f) - P(c) = K_1(f - c)^n$ and $P(L) - P(c) = K_2(L - c)^n$, for some constant $K_1, K_2$, or $P(f) = P(L)$. In the proof of Theorem E clearly both the arguments (i) and (ii) fail and so in general $P(f), P(L)$ not suppose to share $P(c)$ for any arbitrary $f$ and $L$. In other words the proof of Theorem E in [12] is not correct and so there is a gap in the proof of Theorem E.

Remark 1.3. According to the Theorem F [12] we have, if $f$ and $L$ share $S = \{w : P(w) = 0\}$ IM, then for $n > \max\{2m + 4, 4k + 9\}$ one can get $f = L$, where $n, m, k$ and $f, L$ are mentioned in Theorem F. If possible let us assume for some $m$ Theorem F holds. Then obviously from given condition we have

\[ n > 4k + 9 \implies n > 4n - 4m + 9 \implies 4m > 3n + 9 \]

and $n > 2m + 4$, both together implies $4m > 6m + 21$, which is absurd. So there exist no such $m$ for which Theorem F is true. Hence validity of Theorem F is also at stake.

In view of Remarks 1.2 and 1.3 we see that the very existence of the whole paper [12] is at stake.

In this paper we have improved Theorem D by relaxing the nature of sharing the set with the notion of weighted sharing. We have also presented and proved the corrected form of Theorems E and F on the uniqueness of $L$-function and meromorphic functions. Thus, Sahoo-Halder’s [12] results have been fully rectified.

Before presenting the main results we invoke the definition of weighted sharing.

Definition 1.1. Let $k$ be a non-negative integer or infinity. For $a \in \mathbb{C} \cup \{\infty\}$ we denote by $E_k(a; f)$ the set of all $a$-points of $f$, where an $a$-points of $f$ of multiplicity $m (\leq k)$ counted $m$ times and $m(> k)$ then it counted $k + 1$ times. If $E_k(a; f) = E_k(a; g)$, we say that $f, g$ share the value $a$ with weight $k$.

We write $f, g$ share $(a, k)$ to mean that $f, g$ share the value $a$ with weight $k$. Clearly if $f, g$ share $(a, k)$ then $f, g$ share $(a, p)$ for any integer $p$, $0 \leq p < k$. Also note $f, g$ share a value a IM or CM, $f, g$ share $(a, 0)$ or $(a, \infty)$ respectively.

Definition 1.2. For $S \subset \mathbb{C} \cup \{\infty\}$, we define $E_f(S, k) = \bigcup_{a \in S} E_k(a; f)$, where $k$ is a non-negative integer or infinity. Clearly $E_f(S) = E_f(S, \infty)$.

In particular $E_f(S, k) = E_g(S, k)$ and $E_f(\{a\}, k) = E_g(\{a\}, k)$ implies $f$ and $g$ share the set $S$ and the value $a$ with weight $k$.

We first present the following theorem corresponding to Theorem D which provide the corrected form of Theorem F as well.
Theorem 1.1. Let \( S \) be defined as in (1.1). Also let \( f \) be a meromorphic function having finitely many poles in \( \mathbb{C} \) and \( L \) be a non-constant \( L \)-function such that \( E_f(S, s) = E_L(S, s) \). If

(i) \( s \geq 2 \) and \( n > 2m + 4 \), or if
(ii) \( s = 1 \) and \( n > 2m + 5 \), or if
(iii) \( s = 0 \) and \( n > 2m + 10 \); then \( f = L \).

The following corollary is obvious from the above theorem which also relax the CM sharing of \( S \) in Theorem D to weight 2.

Corollary 1.1. Let \( S \) be defined as in (1.1) and \( n > 2m + 4 \). Also let \( f \) be a meromorphic function having finitely many poles in \( \mathbb{C} \) and let \( L \) be a non-constant \( L \)-function. If \( E_f(S, 2) = E_L(S, 2) \), then \( f = L \).

We note that as far as the set \( S \) is concerned, Theorem 1.1 is not valid for all \( m \) with \( \gcd(n, m) = 1 \). For example if we consider \( m = n - 1 \) for \( s \geq 2 \), Theorem 1.1 is not applicable. An elementary calculation will show that when \( 1 \leq m < \frac{4n}{2s-1} \), for \( s \geq 2 \), the theorem is valid. Similarly it can be shown that for \( s = 1 \) or \( 0 \) then \( m \) will have some restrictions. So it will be interesting to investigate the form of Theorem 1.1 for the rest values of \( m \) in order to complete the theorem. The following theorem elucidate in this regard.

Theorem 1.2. Let \( S_1 \) be defined as in (1.2), \( f \) be a meromorphic function having finitely many poles in \( \mathbb{C} \) and \( L \) be a non-constant \( L \)-function such that \( E_f(S_1, s) = E_L(S_1, s) \). If

(i) \( s \geq 2 \) and \( n > 2m + 4 \), or if
(ii) \( s = 1 \) and \( n > 2m + 5 \), or if
(iii) \( s = 0 \) and \( n > 2m + 10 \); then \( f = L \).

Corollary 1.2. In Theorem 1.2 we see that \( \frac{4n}{2s-1} < k = n - m \leq n - 1 \) and a close look will reveal that this will supplement the values of \( m \) for the case \( s \geq 2 \) in Theorem 1.1.

In Theorem C, \( c \) has been considered as non-zero, so it will be interesting to investigate the theorem for \( c = 0 \). In the next theorem, we have rectified Theorem E considering two special form of \( c \). However we have not succeeded to get the result for any arbitrary \( c \).

Theorem 1.3. Let \( S \) be defined as in (1.1) and \( f \) be a meromorphic function having finitely many poles in \( \mathbb{C} \) and let \( L \) be a non-constant \( L \)-function. Suppose \( E_f(S, s) = E_L(S, s) \) and \( E_f(c, t) = E_L(c, t) \) for some finite \( c \in (0, a_1, a_2, \ldots, a_{n-m}) \) but \( c \notin S \), where \( a_i \) (\( i = 1, 2, \ldots, n-m \)) are zeros of \( nz^m - m \). First suppose

(I) \( c = 0, t = 0 \) and
(ii) \( s \geq 2, n \geq 2m + 3 \) or
(ii) \( s = 1, n \geq 2m + 4 \) or
(iii) \( s = 0, n \geq 2m + 9 \); then we have \( f = L \).

Next suppose

(II) \( c \) is a root of \( nz^k + ma = 0, k = n - m \) and \( l = n \). If
(i) \( s \geq 2, t = 1 \) and \( n \geq 2k + 3 \) or
(ii) \( s = 1, t = 0 \) and \( n \geq 2k + 4 \) or
(iii) \( s = 0, t = 0 \) and \( n \geq 2k + 7 \), then we have \( f = L \).

We assume that the readers are familiar with the standard notations of Nevanlinna theory such as the Nevanlinna characteristic function \( T(r, f) \), the proximity function \( m(r, f) \), the reduced counting function \( N(r, \infty; f) \), and so on, which are well explained in [5]. Here we use the symbol \( \rho(f) \) to denote the order of a non-constant meromorphic function \( f \), which is defined as

\[
\rho(f) = \limsup_{r \to \infty} \frac{\log^+ T(r, f)}{\log r}
\]

By \( S(r, f) \) we mean any quantity satisfying \( S(r, f) = O(\log(rT(r, f))) \), for all \( r \) possibly outside a set of finite Lebesgue measure. If \( f \) is a function of finite order, then \( S(r, f) = O(\log r) \) for all \( r \). In this paper we consider \( f \) as a non-constant meromorphic function having finitely many poles in \( \mathbb{C} \), then clearly \( N(r, \infty; f) = O(\log r) \). We now explain some more notations and definitions which are used in this paper.
Definition 1.3. For a ∈ C ∪ {∞} we denote by \( N(r, a; f | = 1) \) the counting function of simple a points of \( f \). For a positive integer \( s \) we denote by \( N(r, a; f | ≤ s) \) (\( N(r, a; f | ≥ s) \)) the counting function of those a-points of \( f \) whose multiplicity are not greater(less) than \( s \), where each a-point is counted according to it’s multiplicity.

Also \( \overline{N}(r, a; f | ≤ s) \) (\( \overline{N}(r, a; f | ≥ s) \)) is defined similarly, where in counting the a-points counted exactly once.

Definition 1.4. We denote \( N_2(r, a; f) = \overline{N}(r, a; f) + \overline{N}(r, a; f | ≥ 2) \).

Definition 1.5. If \( s \) is a positive integer, we denote by \( N(r, a; f | = s) \) the counting function of those a-points of \( f \) whose multiplicity is \( s \), where each point counted according to its multiplicity.

Also \( \overline{N}(r, a; f | = s) \) is defined similarly, where in counting the a-points counted exactly once.

Let \( z_0 \) be a point of \( f \) and \( g \) of multiplicity \( p \) and \( q \) respectively. Then by \( N_E^{(1)}(r, a; f) \) we denote the counting function of those a-points of \( f \) and \( g \) where \( p = q = 1 \).

Definition 1.6. Let \( f \), \( g \) share a value a IM. We denote by \( N_*(r, a; f, g) \) the counting function of those a-points of \( f \) whose multiplicities are different from multiplicities of the corresponding a-points of \( g \), where each a-point is counted exactly once.

Clearly \( N_*(r, a; f, g) = N_*(r, a; f) - N(r, a; f) + \overline{N}(r, a; f) \).

Definition 1.7. Let \( a_1, b_1, b_2, \ldots, b_q \in C \cup \{∞\} \). We denote by \( N(r, a; f | g ≠ b_1, b_2, \ldots, b_q) \) the counting function of those a-points of \( f \), counted according to its multiplicity, which are not \( b_i \) points of \( g \) for \( i = 1, 2, \ldots, q \).

Definition 1.8. Let \( P(z) \) be a polynomial such that \( P'(z) \) has mutually \( k \) distinct zeros given by \( d_1, d_2, \ldots, d_k \) with multiplicities \( q_1, q_2, \ldots, q_k \) respectively. Then \( P(z) \) is said to satisfy the critical injection property if \( P(d_i) ≠ P(d_j) \) for \( i ≠ j \), where \( i, j \in \{1, 2, \ldots, k\} \).

2. LEmmA

Next, we present some lemmas that will be needed in the sequel. Henceforth, we denote by \( H, \Phi \) the following functions:

\[
H = \left( \frac{F''}{F'} - \frac{2F'}{F - 1} \right) - \left( \frac{G''}{G'} - \frac{2G'}{G - 1} \right)
\]

and

\[
\Phi = \frac{F'}{F - 1} - \frac{G'}{G - 1}
\]

Lemma 2.1. Let \( F \) and \( G \) share (1, 0) and \( H ≠ 0 \). Then,

\[
N_E^{(1)}(r, 1; F) ≤ N(r, H) + S(r, F) + S(r, G).
\]

Lemma 2.2. If two non-constant meromorphic function \( F \) and \( G \) share (1, m) and \( H ≠ 0 \) then,

\[
N(r, ∞; H) ≤ \overline{N}(r, 0; F | ≥ 2) + \overline{N}(r, 0; G | ≥ 2) + \overline{N}_*(r, 1; F, G) + \overline{N}(r, ∞; F | ≥ 2) + \overline{N}(r, ∞; G | ≥ 2)
\]

\[
+ \overline{N}_0(r, 0; F') + \overline{N}_0(r, 0; G'),
\]

where, \( \overline{N}_0(r, 0; F') \) is the reduced counting function for those zeros of \( F' \), which are not zeros of \( F(F - 1) \) and \( \overline{N}_0(r, 0; G') \) is similarly defined.

Lemma 2.3. Let \( P(f) = \sum_{k=0}^{n} a_k f^k / \sum_{j=0}^{m} b_j f^j \), be an irreducible polynomial in \( f \), with constants coefficient \( \{a_k\} \) and \( \{b_j\} \) where \( a_n ≠ 0 \) and \( b_m ≠ 0 \). Then

\[
T(r, P(f)) = dT(r, f) + S(r, f),
\]

where \( d = \max\{m, n\} \).

Lemma 2.4. Let \( P(w) = w^n + aw^m + b \) and \( P_1(w) = w^n + aw^{n-m} + b \) be two polynomials, where \( n \) and \( m \) be relatively prime positive integers and \( a, b \) be two non-zero constants. Then they are critically injective polynomials with at most one multiple zero and at least \( n - 2 \) simple zeros, where the multiplicity of the multiple zero is exactly 2.
Proof. Clearly from the given polynomial $P(w)$, we have $P'(w) = \frac{z^{m-1}(nz^{n-m} + ma)}{z}$. Suppose the zeros of $P'(w)$ are $a_1, a_2, ..., a_{n-m}$, where $a_i$'s $(i = 1, 2, ..., n-m)$ are given as in Theorem 1.3.

Clearly $P(0) \neq P(a_i)$ for $i = 1, 2, ..., n-m$. Now suppose contrary to the statement of the lemma, $a_i, a_j \ (1 \leq i < j \leq n-m, P(a_i) = P(a_j)$.

Now since $a_i, a_j$ are the zeros of $nz^{n-m} + ma$, we have $na_i^{n-m} + ma = na_j^{n-m} + ma \implies a_i^{n-m} = a_j^{n-m}$. Using this, from $P(a_i) = P(a_j)$ we get $a_i^{m} = a_j^{m}$. Since gcd$(n, m) = 1$, then from $a_i^{n-m} = a_j^{n-m}$ and $a_i^{n} = a_j^{n}$, we get $a_i = a_j$, a contradiction. Hence $P(a_i) = P(a_j) \implies a_i = a_j$ or in other words $P(a_i) \neq P(a_j)$ for $i \neq j$. So from the definition it follows that $P(w)$ is critically injective. Also it is obvious from the definition of critically injective polynomial, it has at most one multiple zero. For, if not then the two distinct multiple zeros say $\zeta_1$ and $\zeta_2$ would yield $P(\zeta_1) = P(\zeta_2)$, where $\zeta_1, \zeta_2 \in \{a_1, a_2, ..., a_{n-m}\}$. Therefore $P(w)$ must contain at most one multiple zero of multiplicity two.

Similarly one can prove the result for $P_1(w)$ and hence the proof is complete. \qed

Lemma 2.5. \cite{1} If $F$ and $G$ share $(1, s)$ then

$$\mathcal{N}(r, 1; F) + \mathcal{N}(r, 1; G) + \left(\frac{s - 1}{2}\right) \mathcal{N}_s(r, 1; F, G) - N^{1)}(r, 1; F) \leq \frac{1}{2}(N(r, 1; F) + N(r, 1; G)).$$

Lemma 2.6. Let $F = -\frac{f}{f + b}$ and $G = -\frac{g}{g + b}$, where $f$ and $g$ are any two non-constant meromorphic functions and $n, m$ are relatively prime positive integers, such that $n > m \geq 1$, and $a, \ b$ are non-zero finite constants. Let $\gamma_i, \ i = 1, 2, ..., m$ are roots of $aw^n + b = 0$. If $H \neq 0$ and $E_f(S, s) = E_g(S, s)$ where $S$ is defined as in \cite{1} then,

$$\frac{n}{2}(T(r, f) + T(r, g)) \leq 2(\mathcal{N}(r, 0; f) + \mathcal{N}(r, 0; g) + \mathcal{N}(r, \infty; f) + \mathcal{N}(r, \infty; g)) + \sum_{i=1}^{m}(N_2(r, \gamma_i; f)

+ N_2(r, \gamma_i; g)) + \left(\frac{3}{2} - s\right) \mathcal{N}_s(r, 1; F, G) + S(r, f) + S(r, g).$$

Proof. Clearly here $F$ and $G$ share $(1, s)$. By the Second Fundamental Theorem and using Lemmas 2.3, 2.4, 2.2 and 2.6 we have,

$$n(T(r, f) + T(r, g)) = T(r, F) + T(r, G)

\leq \mathcal{N}(r, 1; F) + \mathcal{N}(r, 0; F) + \mathcal{N}(r, \infty; F) + \mathcal{N}(r, 1; G) + \mathcal{N}(r, 0; G) + \mathcal{N}(r, \infty; G) - N_0(r, 0; F') - N_0(r, 0; G') + S(r, F) + S(r, G)

\leq \frac{n}{2}(T(r, f) + T(r, g)) + N^{1)}(r, 1; F, G) + \left(\frac{1}{2} - s\right) \mathcal{N}_s(r, 1; F, G) + \mathcal{N}(r, 0; f)

+ \mathcal{N}(r, 0; af^m + b) + \mathcal{N}(r, 0; g) + \mathcal{N}(r, \infty; g) + \mathcal{N}(r, 0; ag^m + b) - N_0(r, 0; F') - N_0(r, 0; G') + S(r, f) + S(r, g),$$

i.e.,

$$\frac{n}{2}(T(r, f) + T(r, g)) \leq 2\mathcal{N}(r, \infty; f) + 2\mathcal{N}(r, \infty; g) + 2\mathcal{N}(r, 0; f) + 2\mathcal{N}(r, 0; g) + N_2(r, 0; af^m + b)

+ N_2(r, 0; ag^m + b) + \left(\frac{3}{2} - s\right) \mathcal{N}_s(r, 1; F, G) + S(r, f) + S(r, g)

\leq 2(\mathcal{N}(r, 0; f) + \mathcal{N}(r, 0; g) + \mathcal{N}(r, \infty; f) + \mathcal{N}(r, \infty; g)) + \sum_{i=1}^{m}(N_2(r, \gamma_i; f) + N_2(r, \gamma_i; g))

+ \left(\frac{3}{2} - s\right) \mathcal{N}_s(r, 1; F, G) + S(r, f) + S(r, g).$$

\qed
Lemma 2.7. Let $F = -(f^n + af^{n-m})/b$ and $G = -(g^n + ag^{n-m})/b$, where $f$ and $g$ be any two non-constant meromorphic functions and $n$, $m$ be relatively prime positive integers such that $n > m \geq 1$, and $a$, $b$ be non-zero finite constants. Let $\delta_i$, $i = 1, 2, \ldots, m$ be the distinct roots of the equation $w^m + a = 0$. If $H \neq 0$ and $E_f(S_1, s) = E_g(S_1, s)$ where $S_1$ is defined as in Lemma 2.6. Then,

$$\frac{n}{2}(T(r, f) + T(r, g)) \leq 2(N(r, 0; f) + N(r, 0; g) + N(r, \infty; f) + N(r, \infty; g)) + \sum_{i=1}^{m} (N(r, \delta_i; f) + N_2(r, \delta_i; g) + \left(\frac{3}{2} - s\right) N'(r, 1; F, G) + S(r, f) + S(r, g)).$$

Proof. We omit the proof since this is similar to the proof of Lemma 2.6.

Now before discussing the next lemmas we define some notations.

By $\Theta(Q(w))$ we denote the number of distinct zeros of any polynomial $Q(w)$ of degree $d$ and here

$$\chi_d = 0, \text{ when } \Theta(Q(w)) = d$$

$$= 1, \text{ when } \Theta(Q(w)) = d - 1.$$  

Lemma 2.8. Let $F$ and $G$ be defined as in Lemma 2.7 and share $(1, s)$ then

$$\overline{N}_L(r, 1; F) \leq \frac{1}{s + 1} \left( N(r, 0; f) + \overline{N}(r, \infty; f) + \chi_d^F N(r, \alpha_j; f) \right) + S(r, f),$$

where $\alpha_j$ ($1 \leq j \leq n - 1$) be the multiple root of the equation $P(w) = w^n + aw^m + b = 0$.

Proof. In view of Lemma 2.4, first suppose that the equation $P(w) = w^n + aw^m + b = 0$ has one multiple root and assume that as $\alpha_j$ ($1 \leq j \leq n - 1$). Then $\chi_d^F = 1$.

$$\overline{N}_L(r, 1; F) \leq \overline{N}(r, 0; f') \geq s + 2$$

$$\leq \overline{N}(r, 0; F') \geq s + 1; F = 1$$

$$\leq \frac{1}{s + 1} \overline{N}(r, 0; f') + \left( N(r, 0; f') - N_o(r, 0; f') \right)$$

$$\leq \frac{1}{s + 1} \left( N(r, 0; f'), N(r, \alpha_j; f) - N_o(r, 0; f') \right)$$

$$\leq \frac{1}{s + 1} \left( N(r, 0; f'), N(r, \alpha_j; f) - N_o(r, 0; f') \right)$$

$$\leq \frac{1}{s + 1} \left( N(r, 0; f'), N(r, \alpha_j; f) - N_o(r, 0; f') \right) + S(r, f)$$

$$\leq \frac{1}{s + 1} \left( N(r, 0; f'), N(r, \alpha_j; f) - N_o(r, 0; f') \right) + S(r, f),$$

where $N_o(r, 0; f') = N(r, 0; f') \neq 0, \alpha_1, \alpha_2, \ldots, \alpha_{n-1}$.

Next suppose all the $n$ roots of $P(w)$ are distinct. Then $\chi_d^F = 0$, and also from above calculations we have

$$\overline{N}_L(r, 1; F) \leq \frac{1}{s + 1} \left( N(r, 0; f) + \overline{N}(r, \infty; f) - N(r, 0; f') \right) + S(r, f),$$

hence the proof is complete.

Lemma 2.9. Let $F$ and $G$ be defined in Lemma 2.7 share $(1, s)$ then

$$\overline{N}_L(r, 1; F) \leq \frac{1}{s + 1} \left( N(r, 0; f) + \overline{N}(r, \infty; f) + \chi_d^F N(r, \beta_j; f) \right) + S(r, f),$$

where $\beta_j$ ($1 \leq j \leq n - 1$) be the multiple root of the equation $P_i(w) = w^n + aw^n - b = 0$.

Proof. We omit this proof because it is similar to the proof of Lemma 2.8.

Lemma 2.10. Let $f$ be a non-constant meromorphic function having finitely many poles and $L$ be a $L$-function such that $E_f(S, s) = E_L(S, s)$, where $S$ is defined as in [10]. Then for $n > 2$,

$$\frac{f^n}{af^m + b} \neq 1.$$
Proof. Contrary to the hypothesis let us take
\[ \frac{f^n}{af^m + b} = 1. \]

By Lemma 2.3 we have
\[ (2.1) \quad T(r, f) = T(r, \mathcal{L}) + S(r, \mathcal{L}). \]

Since \( f \) has finite number of poles and \( \mathcal{L} \) has at most one pole, we have \( \overline{N}(r, \infty; f) = \overline{N}(r, \infty; \mathcal{L}) = O(\log r) \). Also from Lemma 2.11 it is obvious that \( S(r, f) = S(r, \mathcal{L}) = O(\log r) \).

As mentioned in Lemma 2.6 we know that \( \gamma_1, \gamma_2, \ldots, \gamma_m \) are roots of \( aw^m + b = 0 \). Let \( z_0 \) be a zero of \( af^m + b \) with multiplicity \( p \) and also a zero of \( \mathcal{L} \) with multiplicity \( q \).

Then \( p = nq \implies p \geq n \).

Thus
\[ \overline{N}(r, \gamma_i; f) \leq \frac{1}{n} \overline{N}(r, \gamma_i; f). \]

By the same arguments one can show
\[ \overline{N}(r, \gamma_i; \mathcal{L}) \leq \frac{1}{n} \overline{N}(r, \gamma_i; \mathcal{L}) \]

Now using this, (2.1) and the Second Fundamental Theorem we get
\[ mT(r, f) \leq \overline{N}(r, 0; f) + \overline{N}(r, \infty; f) + \sum_{i=1}^{m} \overline{N}(r, \gamma_i; f) + S(r, f) \]
\[ \leq \overline{N}(r, \infty; \mathcal{L}) + \overline{N}(r, 0; a\mathcal{L}^m + b) + \frac{1}{n} \sum_{i=1}^{m} \overline{N}(r, \gamma_i; f) + O(\log r) \]
\[ \leq \frac{2m}{n} T(r, f) + O(\log r), \]
which gives a contradiction.

\[ \square \]

Lemma 2.11. Let \( f \) be a meromorphic function having finitely many poles in \( \mathbb{C} \) and \( S \) (or \( S_1 \)) be defined as in (1.2) (1.3). If \( f \) and a non-constant \( L \)-function \( \mathcal{L} \) share the set \( S \) (or \( S_1 \)) IM, then \( \rho(f) = \rho(\mathcal{L}) = 1 \).

Proof. We omit the proof as it can be found out in the proof of Theorem 5, {p. 6, [15]}. \[ \square \]

Lemma 2.12. Let \( F \) and \( G \) be defined in Lemma 2.6 such that they share (1, s) and \( f, g \) share \( \{0\} \) IM, then
\[ \overline{N}(r, 0; f) = \overline{N}(r, 0; g) \leq \frac{1}{n-1} (\overline{N}_*(r, 1; F, G) + \overline{N}(r, \infty; f) + \overline{N}(r, \infty; g) + \overline{N}(r, 0; af^m + b) + \overline{N}(r, 0; ag^m + b)) + S(r, f) + S(r, g). \]

Proof. Since \( f, g \) share \( (0, 0) \), it follows that
\[ \overline{N}(r, 0; f) = \overline{N}(r, 0; g) \leq \frac{1}{n-1} \overline{N}(r, 0; \Phi) \]
\[ \leq \frac{1}{n-1} T(r, \Phi) + O(1) \]
\[ \leq \frac{1}{n-1} \overline{N}(r, \infty; \Phi) + S(r, F) + S(r, G) \]
\[ \leq \frac{1}{n-1} (\overline{N}_*(r, 1; F, G) + \overline{N}(r, \infty; F) + \overline{N}(r, \infty; G)) + S(r, f) + S(r, g) \]
\[ \leq \frac{1}{n-1} (\overline{N}_*(r, 1; F, G) + \overline{N}(r, \infty; f) + \overline{N}(r, \infty; g) + \overline{N}(r, 0; af^m + b) + \overline{N}(r, 0; ag^m + b)) + S(r, f) + S(r, g). \]

\[ \square \]
3. PROOFS OF THE THEOREMS

Proof of Theorem 1.2. Let us consider \( F = -(f^n + af^{n-m})/b \) and \( G = -(L^n + aL^{n-m})/b \), where \( f \) has finitely many poles. As \( f \) and \( L \) share \( S_1 = \{ w : P_1(w) = 0 \} \) with weight \( s \), then clearly \( F \) and \( G \) share \( (1, s) \).

It is given that \( f \) has finite number of poles, therefore \( N(r, \infty; f) = O(\log r) \). As \( L \) has at most one pole, \( N(r, \infty; L) = O(\log r) \). Also from Lemma 2.11 we have \( \rho(f) = \rho(L) = 1 \). Therefore it is obvious that, \( S(r; f) = S(r; L) = O(\log r) \).

Let us consider \( H \not= 0 \).

Case I: Suppose \( w^n + aw^{n-m} + b = 0 \) has no multiple roots. Then using Lemma 2.7 and Lemma 2.9 we have

\[
(3.1) \quad \frac{n}{2} T(r) \\
\leq 2(N(r, 0; f) + N(r, 0; L)) + \sum_{i=1}^{m} (N_2(r, \delta_i; f) + N_2(r, \delta_i; L)) + \left( \frac{3}{2} - s \right) N_s(r, 1; F, G) + O(\log r)
\]

\[
\leq (2 + m)T(r) + \left( \frac{3}{2} - s \right) N_L(r, 1; F) + N_L(r, 1; G) + O(\log r)
\]

\[
\leq (2 + m)T(r) + \left( \frac{3}{2} - s \right) s + 1 (N(r, 0; f) + N(r, 0; L)) + O(\log r),
\]

where \( T(r) = T(r, f) + T(r, L) \).

Clearly when

(i) \( s \geq 2, n > 2m + 4 \) or when
(ii) \( s = 1, n > 2m + 5 \) or when
(iii) \( s = 0, n > 2m + 10; \)

from (3.1) we get a contradiction.

Case II: Again considering consider \( w^n + aw^{n-m} + b = 0 \) has a multiple root (say \( \beta_j \)), i.e. the equation has \( n - 1 \) distinct roots. Then proceeding same as in above (3.1) we get

\[
(3.2) \quad \frac{n}{2} T(r) \\
\leq (2 + m)T(r) + \left( \frac{3}{2} - s \right) N(r, 0; f) + N(r, 0; L) + N(r, \beta_j; f) + N(r, \beta_j; L) + O(\log r)
\]

Clearly from (3.2) and in view of the conditions (i), (ii), (iii) given in Case I, we arrive at a contradiction again.

Therefore \( H \equiv 0 \) and so integrating both sides we get,

\[
(3.3) \quad \frac{1}{G - 1} = \frac{A}{F - 1} + B,
\]

where \( A, B \) are two constants, \( A \neq 0 \). From Lemma 2.3 and (3.3) we have,

\[
(3.4) \quad T(r, L) = T(r, f) + O(1).
\]

At first let \( B \) is non-zero. Then

\[
G - 1 = \frac{F - 1}{A + B(F - 1)}.
\]

If \( A - B \neq 0 \) then zeros of \( F + (A - B)/B \) are poles of \( G - 1 = -(L^n + aL^{n-m} + b)/b \). Now \( F + (A - B)/B \) has at least \( n - 1 \) zeros for all \( 1 \leq m < n \). Then \( -(L^n + aL^{n-m} + b)/b \) has more than one pole implies \( L \) has more than one pole, which is a contradiction.

Therefore \( A - B = 0 \). Then

\[
G - 1 = \frac{F - 1}{BF}.
\]
Using the same arguments for \( m > 2 \), one can show \( B = 0 \). But the argument fails if for \( m \leq 2 \), \( f \) has two exceptional values (say-\( \xi_1, \xi_2 \)) or for \( m = 1 \), the same has one exceptional value (say-\( v \in \{0, -a\} \)). Then using the Second Fundamental Theorem we will get a contradiction again. Hence in any case \( B = 0 \). From (3.3) we have

\[
G - 1 = \frac{1}{A}(F - 1),
\]

\[\text{i.e., } \left( \mathcal{L}^n + a\mathcal{L}^{n-m} + b \right) = \frac{1}{A}\left( f^n + af^{n-m} + b \right). \]

\[\text{i.e., } \mathcal{L}^n + a\mathcal{L}^{n-m} + b - \frac{b}{A} = \frac{1}{A}(f^n + af^{n-m}). \]

Let us consider \( A \neq 1 \) then \( b/A \neq b \). So \( w^n + aw^m + b - b/A = 0 \) has atleast \( n - 1 \) distinct roots (say \( p_i, i = 1, 2, \ldots, n - 1 \)), then by the Second Fundamental Theorem, and (3.4) we get from above

\[
(n - 2)T(r, \mathcal{L}) \leq \sum_{i=1}^{n-1} N(r, p_i; \mathcal{L}) + \overline{N}(r, \infty; \mathcal{L}) + S(r, \mathcal{L})
\]

\[
\leq \overline{N}(r, 0; f) + \sum_{i=1}^{m} \overline{N}(r, \delta_i; f) + O(\log r)
\]

\[
\leq (m + 1)T(r, f) + O(\log r),
\]

which implies \( n \leq m + 3 \), a contradiction for \( n > 2m + 4 \).

Therefore our assumption is wrong. Hence \( A = 1 \) and therefore

\[F = G.\]

Now,

\[f^n - \mathcal{L}^n = -a(f^{n-m} - \mathcal{L}^{n-m}).\]

\[\text{i.e., } \mathcal{L}^m(h^n - 1) = -a(h^{n-m} - 1).\]

\[\text{i.e., } \mathcal{L}^m = -a\frac{h^{n-m} - 1}{h^n - 1}.\]

At first assume \( h = f/\mathcal{L} \) is a non-constant meromorphic function. Then since \( \gcd(m,n)=1 \), for \( n > 2m + 4 \), from above we get \( \mathcal{L} \) has more than one pole, which is a contradiction.

Therefore \( h \) is a constant, satisfying \( h^n - 1 = h^{n-m} - 1 = 0 \implies h = 1 \implies f = \mathcal{L}. \)

\[\square\]

**Proof of Theorem 2.1** Let us consider \( F = -\frac{f^n}{af^{n+b}} \) and \( G = -\frac{f^m}{af^{m+b}} \), where \( f \) has finitely many poles. As \( f \) and \( \mathcal{L} \) share \( S = \{w \mid P(w) = 0\} \) with weight \( s \), i.e. \( E_f(S, s) = E_g(S, s) \) then clearly \( F \) and \( G \) share \( (1, s) \). Let us consider \( H \neq 0 \).

**Case 1** : Let us consider \( w^n + aw^m + b = 0 \) has no multiple root. Then using Lemma 2.20 and Lemma 2.8 we have

\[
\frac{n}{2} T(r) \leq 2(\overline{N}(r, 0; f) + \overline{N}(r, 0; \mathcal{L})) + \sum_{i=1}^{m} \left( N_2(r, \gamma_i; f) + N_2(r, \gamma_i; \mathcal{L}) \right)
\]

\[
+ \left( \frac{3}{2} - s \right) \overline{N}_L(r, 1; F, G) + O(\log r)
\]

\[
\leq (2 + m)T(r) + \left( \frac{3}{2} - s \right) \left( \overline{N}_L(r, 1; F) + \overline{N}_L(r, 1; G) \right) + O(\log r)
\]

\[
\leq (2 + m)T(r) + \frac{\left( \frac{3}{2} - s \right)}{s + 1} \left( \overline{N}(r, 0; f) + \overline{N}(r, 0; \mathcal{L}) \right) + O(\log r).
\]
When

\[(i) \quad s \geq 2, \quad n > 2m + 4 \text{ or when} \]
\[(ii) \quad s = 1, \quad n > 2m + 5 \text{ or when} \]
\[(iii) \quad s = 0, \quad n > 2m + 10; \]

from (3.5), we get a contradiction.

Case II: Consider \(w^n + aw^m + b = 0\) has a multiple root (say \(\alpha_j\)), i.e. the equation has \(n - 1\) distinct roots. Then proceeding same as in (3.5) we get

\[
\frac{n}{2}T(r) \leq (2 + m)T(r) + \left(\frac{\frac{2}{s} - s}{s + 1}\right)\left(\overline{N}(r; f) + \overline{N}(r, 0; L) + N(r, \alpha_j; f) + N(r, \alpha_j; L)\right)
+ O(\log r).
\]

Clearly from (3.6) and for the conditions (i), (ii), (iii) given in Case I, we again arrive at a contradiction.

Therefore from Case I and Case II we have \(H \equiv 0\). In this respect, we have \(F\) and \(G\) share 1CM.

On integration we have

\[
F = AG + B CG + D,
\]

where \(A, B, C, D\) are constants such that \(AD - BC \neq 0\). Thus by Lemma 2.3

\[
T(r, f) = T(r, L) + S(r, L).
\]

As \(AD - BC \neq 0\), so \(A = C = 0\) never occur. Thus we consider the following cases:

Case 1: \(AC \neq 0\)

In this case

\[
F - \frac{A}{C} = \frac{BC - AD}{C(CG + D)}.
\]

So,

\[
\overline{N}(r, \frac{A}{C}; f) = \overline{N}(r, \infty; G).
\]

Using the Second Fundamental Theorem and (3.8) we get

\[
nT(r, f) + O(1) = T(r, F)
\leq \overline{N}(r, 0; f) + \overline{N}(r, \infty; f) + \overline{N}(r, \frac{A}{C}; f) + S(r, F)
\leq \overline{N}(r, 0; f) + \overline{N}(r, \infty; f) + \overline{N}(r, 0; af^m + b) + \overline{N}(r, \infty; L) + \overline{N}(r, 0; aL^m + b) + S(r, f)
\leq (2m + 1)T(r, f) + O(\log r),
\]

which is a contradiction for \(n > 2m + 4\).

Case 2: \(AC = 0\).

Subcase 2.1: \(A = 0\) and \(C \neq 0\).

In this case \(B \neq 0\) and let us suppose \(D \neq 0\). Then

\[
F = \frac{1}{\gamma G + \delta},
\]

where \(\gamma = C/B\), \(\delta = D/B\). If \(F\) has no one point, then by the Second Fundamental Theorem we get

\[
nT(r, f) + O(1) = T(r, F)
\leq \overline{N}(r, 0; f) + \overline{N}(r, \infty; f) + \overline{N}(r, 1, F) + S(r, F)
\leq \overline{N}(r, 0; f) + \overline{N}(r, \infty; f) + \overline{N}(r, 0; af^m + b) + S(r, f)
\leq (m + 1)T(r, f) + O(\log r),
\]

gives a contradiction for \(n > 2m + 4\).
Therefore 1 is not an exceptional value of $F$. So $\gamma + \delta = 1$ and $\gamma \neq 0$. 
So,

$$F = \frac{1}{\gamma G + 1 - \gamma}.$$ 

Since $D \neq 0 \implies \delta \neq 0$, we have $\gamma \neq 1$ and then by the Second Fundamental Theorem and (3.8) we get

$$nT(r, L) + O(1) = T(r, G)$$

$$\leq N(r, 0; G) + N(r, \infty; G) + N(r, -(1-\gamma)/\gamma; G) + S(r, G)$$

$$\leq N(r, 0; L) + N(r, \infty; L) + N(r, 0; aL^m + b) + N(r, \infty; f) + N(r, 0; af^m + b) + S(r, g)$$

$$\leq nT(r, L) + O(\log r),$$

which gives a contradiction for $n > 2m + 4.$

Thus our assumption is wrong, so $D = 0$ and $\gamma = 1$ which implies $FG = 1$, impossible by Lemma 2.10.

**Subcase 2.2 :** $A \neq 0$ and $C = 0.$

In this case $D \neq 0$ and $F = \lambda G + \mu$, where $\lambda = A/D$ and $\mu = B/D$.

If $F$ has no one point then proceeding similarly as above we get a contradiction.

Thus $\lambda + \mu = 1$ with $\lambda \neq 0$ and then

$$F = \lambda G + 1 - \lambda.$$ 

Then $N(r, -(1-\lambda)/\lambda; G) = N(r, 0; F)$.

Using the Second Fundamental Theorem and (3.8) we get

$$nT(r, L) + O(1) = T(r, G)$$

$$\leq N(r, 0; G) + N(r, \infty; G) + N(r, -(1-\lambda)/\lambda; G) + S(r, G)$$

$$\leq N(r, 0; L) + N(r, \infty; L) + N(r, 0; aL^m + b) + N(r, 0; f) + S(r, g)$$

$$\leq nT(r, L) + O(\log r),$$

a contradiction for $n > 2m + 4$.

Therefore $\lambda = 1$ and hence

$$\text{i.e., } -\frac{f^n}{af^m + b} = -\frac{L^n}{aL^m + b},$$

$$\text{i.e., } aL^m(1 - h^{n-m}) = -b(1 - h^n).$$

(3.9)

At first let us assume $h (= \frac{\xi}{f})$ is a non-constant meromorphic function. Then we have,

$$L^m = -\frac{b(1 - h^n)}{a(1 - h^{n-m})} = -\frac{-b(h - u)(h - u^2)\ldots(h - u^{n-1})}{a(h - v)(h - v^2)\ldots(h - v^{m-1})},$$

where $\gcd(n,m)=1$ and $u = \exp \frac{2\pi i}{n}$, $v = \exp \frac{2\pi i}{m}$.

Since $L$ has at most one pole in $C$, it follows that $h$ has at least $n - m - 2$ exceptional values among \{v, v^2, \ldots, v^{n-m-1}\}. Clearly this is a contradiction for $n > 2m + 4$.

Hence in that case $h$ is a constant meromorphic function. Now from (3.3) we have $h = 1 \implies f = L.$
Proof of Theorem 1.3. Let $F$ and $G$ be defined as in Theorem 1.1. Clearly $F$, $G$ share $(1, s)$. We consider two cases.

**Case I:** Let $c = 0$ and $H \neq 0$. It is given that $f$ and $L$ share $(0, 0)$. From Lemma 2.2 we have

\[
N(r, \infty; H) \leq \overline{N}_*(r, 0; f, L) + \overline{N}_*(r, 1; F, G) + \overline{N}_*(r, 0; a f^m + b | \geq 2) + \overline{N}(r, 0; a L^m + b | \geq 2) + O(\log r).
\]

Using this and proceeding same as in Lemma 2.6 we obtain

\[
(3.10) \quad \frac{n}{2} T(r) \leq 3 \overline{N}(r, 0; f) + \sum_{i=1}^{m} \left( N_2(r, \gamma_i; f) + N_2(r, \gamma_i; L) \right) + \left( \frac{3}{2} - s \right) \overline{N}_*(r, 1; F, G)
\]

\[+ O(\log r). \]

Using Lemma 2.7 in (3.10) we have

\[
(3.11) \quad \frac{n}{2} T(r) \leq \frac{3m}{n-1} T(r) + \sum_{i=1}^{m} \left( N_2(r, \gamma_i; f) + N_2(r, \gamma_i; L) \right) + \left( \frac{3}{2} + \frac{3}{n-1} - s \right) \overline{N}_*(r, 1; F, G)
\]

\[+ O(\log r). \]

First consider $w^n + a w^m + b = 0$ has a multiple root (say $\alpha_j$). Then by Lemma 2.8 and proceeding in the same way as done in Case II of Theorem 1.1 from (3.11) and for

\[
(i) \quad s \geq 2, \ n \geq 2m + 3 \ or \ for
\]

\[
(ii) \quad s = 1, \ n \geq 2m + 4 \ or \ for
\]

\[
(iii) \quad s = 0, \ n \geq 2m + 9,
\]

we can get a contradiction.

Next suppose $w^n + a w^m + b = 0$ has no multiple roots, then dealing in the same way and by the same arguments, again we can get a contradiction. Therefore $H \equiv 0$.

So we have $F$ and $G$ share $(1, \infty)$.

Now by integration we have

\[
F = \frac{AG + B}{CG + D}.
\]

where $A, B, C, D$ are constant such that $AD - BC \neq 0$.

Again proceeding in the same manner as done in the last part of Theorem 1.1 we have

\[
f^n \frac{F}{a f^m + b} = \frac{L^n}{a L^m + b}.
\]

Therefore $f$ and $L$ share $0$ CM. Then considering $h(=\frac{L}{f}) \neq 1$ we have

\[
L^m = \frac{-b(h - u)(h - u^2) \ldots (h - u^{n-1})}{a(h - v)(h - v^2) \ldots (h - v^{n-m-1})},
\]

where $\gcd(n,m) = 1$ and $u = \exp \frac{2\pi i}{n}$, $v = \exp \frac{2\pi i}{n-m}$.

The possible poles of $L$ can come from poles of $h$ and $v^j$ ($j = 1, 2, \ldots, n - m - 1$) points of $h$.

Since $L$ has at most one pole in $C$, it follows that for $n \geq 2m + 3$, among these $n - m$ values of $h$, at least $n - m - 1 \geq m + 2 \geq 3$ are exceptional values, a contradiction. Hence in that case $h = 1 \implies f \equiv L$.

**Case II:** It is given that $c \notin S$ is a root of $n z^{n-m} + ma = 0$. Therefore $c$ is not a zero of $P(w)$. Also it is given $E_f(S, s) = E_g(S, s)$ and $E_f(c, t) = E_g(c, t)$. Let us define $F = \frac{f^n a f^m}{b}$, $G = \frac{L^n a L^m}{b}$. Then clearly $F$ and $G$ share $(1, s)$.

According to the hypothesis we know that $P(w)$ has no multiple zeros, i.e. $\alpha_i, i = 1, 2, \ldots, n$ are distinct zeros of $P(w)$. Without loss of generality we may assume $c = a_{n-m}$, where $a_i (i = 1, 2, \ldots, n - m)$ are given in the statement of Theorem 1.3.
Assuming \( H \neq 0 \) and from Lemma 2.4 we have

\[
N(r, \infty; H) \leq \mathcal{N}(r, 0; f) + \mathcal{N}(r, 0; \mathcal{L}) + \sum_{i=1}^{n-m-1} \{ \mathcal{N}(r, a_i; f) + \mathcal{N}(r, a_i; \mathcal{L}) \} + \mathcal{N}_*(r, c; f, \mathcal{L}) + \mathcal{N}_*(r, 0; f') + \mathcal{N}_*(r, 1; F, G) + \mathcal{N}_*(r, 0; \mathcal{L}') + O(\log r),
\]

where \( \mathcal{N}_*(r, 0; f') \) is the reduced counting function of those zeros of \( f' \) which are not zeros of \( f(f - a_1) \ldots (f - a_{n-m})(F - 1) \).

Next by the Second Fundamental Theorem and Lemma 2.5 we get,

\[
\frac{1}{2}(n - m)T(r) \leq \mathcal{N}(r, 0; f) + \mathcal{N}(r, 0; \mathcal{L}) + \mathcal{N}(r, \infty; f) + \mathcal{N}(r, \infty; \mathcal{L}) + \mathcal{N}(r, 1; F) + \mathcal{N}(r, 1; G)
\]

\[
+ \sum_{i=1}^{n-m} \{ \mathcal{N}(r, a_i; f) + \mathcal{N}(r, a_i; \mathcal{L}) \} - \mathcal{N}_*(r, 0; f') - \mathcal{N}_*(r, 0; \mathcal{L}') + S(r, f) + S(r, \mathcal{L}).
\]

i.e.,

\[
\frac{n}{2}T(r) \leq 2(\mathcal{N}(r, 0; f) + \mathcal{N}(r, 0; \mathcal{L})) + \left( \frac{3}{2} - s \right) \mathcal{N}_*(r, 1; F, G) + (k - 1)T(r) + \mathcal{N}_*(r, f, \mathcal{L}) + \mathcal{N}_*(r, c; f, \mathcal{L})
\]

\[
+ O(\log r).
\]

i.e.,

\[
(3.12) \quad \frac{n}{2}T(r) \leq (k + 1)T(r) + \left( \frac{3}{2} - s \right) \mathcal{N}_*(r, 1; F, G) + \frac{1}{t + 2} (\mathcal{N}(r, c; f) + \mathcal{N}(r, c; \mathcal{L})) + O(\log r),
\]

where \( k = n - m \geq 1 \). Next using (3.12) and proceeding in the same way as done in Case I of Theorem 1.2 for

(i) \( s \geq 2, t = 1 \) and \( n \geq 2k + 3 \), or for

(ii) \( s = 1, t = 0 \) and \( n \geq 2k + 4 \), or for

(iii) \( s = 0, t = 0 \) and \( n \geq 2k + 7 \),

we arrive at a contradiction.

Therefore \( H \equiv 0 \). Then integrating both sides we get,

\[
\frac{1}{G - 1} = \frac{A}{F - 1} + B,
\]

where \( A(\neq 0), B \) are two constants. Again proceeding in the same manner as done in the last part of Theorem 1.2 we have

\[
G - 1 = \frac{1}{A}(F - 1)
\]

\[
(L^n + aL^m + b) = \frac{1}{A}(f^n + af^m + b)
\]

\[
L^n + aL^m + b - \frac{b}{A} = \frac{1}{A}(f^n + af^m)
\]

and dealing in the same way as in the rest part of Theorem 1.2 we will get \( f = L \). \( \Box \)
