Selberg’s zeta function for the modular group in the critical strip

Yasufumi Hashimoto

Abstract

In the present paper, we study the growth of the Selberg zeta function for the modular group in the critical strip.

1 Introduction and the main theorem

Let $H := \{x + y\sqrt{-1} \mid x, y \in \mathbb{R}, y > 0\}$ be the upper half plane and $\Gamma$ a discrete subgroup of $\text{SL}_2(\mathbb{R})$ with $\text{vol}(\Gamma \backslash H) < \infty$. Denote by $\text{Prim}(\Gamma)$ the set of primitive hyperbolic conjugacy classes of $\Gamma$ and $N(\gamma)$ the square of the larger eigenvalue of $\gamma$. The Selberg zeta function for $\Gamma$ is defined by

$$Z_\Gamma(s) := \prod_{\gamma \in \text{Prim}(\Gamma), n \geq 0} (1 - N(\gamma)^{-s-n}), \quad \text{Res} > 1.$$

It is well known that $Z_\Gamma(s)$ is analytically continued to the whole complex plane and has a functional equation between the values at $s$ and $1 - s$ (see, e.g. [5]). The aim of the present paper is to study the growth of $Z_\Gamma(s)$ in the critical strip as $|\text{Im} s| \to \infty$.

For the Riemann zeta function

$$\zeta(s) := \prod_p (1 - p^{-s})^{-1}, \quad \text{Res} > 1,$$

there have been various works on the growth in the critical strip. In fact, it was proved [6] that

$$\zeta(1/2 + iT) \ll_\epsilon T^{32/205 + \epsilon}$$

and has been considered that $\zeta(1/2 + iT) \ll_\epsilon T^\epsilon$ as $T \to \infty$. On the other hand, it is known that

$$\log Z_\Gamma(\sigma + iT), \frac{Z_\Gamma'(\sigma + iT)}{Z_\Gamma(\sigma + iT)} \ll_\epsilon T^{2-2\sigma + \epsilon}, \quad \text{as} \quad T \to \infty \quad (1.1)$$

for $1/2 < \sigma < 1$ (see [5] for co-compact $\Gamma$ and [7] for $\Gamma = \text{SL}_2(\mathbb{Z})$). This means that the growth of $Z_\Gamma(s)$ is exponential of $|\text{Im} s|$ and is quite different to the Riemann zeta function.

In the present paper, we improve (1.1) for the modular group. The main result is as follows.

MSC: primary: 11M36; secondary: 11F72
Theorem 1.1. Let $\Gamma = \text{SL}_2(\mathbb{Z})$ and $s = \sigma + iT$ with $1/2 < \sigma < 1$. Then we have
\[
\frac{Z'_\Gamma(s)}{Z_\Gamma(s)} \ll \epsilon \begin{cases}
T^{\frac{19}{20} - \frac{29}{40} \sigma + \epsilon}, & \left( \frac{5}{2} < \sigma \leq \frac{5}{8} \right), \\
T^{\frac{29}{40}(1 - \sigma) + \epsilon}, & \left( \frac{5}{8} < \sigma < 1 \right),
\end{cases}
\] as $T \to \infty$ (1.2)
for any $\epsilon > 0$.

To prove Theorem 1.1 we first describe $Z'_\Gamma(s)/Z_\Gamma(s)$ by a sum over $\gamma \in \text{Prim}(\Gamma)$ as given in Proposition 2.1. For $\Gamma = \text{SL}_2(\mathbb{Z})$, such a sum can be expressed in terms of the class numbers and the fundamental units of the primitive indefinite binary quadratic forms, and then we can prove Theorem 1.1 by using the large sieve method for the Dirichlet $L$ function and van-der Corput’s exponential sum estimate.

2 Proof of Theorem 1.1

We first state the following explicit formula for $Z'_\Gamma(s)/Z_\Gamma(s)$ to prove Theorem 1.1.

Proposition 2.1. Let $s = \sigma + iT \in \mathbb{C}$ with $1/2 < \sigma < 1$. Then we have
\[
\frac{Z'_\Gamma(s)}{Z_\Gamma(s)} = \sum_{\gamma \in \text{Prim}(\Gamma), j \geq 1} \frac{\log N(\gamma)}{N(\gamma)^j} \left( \frac{1 - \frac{N(\gamma)^j}{x}}{x} \right) N(\gamma)^{-js} + O_\epsilon \left( T^{-2x^{1-\sigma}} + T^{1+\epsilon}x^{\frac{1}{2} - \sigma + \epsilon} \right), \quad \text{as} \quad T, x \to \infty
\]
for any $\epsilon > 0$.

Proof. For $V = T^3$ and $\epsilon > 0$, let $C$ be the rectangle with the corners $1 + \epsilon - iV, 1 + \epsilon + iV, 1/2 + \epsilon + iV, 1/2 + \epsilon - iV$, and
\[
J := \frac{1}{2\pi i} \int_{\partial C} \frac{Z'_\Gamma(z)}{Z_\Gamma(z)} \frac{x^{z-s}}{(z-s)(z-s+1)} \, dz,
\]
where the integral is in an anti-clockwise direction. Since the singular point of $Z'_\Gamma(z)/Z_\Gamma(z)$ in $C$ is only a single pole at $z = 1$, we have
\[
J = \frac{Z'_\Gamma(s)}{Z_\Gamma(s)} + \frac{x^{s-1}}{(1-s)(2-s)}
\] (2.1)
by the residue theorem. Next, divide $J$ by
\[
2\pi i J = \int_{\partial C} \int_{1+\epsilon+i\infty}^{1+\epsilon-i\infty} - \int_{1+\epsilon-i\infty}^{1+\epsilon+i\infty} \int_{1+\epsilon+iV}^{1/2+\epsilon+iV} + \int_{1+\epsilon+iV}^{1/2+\epsilon-iV} + \int_{1/2+\epsilon-iV}^{1+\epsilon-iV} =: J_1 - J_2 - J_3 + J_4 + J_5 + J_6.
\]
Due to (1.1), we can bound $J_2, \ldots, J_6$ by

$$J_2, J_3 \ll \epsilon \int_V^\infty |u|^\epsilon \frac{x^{1-\sigma}}{(u-T)^2 + 1} \, du \ll V^{-1+\epsilon} x^{1-\sigma},$$  

(2.2)

$$J_4, J_6 \ll \epsilon V^{1+\epsilon} x^{1-\sigma} (V-T)^{-2} \ll V^{-1} x^{1-\sigma},$$  

(2.3)

$$J_5 \ll \epsilon \int_{-V}^V |u|^{1+\epsilon} \frac{x^{1/2-\sigma}}{(u-T)^2 + 1} \, du \ll \epsilon T^{1+\epsilon} x^{1/2-\sigma}.$$  

(2.4)

The remaining term $J_1$ is given by

$$\frac{1}{2\pi i} J_1 = \sum_{\gamma \in \text{Prim}(\Gamma), j \geq 1} \frac{\log N(\gamma)}{1-N(\gamma)^{-j}} N(\gamma)^{-js} \cdot \frac{1}{2\pi i} \int_{1-s+\epsilon-i\infty}^{1-s+\epsilon+i\infty} \frac{(x/N(\gamma)^j)^z}{z(z+1)} \, dz$$

$$= \sum_{\gamma \in \text{Prim}(\Gamma), j \geq 1, N(\gamma)^j \leq x} \frac{\log N(\gamma)}{1-N(\gamma)^{-j}} \left( 1 - \frac{N(\gamma)^j}{x} \right) N(\gamma)^{-js},$$  

(2.5)

The proposition follows from (2.1)–(2.5).

It is known that there is a one-to-one correspondence between equivalence classes of primitive indefinite binary quadratic forms and the elements of $\text{Prim}(\text{SL}_2(\mathbb{Z}))$, and its correspondence is given as follows.

$$[a, b, c] = ax^2 + bxy + cy^2 \leftrightarrow \begin{pmatrix} t + bu & -cu \\ 2au & t - bu \end{pmatrix},$$  

(2.6)

where $D := b^2 - 4ac$ is the discriminant of $[a,b,c]$ and $(t,u)$ is the smallest positive solution of the Pell equation $t^2 - Du^2 = 4$ (see e.g. Chap. 5 in [3]). Due to the correspondence above, we have

$$\psi_s(x) := \sum_{\gamma \in \text{Prim}(\Gamma), j \geq 1, N(\gamma)^j \leq x} \frac{\log N(\gamma)}{1-N(\gamma)^{-j}} \left( 1 - \frac{N(\gamma)^j}{x} \right) N(\gamma)^{-js}$$

$$= \sum_{D \in \mathcal{D}, j \geq 1, \epsilon_1(D)^j \leq x^{1/2}} 2 \log \epsilon_1(D) h(D) \frac{\epsilon_1(D)^2 j}{1-\epsilon_1(D)^{-2j}} \left( 1 - \frac{\epsilon_1(D)^2 j}{x} \right) \epsilon_1(D)^{-2js},$$

where $\mathcal{D}$ is the set of $D > 0$ with $D \equiv 0, 1 \text{ mod } 4$, $\epsilon_1(D) := \frac{1}{2} (t + u \sqrt{D}) = \frac{1}{2} (t + \sqrt{t^2 - 4})$ and $h(D)$ is the class number in the narrow sense (see also [10]). Applying the works of Kuznetsov and Bykovskii [9, 2] (see also [11, 1]), we can write $\psi_s(x)$ as follows.

$$\psi_s(x) = 2 \sum_{3 \leq t < X} L(1, t^2 - 4) \left( 1 - \frac{\epsilon(t)^2}{x} \right) \epsilon(t)^{1-2s},$$  

(2.7)
where \( X := x^{1/2} + x^{-1/2} \), \( \epsilon(t) := \frac{1}{2}(t + \sqrt{t^2 - 1}) \) and

\[
L(z, D) := \sum_{d^2 = D} 1^{1-2z} L \left( z, \left( \frac{d}{\sigma} \right) \right) = \sum_{d^2 = D} \sum_{n \geq 1} \left( \frac{d}{n} \right) n^{-z}.
\]

To estimate \( \psi_s(X) \), we prepare the following two lemmas.

**Lemma 2.2.** (Theorem 2 of [4]) For \( z \in \mathbb{C} \) and a Dirichlet character \( \chi \), let \( L(z, \chi) := \sum_{n \geq 1} \chi(n)n^{-z} \) be the Dirichlet L-function. Then we have

\[
\sum_{\chi \in S(Q)} \left| L \left( \frac{1}{2} + iu, \chi \right) \right|^4 \ll_{\varepsilon} (Q(|u| + 1))^{1+\varepsilon}
\]

for \( \varepsilon > 0 \), where \( S(Q) \) is the set of all real primitive characters of conductor at most \( Q \).

**Lemma 2.3.** (see, e.g. Corollary 8.13, 8.19 of [3]) Let \( a, b \) be real numbers with \( b - a \geq 1 \) and \( f(x) \) a real function. Suppose that \( f(x) \) satisfies that \( \Lambda_2 \leq |f^{(2)}(x)| \leq \eta_2 \Lambda_2 \) and \( \Lambda_3 \leq |f^{(3)}(x)| \leq \eta_3 \Lambda_3 \) on \([a, b]\) for some \( \Lambda_2, \Lambda_3 > 0 \) and \( \eta_2, \eta_3 \geq 1 \). Then we have

\[
\sum_{a<n<b} e(f(n)) \ll \eta_2 \Lambda_2^{1/2} (b-a) + \Lambda_2^{-1/2},
\]

\[
\sum_{a<n<b} e(f(n)) \ll \eta_3^{1/2} \Lambda_3^{1/6} (b-a) + \Lambda_3^{-1/6} (b-a)^{1/2},
\]

where the implied constants are absolute.

**Proof of Theorem [1.1]** We first study \( \psi_s(x) \). Denote by \( s = \sigma + iT \) with \( 1/2 < \sigma < 1 \) and define the value \( \lambda_q(D) \) by \( L(z, D) = \sum_{q \geq 1} \lambda_q(D)q^{-z} \). Due to §5 of [11], we have

\[
L(1, D) = \sum_{q \geq 1} \lambda_q(D)q^{-1}e^{-q/U} - \frac{1}{2\pi i} \int_{\frac{1}{2}+i\infty}^{\frac{1}{2}+i\infty} L(z, D)U^{z-1}\Gamma(z-1)dz
\]

for \( U > 0 \). Then \( \psi_s(x) \) is written as follows.

\[
\psi_s(x) = 2 \sum_{q \geq 1} q^{-1}e^{-q/U} \sum_{3 \leq t < X} \lambda_q(t^2 - 4) \left( 1 - \frac{\epsilon(t)^2}{x} \right) \epsilon(t)^{1-2s}
\]

\[
- \frac{1}{\pi i} \int_{\frac{1}{2}-i\infty}^{\frac{1}{2}+i\infty} U^{z-1}\Gamma(z-1) \sum_{3 \leq t < X} L(z, t^2 - 4) \left( 1 - \frac{\epsilon(t)^2}{x} \right) \epsilon(t)^{1-2s}dz
\]

\[=: A_1 + A_2.\]

By the definition of \( L(z, D) \), we see that

\[
\sum_{3 \leq t < X} \left| L \left( \frac{1}{2} + iu, t^2 - 4 \right) \right|^4 \ll_{\varepsilon} X^\varepsilon \sum_{\chi \in S(X^2)} \left| L \left( \frac{1}{2} + iu, \chi \right) \right|^4,
\]
and then we get
\[
\sum_{3 \leq t < X} \left| L \left( \frac{1}{2} + iu, t^2 - 4 \right) \right| \ll \epsilon X^{\frac{3}{4} + \epsilon} (|u| + 1)^{\frac{1}{4} + \epsilon}
\]
due to Lemma 2.2 and Hölder’s inequality. Thus \( A_2 \) can be bounded by
\[
A_2 \ll \epsilon U^{-\frac{1}{2}} \int_{\frac{1}{2} - i\infty}^{\frac{1}{2} + i\infty} |\Gamma(z - 1)| \sum_{3 \leq t < X} |L(z, t^2 - 4)|\epsilon(t)^{1-2\sigma} \, dz \ll \epsilon U^{-\frac{1}{2}} x^{\frac{1}{3} - \sigma + \epsilon}. \tag{2.8}
\]

According to Lemma 2.3 of [11], we have
\[
A_1 = \sum_{q \geq 1} q^{-1} e^{-q/U} \sum_{q_1 q_2 = q} q_2^{-1} \sum_{k \mod q_2} S(k^2, 1; q_2) \sum_{3 \leq t < X} e \left( \frac{kt}{q_2} - \frac{T}{\pi} \log \epsilon(t) \right) \left( 1 - \frac{\epsilon(t)^2}{x} \right) \epsilon(t)^{1-2\sigma}, \tag{2.9}
\]
where \( e(x) := e^{2\pi i x} \) and
\[
S(n, m; c) := \sum_{a, b \mod c} e \left( \frac{am + bn}{c} \right)
\]
is the Kloosterman sum. It is easy to see that Lemma 2.3 yields the exponential sum estimate
\[
\sum_{N \leq t < 2N} e \left( \frac{kt}{q_2} - \frac{T}{\pi} \log \epsilon(t) \right) \ll \min(T^{\frac{1}{2}} + T^{\frac{1}{8} N}, T^{\frac{1}{4} N^{\frac{1}{2}}}) \ll \begin{cases} T^{\frac{1}{2}}, & (N < T^{2/3}), \\ T^{\frac{1}{4}}, & (T^{2/3} \leq N < T), \\ T^{-\frac{1}{4} N}, & (N \geq T) \end{cases}
\]
for \( N > 1 \), and then the sum over \( t \) in (2.9) can be bounded by
\[
\sum_{3 \leq t < X} e \left( \frac{kt}{q_2} - \frac{T}{\pi} \log \epsilon(t) \right) \left( 1 - \frac{\epsilon(t)^2}{x} \right) \epsilon(t)^{1-2\sigma} \ll T^{-\frac{1}{2} x^{1-\sigma}} + T^{\frac{1}{2} - \frac{3}{4} \sigma} + T^{\frac{1}{3}}.
\]

Since \( S(k^2, 1; q_2) \ll \epsilon q_2^{1/2 + \epsilon} \), we can estimate \( A_1 \) as follows.
\[
A_1 \ll U^{1/2 + \epsilon} (T^{-\frac{1}{2} x^{1-\sigma}} + T^{\frac{1}{2} - \frac{3}{4} \sigma} + T^{\frac{1}{3}}). \tag{2.10}
\]

Combining (2.8), (2.10) and Proposition 2.1 we have
\[
\frac{Z_T'(s)}{Z_T(s)} \ll \epsilon \frac{T^{\frac{1}{3} x^{1/2 - \sigma + \epsilon}} + (T^{\frac{1}{2} x^{1/2 - \sigma}} + T^{\frac{1}{2}}) + x^{\frac{3}{8} - \frac{3}{4} \sigma + \epsilon} + T^{-2} x^{1-\sigma} + T^{1+\epsilon} x^{1/2 - \sigma + \epsilon}}.
\]

The result of Theorem 1.1 for \( \frac{1}{2} < \sigma < \frac{5}{8} \) is derived from the above with \( x = T^{\frac{20}{3}} \). We can obtain the result for \( \frac{5}{8} < \sigma < 1 \) by the Phragmen-Lindelöf convexity theorem.
