The structure of the moduli spaces of toric dynamical systems

Abstract

We consider complex balanced mass-action systems, also called \textit{toric} dynamical systems. They are polynomial dynamical systems arising from reaction networks and have remarkable dynamical properties. We study the topological structure of their moduli spaces (i.e., the toric locus). First we show that the complex balanced equilibria depend continuously on the parameter values. Using this result, we prove that the moduli space of any toric dynamical system is connected. In particular, we emphasize the product structure of the moduli space: it is homeomorphic to the product of the set of complex balanced flux vectors and the affine invariant polyhedron.

1 Introduction

In this paper we study polynomial dynamical systems obtained from bio-chemical reaction networks. In particular, we are interested in complex balanced mass-action systems. Introduced by Horn and Jackson in [11], complex balanced dynamical systems are a large class of nonlinear dynamical systems that are known or conjectured to have very strong dynamical behaviours. For instance, Horn and Jackson proved that complex balanced dynamical systems posses exactly one positive equilibrium in each stoichiometric compatibility class (i.e., invariant polyhedron). In addition, the steady states are known to be locally asymptotically stable. One of the most important line of research in the field of chemical reaction network theory is the Global Attractor Conjecture, which says that complex balanced mass-action systems have a globally attracting point in each stoichiometric compatibility class. This has been already proven in several cases, under mild hypotheses. For the state of the art, we refer the reader to [19]. See also [3]. A proof in all generality of the Global Attractor Conjecture has been proposed by Craciun in [2].

Complex balanced dynamical systems have also been called toric dynamical systems (see [5]), due to the nice algebraic properties of their moduli spaces. In particular, the locus in the parameter space of a reaction network which gives rise to complex balanced dynamical systems is called the toric locus. This is due to the fact that, after a change of coordinates, the toric locus is a variety in the positive orthant given by a toric ideal.

The study of the toric locus (i.e., the moduli space) of polynomial dynamical systems has become increasingly important, especially for applications. Recent interesting results appeared in [15], where methods to expand the toric locus are proposed in the form of a systematic algorithm. Namely, the authors of [15] prove that the locus in the parameter space known to give rise to complex balanced dynamical systems (i.e. the toric locus) can sometimes be extended from a set of Lebesgue measure zero to a positive measure set, by means of real algebraic geometry and with the help of Euclidean embedded graphs. The extended set of parameters was called the disguised toric locus in [15].

Motivated by the very strong dynamical properties that (disguised) toric dynamical systems enjoy, our goal in this paper is to study the topological structure of the moduli space of toric dynamical systems.

One of our main contributions is to show that the complex balanced equilibria depend continuously on the parameter values. This is Theorem 3.5. We further use this result to prove that the moduli space of any toric dynamical system is connected. See Theorem 4.1. Furthermore, in Theorem 5.4 we show that the moduli space is homeomorphic to the product of the set of complex balanced flux vectors and the affine invariant polyhedron. The connectedness of the moduli space is an important asset in applications where one is interested in complex balanced dynamical systems. For instance, one could leverage the fact that the toric locus is connected in order to extend certain local properties globally.

2 Preliminaries

In this section we give standard definitions and notations that we use in the rest of the paper. We follow [19]. See also [15], [5], [3], [1]. In addition, we also give a motivating example for studying the moduli space of toric dynamical systems (Example 2.10).

**Definition 2.1.** A reaction network is a Euclidean embedded graph, i.e., a directed graph $G = (V, E)$ embedded in $\mathbb{R}^n$, with no self-loops. The set of vertices is denoted by $V \subseteq \mathbb{R}^n$, while $E \subseteq V \times V$ denotes the set of edges. We denote by $y_i \rightarrow y_j$ the reaction vectors. Each edge $y_i \rightarrow y_j$ of $E$ is decorated with a positive real number $k_{ij}$, called reaction rate. The reaction rate vector is denoted by $k := (k_{ij}) \in \mathbb{R}^E_{>0}$.

**Remark 2.2.** The dimension of the Euclidean space $\mathbb{R}^n$ is the number of species of the reaction, while the set of vertices represents the set of reaction complexes.

**Definition 2.3.** Given a Euclidean embedded graph $G = (V, E)$ and a vector of reaction rates $k \in \mathbb{R}^E_{>0}$ decorating the edges of $G$, the mass-action dynamical system in the positive orthant generated by $(G, k)$ is

$$\frac{dx}{dt} = \sum_{y_i \rightarrow y_j \in E} k_{y_i \rightarrow y_j} x^{y_i}(y_j - y_i).$$

Here $x \in \mathbb{R}^n_{>0}$ and $x_i$, for $i = 1, \ldots, n$ represents the concentration of the species $i$. We consider them as functions of time, $x_i = x_i(t)$ and we use the multi-index notation: $x^{y_i} := x_1^{y_i1} \ldots x_n^{y_in}$ and $y_i := (y_{i1}, \ldots, y_{in})$.

**Example 2.4.** In Figure 1, we give an example of a dynamical system generated by a graph $G$ (see also [3, Example 2.5]).

![Figure 1: A reaction network with three complexes.](image)

Under the assumption of mass-action kinetics, the reaction network $G$ generates the following dynamical system:

$$\frac{dx}{dt} = k_{12} \begin{pmatrix} 1 \\ 0 \end{pmatrix} + k_{23} x_1 \begin{pmatrix} -1 \\ 1 \end{pmatrix} + k_{31} x_2 \begin{pmatrix} 0 \\ -1 \end{pmatrix} = \begin{pmatrix} k_{12} - k_{23} x_1 \\ k_{23} x_1 - k_{31} x_2 \end{pmatrix}.$$
Notation 2.5. Following [5, page 2] (see also [9, page 55]), denote by
\[
Y := (y_{ij})
\]
the $n \times m$ matrix whose columns are the vectors $y_i$. Here $m$ denotes the number of vertices (i.e. of complexes). Let
\[
\Psi(x) := \begin{pmatrix}
x^{y_1} \\
\vdots \\
x^{y_m}
\end{pmatrix}
\]
Label each directed edge $y_i \to y_j \in E$ with a positive number $k_{ij} \in \mathbb{R}_{>0}$, called the rate of the corresponding reaction. Denote by $A_k$ the transpose of the negative of the Laplacian of $G$. Then the mass-action dynamical system associated to $(G, k)$ from Equation 1 is the system given by the following ordinary differential equations:
\[
\frac{dx}{dt} = Y \cdot A_k \cdot \Psi(x).
\]
Note that our notation in Equation (5) is different from the one in [5, page 2], by transposing.

Example 2.6. Revisiting Example 2.4, we have
\[
\Psi(x) = \begin{pmatrix}
1 \\
x_1 \\
x_2
\end{pmatrix},
\]
\[
A_k = \begin{pmatrix}
-k_{12} & 0 & k_{31} \\
k_{12} & -k_{23} & 0 \\
0 & k_{23} & -k_{31}
\end{pmatrix},
\]
and
\[
Y = \begin{pmatrix}
0 & 1 & 0 \\
0 & 0 & 1
\end{pmatrix}.
\]

Definition 2.7. Let us consider a Euclidean embedded graph $G$. The vector subspace spanned by the edges of $G$ in $\mathbb{R}_n$ is called the stoichiometric compatibility class and we denote it by $S$. For a fixed $x_0 \in \mathbb{R}_n^+$, the space $(x_0 + S) \cap \mathbb{R}_n^+$ is called the affine invariant polyhedron of $x_0$.

Definition 2.8. Let us consider a Euclidean embedded graph $G = (V, E)$ and a vector of rate constants $k \in \mathbb{R}^{E}_{>0}$ decorating its edges. We say that the pair $(G, k)$ satisfies the complex balanced condition if there exists a state $\tilde{x}_0 \in \mathbb{R}_n^+$ such that the equation
\[
\sum_{y \to y' \in E} k_{y \to y'} \tilde{x}_0^{y'} = \left( \sum_{y' \to y \in E} k_{y' \to y} \right) \tilde{x}_0^{y'}
\]
is satisfied for every vertex (i.e., complex) $y' \in V$.

Such a state $\tilde{x}_0$ is called a complex balanced steady state. We say that the dynamical system generated by $(G, k)$ is a complex balanced dynamical system.
Note that, following Notation 2.5, the equality (6) is equivalent to

\[ A_k \cdot \Psi(\tilde{x}_0) = 0. \]

See [10, Section 6]. In [5], complex balanced dynamical systems were also called toric dynamical systems, due to the nice algebraic and combinatorial properties that their moduli spaces have.

**Definition 2.9.** Consider a Euclidean embedded graph \( G = (V, E) \). We denote by \( V(G) \subseteq \mathbb{R}^E_+ \) the set of parameters \( k_{ij} \) for which the dynamical system generated by \((G, k)\) is toric. We refer to \( V(G) \) as the *moduli space* of toric dynamical systems given by the Euclidean embedded graph \( G \).

In Example 2.4, the moduli space \( V(G) \) is the whole positive orthant \( \mathbb{R}^3_+ \). This follows from a classical result by Horn, Jackson and Feinberg, known in the literature as *Deficiency Zero Theorem* (see [7, Theorem 16.2.2]). However, the purpose of Example 2.10 below is to serve as a motivation for studying the topological structure of the moduli space of toric dynamical systems. This is due to the fact that in general, these spaces can have quite complicated algebraic descriptions and are usually not easy to study. Increasing interest for the moduli spaces of toric dynamical systems, also called the (disguised) toric locus, has been shown recently. See for instance [15], where methods to expand the toric locus from a set of Lebesgue measure zero to a positive measure set are proposed in the form of a systematic algorithm.

**Example 2.10.** Let us consider the reaction network \( G \) as in Figure 2. The moduli space \( V(G) \in \mathbb{R}^4_+ \) is the algebraic variety given by the following two equations:

\[
(k_{43}k_{32}k_{21})(k_{21}k_{14}k_{43}) = (k_{14}k_{43}k_{32})^2
\]

and

\[
(k_{14}k_{43}k_{32})(k_{32}k_{21}k_{14}) = (k_{21}k_{14}k_{43})^2.
\]

**Remark 2.11.** Using a change of coordinates as in [5] (see Notation 3.7 below), these conditions can be rewritten as

\[ K_1K_3 = K_2^2 \]

and

\[ K_2K_4 = K_3^2, \]

where

\[
K_1 := k_{43}k_{32}k_{21}, \\
K_2 := k_{14}k_{43}k_{32}, \\
K_3 := k_{21}k_{14}k_{43}
\]

and

\[ K_4 := k_{32}k_{21}k_{14}. \]

Therefore under this change of coordinates the moduli space becomes a toric variety, which is in accordance with the general theory proved in [5].
Definition 2.12 is inspired from [5].

**Definition 2.12.** Define the complex balancing ideal $C_G$ as the saturation of the ideal $\langle A_k \cdot \Psi(x) \rangle$ with the product $x_1 x_2 \ldots x_s$. Here the generators of the ideal $\langle A_k \cdot \Psi(x) \rangle$ are the entries of the column vector $A_k \cdot \Psi(x)$.

The complex balanced variety is the variety of the ideal obtained by eliminating the variables $k_{ij}$ from the complex balancing ideal $C_G$.

**Definition 2.13.** We call the complex balanced equilibria, denoted by $V_{\bar{x}}(G, k)$, the intersection of the complex balanced variety with the positive orthant $\mathbb{R}_{>0}^s$, where $s$ is the dimension of the stoichiometric compatibility class of the dynamical system generated by $(G, k)$.

### 3 Complex balanced equilibria depend continuously on the parameter values

Let us fix some $x_0$ in the state space.

Let $\mathcal{S}$ denote the stoichiometric compatibility class of $G$. Define the map

$$Q_{x_0} : \mathcal{V}(G) \to (x_0 + \mathcal{S}) \cap \mathbb{R}_{>0}^n,$$

such that

$$Q_{x_0}(k) := \bar{x}_0,$$

where $\bar{x}_0$ is the corresponding complex balance equilibrium in the affine invariant polyhedron $(x_0 + \mathcal{S}) \cap \mathbb{R}_{>0}^n$ of $x_0$.

**Remark 3.1.** The map $Q_{x_0}$ is well-defined, by classical work of Horn and Jackson (see for instance [19, Theorem 2.3] and [7, Theorem 15.2.2 and 15.2.4]): for a given $\bar{k} \in \mathcal{V}(G)$, there exist a unique equilibrium of the dynamical system generated by $(G, \bar{k})$, in each invariant polyhedron. See also [10, Theorem 6.4].
Lemma 3.2. The map $Q_{x_0}$ is surjective.

Proof. We have that $Q_{x_0}(\tilde{k}) = \tilde{x}_0$. Let us take a point $\hat{x} \in (x_0 + S) \cap \mathbb{R}_0^n$. We want to find $\hat{k}$ such that $Q_{x_0}(\hat{k}) = \hat{x}$. Define

$$\hat{k}_{y_1 \rightarrow y_j} := \frac{\tilde{k}_{y_1 \rightarrow y_j} \tilde{x}_0^{y_i}}{\tilde{x}^{y_i}}.$$  

(9)

Since $Q_{x_0}(\tilde{k}) = \tilde{x}_0$, the pair $(\tilde{k}, \tilde{x}_0)$ satisfies the complex balanced condition (6). By (9) we have the equality: $\hat{k}_{y_1 \rightarrow y_j} \hat{x}^{y_i} = \tilde{k}_{y_1 \rightarrow y_j} \tilde{x}_0^{y_i}$. In other words, on each edge $y_1 \rightarrow y_j$ the fluxes are the same. Therefore, the pair $(\hat{k}, \hat{x})$ also satisfies the complex balanced condition (6). Hence $Q_{x_0}(\hat{k}) = \hat{x}$. \qed

Lemma 3.3. Fix $\hat{x} \in Q_{x_0}(\mathcal{V}(G))$. Then the preimage $Q_{x_0}^{-1}(\hat{x})$ is connected.

Proof. Since $\hat{x} \in Q_{x_0}(\mathcal{V}(G))$, there exists $\tilde{k}$ such that the complex balanced condition is satisfied:

$$\sum_{y_1 \rightarrow y_j} \hat{k}_{y_1 \rightarrow y_j} \hat{x}^{y_i} = \left( \sum_{y_j \rightarrow y_i} \hat{k}_{y_j \rightarrow y_i} \right) \hat{x}^{y_j}. \tag{10}$$

We claim that the fibre is connected because the fibre is a convex set. Notice that (10) is a linear equality in the entries of $\hat{k}$. If relation (10) is true for a vector $k^*$ and for another vector $k^{**}$, then relation (10) is true for any convex combination of $k^*$ and $k^{**}$. \qed

Lemma 3.4. The map $Q_{x_0}$ is open.

Proof. Choose an open neighbourhood $U \subseteq \mathcal{V}(G)$, of a point $\tilde{k} \in \mathcal{V}(G)$. We want to show that $Q_{x_0}(U)$ is open in $(x_0 + S) \cap \mathbb{R}_0^n$. Let $\tilde{x}_0 := Q_{x_0}(\tilde{k})$.

More precisely, we want to find a small neighbourhood of $\tilde{x}_0$ that is contained in $Q_{x_0}(U)$. Equivalently, we want to show that for any point $\hat{x}$ close enough to $\tilde{x}_0$, there exists $\hat{k} \in U$ close enough to $\tilde{k}$, such that $\hat{x} = Q_{x_0}(\hat{k})$.

Define $\hat{k}$ such that the following relations hold for any edge $y_1 \rightarrow y_j$ of the reaction network $G$:

$$\hat{k}_{y_1 \rightarrow y_j} := \frac{\tilde{k}_{y_1 \rightarrow y_j} \tilde{x}_0^{y_i}}{\tilde{x}^{y_i}}.$$  

(11)

The following equality

$$\frac{\hat{k}_{y_j \rightarrow y_j}}{\hat{k}_{y_1 \rightarrow y_j}} = \frac{\tilde{x}_0^{y_i}}{\tilde{x}^{y_i}} \tag{12}$$

guarantees that for $\hat{x}$ close enough to $\tilde{x}_0$, we have $\hat{k}_{y_1 \rightarrow y_j}$ close enough to $\tilde{k}_{y_1 \rightarrow y_j}$. \qed

Theorem 3.5 below is the main result of this section. We use this result in Section 4 and 5, where we show the connectedness property of the moduli spaces of toric dynamical systems.
Theorem 3.5. The complex balanced equilibria depend continuously on the parameter values. In other words, the map $Q_{x_0}$ is continuous.

Before the proof of Theorem 3.5, we need some notations and lemmas.

Definition 3.6. Let us consider a strongly connected graph $G$. Fix a vertex $v$ of $G$. A spanning $v$-tree $T$ is a subgraph of $G$, such that $T$ is a tree with the root $v$.

Notation 3.7. Let us consider a strongly connected graph $G$. Let $k^T$ denote the product of the labels of the edges of the tree $T$ in $G$.

Inspired by the Matrix-Tree theorem [16, Theorem 5.6.4] (see also [5, Proposition 3]), let us denote by

\begin{equation}
K_i := \sum_{T \text{ a } i\text{-tree}} k^T.
\end{equation}

Example 3.8. Let us consider the complete bidirected graph $G$ with three vertices from Figure 3. See [5, Example 1] and [15, Section 3].

The moduli space

\[ \mathcal{V}(G) = \{ k \in \mathbb{R}^6_{>0} \mid (k_{21}k_{31} + k_{32}k_{21} + k_{23}k_{31})(k_{13}k_{23} + k_{21}k_{13} + k_{12}k_{23}) - (k_{12}k_{32} + k_{13}k_{32} + k_{31}k_{12})^2 = 0 \}. \]

Following Notation 3.7, we have:

\begin{align*}
K_1 &:= k_{21}k_{31} + k_{32}k_{21} + k_{23}k_{31}; \\
K_2 &:= k_{12}k_{32} + k_{13}k_{32} + k_{31}k_{12}; \\
K_3 &:= k_{13}k_{23} + k_{21}k_{13} + k_{12}k_{23}, \end{align*}

and the equation defining the moduli space $\mathcal{V}(G)$, in the new coordinates, becomes $K_1K_3 = K_2^2$.

See also Remark 2.11.
Proposition 3.9. [5, Proposition 3] Let us consider a strongly connected graph $G$ with $m$ vertices. Denote by $A_k$ the transpose of the negative of the Laplacian matrix of $G$. Let $M_i$ be the matrix obtained by removing the $i$-th row and the $i$-th column of $A_k$. Then we have:

(15) \[ \det(M_i) = (-1)^{m-1}K_i, \]

where $K_i = \sum \tan_{i, \text{tree}} k^T$, as in Notation 3.7.

The next result gives a characterization of the complex balanced equilibria. The conclusion of Proposition 3.10 can be obtained from results in [5]. We include a proof here, for completion.

Proposition 3.10. Let us consider a weakly reversible graph $G$ with $l$ connected components (i.e., linkage classes). Fix a vector $K \in \mathbb{R}^m_>$ that satisfies $K_i = \sum \tan_{a, i, \text{tree}} k$ for some $k \in \mathbb{R}^E_{>0}$. For each connected component, consider the equations (see Notation 2.5):

(16) \[ K_i x_j^y - K_j x_i^y = 0, \]

where $i$ and $j$ are indices belonging to the same connected component of $G$.

Then $x$ is a complex balanced equilibrium for rate constants given by the vector $k$ above if and only if Equations (16) are satisfied.

Proof. After eventually relabelling the vertices of $G$, the matrix $A_k$ (see Notation 2.5) is a block matrix: for each connected component of $G$ we have a block. We thus may safely assume in the proof that the graph $G$ has a single connected component. Afterwards the result can be generalized for any number of connected components, by using the block decomposition of $A_k$.

Firstly, Equations (16) are necessary conditions for $x$ to be a complex balanced equilibrium. This follows from [5, Corollary 4].

Secondly, let us now prove that Equations (16) are also sufficient.

The determinant of $A_k$ is zero and $\text{rank}(A_k) = m - 1$ (see [5, Section 2]). By expanding the determinant of $A_k$ in terms of its minors and by using Proposition 3.9, we obtain that $A_k \cdot K = 0$. In other words, the vector $K$ belongs to the null-space of $A_k$, denoted by $\ker(A_k)$. Note that the dimension of $\ker(A_k)$ is one. By Equations (16), the vectors $K$ and $\Psi(x)$ are proportional. Since $K \in \ker(A_k)$, we obtain $\Psi(x) \in \ker(A_k)$, that is $A_k \cdot \Psi(x) = 0$. By Definition 2.8 and relation (7), $x$ is a complex balanced equilibrium.

We are now ready to prove the continuity of the map $Q_{x_0}$ (Theorem 3.5).

Proof. Recall the definition of the map $Q_{x_0}$ (Equation (8)): $Q_{x_0} : \mathcal{V}(G) \to (x_0 + S) \cap \mathbb{R}^n_>$, such that $Q_{x_0}(k) = \tilde{x}_0$, where $\tilde{x}_0$ is the corresponding complex balance equilibrium in the invariant polyhedron $(x_0 + S) \cap \mathbb{R}^n_>$. The proof of the continuity of the map $Q_{x_0}$ consists of three steps.

Step A

By the explicit formulas from Notation 3.7, the vector $K = (K_i)$ depends continuously on the parameters $k = (k_{ij})$ values.

Step B

The next result gives a characterization of the complex balanced equilibria. The conclusion of Proposition 3.10 can be obtained from results in [5]. We include a proof here, for completion.

Proposition 3.10. Let us consider a weakly reversible graph $G$ with $l$ connected components (i.e., linkage classes). Fix a vector $K \in \mathbb{R}^m_>$ that satisfies $K_i = \sum \tan_{a, i, \text{tree}} k$ for some $k \in \mathbb{R}^E_{>0}$. For each connected component, consider the equations (see Notation 2.5):

(16) \[ K_i x_j^y - K_j x_i^y = 0, \]

where $i$ and $j$ are indices belonging to the same connected component of $G$.

Then $x$ is a complex balanced equilibrium for rate constants given by the vector $k$ above if and only if Equations (16) are satisfied.

Proof. After eventually relabelling the vertices of $G$, the matrix $A_k$ (see Notation 2.5) is a block matrix: foreach connected component of $G$ we have a block. We thus may safely assume in the proof that the graph $G$ has a single connected component. Afterwards the result can be generalized for any number of connected components, by using the block decomposition of $A_k$.

Firstly, Equations (16) are necessary conditions for $x$ to be a complex balanced equilibrium. This follows from [5, Corollary 4].

Secondly, let us now prove that Equations (16) are also sufficient.

The determinant of $A_k$ is zero and $\text{rank}(A_k) = m - 1$ (see [5, Section 2]). By expanding the determinant of $A_k$ in terms of its minors and by using Proposition 3.9, we obtain that $A_k \cdot K = 0$. In other words, the vector $K$ belongs to the null-space of $A_k$, denoted by $\ker(A_k)$. Note that the dimension of $\ker(A_k)$ is one. By Equations (16), the vectors $K$ and $\Psi(x)$ are proportional. Since $K \in \ker(A_k)$, we obtain $\Psi(x) \in \ker(A_k)$, that is $A_k \cdot \Psi(x) = 0$. By Definition 2.8 and relation (7), $x$ is a complex balanced equilibrium.

We are now ready to prove the continuity of the map $Q_{x_0}$ (Theorem 3.5).

Proof. Recall the definition of the map $Q_{x_0}$ (Equation (8)): $Q_{x_0} : \mathcal{V}(G) \to (x_0 + S) \cap \mathbb{R}^n_>$, such that $Q_{x_0}(k) = \tilde{x}_0$, where $\tilde{x}_0$ is the corresponding complex balance equilibrium in the invariant polyhedron $(x_0 + S) \cap \mathbb{R}^n_>$. The proof of the continuity of the map $Q_{x_0}$ consists of three steps.

Step A

By the explicit formulas from Notation 3.7, the vector $K = (K_i)$ depends continuously on the parameters $k = (k_{ij})$ values.
The set of complex balanced equilibria depends continuously on $K$. This follows from the characterization of the set of complex balanced equilibria from Proposition 3.10. Let us be more precise.

By Equation (16), we obtain

\[(17) \quad K_i x^y = K_j x^y.\]

This yields

\[(18) \quad \log K_i + y_j \log x = \log K_j + y_i \log x\]

in multivariate notation. This can be seen as a system of linear equations with unknowns the entries of $\log x$.

Therefore, the set of vectors $\{ (\log x_1, \ldots, \log x_n) \}$ is the preimage of a linear map and it depends continuously on $K$. After applying the exponential map, the set of complex balanced equilibria still varies continuously on $K$.

**Step C**

The intersection point between the set of complex balanced equilibria and the affine invariant polyhedron $(x_0 + S) \cap \mathbb{R}^n_\geq 0$ varies continuously with $K$. This follows from Step B, since by [4, Lemma 5.4, page 16] this intersection is transversal.

\[\square\]

**Definition 3.11.** [14, page 52] A surjective continuous open map is called a *quotient map*.

**Corollary 3.12.** The map $Q_{x_0}$ is a quotient map.

**Proof.** By Theorem 3.5, the map $Q_{x_0}$ is continuous. By Lemma 3.4, $Q_{x_0}$ is open, and we proved the surjectivity in Lemma 3.2. \[\square\]

## 4 \( \mathcal{V}(G) \) is connected

The main result of Section 4 is the following theorem:

**Theorem 4.1.** If $G$ is weakly reversible, then the variety $\mathcal{V}(G)$ is connected.

**Proof.** Recall that by Lemma 3.3, for a fixed $\hat{x} \in (x_0 + S) \cap \mathbb{R}^n_\geq 0$, the preimage $Q_{x_0}^{-1}(\hat{x})$ is connected. In addition, note that the invariant polyhedron $(x_0 + S) \cap \mathbb{R}^n_\geq 0$ is also connected. By Corollary 3.12, the map the map $Q_{x_0}$ is a quotient map (it is continuous, surjective and open).

We now argue by contradiction. Let us suppose that the set $\mathcal{V}(G)$ is not connected. Then there exists a surjective continuous map $\mu : \mathcal{V}(G) \to \{0, 1\}$.

Consider the following commutative diagram (see Figure 4):
Here the function \( \nu : (x_0 + S) \cap \mathbb{R}^n_{>0} \to \{0, 1\} \), such that \( \mu = \nu \circ Q_{x_0} \) is well-defined by Lemma 3.3. By [18, Theorem 9.4]), since \( Q_{x_0} \) is a quotient map, we have the following equivalence: \( \nu \) is continuous if and only if \( \mu \) is continuous. Thus we conclude that \( \nu \) is a continuous function.

Since \( \mu \) is surjective, we get that \( \nu \) is surjective. This is in contradiction with the fact that the domain of \( \nu \), namely \((x_0 + S) \cap \mathbb{R}^n_{>0}\), is connected, while the set \( \{0, 1\} \) is disconnected. A continuous map with values in \( \{0, 1\} \) is constant if its domain is connected. Thus our initial supposition was false, and we conclude that \( \mathcal{V}(G) \) is connected.

5 \( \mathcal{V}(G) \) is a product space

In this section we consider a weakly reversible graph \( G = (V, E) \) and show that the toric locus \( \mathcal{V}(G) \) is a product space (see Theorem 5.4).

5.1 The space of complex balanced fluxes

Definition 5.1. Given a Euclidean embedded graph \( G = (V, E) \), a vector \( \beta \in \mathbb{R}^E_{>0} \) is called a flux vector. A complex balanced flux vector is \( \beta \in \mathbb{R}^E_{>0} \) such that the following equalities are satisfied, for each vertex \( y \in V \):

\[
\sum_{y \to y' \in E} \beta_{y \to y'} = \sum_{y' \to y \in E} \beta_{y' \to y}.
\]

The set of complex balanced flux vectors is denoted by \( \mathcal{B}(G) \).

Proposition 5.2. The set \( \mathcal{B}(G) \) is a convex cone in \( \mathbb{R}^E_{>0} \).

Proof. The set \( \mathcal{B}(G) \) is the intersection of the linear subspace given by the system of equations (19) with the positive orthant \( \mathbb{R}^E_{>0} \). Let us be more precise. For each vertex of \( G \) we have one complex balance equation (19), which is a linear equation in the coordinates of the flux vector \( \beta \in \mathcal{B}(G) \). For any two vectors \( \beta_1 \) and \( \beta_2 \) in \( \mathcal{B}(G) \), the complex balanced conditions are verified by any linear combination of \( \beta_1 \) and \( \beta_2 \) with non-negative coefficients. Thus \( \mathcal{B}(G) \) is a convex cone in \( \mathbb{R}^E_{>0} \) (see [8, Chapter 1], [20, page 28] for an introduction to the subject). \( \square \)

Corollary 5.3. The set \( \mathcal{B}(G) \) is connected.
5.2 The product space

The goal of this section is to establish the product structure of the moduli spaces of toric dynamical systems via an explicitly constructed homeomorphism.

Theorem 5.4. Let us consider a weakly reversible graph $G$. The toric locus $\mathcal{V}(G) \subseteq \mathbb{R}_+^E$ is homeomorphic to the product space $[(x_0 + S) \cap \mathbb{R}_{>0}^n] \times \mathcal{B}(G)$, i.e.

\begin{equation}
\mathcal{V}(G) \simeq [(x_0 + S) \cap \mathbb{R}_{>0}^n] \times \mathcal{B}(G),
\end{equation}

where $(x_0 + S) \cap \mathbb{R}_{>0}^n$ is the invariant polyhedron that contains $x_0 \in \mathbb{R}_+^n$, and $\mathcal{B}(G)$ denotes the set of complex balanced flux vectors.

Throughout this section we assume there is a fixed arbitrary $x_0 \in \mathbb{R}_+^n$. In what follows we will show that there exists a homeomorphism $\varphi$, between the product space $[(x_0 + S) \cap \mathbb{R}_{>0}^n] \times \mathcal{B}(G)$ and $\mathcal{V}(G)$.

Definition 5.5. Let $\varphi : [(x_0 + S) \cap \mathbb{R}_{>0}^n] \times \mathcal{B}(G) \to \mathcal{V}(G)$ be the map given by:

\begin{equation}
\varphi(x, \beta) := \left( \frac{\beta_{y \to y'}}{x^y} \right)_{y \to y' \in E}.
\end{equation}

Remark 5.6. The map $\varphi$ is well-defined, because if we define

\begin{equation}
k_{y \to y'} := \frac{\beta_{y \to y'}}{x^y},
\end{equation}

then the pair $(G, k)$ will satisfy the complex balanced condition (see Definition 2.8) at the complex balanced equilibrium point $x$, since $\beta$ is a complex balanced flux vector (see Equation (19)). Also, by definition, $\varphi$ is continuous.

Proposition 5.7. The map $\varphi$ is surjective.

Proof. Fix $k \in \mathcal{V}(G)$. Then by Remark 3.1, there exists $x \in (x_0 + S) \cap \mathbb{R}_{>0}^n$ that is a complex balance equilibrium in $(x_0 + S) \cap \mathbb{R}_{>0}^n$ corresponding to the given $k$. Now, solve for $\beta$ the following equations:

\begin{equation}
\frac{\beta_{y \to y'}}{x^y} = k_{y \to y'},
\end{equation}

for every edge $y \to y' \in E$ and obtain $\varphi(x, \beta) = k$. \qed

Proposition 5.8. The map $\varphi$ is injective.

Proof. Let us consider $(\hat{x}, \hat{\beta}) \in [(x_0 + S) \cap \mathbb{R}_{>0}^n] \times \mathcal{B}(G)$ and $(\hat{x}, \hat{\beta}) \in [(x_0 + S) \cap \mathbb{R}_{>0}^n] \times \mathcal{B}(G)$ such that $\varphi(\hat{x}, \hat{\beta}) = \varphi(\hat{x}, \hat{\beta})$.

Let us denote by $k \in \mathbb{R}_+^E$ the vector given by

\begin{equation}
k_{y \to y'} := \frac{\hat{\beta}_{y \to y'}}{\hat{x}^y}.
\end{equation}
Then by (21), we have the equality
\[
\hat{\beta}_{y \to y'} = k_{y \to y'}.
\]

Since for a fixed \(k\) the complex balanced steady state is \textit{unique} in the affine invariant polyhedron \((x_0 + S) \cap \mathbb{R}_n^+\) (see also Remark 3.1), we obtain \(\hat{x} = \hat{\hat{x}}\).

Finally, by Equations (23) and (24), we obtain \(\hat{\beta}_{y \to y'} = \hat{\beta}_{y \to y'}\), for every edge \(y \to y' \in E\). Therefore \((\hat{x}, \hat{\beta}) = (\hat{\hat{x}}, \hat{\beta})\).

\textbf{Definition 5.9.} Let us consider a weakly reversible graph \(G = (V, E)\) and a vector of rate constants \(k \in \mathbb{R}_E^+\). Denote by \(x \in (x_0 + S) \cap \mathbb{R}_n^+\) the complex balanced equilibrium of \(k\). Namely, \(x = Q_{x_0}(k)\). Define the map
\[
\hat{q} : V(G) \to B(G),
\]
such that \(\hat{q}(k) = \beta\), where \(\beta\) is the complex balanced flux vector satisfying the following equations:
\[
k_{y \to y'} = \frac{\beta_{y \to y'}}{x_y}
\]
for every edge \(y \to y' \in E\).

\textbf{Proposition 5.10.} The map \(\hat{q}\) from Definition 5.9 is continuous.

\textit{Proof.} We prove that each component \(\hat{q}_{y \to y'}\) of the map \(\hat{q}\) is continuous. By Definition 5.9 and Equation (26) we have
\[
\hat{q}_{y \to y'}(k) = \beta_{y \to y'} = k_{y \to y'}(Q_{x_0}(k))_y.
\]
Thus \(\hat{q}_{y \to y'}(k)\) is continuous, since it is a product of continuous functions. \(\square\)

\textbf{Proposition 5.11.} The map \(\varphi^{-1}\) is continuous.

\textit{Proof.} Note that by Proposition 5.8 and Proposition 5.7, the map \(\varphi\) is bijective. Thus \(\varphi^{-1}\) is well-defined.

By Equation (27), we have:
\[
\varphi_{y \to y'}(Q_{x_0}(k), \hat{q}(k)) = \frac{k_{y \to y'}Q_{x_0}(k)_y}{Q_{x_0}(k)_y} = k_{y \to y'}.
\]

Therefore
\[
\varphi(Q_{x_0}(k), \hat{q}(k)) = k
\]
and thus
\[
\varphi^{-1}(k) = (Q_{x_0}(k), \hat{q}(k))
\]
Since both \(Q_{x_0}(k)\) and \(\hat{q}(k)\) are continuous, we get that \(\varphi^{-1}\) is continuous. \(\square\)

\textbf{Corollary 5.12.} The map \(\varphi\) is a homeomorphism.

\textit{Proof.} This follows from Remark 5.6, Proposition 5.11, Proposition 5.8 and Proposition 5.7. \(\square\)

This concludes the proof of Theorem 5.4.
5.3 Codimension $\delta$

The notion of deficiency of a reaction network was introduced by Feinberg and Horn [6, 12] and is a key property in the study of complex balanced steady states of a network ([7], [11], [19, Section 2.2]).

**Definition 5.13.** ([7, 19]) Let us consider a Euclidean embedded graph $G$. Denote by $s$ the dimension of the stoichiometric subspace $S$, by $l$ the number of connected components of $G$, and by $m$ the number of vertices of $G$. The deficiency of a Euclidean embedded graph $G$ is the (non-negative) integer

\[
\delta := m - s - l.
\]

One of the main results in chemical reaction network theory is the deficiency zero theorem due to Feinberg and Horn [6, 12], which implies that a mass-action dynamical system is complex-balanced for all reaction rates if and only if it has deficiency zero and it is weakly reversible. In [5] it was shown that, given a weakly reversible reaction network $G$, the set of reaction rate constants $k \in \mathbb{R}^E_>$ that generate a complex balanced mass-action system is an algebraic variety of codimension $\delta$ in $\mathbb{R}^E_>$ (see [5, Theorem 9]). In other words, the codimension of the moduli space of toric dynamical systems is $\delta$:

\[
\text{codim}(\mathcal{V}(G)) = \delta.
\]

In the following we will recover this result, using the product structure of the moduli space $\mathcal{V}(G)$, from Theorem 4.1 above.

**Proposition 5.14.** The dimension of $\mathcal{V}(G)$ is $|E| - m + s + l$.

*Proof.* By Theorem 5.4, we have that

\[
\dim(\mathcal{V}(G)) = \dim((X_0 + S) \cap \mathbb{R}^n_>) + \dim(B(G)).
\]

Since $\dim((X_0 + S) \cap \mathbb{R}^n_>) = s$, the only thing left to prove is that $\dim(B(G)) = |E| - m + l$.

By Definition 5.1, the set $B(G) \subseteq \mathbb{R}^E_>$ is given by set of complex balanced flux vectors. Since the complex balanced conditions are analogous to Kirchhoff junction rules (see [13], [17]), for each connected component of $G$ there are $m_i - 1$ independent linear conditions defining $B(G)$. Here $m_i$ denotes the number of vertices in the $i^{th}$ linkage class. This gives a total of $m - l$ independent linear conditions. \(\square\)

As a corollary of Proposition 5.14, we recover the result from [5, Theorem 9]:

**Corollary 5.15.** Let us consider a weakly reversible graph $G$. Then the codimension of the moduli space $\mathcal{V}(G) \subseteq \mathbb{R}^E_>$ is $\delta$.

*Proof.* We have $\text{codim}(\mathcal{V}(G)) = |E| - (|E| - m + s + l) = \delta$. \(\square\)
6 Bijective affine transformations preserve the moduli spaces

**Theorem 6.1.** Let us consider a weakly reversible graph (i.e., reaction network) $G_1$. If $G_2$ is a bijective affine image of the reaction network $G_1$, then they have the same toric moduli spaces, i.e.,

$$\mathcal{V}(G_1) = \mathcal{V}(G_2).$$

**Proof.** This follows from [5, Theorem 9] and from the Matrix-Tree theorem. In particular see [5, Section 2, page 5]: the change of coordinates given by the spanning trees in the two graphs are the same.
