Abstract

We present the development of the approach to thermodynamics based on measurement. First of all, we recall that considering classical thermodynamics as a theory of measurement of extensive variables one gets the description of thermodynamic states as Legendrian or Lagrangian manifolds representing the average of measurable quantities and extremal measures. Secondly, the variance of random vectors induces the Riemannian structures on the corresponding manifolds. Computing higher order central moments one drives to the corresponding higher order structures, namely, the cubic and the fourth order forms. The cubic form is responsible for the skewness of the extremal distribution. The condition for it to be zero gives us so-called symmetric processes. The positivity of the fourth order structure gives us an additional requirement to thermodynamic state.

1 Introduction

The geometrical interpretation of thermodynamic systems in equilibrium goes back already to the 19th century [1] and is reflected recently in [2]. In modern terms, it is clear that thermodynamic states are Legendrian submanifolds of the contact space where the structure form is the first law of thermodynamics. Additional structures, such as Riemannian structures on these Legendrian manifolds, were studied in, for example, [3]. Considering thermodynamics in the context of measurement of random vectors [4], one gets both structures as coming from the minimal information gain or Kullback-Leibler divergence principle [9]. Namely, Legendrian manifolds represent averages of measurable quantities (or extremal probability distributions) that are extensive thermodynamic variables, while the Riemannian structure is their variance, i.e. contact and Riemannian structures are the first two central moments of random vectors. It is worth to say that both these structures were widely studied, but at the same time the higher order structures, corresponding to central moments of higher order, have not been addressed before.

In this paper, we develop the geometrical approach to thermodynamic states and extend it by considering the third and fourth order moments and corresponding symmetric forms of the third and the fourth order on Legendrian manifolds of two types of gases, ideal and van der Waals. The third order symmetric form represents the skewness of the extremal probability distribution, and thermodynamic processes along which the skewness is equal to zero we therefore call symmetric. We

*E-mail: valentin.lychagin@uit.no
†E-mail: mihail_roop@mail.ru
elaborate such processes for ideal gases explicitly, and in the case of real gases represented by the van der Waals model we show that there are domains on their Legendrian manifold where there are either three types of such processes, or one. It is natural to require that the fourth order symmetric form must be positive. It is known that the positivity of the variance leads to the notion of thermodynamic phases [4], and the positivity of the fourth order form gives us an additional separation of applicable phases.

2 Geometry, Measurement, Thermodynamics

In this section, we briefly recall how contact geometry naturally appears in the context of measurement, as well as how symmetric $k$-forms represent $k$th central moments. For details we refer to [4, 5, 7].

Let $(\Omega, \mathcal{A}, q)$ be a probability space, where $\Omega$ is a sample space, $\mathcal{A}$ is a $\sigma$-algebra on $\Omega$, and $q$ is a probability measure. Then, a random vector $X : (\Omega, \mathcal{A}, q) \to W$, where $W$ is a vector space, $\dim W = n$ is a measurement of $x_0 \in W$ if $E_q X = x_0$. To measure another vector $x \in W$ one has to choose another measure $dp = \rho dq$, where $\rho$ is a probability density, such that

$$E_p X = \int_{\Omega} X \rho dq = x, \quad \int_{\Omega} \rho dq = 1. \quad (1)$$

To find $\rho$ we also use the principle of minimal information gain:

$$I(\rho) = \int_{\Omega} \rho \ln \rho dq \to \min.$$

This gives us the extremal probability distribution (see [4]):

$$\rho = \frac{e^{\langle \lambda, X \rangle}}{Z(\lambda)},$$

where $\lambda \in W^*$, and $Z(\lambda) = \int_{\Omega} e^{\langle \lambda, X \rangle} dq$.

Introducing the Hamiltonian $H(\lambda) = -\ln Z(\lambda)$ and using the first relation in (1), we obtain that the measurement belongs to a manifold

$$L = \{ x = -\frac{\partial H}{\partial \lambda} \} \subset W \times W^*,$$

which is Lagrangian with respect to the symplectic form

$$\omega = \sum_{i=1}^{n} d\lambda_i \wedge dx_i,$$

i.e. $\omega|_L = 0$. Considering the relation $x_i = -H_{\lambda_i}$, $i = 1, \ldots, n$ as an equation for $\lambda_i$, one gets (locally) $\lambda_i = \lambda_i(x)$. The information gain $I(x)$ is a function on $L$ which is related with Hamiltonian $H(\lambda)$ as

$$I(x) = H(\lambda(x)) + \langle \lambda(x), x \rangle.$$

Therefore, we have $I_{\lambda_i} = \lambda_i$ and if $u$ is a coordinate on $\mathbb{R}$ then the submanifold

$$\tilde{L} = \{ u = I(x), \lambda_i = I_{\lambda_i} \} \subset W \times W^* \times \mathbb{R}$$

is Legendrian with respect to the contact form $\theta = du - \sum_{i=1}^{n} \lambda_i dx_i$. 

2
Recall that in thermodynamics of gases \( x = (e, v) \in W, \lambda = (T^{-1}, pT^{-1}) \in W^* \), \( I(x) = -S(e, v) \), where \( e \) and \( v \) are specific inner energy and specific volume respectively, \( T \) is temperature, \( p \) is pressure, and the contact structure is

\[
\theta = -ds + T^{-1}de + pT^{-1}dv,
\]

and the Legendrian manifold is given by

\[
\tilde{L} = \left\{ s = S(e, v), p = \frac{S_e}{S_e}, T = \frac{1}{S_e} \right\} \subset W \times W^* \times \mathbb{R}.
\]

The \( k \)th central moment \( \sigma_k \) is a symmetric \( k \)-form on \( W \):

\[
S^k(W) \ni \sigma_k = \int_{\Omega} (X - \bar{X})^k \rho dq.
\]

In coordinates \((\lambda_1, \ldots, \lambda_n)\) on the Legendrian manifold \( \tilde{L} \) it is given by

\[
\sigma_k = -\sum_{|\alpha| = k} \frac{\partial^k H}{\partial \lambda_1^{\alpha_1} \cdots \partial \lambda_n^{\alpha_n}} d\lambda_1^{\alpha_1} \otimes \cdots \otimes d\lambda_n^{\alpha_n},
\]

where \( \alpha = (\alpha_1, \ldots, \alpha_n) \) is a multi index. In coordinates \((x_1, \ldots, x_n)\) on \( \tilde{L} \) it is given by

\[
\sigma_k = \sum_{|\alpha| = k} \frac{\partial^k I}{\partial x_1^{\alpha_1} \cdots \partial x_n^{\alpha_n}} dx_1^{\alpha_1} \otimes \cdots \otimes dx_n^{\alpha_n},
\]

and since in thermodynamics \( I(x) = -S(e, v) \), and \( x = (e, v) \), the \( k \)th order form takes the form

\[
\sigma_k = -\sum_{|\alpha| = k} \frac{\partial^k S}{\partial x_1^{\alpha_1} \cdots \partial x_n^{\alpha_n}} dx_1^{\alpha_1} \otimes \cdots \otimes dx_n^{\alpha_n}.
\]

**Remark 1**

1. Let \( J^k(W) \) be a space of \( k \)-jets of functions on \( W \) with canonical coordinates \((x, u, u_\alpha), |\alpha| \leq k \). One can consider the \( k \)th prolongation \( \tilde{L}^k \) of \( L \):

\[
\tilde{L}^k = \left\{ u = I(x), u_\alpha = \frac{\partial^{|\alpha|} I}{\partial x_1^{\alpha_1} \cdots \partial x_n^{\alpha_n}} \right\} \subset J^k(W).
\]

Then, tensors \( \sigma_k \) are restrictions of the universal tensors \( \Theta_k \)

\[
\Theta_k = \sum_{|\alpha| = k} u_\alpha dx_1^{\alpha_1} \otimes \cdots \otimes dx_n^{\alpha_n}
\]

to the manifold \( \tilde{L}^k \).

2. Assume that the information gain function \( I(x_1, \ldots, x_n) \) is homogeneous of degree 1 with respect to \( x_n \), i.e.

\[
I(x_1, \ldots, x_n) = x_n \tilde{I}\left(\frac{x_1}{x_n}, \ldots, \frac{x_{n-1}}{x_n}\right),
\]

then, universal tensors on \( J^k\left(\tilde{W}\right) \), where \( \tilde{W} = \mathbb{R}^{n-1}(\tilde{x}_1, \ldots, \tilde{x}_{n-1}) \), and \( \tilde{x}_i = x_i/x_n \) being restricted to the surface

\[
\tilde{L}^k = \left\{ u = \tilde{I}(x), u_\alpha = \frac{\partial^{|\alpha|} \tilde{I}}{\partial \tilde{x}_1^{\alpha_1} \cdots \partial \tilde{x}_{n-1}^{\alpha_{n-1}}} \right\} \subset J^k\left(\tilde{W}\right)
\]
give us tensors
\[ \bar{\sigma}_k = \sum_{|\alpha| = k} \frac{\partial^{k} \bar{T}}{\partial x_{1}^{\alpha_1} \cdots \partial x_{n-1}^{\alpha_{n-1}}} \otimes \cdots \otimes \partial x_{n-1}^{\alpha_{n-1}}. \]

In thermodynamics, this fact allows us to consider Legendrian manifolds in the space of specific variables and structures on them.

It is natural to require that all the even order symmetric forms must be positive on Legendrian manifolds. In case of \( k = 2 \) this condition leads to the notion of phases [4, 5]. Further we will elaborate symmetric forms of orders \( k = 3 \) and \( k = 4 \).

It is worth to mention that central moments \( \sigma_k \) are preserved by the affine group \( \text{Aff}(W) \) action. In [7, 8] the central moments are used to construct scalar differential invariants of \( \text{Aff}(W) \).

3 Third Central Moment \( \sigma_3 \)

The third central moment \( \sigma_3 \) is nothing but skewness of the probability distribution \( \rho \). From the thermodynamic perspective the symmetric 3-form \( \sigma_3 \) gives us a special type of thermodynamic processes, along which this form vanishes. From geometrical viewpoint thermodynamic processes are considered to be contact vector fields preserving the Legendrian manifold \( \hat{L} \). Assuming that these vector fields have no singular points one may look for such processes in the form

\[ X = \frac{\partial}{\partial e} + q \frac{\partial}{\partial e}. \]

The condition \( \sigma_3(X, X, X) = 0 \) forces the following equation on the coefficient \( q \):

\[ S_{evv}q^3 + 3S_{evv}q^2 + 3S_{evv}q + S_{eee} = 0. \] (2)

3.1 Ideal Gas

For ideal gases, the entropy function is given by

\[ S(e, v) = R \ln \left( e^{n/2} v \right), \]

where \( R \) is a universal gas constant, \( n \) is the degree of freedom. Equation (2) in case of ideal gases takes the form

\[ \frac{2q^3}{v^3} + \frac{n}{e} = 0. \]

The vector field \( X \) then takes the form

\[ X = \frac{\partial}{\partial e} + \left( \frac{n}{2} \right)^{1/3} v \frac{\partial}{\partial e}. \]

Its trajectories are shown in Fig. 1.

3.2 van der Waals Gas

In case of van der Waals gas we use the reduced thermodynamic variables, in terms of which the entropy function is

\[ S(e, v) = R \ln \left( \left( e + \frac{3}{v} \right)^{4n/3} (3v - 1)^{8/3} \right). \]
Here, equation (2) is

\[
(54e^3v^6 - 243e^2nv^5 + 243e^2nv^4 + 486e^2v^5 - 81e^2nv^3 - \\
-729env^4 + 9e^2nv^2 + 729env^3 + 1458ev^4 - 243env^2 - 729nv^3 + \\
+ 27env + 729nv^2 + 1458v^3 - 243nv + 27n)q^3 + \\
+ (-243env^6 + 243env^5 - 81env^4 + 9env^3)q^2 + (-243nv^7 + 243env^6 - 81nv^5 + 9nv^4)q + \\
+ 27n^9 - 27nv^8 + 9nv^7 - nv^6 = 0.
\]

In general, equation (3) may have either three or one real roots, depending on the determinant of the cubic (3). Therefore we get domains where there are either three symmetric processes, or only one. They are shown in Fig. 2. We use here coordinates \((T, v)\), where \(T\) is temperature, instead of \((e, v)\). In this figure, the pink domain corresponds to that on the Legendrian manifold where there are three real roots of (3). The blue line separates the domains where the 2-form \(\sigma_2\) is positive (above) and negative (under). Thus we can see that in this case there is only one transition from three symmetric processes to one. In Fig. 3, there are two transitions from three symmetric processes to one.

4 Fourth Central Moment \(\sigma_4\)

The analysis here is similar to that in the previous section. Consider the vector field

\[X = x_1 \frac{\partial}{\partial e} + x_2 \frac{\partial}{\partial v}.
\]

The conditions \(\sigma_4 > 0\) and \(\sigma_2 > 0\) yield that the homogeneous polynomials \(P_1(x_1, x_2) = \sigma_4(X, X)\) and \(P_2(x_1, x_2) = \sigma_4(X, X, X, X)\) in \(x_1\) and \(x_2\) are positive.

4.1 Ideal Gas

In case of ideal gas one gets

\[P_1(x_1, x_2) = \frac{nx_1^2}{2e^2} + \frac{x_2^3}{q^2}, \quad P_2(x_1, x_2) = \frac{3nx_1^4}{e^4} + \frac{6x_2^4}{q^4},\]
and both conditions hold on the entire Legendrian manifold.

4.2 van der Waals Gas

In this case, the standard analysis shows that the condition $\sigma_2 > 0$ holds not everywhere, as well as $\sigma_4 > 0$ does. The first condition gives us liquid and gas phase, while the second one is an additional requirement to applicable with respect to $\sigma_2$ states. This is shown in Fig. 4. In the pink domain both conditions $\sigma_2 > 0$ and $\sigma_4 > 0$ hold. The red line separates domains where $\sigma_2$ has opposite signs. We can see that the positivity of $\sigma_4$ gives us an additional clarification of the applicability of the van der
Figure 4: Applicable domains for van der Waals gas, $n = 3$.

Waals model.
